Set this keyword to produce stacked histogram-style plots. Each data value is rendered as a box covering the XY extent of the cell and with a height proportional to the Z value.

If the *X* and *Y* arguments are specified, only N_x-1 columns and N_y-1 rows are drawn. (This means that the last row and column of array data are not displayed.) The rectangular area covered by *Z*[*i*, *j*] is given by *X*[*i*], *X*[*i*+1], *Y*[*j*], and *Y*[*j*+1].

LOWER_ONLY

Set this keyword to draw only the lower surface of the object. By default, both surfaces are drawn.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SURFACE in the system variable field !P.T. Use this keyword when combining the output of SURFACE with additional output from other routines in the same plot.

When used with AXIS, the SAVE keyword parameter saves the scaling parameters established by the call in the appropriate axis system variable, !X, !Y, or !Z. This causes subsequent overplots to be scaled to the new axis.

For example, to display a two-dimensional array using SURFACE, and to then superimpose contours over the surface (this example assumes that !P.T3D is zero, its default value.), enter the following commands:

```
; Make a surface plot and save the transformation:
SURFACE, Z, /SAVE

; Make contours, don't erase, use the 3-D to 2-D transform placed
; in !P.T by SURFACE:
CONTOUR, Z, /NOERASE, /T3D
```

To display a surface and to then display a flat contour plot, registered above the surface:

```
; Make the surface, save transform:
SURFACE, Z, /SAVE

; Now display a flat contour plot, at the maximum Z value
; (normalized coordinates):
CONTOUR, Z, /NOERASE, /T3D, ZVALUE=1.0
```

You can display the contour plot below the surface with by using a ZVALUE of 0.0.

SHADES

This keyword allows user-specified coloring of the mesh surfaces. Set this keyword to an array that specifies the color index of the lines emanating from each data point toward the top and right.

Warning

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting `DEVICE, DECOMPOSED=0`. See "DEVICE" on page 472 and "DECOMPOSED" on page 3777.

SKIRT

This keyword represents a Z-value at which to draw a skirt around the array. The Z value is expressed in data units. The default is no skirt.

If the skirt is drawn, each point on the four edges of the surface is connected to a point on the skirt which has the given Z value, and the same X and Y values as the edge point. In addition, each point on the skirt is connected to its neighbor.

UPPER_ONLY

Set this keyword to draw only the upper surface of the object. By default, both surfaces are drawn.

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

ZAXIS

This keyword specifies the placement of the Z axis for the SURFACE plot.

By default, SURFACE draws the Z axis at the upper left corner of the axis box. To suppress the Z axis, use `ZAXIS=-1` in the call. The position of the Z axis is determined from the value of ZAXIS as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

ZLOG

Set this keyword to specify a logarithmic Z axis.

Graphics Keywords Accepted

See Appendix H, “Graphics Keywords”, for the description of graphics and plotting keywords not listed above. BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, LINESTYLE, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE.

Examples

```
; Create a simple dataset to display:
D = DIST(30)

; Plot a simple wire-mesh surface representation of D:
SURFACE, D
```

```
; Create a wire-mesh plot of D with a title and a "skirt" around
; the edges of the dataset at Z=0:
SURFACE, D, SKIRT=0.0, TITLE = 'Surface Plot', CHARSIZE = 2
```

Version History

Introduced: Original

See Also

CONTOUR, SHADE_SURF

SURFR

The SURFR procedure sets up 3-D transformations. This procedure duplicates the rotation, translation, and scaling features of the SURFACE routine, but does not display any data. The resulting transformations are stored in the !P.T system variable.

This routine is written in the IDL language. Its source code can be found in the file `surfr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

SURFR [, AX=*degrees*] [, AZ=*degrees*]

Arguments

None.

Keywords

AX

Angle of rotation about the X axis. The default is 30 degrees.

AZ

Angle of rotation about the Z axis. The default is 30 degrees.

Version History

Introduced: Original

See Also

SCALE3, SCALE3D, T3D

SVDC

The SVDC procedure computes the Singular Value Decomposition (SVD) of a square (*n* x *n*) or non-square (*n* x *m*) array as the product of orthogonal and diagonal arrays. SVD is a very powerful tool for the solution of linear systems, and is often used when a solution cannot be determined by other numerical algorithms.

The SVD of an (*n* x *m*) non-square array *A* is computed as the product of an (*n* x *m*) column orthogonal array *U*, an (*n* x *n*) diagonal array *SV*, composed of the singular values, and the transpose of an (*n* x *n*) orthogonal array V: $A = U\ SV\ V^T$

SVDC is based on the routine `svdcmp` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the LA_SVD procedure.

Syntax

SVDC, *A*, *W*, *U*, *V* [, /COLUMN] [, /DOUBLE] [, ITMAX=*value*]

Arguments

A

The square (*n* x *n*) or non-square (*n* x *m*) single- or double-precision floating-point array to decompose.

W

On output, *W* is an *n*-element output vector containing the “singular values.”

U

On output, *U* is an *n*-column, *m*-row orthogonal array used in the decomposition of *A*.

V

On output, *V* is an *n*-column, *n*-row orthogonal array used in the decomposition of *A*.

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 30.

Examples

To find the singular values of an array A:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7,  2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0,  4.3, 2.2], $
     [0.0, 5.5,  3.8, 0.2]]

; Compute the Singular Value Decomposition:
SVDC, A, W, U, V

; Print the singular values:
PRINT, W
```

IDL prints:

```
8.81973      2.65502      4.30598      6.84484
```

To verify the decomposition, use the relationship A = U ## SV ## TRANSPOSE(V), where SV is a diagonal array created from the output vector W:

```
sv = FLTARR(4, 4)
FOR K = 0, 3 DO sv[K,K] = W[K]
result = U ## sv ## TRANSPOSE(V)
PRINT, result
```

IDL prints:

```
      1.00000      2.00000     -1.00000      2.50000
      1.50000      3.30000    -0.500001      2.00000
      3.10000     0.700000      2.20000      0.00000
  2.23517e-08     0.300000     -2.00000      5.30000
      2.10000     0.999999      4.30000      2.20000
 -3.91155e-07      5.50000      3.80000     0.200000
```

This is the input array, to within machine precision.

CHOLDC, LA_SVD, LUDC, SVSOL, "Linear Systems" in Chapter 22 of the *Using IDL* manual.

SVDFIT

The SVDFIT function performs a least squares fit with optional error estimates. Either a user-supplied function written in the IDL language or a built-in polynomial can be used to fit the data.

SVDFIT is based on the routine `svdfit` described in section 15.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SVDFIT(*X*, *Y* [, *M*] [, A=*vector*] [, CHISQ=*variable*] [, COVAR=*variable*] [, /DOUBLE] [, FUNCTION_NAME=*string*] [, /LEGENDRE] [, MEASURE_ERRORS=*vector*] [, SIGMA=*variable*] [, SING_VALUES=*variable*] [, SINGULAR=*variable*] [, STATUS=*variable*] [, TOL=*value*] [, VARIANCE=*variable*] [, YFIT=*variable*])

Return Value

Returns a vector of coefficients.

Arguments

X

An n-element vector of independent variables.

Y

A vector of dependent variables, the same length as *X*.

M

The number of coefficients in the fitting function. For polynomials, *M* is equal to the degree of the polynomial + 1. If the *M* argument is not specified, you must supply initial coefficient estimates using the A keyword. In this case, *M* is set equal to the number of elements of the array specified by the A keyword.

Keywords

A

This keyword is both an input and output keyword. Set this keyword equal to a variable containing a vector of initial estimates for the fitted function parameters. On exit, SVDFIT returns in this variable a vector of coefficients that are improvements of the initial estimates. If A is supplied, the *M* argument will be set equal to the number of elements in the vector specified by A.

CHISQ

Set this keyword equal to a named variable that will contain the value of the chi-sqaure goodness-of-fit.

COVAR

Set this keyword equal to a named variable that will contain the covariance matrix of the fitted coefficients.

Note

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FUNCTION_NAME

Set this keyword equal to a string containing the name of a user-supplied IDL basis function with *M* coefficients. If this keyword is omitted, and the LEGENDRE keyword is not set, IDL assumes that the IDL procedure SVDFUNCT, found in the file `svdfunct.pro`, located in the `lib` subdirectory of the IDL distribution, is to be used. SVDFUNCT uses the basis functions for the fitting polynomial:

$$y = \sum_{i=0}^{M} A(i)x^{i}$$

The function to be fit must be written as an IDL function and compiled prior to calling SVDFIT. The function must accept values of *X* (a scalar), and *M* (a scalar). It must return an *M*-element vector containing the basis functions.

See the "Examples" section below for an example function.

LEGENDRE

Set this keyword to use Legendre polynomials instead of the function specified by the FUNCTION_NAME keyword. If the LEGENDRE keyword is set, the IDL uses the function SVDLEG found in the file `svdleg.pro`, located in the `lib` subdirectory of the IDL distribution.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point *Y*[*i*]. This vector must be the same length as *X* and *Y*.

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in *Y*. For Poisson or statistical weighting, MEASURE_ERRORS should be set to SQRT(*Y*).

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note

If MEASURE_ERRORS is omitted, then you are assuming that the polynomial (or your user-supplied model) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by SQRT(CHISQ/(*N*–*M*)), where *N* is the number of points in *X*, and *M* is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

SING_VALUES

Set this keyword to a named variable in which to return the singular values from the SVD. Singular values which have been removed will be set to zero.

SINGULAR

Set this keyword equal to a named variable that will contain the number of singular values returned. This value should be 0. If not, the basis functions do not accurately characterize the data.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- STATUS = 0: The computation was successful.
- STATUS > 0: Singular values were found and were removed. STATUS contains the number of singular values.

Note

If STATUS is not specified, any error messages will be output to the screen.

TOL

Set this keyword to the tolerance used when removing singular values. The default is 10^{-5} for single precision, and $2x10^{-12}$ for double precision (these defaults are approximately 100 and 10000 times the machine precisions for single and double precision, respectively).

Setting TOL to a larger value may remove coefficients that do not contribute to the solution, which may reduce the errors on the remaining coefficients.

VARIANCE

Set this keyword equal to a named variable that will contain the variance (sigma squared) of each coefficient *M*.

WEIGHTS

The WEIGHTS keyword is obsolete and has been replaced by the MEASURE_ERRORS keyword. Code that uses the WEIGHTS keyword will continue to work as before, but new code should use the MEASURE_ERRORS keyword. Note that the definition of the MEASURE_ERRORS keyword is not the same as the WEIGHTS keyword. Using the WEIGHTS keyword, 1/WEIGHTS[i] represents the measurement error for each point Y[i]. Using the MEASURE_ERRORS keyword, the measurement error is represented as simply MEASURE_ERRORS[i].

YFIT

Set this keyword equal to a named variable that will contain the vector of calculated *Y* values.

Examples

This example fits a function of the following form:

$$F(x) = A(0) + A(1)\sin\frac{(2x)}{x} + A(2)\cos(4x)^2$$

First, create the function in IDL, then create a procedure to perform the fit. Create the following file called `example_svdfit.pro`:

```
PRO example_svdfit

; Provide an array of coefficients:
C = [7.77, 8.88, -9.99]
X = FINDGEN(100)/15.0 + 0.1
Y = C[0] + C[1] * SIN(2*X)/X + C[2] * COS(4.*X)^2.

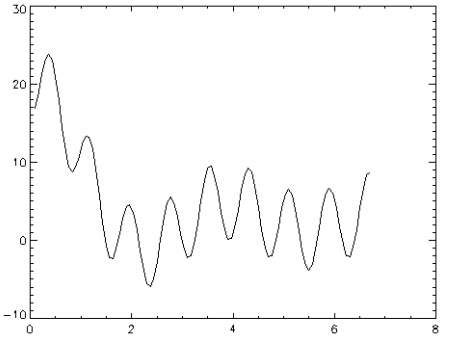
; Set uncertainties to 5%:
measure_errors = 0.05 * Y

; Provide an initial guess:
A=[1,1,1]
result_a = SVDFIT(X, Y, A=A, MEASURE_ERRORS=measure_errors, $
   FUNCTION_NAME='myfunct', SIGMA=SIGMA, YFIT=YFIT)

; Plot the results:
PLOT, X, YFIT
FOR I = 0, N_ELEMENTS(A)-1 DO $
   PRINT, I, result_a[I], SIGMA[I], C[I],$
   FORMAT = $
   '(" result_a ( ",I1," ) = ",F7.4," +- ",F7.4," VS. ",F7.4)'
END

FUNCTION myfunct, X ,M
   RETURN,[ [1.0], [SIN(2*X)/X], [COS(4.*X)^2.] ]
END
```

Place the file `example_svdfit.pro` in a directory in the IDL search path, and enter `example_svdfit` at the command prompt to create the plot.



In addition to creating the above plot, IDL prints:

```
result_a ( 0 ) =  7.7700 +-  0.0390 VS.  7.7700
result_a ( 1 ) =  8.8800 +-  0.0468 VS.  8.8800
result_a ( 2 ) = -9.9900 +-  0.0506 VS. -9.9900
```

Version History

CURVEFIT, GAUSSFIT, LINFIT, LMFIT, POLY_FIT, REGRESS, SFIT

SVSOL

The SVSOL function uses “back-substitution” to solve a set of simultaneous linear equations Ax = b, given the *U*, *W*, and *V* arrays returned by the SVDC procedure. None of the input arguments are modified, making it possible to call SVSOL multiple times with different right hand vectors, *B*.

SVSOL is based on the routine `svbksb` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SVSOL(*U*, *W*, *V*, *B* [, /COLUMN] [, /DOUBLE])

Return Value

Returns the solution to the linear system using decomposition and back substitution.

Arguments

U

An *n*-column, *m*-row orthogonal array used in the decomposition of *A*. Normally, *U* is returned from the SVDC procedure.

W

An *n*-element vector containing “singular values.” Normally, *W* is returned from the SVDC procedure. Small values (close to machine floating-point precision) should be set to zero prior to calling SVSOL.

V

An *n*-column, *n*-row orthogonal array used in the decomposition of *A*. Normally, *V* is returned from the SVDC procedure.

B

An *m*-element vector containing the right hand side of the linear system Ax = b.

Keywords

COLUMN

Set this keyword if the input arrays *U* and *V* are in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To solve the linear system Ax = b using Singular-value decomposition and back substitution, begin with an array A which serves as the coefficient array:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7,  2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0,  4.3, 2.2], $
     [0.0, 5.5,  3.8, 0.2]]

; Define the right-hand side vector B:
B = [0.0, 1.0, 5.3, -2.0, 6.3, 3.8]

; Decompose A:
SVDC, A, W, U, V

; Compute the solution and print the result:
PRINT, SVSOL(U, W, V, B)
```

IDL prints:

```
1.00095   0.00881170     0.984176   -0.0100954
```

This is the correct solution.

SWAP_ENDIAN

The SWAP_ENDIAN function reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

Note

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN also allows structures).

This routine is written in the IDL language. Its source code can be found in the file `swap_endian.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = SWAP_ENDIAN(*Variable* [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN])

Return Value

SWAP_ENDIAN returns values of the same type and structure as the input value, with the pertinent bytes reversed.

Arguments

Variable

The named variable—scalar, array, or structure—to be swapped.

Keywords

SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the SWAP_ENDIAN request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the SWAP_ENDIAN

request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

Examples

```
; Reverse the byte order of A:
A = SWAP_ENDIAN(A)
```

Version History

Introduced: Pre 4.0

SWAP_IF_BIG_ENDIAN and SWAP_IF_LITTLE_ENDIAN keywords added: 5.6

See Also

BYTEORDER, SWAP_ENDIAN_INPLACE

SWAP_ENDIAN_INPLACE

The SWAP_ENDIAN_INPLACE procedure reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

Note

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN_INPLACE also allows structures).

SWAP_ENDIAN_INPLACE differs from the SWAP_ENDIAN function in that it alters the input data in place rather than making a copy as does SWAP_ENDIAN. SWAP_ENDIAN_INPLACE can therefore be more efficient, if a copy of the data is not needed. The pertinent bytes in the input variable are reversed.

This routine is written in the IDL language. Its source code can be found in the file `swap_endian_inplace.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

SWAP_ENDIAN_INPLACE, *Variable* [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN]

Arguments

Variable

The named variable—scalar, array, or structure—to be swapped.

Keywords

SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the SWAP_ENDIAN_INPLACE request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the SWAP_ENDIAN_INPLACE request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

Examples

Reverse the byte order of A:

```
SWAP_ENDIAN_INPLACE, A
```

Version History

Introduced: 5.6

BYTEORDER, SWAP_ENDIAN

SWITCH

The SWITCH statement is used to select one statement for execution from multiple choices, depending upon the value of the expression following the word SWITCH.

Each statement that is part of a SWITCH statement is preceded by an expression that is compared to the value of the SWITCH expression. SWITCH executes by comparing the SWITCH expression with each selector expression in the order written. If a match is found, program execution jumps to that statement and execution continues from that point. Whereas CASE executes at most one statement within the CASE block, SWITCH executes the first matching statement and any following statements in the SWITCH block. Once a match is found in the SWITCH block, execution falls through to any remaining statements. For this reason, the BREAK statement is commonly used within SWITCH statements to force an immediate exit from the SWITCH block.

The ELSE clause of the SWITCH statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the switch statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, program execution continues immediately below the SWITCH without executing any of the SWITCH statements.

SWITCH is similar to the CASE statement. For more information on using SWITCH and other IDL program control statements, as well as the differences between SWITCH and CASE, see Chapter 12, “Program Control” in the *Building IDL Applications* manual.

Syntax

SWITCH *expression* OF

expression: *statement*

...

expression: *statement*

ELSE: *statement*

ENDSWITCH

Examples

This example illustrates how, unlike CASE, SWITCH executes the first matching statement and any following statements in the SWITCH block:

```
x=2

SWITCH x OF
   1: PRINT, 'one'
   2: PRINT, 'two'
   3: PRINT, 'three'
   4: PRINT, 'four'
ENDSWITCH
```

IDL Prints:

```
two
three
four
```

Version History

Introduced: 5.4

CASE

SYSTIME

The SYSTIME function returns the current time as either a date/time string, as the number of seconds elapsed since 1 January 1970, or as a Julian date/time value.

Syntax

String = SYSTIME([0 [, *ElaspedSeconds*]] [, /UTC])

or

Seconds = SYSTIME(1 | /SECONDS)

or

Julian = SYSTIME(/JULIAN [, /UTC])

Return Value

Returns the specified time.

Arguments

SecondsFlag

If *SecondsFlag* is present and nonzero, the number of seconds elapsed since 1 January 1970 UTC is returned as a double-precision, floating-point value.

Otherwise, if *SecondsFlag* is not present or zero, a scalar string containing the date/time is returned in standard 24-character system format as follows:

```
DOW MON DD HH:MM:SS YEAR
```

where DOW is the day of the week, MON is the month, DD is the day of the month, HH is the hour, MM is the minute, SS is the second, and YEAR is the year. By default, the date/time string is adjusted for the local time zone; use the UTC keyword to override this default.

Note

If the JULIAN or SECONDS keyword is set, the *SecondsFlag* argument is ignored.

ElapsedSeconds

If the *SecondsFlag* argument is zero, the *ElapsedSeconds* argument may be set to the number of seconds past 1 January 1970 UTC. In this case, SYSTIME returns the

corresponding date/time string (rather than the string for the current time). The returned date/time string is adjusted for the local time zone, unless the UTC keyword is set. If this argument is present, the JULIAN keyword is not allowed.

Keywords

JULIAN

Set this keyword to specify that the current time is to be returned as a a double precision floating value containing the current Julian date/time. By default, the current time is adjusted for the local time zone; use the UTC keyword to override this default. This keyword is not allowed if the *ElapsedSeconds* argument is present.

Note

If the JULIAN keyword is set, a small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, and seconds. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR. For typical Julian dates, this offset is approximately $6x10^{-10}$ (which corresponds to $5x10^{-5}$ seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

SECONDS

Set this keyword to specify that the current time is to be returned as the number of seconds elapsed since 1 January 1970 UTC. This option is equivalent to setting the *SecondsFlag* argument to a non-zero value.

UTC

Set this keyword to specify that the value returned by SYSTIME is to be returned in Universal Time Coordinated (UTC) rather than being adjusted for the current time zone. UTC time is defined as Greenwich Mean Time updated with leap seconds.

Examples

Print today’s date as a string:

```
PRINT, SYSTIME()
```

Print today’s date as a string in UTC (rather than local time zone):

```
PRINT, SYSTIME(/UTC)
```

Print today's date as a Julian date/time value in UTC:

```
PRINT, SYSTIME(/JULIAN, /UTC), FORMAT='(f12.2)'
```

Compute the seconds elapsed since 1 January 1970 UTC:

```
seconds = SYSTIME(1) ; or seconds = SYSTIME(/SECONDS)
```

Verify that the seconds from the previous example are correct:

```
PRINT, SYSTIME(0, seconds)
```

Print the day of the week:

```
PRINT, STRMID(SYSTIME(0), 0, 3)
```

Compute the time required to perform a 16,384 point FFT:

```
T = SYSTIME(1)
A = FFT(FINDGEN(16384), -1)
PRINT, SYSTIME(1) - T, 'Seconds'
```

Version History

Introduced: Original

T_CVF

The T_CVF function computes the cutoff value *V* in a Student's t distribution with *Df* degrees of freedom such that the probability that a random variable *X* is greater than *V* is equal to a user-supplied probability *P*.

This routine is written in the IDL language. Its source code can be found in the file `t_cvf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = T_CVF(*P*, *Df*)

Return Value

Returns the cutoff value.

Arguments

P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the Student's t distribution.

Keywords

None.

Examples

Use the following command to compute the cutoff value in a Student's t distribution with five degrees of freedom such that the probability that a random variable X is greater than the cutoff value is 0.025.

```
result = T_CVF(0.025, 5)
PRINT, result
```

IDL prints:

```
2.57058
```

Version History

Introduced: 4.0

CHISQR_CVF, F_CVF, GAUSS_CVF, T_PDF

T_PDF

The T_PDF function computes the probability *P* that, in a Student's t distribution with *Df* degrees of freedom, a random variable *X* is less than or equal to a user-specified cutoff value *V*.

This routine is written in the IDL language. Its source code can be found in the file `t_pdf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = T_PDF(*V, Df*)

Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of *V* and *Df*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

V

A scalar or array that specifies the cutoff value(s).

Df

A scalar or array that specifies the number of degrees of freedom of the Student's t distribution.

Keywords

None.

Examples

Use the following command to compute the probability that a random variable X, from the Student's t distribution with 15 degrees of freedom, is less than or equal to 0.691:

```
PRINT, T_PDF(0.691, 15)
```

IDL prints:

```
0.749940
```

Version History

Introduced: 4.0

T3D

The T3D procedure implements three-dimensional transforms.

This routine accumulates one or more sequences of translation, scaling, rotation, perspective, and oblique transformations and stores the result in !P.T, the 3D transformation system variable. All the IDL graphic routines use this (4,4) matrix for output. Note that !P.T3D is *not* set, so for the transformations to have effect you must set !P.T3D = 1 (or set the T3D keyword in subsequent calls to graphics routines).

This procedure is based on that of Foley & Van Dam, *Fundamentals of Interactive Computer Graphics*, Chapter 8, “Viewing in Three Dimensions”. The matrix notation is reversed from the normal IDL sense, i.e., here, the first subscript is the column, the second is the row, in order to conform with this reference.

A right-handed system is used. Positive rotations are counterclockwise when looking from a positive axis position towards the origin.

This routine is written in the IDL language. Its source code can be found in the file `t3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

T3D [, *Array* | , /RESET] [, MATRIX=*variable*] [, OBLIQUE=*vector*]
[, PERSPECTIVE=*p*{eye at (0,0,*p*)}] [, ROTATE=*[x, y, z]*] [, SCALE=*[x, y, z]*]
[, TRANSLATE=*[x, y, z]*] [, /XYEXCH | , /XZEXCH | , /YZEXCH]

Arguments

Array

An optional 4 x 4 matrix used as the starting transformation. If *Array* is missing, the current !P.T transformation is used. *Array* is ignored if /RESET is set.

Keywords

The transformation specified by each keyword is performed in the order of their descriptions below (e.g., if both TRANSLATE and SCALE are specified, the translation is done first).

MATRIX

Set this keyword to a named variable that will contain the result. If this keyword is specified, !P.T is not modified.

OBLIQUE

A two-element vector of oblique projection parameters. Points are projected onto the XY plane at Z=0 as follows:

```
x' = x + z(d * COS(a))
y' = y + z(d * SIN(a))
```

where OBLIQUE[0] = d and OBLIQUE[1] = a.

PERSPECTIVE

Perspective transformation. This parameter is a scalar (p) that indicates the Z distance of the center of the projection. Objects are projected into the XY plane at Z=0, and the “eye” is at point (0,0,p).

RESET

Set this keyword to reset the transformation to the default identity matrix.

ROTATE

A three-element vector of the rotations, in DEGREES, about the X, Y, and Z axes. Rotations are performed in the order of X, Y, and then Z.

SCALE

A three-element vector of scale factors for the X, Y, and Z axes.

TRANSLATE

A three-element vector of the translations in the X, Y, and Z directions.

XYEXCH

Set this keyword to exchange the X and Y axes.

XZEXCH

Set this keyword to exchange the X and Z axes.

YZEXCH

Set this keyword to exchange the Y and Z axes.

Examples

To reset the transformation, rotate 30 degs about the X axis and do perspective transformation with the center of the projection at Z = -1, X=0, and Y=0, enter:

```
T3D, /RESET, ROT = [ 30,0,0], PERS = 1.
```

Transformations may be cascaded, for example:

```
T3D, /RESET, TRANS = [-.5,-.5,0], ROT = [0,0,45]
T3D, TRANS = [.5,.5,0]
```

The first command resets, translates the point (.5,.5,0) to the center of the viewport, then rotates 45 degrees counterclockwise about the Z axis. The second call to T3D moves the origin back to the center of the viewport.

SCALE3, SCALE3D, SURFR

TAG_NAMES

The TAG_NAMES function returns a string array containing the names of the tags in a structure expression. It can also be used to determine the expression's structure name (if the structure has a name).

Syntax

Result = TAG_NAMES(*Expression* [, /STRUCTURE_NAME])

Return Value

Returns structure tag names or the expression's structure name.

Arguments

Expression

The structure expression for which the tag names are returned. This argument must be of structure type. TAG_NAMES does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the names of tags in the outermost structure are returned.

Keywords

STRUCTURE_NAME

Set this keyword to return a scalar string that contains the name of the structure instead of the names of the tags in the structure. If the structure is "anonymous", a null string is returned.

Examples

Print the names of the tags in the system variable !P by entering:

```
PRINT, TAG_NAMES(!P)
```

IDL prints:

```
BACKGROUND CHARSIZE CHARTHICK CLIP COLOR FONT LINESTYLE MULTI
NOCLIP NOERASE NSUM POSITION PSYM REGION SUBTITLE SYMSIZE T
T3D THICK TITLE TICKLEN CHANNEL
```

Print the name of the structure in the system variable !P:

```
PRINT, TAG_NAMES(!P, /STRUCTURE_NAME)
```

IDL prints:

```
!PLT
```

Version History

Introduced: Original

CREATE_STRUCT, N_TAGS

TAN

The TAN function computes the tangent of *X*.

Syntax

Result = TAN(*X*)

Return Value

Returns the tangent of the specified angle.

Arguments

X

The angle for which the tangent is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If *X* is an array, the result has the same structure, with each element containing the tangent of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

```
; Find the tangent of 0.5 radians and store the result in
; the variable T:
T = TAN(0.5)
```

Version History

Introduced: Original

See Also

ATAN, TANH

TANH

The TANH function returns the hyperbolic tangent of X.

Syntax

Result = TANH(*X*)

Return Value

Returns the single- or double-precision hyperbolic tangent.

Arguments

X

The value for which the hyperbolic tangent is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. TANH is defined as:

$$\tanh(x) = \frac{e^{x} - e^{-x}}{e^{x} + e^{-x}}$$

If *X* is an array, the result has the same structure, with each element containing the hyperbolic tangent of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

```
; Find the hyperbolic tangent of 1 radian and print the result:
PRINT, TANH(1)

; Plot the hyperbolic tangent from -5 to +5 with an increment
; of 0.1:
PLOT, TANH(FINDGEN(101)/10. - 5)
```

Version History

Introduced: Original

ATAN, TAN

TEK_COLOR

The TEK_COLOR procedure loads a 32-color colortable similar to the default Tektronix 4115 colortable. This colortable is useful because of its distinct colors.

By default, this palette consists of 32 colors. The first 9 colors are: Index 0=black, 1=white, 2=red, 3=green, 4=blue, 5=cyan, 6=magenta, 8=orange.

Syntax

TEK_COLOR [, *Start_Index*, *Colors*]

Arguments

Start_Index

An optional starting index for the palette. The default is 0. If this argument is included, the colors are loaded into the current colortable starting at the specified index.

Colors

The number of colors to load. The default is 32, which is also the maximum.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

LOADCT, XLOADCT

TEMPORARY

The TEMPORARY function returns a temporary copy of a variable, and sets the original variable to “undefined”. This function can be used to conserve memory when performing operations on large arrays, as it avoids making a new copy of results that are only temporary. In general, the TEMPORARY routine can be used to advantage whenever a variable containing an array on the left hand side of an assignment statement is also referenced on the right hand side.

Syntax

Result = TEMPORARY(*Variable*)

Return Value

Returns a copy of a specified variable.

Arguments

Variable

The variable to be referenced and deleted.

Keywords

None.

Examples

Assume the variable `A` is a large array of integers. The statement:

```
A = A + 1
```

creates a new array for the result of the addition, places the sum into the new array, assigns it to `A`, and then frees the old allocation of `A`. Total storage required is twice the size of `A`. The statement:

```
A = TEMPORARY(A) + 1
```

requires no additional space.

Note

If the operation performed on *Variable* requires that *Variable* be converted to another data type, there is no benefit to using TEMPORARY. For instance, if the

array A in the above example contained byte data rather than integer data, the array would have to be converted to integer type before the addition could be performed. In such a case, memory could not be re-used.

Version History

Introduced: Pre 4.0

See Also

DELVAR

TETRA_CLIP

The TETRA_CLIP function clips a tetrahedral mesh to an arbitrary plane in space and returns a tetrahedral mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex (the trailing array dimension must match the number of vertices in the Vertsin array).

A tetrahedral connectivity array consists of groups of four vertex index values. Each set of four index values specifies four vertices which define a single tetrahedron.

Syntax

Result = TETRA_CLIP (*Plane*, *Vertsin*, *Connin*, *Vertsout*, *Connout* [, AUXDATA_IN=*array*, AUXDATA_OUT=*variable*] [, CUT_VERTS=*variable*])

Return Value

The return value is the number of tetrahedra returned.

Arguments

Plane

Input four-element array describing the equation of the plane to be clipped to. The elements are the coefficients (*a*,*b*,*c*,*d*) of the equation $ax+by+cz+d=0$.

Vertsin

Input array of tetrahedral vertices [3, *n*].

Connin

Input tetrahedral mesh connectivity array.

Vertsout

Output array of tetrahedral vertices [3, *n*].

Connout

Output tetrahedral mesh connectivity array.

Keywords

AUXDATA_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

AUXDATA_OUT

Set this keyword to a named variable to contain an output array of interpolated auxiliary data.

CUT_VERTS

Set this keyword to a named variable to contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be ‘on’ the clipped surface.

Version History

Introduced: 5.5

TETRA_SURFACE

The TETRA_SURFACE function extracts a polygonal mesh as the exterior surface of a tetrahedral mesh. The output of this function is a polygonal mesh connectivity array that can be used with the input Verts array to display the outer surface of the tetrahedral mesh.

Syntax

Result = TETRA_SURFACE (*Verts*, *Connin*)

Return Value

Returns a polygonal mesh connectivity array. When used with the input vertex array, this function yields the exposed tetrahedral mesh surface.

Arguments

Verts

Array of vertices [3, *n*].

Connin

Tetrahedral connectivity array.

Keywords

None.

Version History

Introduced: 5.5

TETRA_VOLUME

The TETRA_VOLUME function computes properties of a tetrahedral mesh array. The basic property is the volume. An auxiliary data array may be supplied which specifies weights at each vertex which are interpolated through the volume during integration. Higher order moments (with respect to the X, Y, and Z axis) may be computed as well (with or without weights).

Syntax

Result = TETRA_VOLUME (*Verts*, *Conn* [, AUXDATA=*array*] [, MOMENT=*variable*])

Return Value

Returns the cumulative (weighted) volume of the tetrahedrons in the mesh.

Arguments

Verts

Array of vertices [3, *n*].

Conn

Tetrahedral connectivity array.

Keywords

AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex. The volume area integral will linearly interpolate these values. The volume integral will linearly interpolate these values within each tetrahedra. The default weight is 1.0 which results in a basic volume.

MOMENT

Set this keyword to a named variable that will contain a three-element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} = \sum_{ntetras} v_i \vec{c}_i$$

where v is the (weighted) volume of the tetrahedron and c is the centroid of the tetrahedron, thus

$$\vec{m} / volume$$

yields the (weighted) centroid of the tetrahedral mesh.

Version History

Introduced: 5.5

THIN

The THIN function returns the “skeleton” of a bi-level image. The skeleton of an object in an image is a set of lines that reflect the shape of the object. The set of skeletal pixels can be considered to be the medial axis of the object. For a much more extensive discussion of skeletons and thinning algorithms, see *Algorithms for Graphics and Image Processing*, Theo Pavlidis, Computer Science Press, 1982. The THIN function is adapted from Algorithm 9.1 (the classical thinning algorithm).

On input, the bi-level image is a rectangular array in which pixels that compose the object have a nonzero value. All other pixels are zero. The result is a byte type image in which skeletal pixels are set to 2 and all other pixels are zero.

Syntax

Result = THIN(*Image* [, /NEIGHBOR_COUNT] [, /PRUNE])

Return Value

Returns the thinned, two-dimensional byte array.

Arguments

Image

The two-dimensional image (array) to be thinned.

Keywords

NEIGHBOR_COUNT

Set this keyword to select an alternate form of output. In this form, output pixel values count the number of neighbors an individual skeletal pixel has (including itself). For example, a pixel that is part of a line will have the value 3 (two neighbors and itself). Terminal pixels will have the value 2, while isolated pixels have the value 1.

PRUNE

If the PRUNE keyword is set, pixels with single neighbors are removed iteratively until only pixels with 2 or more neighbors exist. This effectively removes (or “prunes”) skeleton branches, leaving only closed paths.

Examples

The following commands display the “thinned” edges of a Sobel filtered image:

```
; Open a file for reading:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])

; Create a byte array in which to store the image:
A = BYTARR(192, 192)

; Read first 192 by 192 image:
READU, 1, A

; Close the file:
CLOSE, 1

; Display the image:
TV, A, 0

; Apply the Sobel filter, threshold the image at value 75, and
; display the thinned edges:
TVSCL, THIN(SOBEL(A) GT 75), 1
```

Version History

Introduced: Pre 4.0

THREED

The THREED procedure plots a 2-D array as a pseudo 3-D plot. The orientation of the data is fixed. This routine is written in the IDL language. Its source code can be found in the file `threed.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

THREED, *A* [, *Sp*] [, TITLE=*string*] [, XTITLE=*string*] [, YTITLE=*string*]

Arguments

A

The two-dimensional array to plot.

Sp

The spacing between plot lines. If *Sp* is omitted, the spacing is set to: (MAX(*A*)-MIN(*A*))/ROWS. If *Sp* is negative, hidden lines are not removed.

Keywords

TITLE

Set this keyword to the main plot title.

XTITLE

Set this keyword to the X axis title.

YTITLE

Set this keyword to the Y axis title.

Examples

```
; Create a 2-D dataset:
A = -SHIFT(DIST(30), 15, 15)
; Make a THREED plot:
THREED, A
; Compare to SURFACE:
SURFACE, A
```

SURFACE

TIME_TEST2

The TIME_TEST2 procedure is a general-purpose IDL benchmark program that performs approximately 20 common operations and prints the time required.

This routine is written in the IDL language. Its source code can be found in the file `time_test.pro` in the `lib` subdirectory of the IDL distribution. This file also contains the procedure GRAPHICS_TIMES, used to time graphical operations.

Syntax

TIME_TEST2 [, *Filename*]

Arguments

Filename

An optional string that contains the name of output file for the results of the time test.

Keywords

None.

Examples

```
; Run the computational tests:
TIME_TEST2

; Run the graphics tests. Note that TIME_TEST2 must be compiled
; before GRAPHICS_TIMES will run:
GRAPHICS_TIMES
```

Version History

Introduced: 4.0

SYSTIME

TIMEGEN

The TIMEGEN function returns an array, with specified dimensions, of double-precision floating-point values that represent times in terms of Julian dates.

The Julian date is the number of days elapsed since Jan. 1, 4713 B.C.E., plus the time expressed as a day fraction. Following the astronomical convention, the day is defined to start at 12 PM (noon). Julian date 0.0d is therefore Jan. 1, 4713 B.C.E. at 12:00:00.

The first value of the returned array corresponds to a Julian date start time, and each subsequent value corresponds to the next Julian date in the sequence. The sequence is determined by specifying the time unit (such as months or seconds) and the step size, or spacing, between the units. You can also construct more complicated arrays by including smaller time units within each major time interval.

A small offset is added to each Julian date to eliminate roundoff errors when calculating the day fraction from the hour, minute, second. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date and EPS is the double-precision floating-point precision parameter from MACHAR. For typical Julian dates the offset is approximately $6x10^{-10}$ (which corresponds to $5x10^{-5}$ seconds). This offset ensures that when the Julian date is converted back to the hour, minute, and second, the hour, minute, and second will have the same integer values.

Tip

Because of the large magnitude of the Julian date (1 Jan 2000 is Julian day 2451545), the precision of most Julian dates is limited to 1 millisecond (0.001 seconds). If you are not interested in the date itself, you can improve the precision by subtracting a large offset or setting the START keyword to zero.

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

Syntax

Result = TIMEGEN([*D1,...,D8* | , FINAL=*value*] [, DAYS=*vector*] [, HOURS=*vector*] [, MINUTES=*vector*] [, MONTHS=*vector*] [, SECONDS=*vector*] [, START=*value*] [, STEP_SIZE=*value*] [, UNITS=*string*] [, YEAR=*value*])

Return Value

Returns the specified time values.

Arguments

D_i

The dimensions of the result. The dimension parameters may be any scalar expression. Up to eight dimensions may be specified. If the dimension arguments are not integer values, IDL will truncate them to integer values before creating the new array. The dimension arguments are required unless keyword FINAL is set, in which case they are ignored.

Keywords

DAYS

Set this keyword to a scalar or a vector giving the day values that should be included within each month. This keyword is ignored if the UNITS keyword is set to “Days”, “Hours”, “Minutes”, or “Seconds”.

Note

Day values that are beyond the end of the month will be set equal to the last day for that month. For example, setting `DAY=[31]` will automatically return the last day in each month.

FINAL

Set this keyword to a double-precision value representing the Julian date/time to use as the last value in the returned array. In this case, the dimension arguments are ignored and *Result* is a one-dimensional array, with the number of elements depending upon the step size. The FINAL time may be less than the START time, in which case STEP_SIZE should be negative.

Note

If the step size is not an integer then the last element may not be equal to the FINAL time. In this case, TIMEGEN will return enough elements such that the last element is less than or equal to FINAL.

HOURS

Set this keyword to a scalar or a vector giving the hour values that should be included within each day. This keyword is ignored if UNITS is set to “Hours”, “Minutes”, or “Seconds”.

MINUTES

Set this keyword to a scalar or a vector giving the minute values that should be included within each hour. This keyword is ignored if UNITS is set to “Minutes” or “Seconds”.

MONTHS

Set this keyword to a scalar or a vector giving the month values that should be included within each year. This keyword is ignored if UNITS is set to “Months”, “Days”, “Hours”, “Minutes”, or “Seconds”.

SECONDS

Set this keyword to a scalar or a vector giving the second values that should be included within each minute. This keyword is ignored if UNITS is set to “Seconds”.

START

Set this keyword to a double-precision value representing the Julian date/time to use as the first value in the returned array. The default is 0.0d [corresponding to January 1, 4713 B.C.E. at 12 pm (noon)].

Note

If subintervals are provided by MONTHS, DAYS, HOURS, MINUTES, or SECONDS, then the first element may not be equal to the START time. In this case the first element in the returned array will be greater than or equal to START.

Tip

Other array generation routines in IDL (such as FINDGEN) do not allow you to specify a starting value because the resulting array can be added to a scalar representing the start value. For TIMEGEN it is correct to add a scalar to the array if the units are days, hours, minutes, seconds, or sub-seconds. For example:

```
MyTimes = TIMEGEN(365, UNITS="Days") + SYSTIME(/JULIAN)
```

However, if the units are months or years, the start value is necessary because the number of days in a month or year can vary depending upon the year in which they

fall (for instance, consider leap years). For example:

```
MyTimes = TIMEGEN(12, UNITS="Months", START=JULDAY(1,1,2000))
```

STEP_SIZE

Set this keyword to a scalar value representing the step size between the major intervals of the returned array. The step size may be negative. The default step size is 1. When the UNITS keyword is set to “Years” or “Months”, the STEP_SIZE value is rounded to the nearest integer.

UNITS

Set this keyword to a scalar string indicating the time units to be used for the major intervals for the generated array. Valid values include:

- “Years” or “Y”
- “Months” or “M”
- “Days” or “D”
- “Hours” or “H”
- “Minutes” or “I”
- “Seconds” or “S”

The case (upper or lower) is ignored. If this keyword is not specified, then the default for UNITS is the time unit that is larger than the largest keyword present:

Largest Keyword Present	Default UNITS
SECONDS=*vector*	“Minutes”
MINUTES=*vector*	“Hours”
HOURS=*vector*	“Days”
DAYS=*vector*	“Months”
MONTHS=*vector*	“Years”
YEAR=*value*	“Years”

Table 131: Defaults for the UNITS keyword

If none of the above keywords are present, the default is UNITS="Days".

YEAR

Set this keyword to a scalar giving the starting year. If YEAR is specified then the starting year from START is ignored.

Examples

Generate an array of 366 time values that are one day apart starting with January 1, 2000:

```
MyDates = TIMEGEN(366, START=JULDAY(1,1,2000))
```

Generate an array of 20 time values that are 12 hours apart starting with the current time:

```
MyTimes = TIMEGEN(20, UNITS='Hours', STEP_SIZE=12, $
   START=SYSTIME(/JULIAN))
```

Generate an array of time values that are 1 hour apart from 1 January 2000 until the current time:

```
MyTimes = TIMEGEN(START=JULDAY(1,1,2000), $
   FINAL=SYSTIME(/JULIAN), UNITS='Hours')
```

Generate an array of time values composed of seconds, minutes, and hours that start from the current hour:

```
MyTimes = TIMEGEN(60, 60, 24, $
   START=FLOOR(SYSTIME(/JULIAN)*24)/24d, UNITS='S')
```

Generate an array of 24 time values with monthly intervals, but with subintervals at 5 PM on the first and fifteenth of each month:

```
MyTimes = TIMEGEN(24, START=FLOOR(SYSTIME(/JULIAN)), $
   DAYS=[1,15], HOURS=17)
```

Version History

Introduced: 5.4

See Also

"Format Codes" in Chapter 10 of the *Building IDL Applications* manual, CALDAT, JULDAY, LABEL_DATE, SYSTIME

TM_TEST

The TM_TEST function computes the Student's T-statistic and the probability that two sample populations *X* and *Y* have significantly different means. *X* and *Y* may be of different lengths. The default assumption is that the data is drawn from populations with the same true variance. This type of test is often referred to as the t-means test.

The T-statistic for sample populations *x* and *y* with means $\bar{x}$ and $\bar{y}$ is defined as:

$$T = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{\sum_{j=0}^{N-1} (x_i - \bar{x})^2 + \sum_{j=0}^{M-1} (y_i - \bar{y})^2}{(N + M - 2)} \left(\frac{1}{N} + \frac{1}{M}\right)}}$$

where $x = (x_0, x_1, x_2, ..., x_{N-1})$ and $y = (y_0, y_1, y_2 ..., y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `tm_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TM_TEST(*X*, *Y* [, /PAIRED] [, /UNEQUAL])

Return Value

The result is a two-element vector containing the T-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that *X* and *Y* have significantly different means.

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector.

Y

An *m*-element integer, single-, or double-precision floating-point vector. If the PAIRED keyword is set, *X* and *Y* must have the same number of elements.

Keywords

PAIRED

If this keyword is set, *X* and *Y* are assumed to be paired samples and must have the same number of elements.

UNEQUAL

If this keyword is set, *X* and *Y* are assumed to be from populations with unequal variances.

Examples

```
; Define two n-element sample populations.
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the Student's t-statistic and its significance assuming
; that X and Y belong to populations with the same true variance:
PRINT, TM_TEST(X, Y)
```

IDL prints:

```
5.52839  2.52455e-06
```

The result indicates that *X* and *Y* have significantly different means.

TOTAL

The TOTAL function returns the sum of the elements of *Array*. The sum of the array elements over a given dimension is returned if the *Dimension* argument is present.

Syntax

Result = TOTAL(*Array* [, *Dimension*] [, /CUMULATIVE] [, /DOUBLE] [, /NAN])

Return Value

Returns the array sum for the specified dimensions.

Arguments

Array

The array to be summed. This array can be of any basic type except string. If *Array* is double-precision floating-point, complex, or double-precision complex, the result is of the same type. Otherwise, the result is single-precision floating-point.

Dimension

The dimension over which to sum, starting at one. If this argument is not present or zero, the scalar sum of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*. For example, if the dimensions of *Array* are N_1, N_2, N_3, and *Dimension* is 2, the dimensions of the result are (N_1, N_3), and element *(i,j)* of the result contains the sum:

$$\sum_{k=0}^{N_2-1} A_{i,k,j}$$

Keywords

CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element, i, containing the sum of the input array elements 0 to i. This keyword also works with the Dimension parameter, in which case the sum is performed over the given dimension.

DOUBLE

Set this keyword to perform the summation in double-precision floating-point.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point value NaN in the input data. Elements with the value NaN are treated as missing data. (See "Special Floating-Point Values" in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Note

Since the value NaN is treated as missing data, if *Array* contains only NaN values the TOTAL routine will return 0.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

The thread pool is used for non-cumulative sums, and is not used if the CUMULATIVE keyword is specified. In a cumulative sum, each result value depends on all of the previous results, so overlapped execution is not possible.

You should be aware that when summing a large number of values, the result from TOTAL can depend heavily upon the order in which the numbers are added. Since the thread pool will add values in a different order, you may obtain a different — but equally correct — result than that obtained using the standard non-threaded implementation. This effect occurs because TOTAL uses floating point arithmetic, and the mantissa of a floating point value has a fixed number of significant digits. The effect is especially obvious when using single precision arithmetic, but can also affect double precision computations. Such differences do not mean that the sums are incorrect. Rather, they mean that they are equal within the ability of the floating point representation used to represent them. For more information on floating-point numbers, see "Accuracy & Floating-Point Operations" in Chapter 22 of the *Using IDL* manual.

It is also worth noting that this effect, while illustrated by the use of the thread pool, is not caused by the use of threading. It is simply caused by the different order in

which the numbers are summed, as can be illustrated by the following non-threaded example:

```
vec = FINDGEN(100000)
PRINT, TOTAL(vec, /TPOOL_NO) - TOTAL(REVERSE(vec), /TPOOL_NO)
```

IDL prints:

```
-96768.0
```

As you can see, the small floating-point errors can accumulate across the sum of a large number of values.

Note

The computation above was done on a Sun Sparc workstation. Your result will depend on the architecture of your CPU; it may be slightly different, and in the notable case of Intel-compatible X86 CPUs may actually be zero due to the use of internal 80-bit floating point registers on that CPU which give it better than double precision accuracy for some computations. Nonetheless, you should be aware of the fact that the order of operations can influence the result.

Examples

Example 1

This example sums the elements of a one-dimensional array:

```
; Define a one-dimensional array:
A = [20, 10, 5, 5, 3]

; Sum the elements of the array:
SUMA = TOTAL([20, 10, 5, 5, 3])

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of A = ', SUMA
```

IDL prints:

```
A =   20   10   5   5   3
Sum of A =   43.0000
```

Example 2

The results are different when a multi-dimensional array is used:

```
; Define a multi-dimensional array:
A = FINDGEN(5,5)
```

```
; Sum each of the rows in A:
SUMROWS = TOTAL(A, 1)

; Sum each of the columns in A:
SUMCOLS = TOTAL(A, 2)

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of each row:', SUMROWS
PRINT, 'Sum of each column:', SUMCOLS
```

IDL prints:

```
A = 0.000000   1.00000   2.00000   3.00000   4.00000
    5.00000    6.00000   7.00000   8.00000   9.00000
    10.0000    11.0000   12.0000   13.0000   14.0000
    15.0000    16.0000   17.0000   18.0000   19.0000
    20.0000    21.0000   22.0000   23.0000   24.0000

Sum of each row:  10.0000  35.0000  60.0000  85.0000  110.000

Sum of each column:  50.0000  55.0000  60.0000  65.0000  70.0000
```

FACTORIAL

TRACE

The TRACE function computes the trace of an *n* by *n* array.

This routine is written in the IDL language. Its source code can be found in the file `trace.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TRACE(*A* [, /DOUBLE])

Return Value

Returns the sum of the values along the array diagonal.

Arguments

A

An *n* by *n* real or complex array.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an array:
A = [[ 2.0,1.0,  1.0, 1.5], $
     [ 4.0, -6.0,  0.0, 0.0], $
     [-2.0,  7.0,  2.0, 2.5], $
     [ 1.0,  0.5,  0.0, 5.0]]

; Compute the trace of A:
result = TRACE(A)

;Print the result:
PRINT, 'TRACE(A) = ', result
```

IDL prints:

```
TRACE(A) =   3.00000
```

TRANSPOSE

The TRANSPOSE function returns the transpose of *Array*. If an optional permutation vector is provided, the dimensions of *Array* are rearranged as well.

Syntax

Result = TRANSPOSE(*Array* [, *P*])

Return Value

Returns the reflection of the array along a diagonal.

Arguments

Array

The array to be transposed.

P

A vector specifying how the dimensions of *Array* will be permuted. The elements of *P* correspond to the dimensions of *Array*; the *i*th dimension of the output array is dimension *P*[*i*] of the input array. Each element of the vector *P* must be unique. Dimensions start at zero and can not be repeated.

If *P* is not present, the order of the dimensions of *Array* is reversed.

Keywords

None.

Examples

Example 1

Print a simple array and its transpose by entering:

```
; Create an array:
A = INDGEN(3,3)
TRANSA = TRANSPOSE(A)
```

```
; Print the array and its transpose:
PRINT, 'A:'
PRINT, A
PRINT, 'Transpose of A:'
PRINT, TRANSA
```

IDL prints:

```
A:
   0  1  2
   3  4  5
   6  7  8

Transpose of A:
   0  3  6
   1  4  7
   2  5  8
```

Example 2

This example demonstrates multi-dimensional transposition:

```
; Create the array:
A = INDGEN(2, 3, 4)

; Take the transpose, reversing the order of the indices:
B = TRANSPOSE(A)

; Re-order the dimensions of A, so that the second dimension
; becomes the first, the third becomes the second, and the first
; becomes the third:
C = TRANSPOSE(A, [1, 2, 0])

; View the sizes of the three arrays:
HELP, A, B, C
```

IDL prints:

```
A   INT  = Array[2, 3, 4]
B   INT  = Array[4, 3, 2]
C   INT  = Array[3, 4, 2]
```

TRI_SURF

The TRI_SURF function interpolates a regularly- or irregularly-gridded set of points with a smooth quintic surface.

TRI_SURF is similar to MIN_CURVE_SURF but the surface fitted is a smooth surface, not a minimum curvature surface. TRI_SURF has the advantage of being much more efficient for larger numbers of points.

Note

The TRI_SURF function is designed to interpolate low resolution data. Large arrays may cause TRI_SURF to issue the following error message:
`Partial Derivative Approximation Failed to Converge`"
In such cases, interpolation is most likely unnecessary.

This routine is written in the IDL language. Its source code can be found in the file `tri_surf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TRI_SURF(*Z* [, *X*, *Y*] [, /EXTRAPOLATE] [, MISSING=*value*] [, /REGULAR] [, XGRID=*[xstart, xspacing]* | [, XVALUES=*array*]] [, YGRID=*[yxstart, yspacing]* | [, YVALUES=*array*]] [, GS=*[xspacing, yspacing]*] [, BOUNDS=*[xmin, ymin, xmax, ymax]*] [, NX=*value*] [, NY=*value*])

Return Value

The result is s a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

Arguments

X, Y, Z

arrays containing the X, Y, and Z coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

Keywords

EXTRAPOLATE

Set this keyword to cause TRI_SURF to extrapolate the surface to points outside the convex hull of input points. This keyword has no effect if the input points are regularly gridded.

LINEAR

Set this keyword to use linear interpolation, without gradient estimates, instead of quintic interpolation. Linear interpolation does not extrapolate, although it is faster and more numerically stable.

MISSING

Set this keyword equal to the value to which points outside the convex hull of input points should be set. The default is 0. This keyword has no effect if the input points are regularly gridded.

Input Grid Description:

REGULAR

If set, the *Z* parameter is a two-dimensional array of dimensions (*n*,*m*), containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, *Z*. If REGULAR is set, and no grid specifications are present, the grid is set to (0, 1, 2, ...).

XGRID

A two-element array, [*xstart*, *xspacing*], defining the input grid in the *x* direction. Do not specify both XGRID and XVALUES.

XVALUES

An *n*-element array defining the *x* locations of Z[*i*,*j*]. Do not specify both XGRID and XVALUES.

YGRID

A two-element array, [*ystart*, *yspacing*], defining the input grid in the *y* direction. Do not specify both YGRID and YVALUES.

YVALUES

An *n*-element array defining the *y* locations of Z[*i*,*j*]. Do not specify both YGRID and YVALUES.

Output Grid Description:

Note

The output grid must enclose the convex hull of the input points.

GS

The output grid spacing. If present, GS must be a two-element vector [*xs, ys*], where *xs* is the horizontal spacing between grid points and *ys* is the vertical spacing. The default is based on the extents of *x* and *y*. If the grid starts at *x* value *xmin* and ends at *xmax*, then the default horizontal spacing is (*xmax* - *xmin*)/(NX-1). YS is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in *x* and *y* of the output grid: [*xmin, ymin, xmax, ymax*]. If not specified, the grid limits are set to the extent of *x* and *y*.

NX

The output grid size in the *x* direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

NY

The output grid size in the *y* direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

Examples

Example 1

Regularly gridded case:

```
; Make some random data
Z = randomu(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, TRI_SURF(Z, /REGULAR)
```

Example 2

Irregularly gridded case:

```
; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Use a 26 by 26 grid over the rectangle bounding x and y.
; Get the surface:
R = TRI_SURF(Z, X, Y)

; Alternatively, get a surface over the unit square, with spacing
; of 0.05:
R = TRI_SURF(z, x, y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])

; Alternatively, get a 10 by 10 surface over the rectangle bounding
; x and y:
R = TRI_SURF(z, x, y, NX=10, NY=10)
```

Version History

Introduced: Pre 4.0

CONTOUR, MIN_CURVE_SURF

TRIANGULATE

The TRIANGULATE procedure constructs a Delaunay triangulation of a planar set of points. Delaunay triangulations are very useful for the interpolation, analysis, and visual display of irregularly-gridded data. In most applications, after the irregularly gridded data points have been triangulated, the function TRIGRID is invoked to interpolate surface values to a regular grid.

Since Delaunay triangulations have the property that the circumcircle of any triangle in the triangulation contains no other vertices in its interior, interpolated values are only computed from nearby points.

TRIANGULATE can, optionally, return the adjacency list that describes, for each node, the adjacent nodes in the Delaunay triangulation. With this list, the Voronoi polygon (the polygon described by the set of points which are closer to that node than to any other node) can be computed for each node. This polygon contains the area influenced by its associated node. Tiling of the region in this manner is also called Dirichlet, Wigner-Seithz, or Thiessen tessellation.

The grid returned by the TRIGRID function can be input to various routines such as SURFACE, TV, and CONTOUR. See the description of TRIGRID for an example.

TRIANGULATE and TRIDGRID can also be used to perform gridding and interpolation over the surface of a sphere. The interpolation is C_1 continuous, meaning that the result is continuous over both the function value and its first derivative. This feature is ideal for interpolating an irregularly-sampled dataset over part or all of the surface of the earth (or other (spherical) celestial bodies). Extrapolation outside the convex hull of sample points is also supported. To perform spherical gridding, you must include the FVALUE and SPHERE keywords described below. The spherical gridding technique used in IDL is based on the paper "Interpolation of Data on the Surface of a Sphere", R. Renka, *Oak Ridge National Laboratory Report ORNL/CSD-108*, 1982.

Syntax

TRIANGULATE, *X*, *Y*, *Triangles* [, *B*] [, CONNECTIVITY=*variable*]
[, SPHERE=*variable* [, /DEGREES]] [, FVALUE=*variable*] [, REPEATS=*variable*]

Arguments

X

An array that contains the X coordinates of the points to be triangulated.

Y

An array that contains the Y coordinates of the points to be triangulated. Parameters *X* and *Y* must have the same number of elements.

Triangles

A named variable that, on exit, contains the list of triangles in the Delaunay triangulation of the points specified by the X and Y arguments. Triangles is a longword array dimensioned (3, *number of triangles*), where `Triangles[0, i]`, `Triangles[1, i]`, and `Triangles[2, i]` contain the indices of the vertices of the *i*-th triangle (i.e., `X[Tr[*, i]]` and `Y[Triangles[*, i]]` are the X and Y coordinates of the vertices of the *i*-th triangle).

B

An optional, named variable that, upon return, contains a list of the indices of the boundary points in counterclockwise order.

Keywords

CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the *N* nodes (xy point) is returned. The list has the following form:

Each element *i*, $i \leq 0 < N$, contains the starting index of the connectivity list for node *i* within the list array. To obtain the adjacency list for node i, extract the list elements from LIST[*i*] to LIST[*i*+1]-1.

The adjacency list is ordered in the counter-clockwise direction. The first item on the list of boundary nodes is the subscript of the node itself. For interior nodes, the list contains the subscripts of the adjacent nodes in counter-clockwise order.

For example, the call:

```
TRIANGULATE, X, Y, CONNECTIVITY = LIST
```

returns the adjacency list in the variable LIST. The subscripts of the nodes adjacent to X[i] and Y[i] are contained in the array:

```
LIST[LIST[i] : LIST[i+1]-1]
```

DEGREES

Set this keyword to indicate that the *X* and *Y* arguments contain longitude and latitude coordinates specified in degrees. This keyword is only effective if the SPHERE

keyword is specified. If DEGREES is not set, *X* and *Y* are assumed to be specified in radians when a spherical triangulation is performed.

FVALUE

Set this keyword to a named variable that contains sample values for each longitude/latitude point in a spherical triangulation. On output, the elements of FVALUE are rearranged to correspond to the new ordering of *X* and *Y* (as described in the SPHERE keyword, below). This reordered array can be passed to TRIGRID to complete the interpolation.

REPEATS

Set this keyword to a named variable to return a (2, *n*) list of the indices of duplicated points. That is, for each *i*,

```
X[REPEATS[0,i]] = X[REPEATS[1,i]]
```

and

```
Y[REPEATS[0,i]] = Y[REPEATS[1,i]]
```

Note

Use the GRID_INPUT procedure to handle repeated points (duplicate locations).

SPHERE

Set this keyword to a named variable in which the results from a spherical triangulation are returned. This result is a structure that can be passed to TRIGRID to perform spherical gridding. The structure contains the 3D Cartesian locations sample points and the adjacency list that describes the triangulation.

When spherical triangulation is performed, *X* and *Y* are interpreted as longitude and latitude, in either degrees or radians (see the DEGREE keyword, above). Also, the order of the elements within the *X* and *Y* parameters is rearranged (see the FVALUE keyword, above).

Examples

For some examples using the TRIANGULATE routine, see the TRIGRID function.

Version History

Introduced: Pre 4.0

See Also

SPH_SCAT, TRIGRID

TRIGRID

Given data points defined by the parameters *X, Y,* and *Z* and a triangulation of the planar set of points determined by *X* and *Y,* the TRIGRID function returns a regular grid of interpolated *Z* values. Linear or smooth quintic polynomial interpolation can be selected. Extrapolation for gridpoints outside of the triangulation area is also an option.

An input triangulation can be constructed using the procedure TRIANGULATE. Together, the TRIANGULATE procedure and the TRIGRID function constitute IDL's solution to the problem of irregularly-gridded data, including spherical gridding.

Syntax

Result = TRIGRID(*X*, *Y*, *Z*, *Triangles* [, *GS*, *Limits*])

For spherical gridding: *Result* = TRIGRID(*F* , *GS*, *Limits*, SPHERE=*S*)

Keywords: [, /DEGREES] [, EXTRAPOLATE=*array* | , /QUINTIC] [, INPUT=*variable*] [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, MISSING=*value*] [, NX=*value*] [, NY=*value*] [, SPHERE=*variable*] [, XGRID=*variable*] [, YGRID=*variable*] [, XOUT=*vector*, YOUT=*vector*]

Return Value

The resulting grid is a two-dimensional array with user-specified bounds and spacing. The data type of the resulting grid is either floating-point or double-precision floating-point depending upon the data type of *Z*.

Arguments

X, Y, Z

Input arrays of X, Y, and Z coordinates of data points. Integer, long, double-precision and floating-point values are allowed. In addition, *Z* can be a complex array. All three arrays must have the same number of elements.

F

When performing a spherical gridding, this argument should be the named variable that contains the rearranged sample values that were returned by TRIANGULATE's FVALUE keyword.

Triangles

A longword array of the form output by TRIANGULATE. That is, *Triangles* has the dimensions (3, *number of triangles*) and, for each *i*, `Triangles[0,i]`, `Triangles[1,i]`, and `Triangles[2,i]` are the indices of the vertices of the *i*-th triangle.

GS

If present, *GS* should be a two-element vector [*XS, YS*], where *XS* is the horizontal spacing between grid points and *YS* is the vertical spacing. The default is based on the extents of *X* and *Y*. If the grid starts at *X* value x_0 and ends at x_1,then the horizontal spacing is

$(x_1 - x_0)/50$

The default for *YS* is computed in the same way. Since the default grid spacing divides each axis into 50 intervals and produces 51 samples, TRIGRID returns a grid with dimensions (51, 51).

If the NX or NY keywords are set to specify the output grid dimensions, either or both of the values of *GS* may be set to 0. In this case, the grid spacing is computed as the respective range divided by the dimension minus one:

$(x_1 - x_0)/(NX-1)$ and $(y_1 - y_0)/(NY-1)$

For spherical gridding, *GS* is assumed to be specified in radians, unless the DEGREES keyword is set.

Limits

If present, *Limits* should be a four-element vector $[x_0, y_0, x_1, y_1]$ that specifies the data range to be gridded (x_0 and y_0 are the lower X and Y data limits, and x_1 and y_1 are the upper limits). The default for *Limits* is:

```
[MIN(X), MIN(Y), MAX(X), MAX(Y)]
```

If the NX or NY keywords are not specified, the size of the grid produced is specified by the value of *Limits*. If the NX or NY keywords are set to specify the output grid dimensions, a grid of the specified size will be used regardless of the value of *Limits*.

Keywords

DEGREES

For a spherical gridding, set this keyword to indicate that the grid spacing (the *GS* argument) is specified in degrees rather than radians.

EXTRAPOLATE

Set this keyword equal to an array of boundary node indices (as returned by the optional parameter B of the TRIANGULATE procedure) to extrapolate to grid points outside the triangulation. The extrapolation is not smooth, but should give acceptable results in most cases.

Setting this keyword sets the quintic interpolation mode, as if the QUINTIC keyword has been specified.

INPUT

Set this keyword to a named variable (which must be an array of the appropriate size to hold the output from TRIGRID) in which the results of the gridding are returned. This keyword is provided to make it easy and memory-efficient to perform multiple calls to TRIGRID. The interpolates within each triangle overwrite the array and the array is not initialized.

MAX_VALUE

Set this keyword to a value that represents the maximum *Z* value to be gridded. Data larger than this value are treated as missing data and are not gridded.

MIN_VALUE

Set this keyword to a value that represents the minimum *Z* value to be gridded. Data smaller than this value are treated as missing data and are not gridded.

MISSING

The *Z* value to be used for grid points that lie outside the triangles in *Triangles*. The default is 0. This keyword also applies to data points outside the range specified by MIN_VALUE and MAX_VALUE.

Note

Letting MISSING default to 0 does not always produce the same result as explicitly setting it to 0. For example, if you specify INPUT and not EXTRAPOLATE, letting MISSING default to 0 will result in the INPUT values being used for data outside the Triangles; explicitly setting MISSSING to 0 will result in 0 being used for the data outside the Triangles.

NX

The output grid size in the *x* direction. The default value is 51.

NY

The output grid size in the *y* direction. The default value is 51.

QUINTIC

If QUINTIC is set, smooth interpolation is performed using Akima's quintic polynomials from "A Method of Bivariate Interpolation and Smooth Surface Fitting for Irregularly Distributed Data Points" in *ACM Transactions on Mathematical Software*, 4, 148-159. The default method is linear interpolation.

Derivatives are estimated by Renka's global method in "A Triangle-Based C1 Interpolation Method" in *Rocky Mountain Journal of Mathematics*, vol. 14, no. 1, 1984.

QUINTIC is not available for complex data values. Setting the EXTRAPOLATE keyword implies the use of quintic interpolation; it is not necessary to specify both.

SPHERE

For a spherical gridding, set this keyword to the named variable that contains the results of the spherical triangulation returned by TRIANGULATE's SPHERE keyword.

XGRID

Set this keyword to a named variable that will contain a vector of *X* values for the output grid.

XOUT

Set this keyword to a vector specifying the output grid *X* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. If keyword NX is also supplied then only the first NX points of XOUT will be used.

YGRID

Set this keyword to a named variable that will contain a vector of *Y* values for the output grid.

The following table shows the interrelationships between the keywords EXATRAPOLATE, INPUT, MAX_VALUE, MIN_VALUE, MISSING, and QUINTIC.

INPUT	EXTRAPOLATE	MISSING	Not in Triangles	Beyond MIN_VALUE, MAX_VALUE
no	no	no	uses 0	uses 0
no	no	yes	uses MISSING	uses MISSING
no	yes	no	EXTRAPOLATEs	uses 0
no	yes	yes	EXTRAPOLATEs	uses MISSING
yes	no	no	uses INPUT	uses INPUT
yes	no	yes	uses MISSING	uses MISSING
yes	yes	no	EXTRAPOLATEs	uses INPUT
yes	yes	yes	EXTRAPOLATEs	uses MISSING

Table 132: Keyword Interrelationships for the TRIGRID function

YOUT

Set this keyword to a vector specifying the output grid *Y* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If keyword NY is also supplied then only the first NY points of YOUT will be used.

Examples

Example 1

This example creates and displays a 50 point random normal distribution. The random points are then triangulated, with the triangulation displayed. Next, the interpolated surface is computed and displayed using linear and quintic interpolation. Finally, the smooth extrapolated surface is generated and shown.

```
PRO TrigridExample

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
```

```
y = RANDOMN(seed, 50)

; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1
in=' '
READ,"Press enter",in

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

; Show the triangles:
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN & $
   ; Subscripts of vertices [0,1,2,0]:
   t = [tr[*,i], tr[0,i]] & $
   ; Connect triangles:
   PLOTS, x[t], y[t] & $
ENDFOR

; Show linear surface:
SURFACE, TRIGRID(x, y, z, tr)
in=' '
READ,"Press enter",in

; Show smooth quintic surface:
SURFACE, TRIGRID(x, y, z, tr, /QUINTIC)
in=' '
READ,"Press enter",in

; Show smooth extrapolated surface:
SURFACE, TRIGRID(x, y, z, tr, EXTRA = b)
in=' '
READ,"Press enter",in

; Output grid size is 12 x 24:
SURFACE, TRIGRID(X, Y, Z, Tr, NX=12, NY=24)
in=' '
READ,"Press enter",in

; Output grid size is 20 x 11. The X grid is
; [0, .1, .2, ..., 19 * .1 = 1.9].  The Y grid goes from 0 to 1:
SURFACE, TRIGRID(X, Y, Z, Tr, [.1, .1], NX=20)
in=' '
READ,"Press enter",in
```

```
; Output size is 20 x 40.  The range of the grid in X and Y is
; specified by the Limits parameter.  Grid spacing in X is
; [5-0]/(20-1) = 0.263.  Grid spacing in Y is (4-0)/(40-1) = 0.128:
SURFACE, TRIGRID(X, Y, Z, Tr, [0,0], [0,0,5,4],NX=20, NY=40)
in=' '
READ,"Press enter",in

WDELETE

END
```

Example 2

This example shows how to perform spherical gridding:

```
PRO SphericalGrid
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. - 180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. - 90.

; Make a fake function value to be passed to FVALUE. The system
; variable !DTOR contains the conversion value for degrees to
; radians.
f = SIN(lon * !DTOR)^2 * COS(lat * !DTOR)

; Perform a spherical triangulation:
TRIANGULATE, lon, lat, tr, $
    SPHERE=s, FVALUE=f, /DEGREES

; Perform a spherical triangulation using the values returned from
; TRIANGULATE. The result, r, is a 180 by 91 element array:
r=TRIGRID(f, SPHERE=s, [2.,2.],$
   [-180.,-90.,178.,90.], /DEGREES)

; Display the surface
SURFACE, r
END
```

Example 3

This example demonstrates the use of the INPUT keyword:

```
PRO TrigridInputKeyword

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)
```

```
; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

;Show the triangles.
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN $
   ; Subscripts of vertices [0,1,2,0]:
   t = [tr[*,i], tr[0,i]] & $
   ; Connect triangles:
   PLOTS, x[t], y[t]
ENDFOR

; The default size for the return value of trigrid. xtemp should be
; the same type as Z. xtemp provides temporary space for trigrid:
xtemp=FLTARR(51,51)
xtemp = TRIGRID(x, y, z, INPUT = xtemp, tr)

; Show linear surface:
SURFACE, xtemp, TITLE='Linear surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, /QUINTIC)

; Show smooth quintic surface:
SURFACE, xtemp, TITLE='Smooth Quintic surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, EXTRA = b)

; Show smooth extrapolated surface:
SURFACE, xtemp, TITLE='Smooth Extrapolated surface', CHARSIZE=2
in=' '
READ,"Press enter",in
END
```

Example 4

The XOUT and YOUT keywords allow you to obtain an irregular interval from the TRIGRID routine. This example creates an irregularly-gridded dataset of a Gaussian surface. A grid is formed from these points with the TRIANGULATE and TRIGRID routines. The inputs to the XOUT and YOUT keywords are determined at random to produce an irregular interval. These inputs are sorted before setting them to XOUT and YOUT because these keywords require monotonically ascending or descending

values. The lines of the resulting surface are spaced at the irregular intervals provided by the settings of the XOUT and YOUT keywords.

```
PRO GriddingIrregularIntervals

; Make 100 normal x, y points:
x = RANDOMN(seed, 100)
y = RANDOMN(seed, 100)
PRINT, MIN(x), MAX(x)
PRINT, MIN(y), MAX(y)

; Make a Gaussian surface:
z = EXP(-(x^2 + y^2))

; Obtain triangulation:
TRIANGULATE, x, y, triangles, boundary

; Create random x values.  These values will be used to
; form the x locations of the resulting grid.
gridX = RANDOMN(seed, 30)
; Sort x values. Sorted values are required for the XOUT
; keyword.
sortX = UNIQ(gridX, SORT(gridX))
gridX = gridX[sortX]
; Output sorted x values to be used with the XOUT
; keyword.
PRINT, 'gridX:'
PRINT, gridX

; Create random y values.  These values will be used to
; form the y locations of the resulting grid.
gridY = RANDOMN(seed, 30)
; Sort y values. Sorted values are required for the YOUT
; keyword.
sortY = UNIQ(gridY, SORT(gridY))
gridY = gridY[sortY]
; Output sorted y values to be used with the YOUT
; keyword.
PRINT, 'gridY:'
PRINT, gridY

; Derive grid of initial values.  The location of the
; resulting grid points are the inputs to the XOUT and
; YOUT keywords.
grid = TRIGRID(x, y, z, triangles, XOUT = gridX, $
   YOUT = gridY, EXTRAPOLATE = boundary)
```

```
; Display resulting grid.  The grid lines are not
; at regular intervals because of the randomness of the
; inputs to the XOUT and YOUT keywords.

TRIQL

The TRIQL procedure uses the QL algorithm with implicit shifts to determine the eigenvalues and eigenvectors of a real, symmetric, tridiagonal array. The routine TRIRED can be used to reduce a real, symmetric array to the tridiagonal form suitable for input to this procedure.

TRIQL is based on the routine `tqli` described in section 11.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the LA_TRIQL procedure.

Syntax

TRIQL, *D*, *E*, *A* [, /DOUBLE]

Arguments

D

On input, this argument should be an *n*-element vector containing the diagonal elements of the array being analyzed. On output, *D* contains the eigenvalues.

E

An *n*-element vector containing the off-diagonal elements of the array. E_0 is arbitrary. On output, this parameter is destroyed.

A

A named variable that returns the *n* eigenvectors. If the eigenvectors of a tridiagonal array are desired, *A* should be input as an identity array. If the eigenvectors of an array that has been reduced by TRIRED are desired, *A* is input as the array *Q* output by TRIRED.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To compute eigenvalues and eigenvectors of a real, symmetric, tridiagonal array, begin with an array A representing a symmetric array:

```
; Create the array A:
A = [[ 3.0,  1.0, -4.0], $
    [ 1.0,  3.0, -4.0], $
    [-4.0, -4.0,  8.0]]

; Compute the tridiagonal form of A:
TRIRED, A, D, E

; Compute the eigenvalues (returned in vector D) and the
; eigenvectors (returned in the rows of the array A):
TRIQL, D, E, A

; Print eigenvalues:
PRINT, 'Eigenvalues:'
PRINT, D

; Print eigenvectors:
PRINT, 'Eigenvectors:'
PRINT, A
```

IDL prints:

```
Eigenvalues:
  2.00000  4.76837e-7  12.0000

Eigenvectors:
  0.707107  -0.707107   0.00000
 -0.577350  -0.577350  -0.577350
 -0.408248  -0.408248   0.816497
```

The exact eigenvalues are:

```
[2.0, 0.0, 12.0]
```

The exact eigenvectors are:

```
[ 1.0/sqrt(2.0), -1.0/sqrt(2.0), 0.0/sqrt(2.0)],
[-1.0/sqrt(3.0), -1.0/sqrt(3.0), -1.0/sqrt(3.0)],
[-1.0/sqrt(6.0), -1.0/sqrt(6.0), 2.0/sqrt(6.0)]
```

TRIRED

The TRIRED procedure uses Householder's method to reduce a real, symmetric array to tridiagonal form.

TRIRED is based on the routine `tred2` described in section 11.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the LA_TRIRED procedure.

Syntax

TRIRED, *A*, *D*, *E* [, /DOUBLE]

Arguments

A

An *n* by *n* real, symmetric array that is replaced, on exit, by the orthogonal array *Q* effecting the transformation. The routine TRIQL can use this result to find the eigenvectors of the array *A*.

D

An *n*-element output vector containing the diagonal elements of the tridiagonal array.

E

An *n*-element output vector containing the off-diagonal elements.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

See the description of TRIQL for an example using this function.

Version History

Introduced: 4.0

EIGENVEC, ELMHES, HQR, LA_TRIRED, TRIQL

TRISOL

The TRISOL function solves tridiagonal systems of linear equations that have the form: $A^TU = R$

Note

Because IDL subscripts are in column-row order, the equation above is written $A^TU = R$ rather than $AU = R$. The result *U* is a vector of length *n* whose type is identical to *A*.

TRISOL is based on the routine `tridag` described in section 2.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the LA_TRISOL procedure.

Syntax

Result = TRISOL(*A*, *B*, *C*, *R* [, /DOUBLE])

Return Value

Returns a vector containing the solutions.

Arguments

A

A vector of length *n* containing the *n*-1 sub-diagonal elements of A^T. The first element of *A*, A_0, is ignored.

B

An *n*-element vector containing the main diagonal elements of A^T.

C

An *n*-element vector containing the *n*-1 super-diagonal elements of A^T. The last element of *C*, C_{n-1}, is ignored.

R

An *n*-element vector containing the right hand side of the linear system $A^T U = R$.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Example

To solve a tridiagonal linear system, begin with an array representing a real tridiagonal linear system. (Note that only three vectors need be specified; there is no need to enter the entire array shown.)

$$\begin{bmatrix} -4.0 & 1.0 & 0.0 & 0.0 \\ 2.0 & -4.0 & 1.0 & 0.0 \\ 0.0 & 2.0 & -4.0 & 1.0 \\ 0.0 & 0.0 & 2.0 & -4.0 \end{bmatrix}$$

```
; Define a vector A containing the sub-diagonal elements with a
; leading 0.0 element:
A = [0.0, 2.0, 2.0, 2.0]

; Define B containing the main diagonal elements:
B = [-4.0, -4.0, -4.0, -4.0]

; Define C containing the super-diagonal elements with a trailing
; 0.0 element:
C = [1.0, 1.0, 1.0, 0.0]

; Define the right-hand side vector:
R = [6.0, -8.0, -5.0, 8.0]

; Compute the solution and print:
result = TRISOL(A, B, C, R)
PRINT, result
```

IDL prints:

```
-1.00000  2.00000  2.00000  -1.00000
```

The exact solution vector is [-1.0, 2.0, 2.0, -1.0].

TRUNCATE_LUN

The TRUNCATE_LUN procedure truncates the contents of a file (which must be open for write access) at the current position of the file pointer. After this operation, all data before the current file pointer remains intact, and all data following the file pointer are gone. The position of the current file pointer is not altered.

Syntax

TRUNCATE_LUN, *Unit*$_1$, ..., *Unit*$_n$

Arguments

Unit$_n$

Scalar or array variables containing the logical file unit numbers of the open files to be truncated.

Keywords

None.

Examples

Example 1

Truncate the entire contents of an existing file:

```
OPENU, unit, 'baddata.dat', /GET_LUN
TRUNCATE_LUN, unit
FREE_LUN, unit
```

Example 2

Given an existing file of 10,000 bytes, throw away the final 5,000 bytes, and then write an additional 2,000 byte array in their place. The resulting file will be 7,000 bytes in length.

```
OPENU, unit, 'mydata.dat', /GET_LUN
POINT_LUN, unit, 5000
TRUNCATE_LUN, unit
WRITEU, unit, BYTARR(2000)
FREE_LUN, unit
```

Version History

Introduced: 5.6

TS_COEF

The TS_COEF function computes the coefficients ϕ_1, ϕ_2, ... , ϕ_P used in a *P*-th order autoregressive time-series forecasting model. This routine is written in the IDL language. Its source code can be found in the file `ts_coef.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TS_COEF(*X*, *P* [, /DOUBLE] [, MSE=*variable*])

Return Value

Returns a *P*-element vector whose type is identical to *X*.

Arguments

X

An *n*-element single- or double-precision floating-point vector containing time-series samples.

P

An integer or long integer scalar that specifies the number of coefficients to be computed.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

MSE

Set this keyword to a named variable that will contain the mean square error of the *P*-th order autoregressive model.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]
; Compute the coefficients of a 5th order autoregressive model:
PRINT, TS_COEF(X, 5)
```

IDL prints:

```
1.30168    -0.111783    -0.224527     0.267629    -0.233363
```

TS_FCAST

TS_DIFF

The TS_DIFF function recursively computes the forward differences of an *n*-element time-series *k* times. This routine is written in the IDL language. Its source code can be found in the file `ts_diff.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TS_DIFF(*X*, *K* [, /DOUBLE])

Return Value

The result is an *n*-element differenced time-series with its last *k* elements as zeros.

Arguments

X

An *n*-element integer, single- or double-precision floating-point vector containing time-series samples.

K

A positive integer or long integer scalar that specifies the number of times *X* is to be differenced. *K* must be in the interval [1, N_ELEMENTS(*X*) - 1].

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an n-element vector of time-series samples:
X = [389, 345, 303, 362, 412, 356, 325, 375, $
     410, 350, 310, 388, 399, 362, 325, 382, $
     399, 382, 318, 385, 437, 357, 310, 391]
; Compute the second forward differences of X:
PRINT, TS_DIFF(X, 2)
```

IDL prints:

```
     2  101   -9 -106   25   81  -15  -95   20
   118  -67  -48    0   94  -40  -34  -47  131
   -15 -132   33  128    0    0
```

Version History

SMOOTH, TS_FCAST

TS_FCAST

The TS_FCAST function computes future or past values of a stationary time-series using a *P*-th order autoregressive model.

A *P*-th order autoregressive model relates a forecasted value x_t of the time series $X = [x_0, x_1, x_2, \ldots, x_{t-1}]$, as a linear combination of *P* past values.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \ldots + \phi_P x_{t-P} + w_t$$

The coefficients $\phi_1, \phi_2, \ldots, \phi_P$ are calculated such that they minimize the uncorrelated random error terms, *wt*.

This routine is written in the IDL language. Its source code can be found in the file `ts_fcast.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TS_FCAST(*X*, *P*, *Nvalues* [, /BACKCAST] [, /DOUBLE])

Return Value

The result is an *Nvalues*-element vector whose type is identical to *X*.

Arguments

X

An *n*-element single- or double-precision floating-point vector containing time-series samples.

P

An integer or long integer scalar that specifies the number of actual time-series values to be used in the forecast. In general, a larger number of values results in a more accurate forecast.

Nvalues

An integer or long integer scalar that specifies the number of future or past values to be computed.

Keywords

BACKCAST

Set this keyword to produce past values (backward forecasts or “backcasts”)

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute and print five future values of the time-series using ten
; time-series values:
PRINT, TS_FCAST(X, 10, 5)

; Compute five past values of the time-series using ten time-series
;values:
PRINT, TS_FCAST(X, 10, 5, /BACKCAST)
```

IDL prints:

```
4.65870      4.58380      4.50030      4.48828      4.46971
6.94862      6.91103      6.86297      6.77826      6.70282
```

Version History

A_CORRELATE, COMFIT, CURVEFIT, SMOOTH, TS_COEF, TS_DIFF

TS_SMOOTH

The TS_SMOOTH function computes central, backward, or forward moving averages of an *n*-element time-series. Autoregressive forecasting and backcasting are used to extrapolate the time-series and compute a moving average for each point.

Note

Central moving averages require *Nvalues*/2 forecasts and *Nvalues*/2 backcasts. Backward moving averages require *Nvalues*-1 backcasts. Forward moving averages require *Nvalues*-1 forecasts.

This routine is written in the IDL language. Its source code can be found in the file `ts_smooth.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TS_SMOOTH(*X*, *Nvalues* [, /BACKWARD] [, /DOUBLE] [, /FORWARD] [, ORDER=*value*])

Return Value

The result is an *n*-element vector of the same data type as the input vector.

Arguments

X

An *n*-element single- or double-precision floating-point vector containing time-series samples. Note that *n* must be greater than or equal to 11.

Nvalues

A scalar of type integer or long integer that specifies the number of time-series values used to compute each moving-average. If central-moving averages are computed (the default), this parameter must be an odd integer greater than or equal to three.

Keywords

BACKWARD

Set this keyword to compute backward-moving averages. If BACKWARD is set, the *Nvalues* argument must be an integer greater than one.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FORWARD

Set this keyword to compute forward-moving averages. If FORWARD is set, the *Nvalues* argument must be an integer greater than one.

ORDER

An integer or long-integer scalar that specifies the order of the autoregressive model used to compute the forecasts and backcasts of the time-series. By default, a time-series with a length between 11 and 219 elements will use an autoregressive model with an order of 10. A time-series with a length greater than 219 will use an autoregressive model with an order equal to 5% of its length. The ORDER keyword is used to override this default.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99,$
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31,$
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute the 11-point central-moving-averages of the time-series:
PRINT, TS_SMOOTH(X, 11)
```

IDL prints:

```
6.65761 6.60592 6.54673 6.47646 6.40480 6.33364
6.27000 6.20091 6.14273 6.09364 6.04455 5.99000
5.92273 5.85455 5.78364 5.72636 5.65818 5.58000
5.50182 5.42727 5.34182 5.24545 5.15273 5.07000
5.00182 4.94261 4.87205 4.81116 4.75828 4.71280
```

Version History

Introduced: 5.0

SMOOTH, TS_DIFF, TS_FCAST

TV

The TV procedure displays images on the image display without scaling the intensity. To display an image with scaling, use the TVSCL procedure.

Note

To display a TrueColor image (an image with 16, 24, or 32 bits per pixel) you must specify the TRUE keyword.

While the TV procedure does not *scale* the intensity of an image, it does convert the input image data to byte type. Values outside the range [0,255] are "wrapped" during the conversion. In addition, for displays with less than 256 colors, elements of the input image with values between !D.TABLE_SIZE and 255 will be displayed using the color index !D.TABLE_SIZE-1.

Syntax

TV, *Image* [, *Position*]

or

TV, *Image* [, *X*, *Y* [, *Channel*]]

Keywords: [, /CENTIMETERS | , /INCHES] [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

Graphics Keywords: [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

Arguments

Image

A vector or two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

X, Y

If *X* and *Y* are present, they specify the lower-left coordinate of the displayed image, relative to the lower-left corner of the screen.

Position

An integer specifying the position for *Image* within the graphics window. Image positions run from the top left of the screen to the bottom right. If a position number is used instead of *X* and *Y*, the position of the image is calculated from the dimensions of the image as follows (integer arithmetic is used).

$$\text{Xsize, Ysize} = \text{Size of display or window}$$

$$\text{Xdim, Ydim} = \text{Dimensions of image to be displayed}$$

$$N_x = \frac{\text{Xsize}}{\text{Ydim}} = \text{Images across screen}$$

$$X = \text{Xdim}\,\text{Position}_{\text{modulo}\,N_x} = \text{Starting X}$$

$$Y = \text{Ysize} - \text{Ydim}\left[1 + \frac{\text{Position}}{N_x}\right] = \text{Starting Y}$$

For example, when displaying 128 by 128 images on a 512 by 512 display, the position numbers run from 0 to 15 as follows:

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

Note

When using a device with scalable pixels (e.g., PostScript), the XSIZE and YSIZE keywords should also be used.

Channel

The memory channel to be written to. The *Channel* argument is identical to the CHANNEL graphics keyword.

Keywords

CENTIMETERS

Set this keyword to indicate that the *X*, *Y*, *Xsize*, *Ysize*, and *Z* arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of (3, *m*, *n*). Specify 2 for row-interleaved images, of size (*m*, 3, *n*), and 3 for band-interleaved images of the form (*m*, *n*, 3).

See “TrueColor Images” on page 3824 for an example using this keyword to write 24-bit images to the PostScript device.

WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the *Image* parameter is converted to short integer type, if necessary, and then written to the display.

XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

Graphics Keywords Accepted

See Appendix H, "Graphics Keywords" for the description of graphics and plotting keywords not listed above. CHANNEL, DATA, DEVICE, NORMAL, T3D, Z.

Examples

```
; Create and display a simple image:
D = BYTSCL(DIST(256)) & TV, D

; Erase the screen:
ERASE

; Use the position parameter to display a number of images in the
; same window.
; Display the image in the upper left corner.
TV, D, 0

; Display another copy of the image in the next position:
TV, D, 1
```

TVCRS

The TVCRS procedure manipulates the display device cursor. The initial state of the cursor is device dependent. Call TVCRS with one argument to enable or disable the cursor. Call TVCRS with two parameters to enable the cursor and place it on pixel location *(X, Y)*.

Syntax

TVCRS [, *ON_OFF*]

or

TVCRS [, *X*, *Y*]

Keywords: [, /CENTIMETERS | , /INCHES] [, /HIDE_CURSOR]

Graphics Keywords: [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

Arguments

ON_OFF

This argument specifies whether the cursor should be on or off. If this argument is present and nonzero, the cursor is enabled. If *ON_OFF* is zero or no parameters are specified, the cursor is turned off.

X

The column to which the cursor is set.

Y

The row to which the cursor is set.

Keywords

CENTIMETERS

Set this keyword to cause X and Y to be interpreted as centimeters, based on the current device resolution.

INCHES

Set this keyword to cause X and Y to be interpreted as inches, based on the current device resolution.

HIDE_CURSOR

By default, disabling the cursor works differently for window systems than for other devices. For window systems, the cursor is restored to the standard cursor used for non-IDL windows (and remains visible), while for other devices it is completely blanked out. If the HIDE keyword is set, disabling the cursor causes it to always be blanked out.

Graphics Keywords Accepted

See Appendix H, “Graphics Keywords” for the description of graphics and plotting keywords not listed above. DATA, DEVICE, NORMAL, T3D, Z.

Examples

To enable the graphics cursor and position it at device coordinate (100, 100), enter:

```
TVCRS, 100, 100
```

To position the cursor at data coordinate (0.5, 3.2), enter:

```
TVCRS, 0.5, 3.2, /DATA
```

CURSOR, RDPIX

TVLCT

The TVLCT procedure loads the display color translation tables from the specified variables. Although IDL uses the RGB color system internally, color tables can be specified to TVLCT using any of the following color systems: RGB (Red, Green, Blue), HLS (Hue, Lightness, Saturation), and HSV (Hue, Saturation, Value). Alpha values may also be used when using the second form of the command. The type and meaning of each argument is dependent upon the color system selected, as described below. Color arguments can be either scalar or vector expressions. If no color-system keywords are present, the RGB color system is used.

Syntax

TVLCT, V_1, V_2, V_3 [, *Start*] [, /GET] [, /HLS | , /HSV]

or

TVLCT, *V* [, *Start*] [, /GET] [, /HLS | , /HSV]

Arguments

TVLCT will accept either three *n*-element vectors (V_1, V_2, and V_3) or a single *n*-by-3 array (*V*) as an argument. The vectors (or columns of the array) have different meanings depending on the color system chosen. If an array *V* is specified, *V*[*,0] is the same as V_1, *V*[*,1] is the same as V_2, *V*[*,2] is the same as V_3. In the description below, we assume that three vectors, V_1, V_2, and V_3 are specified.

The V_1, V_2, and V_3 arguments have different meanings depending upon which color system they represent.

R, G, B Color System

The parameters V_1, V_2, and V_3 contain the Red, Green, and Blue values, respectively. Values are interpreted as integers in the range 0 (lowest intensity) to 255 (highest intensity). The parameters can be scalars or vectors of up to 256 elements. By default, the three arguments are assumed to be R, G, and B values.

H, L, S Color System

Parameters V_1, V_2, and V_3 contain the Hue, Lightness, and Saturation values respectively. All parameters are floating-point. Hue is expressed in degrees and is reduced modulo 360. V_2 (lightness) and V_3 (saturation) and can range from 0 to 1.0. Set the HLS keyword to have the arguments interpreted this way.

H, S, V Color System

Parameters V_1, V_2, and V_3 contain values for Hue, Saturation, and Value (similar to intensity). All parameters are floating-point. Hue is in degrees. The Saturation and Value can range from 0 to 1.0. Set the HSV keyword to have the arguments interpreted this way.

Start

An integer value that specifies the starting point in the color translation table into which the color intensities are loaded. If this argument is not specified, a value of zero is used, causing the tables to be loaded starting at the first element of the translation tables.

Keywords

GET

Set this keyword to return the RGB values from the internal color tables into the V_1, V_2, and V_3 parameters. For example, the statements:

```
TVLCT, H, S, V, /HSV
TVLCT, R, G, B, /GET
```

load a color table based in the HSV system, and then read the equivalent RGB values into the variables R, G, and B.

HLS

Set this keyword to indicate that the parameters specify color using the HLS color system.

HSV

Set this keyword to indicate that the parameters specify color using the HSV color system.

Examples

```
; Create a set of R, G, and B colormap vectors:
R = BYTSCL(SIN(FINDGEN(256)))
G = BYTSCL(COS(FINDGEN(256)))
B = BINDGEN(256)

; Load these vectors into the color table:
TVLCT, R, G, B
```

```
; Display an image to see the effect of the new color table:
TVSCL, DIST(400)
```

Version History

LOADCT, XLOADCT, XPALETTE

TVRD

The TVRD function returns the contents of the specified rectangular portion of the current graphics window or device. (X_0, Y_0) is the coordinate of the lower left corner of the area to be read and N_x, N_y is the size of the rectangle in columns and rows. The result is a byte array of dimensions N_x by N_y. All parameters are optional. If no arguments are supplied, the entire display device area is read.

Important Note about TVRD and Backing Store

On some systems, when backing store is provided by the window system (the RETAIN keyword to DEVICE or WINDOW is set to 1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (set the RETAIN keyword to 2) ensures that the window contents will be read properly. More detailed notes about TVRD and the X Window system can be found below in "Unexpected Results Using TVRD with X Windows" on page 1971.

Note

When using TVRD on 16-bit TrueColor displays only 5 or 6 bits of pixel data are stored for each color channel. Using TVRD on these displays returns channel data where only the high 5 or 6 bits are significant; the other bits are indeterminate.

Syntax

Result = TVRD([X_0 [, Y_0 [, N_x [, N_y [, *Channel*]]]]] [, CHANNEL=*value*] [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS])

Return Value

Returns a byte array of the specified dimensions.

Arguments

X_0

The starting column of data to read. The default is 0.

Y_0

The starting row of data to read. The default is 0.

N_x

The number of columns to read. The default is the width of the display device or window less X_0.

N_y

The number of rows to read. The default is the height of the display device or window less Y_0.

Channel

The memory channel to be read. If not specified, this argument is assumed to be zero. This parameter is ignored on display systems that have only one memory channel.

Keywords

CHANNEL

The memory channel to be read. The CHANNEL keyword is identical to the optional *Channel* argument.

Note

If the display is a 24-bit display, and both the CHANNEL and TRUE parameters are absent, the maximum RGB value in each pixel is returned.

ORDER

Set this keyword to override the current setting of the !ORDER system variable for the current image only. If set, it causes the image to be read from the top down instead of the normal bottom up.

TRUE

If this keyword is present, it indicates that a TrueColor image is to be read, if the display is capable. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The result is an (3, n_x, n_y) pixel-interleaved array if TRUE is 1; or an (n_x, 3, n_y) line-interleaved array if TRUE is 2; or an (n_x, n_y, 3) image-interleaved array if TRUE is 3.

WORDS

Set this keyword to indicate that words are to be transferred from the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the function result is an integer array.

Unexpected Results Using TVRD with X Windows

When using TVRD with the X Windows graphics device, there are two unexpected behaviors that can be confusing to users:

- When reading from a window that is obscured by another window (i.e., the target window has another window “on top” or “in front” of it), TVRD may return the contents of the window in front as part of the image contained in the target window.
- When reading from an iconified window, the X server may return a stream of “BadMatch” protocol events.

IDL uses the Xlib function `XGetSubImage()` to implement TVRD. The following quote is from the documentation for XGetSubImage() found in *The X Window System* by Robert W. Scheifler and James Gettys, Second Edition, page 174. It explains the reasons for the behaviors described above:

“If the drawable is a window, the window must be viewable, and it must be the case that if there were no... overlapping windows, the specified rectangle of the window would be fully visible on the screen, ... or a BadMatch error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured... If the window does not have backing-store, the returned contents of such obscured regions are undefined.”

Hence, the first behavior is caused by attempting to use TVRD on an obscured window that does not have backing store provided by the X server. The result in this case is undefined, meaning that the different servers can produce entirely different results. Many servers simply return the image of the obscuring window.

The second behavior is caused by attempting to read from a non-viewable (i.e., unmapped) window. Although IDL could refuse to allow TVRD to work with unmapped windows, some X servers return valid and useful results. Therefore, TVRD is allowed to attempt to read from unmapped windows.

Both of these behavior problems can be solved by using one of the following methods:

- Always make sure that your target window is mapped and is not obscured before using TVRD on it. The following IDL command can be used:

```
WSET, Window_Index
```

- Make IDL provide backing store (rather than the window system) by setting the RETAIN keyword to DEVICE or WINDOW equal to 2.

For a full description of backing store, see “Backing Store” on page 3806. Note that under X Windows, backing store is a request that may or may not be honored by the X server. Many servers will honor backing store for 8-bit visuals but ignore them for 24-bit visuals because they require three times as much memory.

Examples

```
; Read the entire contents of the current display device into the
; variable T:
T = TVRD()
```

RDPIX, TV, WINDOW

TVSCL

The TVSCL procedure scales the intensity values of *Image* into the range of the image display and outputs the data to the image display at the specified location. The array is scaled so the minimum data value becomes 0 and the maximum value becomes the maximum number of available colors (held in the system variable !D.TABLE_SIZE) as follows:

$$\text{Output} = (\text{!D.TABLE_SIZE} - 1)\frac{\text{Data} - \text{Data}_{\text{min}}}{\text{Data}_{\text{max}} - \text{Data}_{\text{min}}}$$

where the maximum and minimum are found by scanning the array. The parameters and keywords of the TVSCL procedure are identical to those accepted by the TV procedure. For additional information about each parameter, consult the description of TV.

Syntax

TVSCL, *Image* [, *Position*]

or

TVSCL, *Image* [, *X*, *Y* [, *Channel*]]

Keywords: [, /CENTIMETERS | , /INCHES] [, /NAN] [, /ORDER] [, TOP=*value*] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

Graphics Keywords: [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

Arguments

Image

A two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

X, Y

If *X* and *Y* are present, they specify the lower left coordinate of the displayed image.

Position

Image position. See the discussion of the TV procedure for a full description.

Channel

The memory channel to be written. This argument is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel.

Keywords

TVSCL accepts all of the keywords accepted by the TV routine. See "TV" on page 1960. In addition, there are two unique keywords:

NAN

Set this keyword to cause TVSCL to treat elements of *Image* that are not numbers (that is, elements that have the special floating-point values *Infinity* or *NaN*) as missing data, and display them using color index 0 (zero). Note that color index 0 is also used to display elements that have the minimum value in the *Image* array.

TOP

The maximum value of the scaled result. If TOP is not specified, !D.TABLE_SIZE-1 is used. Note that the minimum value of the scaled result is always 0.

Graphics Keywords Accepted

See Appendix H, "Graphics Keywords" for the description of graphics and plotting keywords not listed above. CHANNEL, DATA, DEVICE, NORMAL, T3D, Z.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

Display a floating-point array as an image using the TV command:

```
TV, DIST(200)
```

Note that the image is not easily visible because the values in the array have not been scaled into the full range of display values. Now display the image with the TVSCL command by entering:

```
TVSCL, DIST(200)
```

Notice how much brighter the image appears.

UINDGEN

The UINDGEN function creates an unsigned integer array. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

Result = UINDGEN(D_1 [, ..., D_8])

Return Value

Returns an unsigned integer array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

To create UI, a 10-element by 10-element 16-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
UI = UINDGEN(10, 10)
```

Version History

Introduced: 5.2

UINT

The UINT function returns a result equal to *Expression* converted to unsigned integer type.

Syntax

Result = UINT(*Expression[, Offset [, D_1 [, ..., D_8]]]*)

Return Value

Returns the specified dimensions of the given expression as an unsigned integer type.

Arguments

Expression

The expression to be converted to unsigned integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned integer data. See the description in Chapter 3, “Constants and Variables” in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned integer and stored in the variable B by entering:

```
B = UINT(A)
```

Version History

Introduced: 5.2

UINTARR

The UINTARR function creates an unsigned integer vector or array.

Syntax

Result = UINTARR(D_1 *[, ..., D_8]* [, /NOZERO])

Return Value

Returns an unsigned integer vector or array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, UINTARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and UINTARR executes faster.

Examples

To create L, a 100-element, unsigned integer vector with each element set to 0, enter:

```
L = UINTARR(100)
```

Version History

Introduced: 5.2

UL64INDGEN

The UL64INDGEN function returns an unsigned 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

Result = UL64INDGEN(D_1 [, ..., D_8])

Return Value

Returns the specified unsigned integer array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

To create L, a 10-element by 10-element 64-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
L = UL64INDGEN(10, 10)
```

Version History

Introduced: 5.2

ULINDGEN

The ULINDGEN function returns an unsigned longword array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

Result = ULINDGEN(D_1 [, ..., D_8])

Return Value

Returns the specified unsigned longword array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

To create L, a 10-element by 10-element 32-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
L = ULINDGEN(10, 10)
```

Version History

Introduced: 5.2

ULON64ARR

The ULON64ARR function returns an unsigned 64-bit integer vector or array.

Syntax

Result = ULON64ARR(D_1 *[, ..., D_8]* [, /NOZERO])

Return Value

Returns a vector or array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, ULON64ARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULON64ARR executes faster.

Examples

To create L, a 100-element, unsigned 64-bit vector with each element set to 0, enter:

```
L = ULON64ARR(100)
```

Version History

Introduced: 5.2

See Also

BYTARR, COMPLEXARR, DBLARR, DCOMPLEXARR, FLTARR, INTARR, LON64ARR, LONARR, MAKE_ARRAY, STRARR, UINTARR, ULONARR

ULONARR

The ULONARR function returns an unsigned longword integer vector or array.

Syntax

Result = ULONARR(D_1 *[, ..., D_8]* [, /NOZERO])

Return Value

Returns an unsigned longword integer array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, ULONARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULONARR executes more quickly.

Examples

To create L, a 100-element, unsigned longword vector with each element set to 0, enter:

```
L = ULONARR(100)
```

Version History

Introduced: 5.2

See Also

ULONG

The ULONG function returns a result equal to *Expression* converted to the unsigned longword integer type.

Syntax

Result = ULONG(*Expression[, Offset [, D_1 [, ..., D_8]]]*)

Return Value

Returns the specified dimensions of the given expression as an unsigned longword integer type.

Arguments

Expression

The expression to be converted to unsigned longword integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned longword integer data. See the description in Chapter 3, “Constants and Variables” in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned longword integer and stored in the variable B by entering:

```
B = ULONG(A)
```

BYTE, COMPLEX, DCOMPLEX, DOUBLE, FIX, FLOAT, LONG, LONG64, STRING, UINT, ULONG64

ULONG64

The ULONG64 function returns a result equal to *Expression* converted to the unsigned 64-bit integer type.

Syntax

Result = ULONG64(*Expression[, Offset [, D_1 [, ..., D_8]]]*)

Return Value

Returns the specified dimensions of the given expression as an unsigned 64-bit integer type.

Arguments

Expression

The expression to be converted to unsigned 64-bit integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned 64-bit integer data. See the description in Chapter 3, “Constants and Variables” in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned 64-bit integer and stored in the variable B by entering:

```
B = ULONG64(A)
```

Version History

Introduced: 5.2

BYTE, COMPLEX, DCOMPLEX, DOUBLE, FIX, FLOAT, LONG, LONG64, STRING, UINT, ULONG

UNIQ

The UNIQ function returns the subscripts of the unique elements in an array. Note that repeated elements must be adjacent in order to be found. This routine is intended to be used with the SORT function: see the examples below. This function was inspired by the UNIX `uniq(1)` command.

This routine is written in the IDL language. Its source code can be found in the file `uniq.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = UNIQ(*Array* [, *Index*])

Return Value

UNIQ returns an array of indices into the original array. Note that the index of the last element in each set of non-unique elements is returned. The following expression is a copy of the sorted array with duplicate adjacent elements removed:

Array`(UNIQ(`*Array*`))`

UNIQ returns 0 (zero) if the argument supplied is a scalar rather than an array.

Arguments

Array

The array to be scanned. For UNIQ to work properly, the array must be sorted into monotonic order unless the optional parameter *Idx* is supplied.

Index

This optional parameter is an array of indices into *Array* that order the elements into monotonic order. That is, the expression:

Array`(`*Index*`)`

yields an array in which the elements of *Array* are rearranged into monotonic order. If the array is not already in monotonic order, use the command:

```
UNIQ(Array, SORT(Array))
```

Examples

Find the unique elements of an unsorted array:

```
; Create an array:
array = [1, 2, 1, 2, 3, 4, 5, 6, 6, 5]

; Variable B holds an array containing the sorted, unique values in
; array:
b = array[UNIQ(array, SORT(array))]
PRINT, b
```

IDL prints

```
1    2    3    4    5    6
```

Version History

Introduced: Pre 4.0

SORT, WHERE

USERSYM

The USERSYM procedure is used to define the plotting symbol that marks points when the plotting symbol is set to plus or minus 8. Symbols can be drawn with vectors or can be filled. Symbols can be of any size and can have up to 50 vertices. See"Defining Your Own Plotting Symbols" in Chapter 17 of the *Using IDL* manual .

Syntax

USERSYM, *X* [, *Y*] [, COLOR=*value*] [, /FILL] [, THICK=*value*]

Arguments

X, Y

The *X* and/or *Y* parameters define the vertices of the symbol as offsets from the data point in units of approximately the size of a character. In the case of a vector drawn symbol, the symbol is formed by connecting the vertices in order. If only one argument is specified, it must be a (2, *N*) array of vertices, with element [0, *i*] containing the X coordinate of the vertex, and element [1, *i*] containing the Y. If both arguments are provided, *X* contains only the X coordinates.

Keywords

COLOR

The color used to draw the symbols, or used to fill the polygon. The default color is the same as the line color.

FILL

Set this keyword to fill the polygon defined by the vertices. If FILL is not set, lines are drawn connecting the vertices.

THICK

The thickness of the lines used in drawing the symbol. The default thickness is 1.0.

Examples

Make a large, diamond-shaped plotting symbol. Define the vectors of X values by entering:

```
X = [-6, 0, 6, 0, -6]
```

Define the vectors of Y values by entering:

```
Y = [0, 6, 0, -6, 0]
```

Now call USERSYM to create the new plotting symbol 8. Enter:

```
USERSYM, X, Y
```

Generate a simple plot to test the plotting symbol by entering:

```
PLOT, FINDGEN(20), PSYM = 8
```

PLOT

VALUE_LOCATE

The VALUE_LOCATE function finds the intervals within a given monotonic vector that brackets a given set of one or more search values. This function is useful for interpolation and table-lookup, and is an adaptation of the locate() routine in Numerical Recipes. VALUE_LOCATE uses the bisection method to locate the interval.

Syntax

Result = VALUE_LOCATE (*Vector*, *Value* [, /L64])

Return Value

Each return value, *Result* [*i*], is an index, *j*, into *Vector*, corresponding to the interval into which the given *Value* [*i*] falls. The returned values are in the range $-1 \le j \le N-1$, where *N* is the number of elements in the input vector.

If *Vector* is monotonically increasing, the result *j* is:

if $j = -1$ *Value* [*i*] < *Vector* [0]

if $0 \le j < N-1$ *Vector* [*j*] ≤ *Value* [*i*] < *Vector* [*j*+1]

if $j = N-1$ *Vector* [*N*–1] ≤ *Value* [*i*]

If *Vector* is monotonically decreasing

if $j = -1$ *Vector* [*0*] ≤ *Value* [*i*]

if $0 \le j < N-1$ *Vector* [*j*+1] ≤ *Value* [*i*] < *Vector* [*j*]

if $j = N-1$ *Value* [*i*] < *Vector* [*N*–1]

Arguments

Vector

A vector of monotonically increasing or decreasing values. *Vector* may be of type string, or any numeric type except complex, and may not contain the value NaN (not-a-number).

Value

The value for which the location of the intervals is to be computed. *Value* may be either a scalar or an array. The return value will contain the same number of elements as this parameter.

Keywords

L64

By default, the result of VALUE_LOCATE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

Examples

```
; Define a vector of values.
vec = [2,5,8,10]

; Compute location of other values within that vector.
loc = VALUE_LOCATE(vec, [0,3,5,6,12])
PRINT, loc
```

IDL prints:

```
-1   0   1   1   3
```

Version History

Introduced: 5.3

VARIANCE

The VARIANCE function computes the statistical variance of an *n*-element vector.

Syntax

Result = VARIANCE(*X* [, /DOUBLE] [, /NAN])

Return Value

Returns the floating-point or double-precision statistical variance of the input vector.

Arguments

X

An *n*-element, floating-point or double-precision vector.

Keywords

DOUBLE

If this keyword is set, VARIANCE performs its computations in double precision arithmetic and returns a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results).

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point value NaN in the input data. Elements with the value NaN are treated as missing data. (See "Special Floating-Point Values" in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
x = [1, 1, 1, 2, 5]
; Compute the variance:
result = VARIANCE(x)
PRINT, result
```

IDL prints:

```
3.00000
```

Version History

Introduced: 5.1

VECTOR_FIELD

The VECTOR_FIELD procedure is used to place colored, oriented vectors of specified length at each vertex in an input vertex array. The output can be sent directly to an IDLgrPolyline object. The generated display is generally referred to as a hedgehog display and is used to convey various aspects of a vector field.

Syntax

VECTOR_FIELD, *Field*, *Outverts*, *Outconn* [, ANISOTROPY=*array*] [, SCALE=*value*] [, VERTICES=*array*]

Arguments

Field

Input vector field array. This can be a [3, *x*, *y*, *z*] array or a [2, *x*, *y*] array. The leading dimension is the vector quantity to be displayed.

Outverts

Output vertex array ([3, *N*] or [2, *N*] array of floats). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

Outconn

Output polyline connectivity array to be applied to the output vertices.

Keywords

ANISOTROPY

Set this keyword to a two- or three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0] for three-dimensional data and [1.0, 1.0] for two-dimensional data.

SCALE

Set this keyword to a scalar scaling factor. All vector lengths are multiplied by this value. The default is 1.0.

VERTICES

Set this keyword to a [3, *n*] or [2, *n*] array of points. If this keyword is set, the vector field is interpolated at these points. The resulting interpolated vectors are displayed as line segments at these locations. If the keyword is not set, each spatial sample point in the input Field grid is used as the base point for a line segment.

Version History

Introduced: 5.3

VEL

The VEL procedure draws a velocity (flow) field with arrows following the field proportional in length to the field strength. Arrows are composed of a number of small segments that follow the streamlines.

This routine is written in the IDL language. Its source code can be found in the file `vel.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

VEL, *U*, *V* [, NVECS=*value*] [, XMAX= *value*{*xsize*/*ysize*}]
[, LENGTH=*value*{*longest*/*steps*}] [, NSTEPS=*value*] [, TITLE=*string*]

Arguments

U

The X component at each point of the vector field. *U* must be a 2-D array.

V

The Y component at each point of the vector field. *V* must have the same dimensions as *U*.

Keywords

LENGTH

The length of each arrow line segment expressed as a fraction of the longest vector divided by the number of steps. The default is 0.1.

NSTEPS

The number of shoots or line segments for each arrow. The default is 10.

NVECS

The number of vectors (arrows) to draw. If this keyword is omitted, 200 vectors are drawn.

TITLE

A string containing the title for the plot.

XMAX

X axis size as a fraction of Y axis size. The default is 1.0. This argument is ignored when !P.MULTI is set.

Examples

```
; Create a vector of X values:
X = DIST(20)

; Create a vector of Y values:
Y = SIN(X)*100

; Plot the vector field:
VEL, X, Y
```

Version History

Introduced: Pre 4.0

FLOW3, PLOT_FIELD, VELOVECT

VELOVECT

The VELOVECT procedure produces a two-dimensional velocity field plot. A directed arrow is drawn at each point showing the direction and magnitude of the field.

This routine is written in the IDL language. Its source code can be found in the file `velovect.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

VELOVECT, *U*, *V* [, *X*, *Y*] [, COLOR=*index*] [, MISSING=*value* [, /DOTS]] [, LENGTH=*value*] [, /OVERPLOT] [Also accepts all PLOT keywords]

Arguments

U

The X component of the two-dimensional field. *U* must be a two-dimensional array.

V

The Y component of the two dimensional field. *V* must have the same dimensions as *U*.

X

Optional abscissae values. *X* must be a vector with a length equal to the first dimension of *U* and *V*.

Y

Optional ordinate values. *Y* must be a vector with a length equal to the second dimension of *U* and *V*.

Keywords

Note

Keywords not described here are passed directly to the PLOT procedure and may be used to set options such as TITLE, POSITION, NOERASE, etc.

COLOR

Set this keyword equal to the color index used for the plot.

DOTS

Set this keyword to 1 to place a dot at each missing point. Set this keyword to 0 or omit it to draw nothing for missing points. Has effect only if MISSING is specified.

LENGTH

Set this keyword equal to the length factor. The default of 1.0 makes the longest (*U*,*V*) vector the length of a cell.

MISSING

Set this keyword equal to the missing data value. Vectors with a length greater than MISSING are ignored.

OVERPLOT

Set this keyword to make VELOVECT “overplot”. That is, the current graphics screen is not erased, no axes are drawn, and the previously established scaling remains in effect.

PLOT Keywords

In addition to the keywords described above, all other keywords accepted by the PLOT procedure are accepted by VELOVECT. See PLOT.

Examples

```
; Create some random data:
U = RANDOMN(S, 20, 20)
V = RANDOMN(S, 20, 20)

; Plot the vector field:
VELOVECT, U, V

; Plot the field, using dots to represent vectors with values
; greater than 18:
VELOVECT, U, V, MISSING=18, /DOTS

; Plot with a title. Note that the XTITLE keyword is passed
; directly to the PLOT procedure:
VELOVECT, U, V, MISSING=18, /DOTS, XTITLE='Random Vectors'
```

FLOW3, PLOT, PLOT_FIELD, VEL

VERT_T3D

The VERT_T3D function transforms a 3-D array by a 4x4 transformation matrix. The 3-D points are typically an array of polygon vertices that were generated by SHADE_VOLUME or MESH_OBJ.

This routine is written in the IDL language. Its source code can be found in the file `vert_t3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = VERT_T3D(*Vertex_List* [, DOUBLE=*value*] [, MATRIX=*4x4_array*] [, /NO_COPY] [, /NO_DIVIDE [, SAVE_DIVIDE=*variable*]])

Return Value

Returns the single- or double-precision coordinates of the transformed array.

Arguments

Vertex_List

A 3 x *n* array of 3-D coordinates to transform.

Keywords

DOUBLE

Set this keyword to a nonzero value to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the DOUBLE keyword is implied to be non-zero).

MATRIX

The 4x4 transformation matrix to use. The default is to use the system viewing matrix (!P.T).

NO_COPY

Normally, a copy of *Vertex_list* is transformed and the original *Vertex_list* is preserved. If NO_COPY is set, however, then the original *Vertex_List* will be undefined after the call to VERT_T3D. Using the NO_COPY requires less memory.

NO_DIVIDE

Normally, when a [*x*, *y*, *z*, 1] vector is transformed by a 4x4 matrix, the final homogeneous coordinates are obtained by dividing the *x*, *y*, and *z* components of the result vector by the fourth element in the result vector. Setting the NO_DIVIDE keyword will prevent VERT_T3D from performing this division. In some cases (usually when a perspective transformation is involved) the fourth element in the result vector can be very close to (or equal to) zero.

SAVE_DIVIDE

Set this keyword to a named variable that will hold receive the fourth element of the transformed vector(s). If *Vertex_list* is a vector then SAVE_DIVIDE is a scalar. If *Vertex_list* is an array then SAVE_DIVIDE is an array of *n* elements. This keyword only has effect when the NO_DIVIDE keyword is set.

Examples

Transform four points representing a square in the x-y plane by first translating +2.0 in the positive X direction, and then rotating 60.0 degrees about the Y axis.

```
points = [[0.0, 0.0, 0.0], [1.0, 0.0, 0.0], $
          [1.0, 1.0, 0.0], [0.0, 1.0, 0.0]]
T3D, /RESET
T3D, TRANSLATE=[2.0, 0.0, 0.0]
T3D, ROTATE=[0.0, 60.0, 0.0]
points = VERT_T3D(points)
```

Version History

Introduced: Pre 4.0

T3D

VOIGT

The VOIGT function returns the intensity of an atomic absorption line profile (also known as a VOIGT profile) based on the Voigt damping parameter *a* and the frequency offset *u*, in units of the Doppler width.

The returned line profile $\phi(a, u)$ is defined as:

$$\phi(a, u) \equiv \frac{H(a, u)}{\Delta\nu_D\sqrt{\pi}}$$

where *H* is the classical Voigt function:

$$H(a, u) = \frac{a}{\pi}\int_{-\infty}^{\infty}\frac{e^{-y^2}dy}{a^2 + (u - y)^2}$$

The Doppler width $\Delta\nu_D$ (assuming no turbulence), is defined as:

$$\Delta\nu_D = \frac{\nu_0}{c}b = \frac{\nu_0}{c}\sqrt{2kT/m}$$

where ν_0 is the line center frequency. The dimensionless frequency offset *u* and the damping parameter *a* are determined by:

$$u = \frac{\nu - \nu_0}{\Delta\nu_D}$$

$$a = \frac{\Gamma}{4\pi\Delta\nu_D}$$

Here, Γ is the transition rate:

$$\Gamma = \gamma + 2\nu_{col}$$

where γ is the spontaneous decay rate, and ν_{col} is the atomic collision rate. See *Radiative Processes in Astrophysics* by G. B. Rybicki and A. P. Lightman (1979) p 291 for more information. The algorithm is from Armstrong, *JQSRT 7*, 85. (1967).

Syntax

Result = VOIGT(*A*, *U*)

Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of A and U, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array. If A is double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

A

A scalar or array specifying the values for the Voigt damping parameter.

U

A scalar or array specifying the values for the dimensionless frequency offset in Doppler widths.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Version History

Introduced: Pre 4.0

LEEFILT, ROBERTS, SOBEL

VORONOI

The VORONOI procedure computes the Voronoi polygon of a point within an irregular grid of points, given the Delaunay triangulation. The Voronoi polygon of a point contains the region closer to that point than to any other point.

For interior points, the polygon is constructed by connecting the midpoints of the lines connecting the point with its Delaunay neighbors. Polygons are traversed in a counterclockwise direction.

For exterior points, the set is described by the midpoints of the connecting lines, plus the circumcenters of the two triangles that connect the point to the two adjacent exterior points.

This routine is written in the IDL language. Its source code can be found in the file `voronoi.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

VORONOI, *X*, *Y*, *I0*, *C*, *Xp*, *Yp*, *Rect*

Arguments

X

An array containing the X locations of the points.

Y

An array containing the Y locations of the points.

I0

An array containing the indices of the points.

C

A connectivity list from the Delaunay triangulation. This list is produced with the CONNECTIVITY keyword of the TRIANGULATE procedure.

Xp, Yp

Named variables that will contain the X and Y vertices of Voronoi polygon.

Rect

The bounding rectangle: [Xmin, Ymin, Xmax, Ymax]. Because the Voronoi polygon (VP) for points on the convex hull extends to infinity, a clipping rectangle must be supplied to close the polygon. This rectangle has no effect on the VP of interior points. If this rectangle does not enclose all the Voronoi vertices, the results will be incorrect. If this parameter, which must be a named variable, is undefined or set to a scalar value, it will be calculated.

Examples

To draw the Voronoi polygons of each point of an irregular grid:

```
N = 20

; Create a random grid of N points:
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; Triangulate it:
TRIANGULATE, X, Y, tr, CONN=C

FOR I=0, N-1 DO BEGIN & $
   ; Get the ith polygon:
   VORONOI, X, Y, I, C, Xp, Yp & $
      ; Draw it:
      POLYFILL, Xp, Yp, COLOR = (I MOD 10) + 2 & $
ENDFOR
```

Version History

Introduced: Pre 4.0

TRIANGULATE

VOXEL_PROJ

The VOXEL_PROJ function generates visualizations of volumetric data by computing 2-D projections of a colored, semi-transparent volume. Parallel rays from any given direction are cast through the volume, onto the viewing plane. User-selected colors and opacities can be assigned to arbitrary data ranges, simulating the appearance of the materials contained within the volume.

The VOXEL_PROJ function can be combined with the Z-buffer to render volume data over objects. Cutting planes can also be specified to view selected portions of the volume. Other options include: selectable resolution to allow quick “preview” renderings, and average and maximum projections.

VOXEL_PROJ renders volumes using an algorithm similar to the one described by Drebin, Carpenter, and Hanrahan, in “Volume Rendering”, *Computer Graphics*, Volume 22, Number 4, August 1988, pp. 125-134, but without the surface extraction and enhancement step.

Voxel rendering can be quite time consuming. The time required to render a volume is proportional to the viewing areas size, in pixels, times the thickness of the volume cube in the viewing direction, divided by the product of the user-specified X, Y, and Z steps.

Syntax

Result = VOXEL_PROJ(*V* [, *RGBO*] [, BACKGROUND=*array*] [, CUTTING_PLANE=*array*] [, /INTERPOLATE] [, /MAXIMUM_INTENSITY] [, STEP=*[Sx, Sy, Sz]*] [, XSIZE=*pixels*] [, YSIZE=*pixels*] [, ZBUFFER=*int_array*] [, ZPIXELS=*byte_array*])

Return Value

Returns the specified voxel projection results.

Arguments

V

A three-dimensional array containing the volume to be rendered. This array is converted to byte type if necessary.

RGBO

This optional parameter is used to specify the look-up tables that indicate the color and opacity of each voxel value. This argument can be one of the following types:

- A (256, 4) byte array for TrueColor rendering. This array represents 256 sets of red, green, blue, and opacity (RGBO) components for each voxel value, scaled into the range of bytes (0 to 255). The R, G, and B components should already be scaled by the opacity. For example, if a voxel value of 100 contains a material that is red, and 35% opaque, the RGBO values should be, respectively: [89, 0, 0, 89] because 255 * 0.35 = 89. If more than one material is present, the RGBO arrays contain the sum of the individual RGBO arrays. The content and shape of the RGBO curves is highly dependent upon the volume data and experimentation is often required to obtain the best display.
- A (256, 2) byte array for volumes with only one material or monochrome rendering. This array represents 256 sets of pixel values and their corresponding opacities for each voxel value.
- If this argument is omitted, the average projection method, or maximum intensity method (if the MAXIMUM_INTENSITY keyword is set) is used.

Keywords

BACKGROUND

A one- or three-element array containing the background color indices. The default is (0,0,0), yielding a black background with most color tables.

CUTTING_PLANE

A floating-point array specifying the coefficients of additional cutting planes. The array has dimensions of (4, N), where N is the number of additional cutting planes from 1 to 6. Cutting planes are constraints in the form of:

C[0] * X + C[1] * Y + C[2] * Z + D > 0

The X, Y, and Z coordinates are specified in voxel coordinates. For example, to specify a cutting plane that excludes all voxels with an X value greater than 10:

CUTTING_PLANE = [-1.0, 0, 0, 10.], for the constraint: -X + 10 > 0.

INTERPOLATE

Set this keyword to use tri-linear interpolation to determine the data value for each step on a ray. Otherwise, the nearest-neighbor method is used. Setting this keyword

improves the quality of images produced, especially when the volume has low resolution in relation to the size of the viewing plane, at the cost of more computing time.

MAXIMUM_INTENSITY

Set this keyword to make the value of each pixel in the viewing plane the maximum data value along the corresponding ray. The *RGBO* argument is ignored if present.

STEP

Set this keyword to a three-element vector, [*Sx*, *Sy*, *Sz*], that controls the resolution of the resulting projection. The first two elements contain the step size in the X and Y view plane, in pixels. The third element is the sampling step size in the Z direction, given in voxels. *Sx* and *Sy* must be integers equal to or greater than one, while *Sz* can contain a fractional part. If *Sx* or *Sy* are greater than one, the values of intermediate pixels in the output image are linearly interpolated. Higher step sizes require less time because fewer rays are cast, at the expense of lower resolution in the output image.

XSIZE

The width, in pixels, of the output image. If this keyword is omitted, the output image is as wide as the currently-selected output device.

YSIZE

The height, in pixels, of the output image. If this keyword is omitted, the output image is as tall as the currently selected output device.

ZBUFFER

An integer array, with the same width and height as the output image, that contains the depth portion of the Z-buffer. Include this parameter to combine the previously-read contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

ZPIXELS

A byte array, with the same width and height as the output image, that contains the image portion of the Z-buffer. Include this parameter to combine the contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

Examples

Example 1

In the following example, assume that variable V contains a volume of data, with dimensions Vx by Vy by Vz. The volume contains two materials, muscle tissue represented by a voxel range of 50 to 70, that we want to render with red color, and an opacity of 20; and bone tissue represented by a voxel range of 220-255, that we want to render with white color, and an opacity of 50:

```
; Create the opacity vector:
rgbo = BYTARR(256,4)

; Red and opacity for muscle:
rgbo[50:70, [0,3]] = 20

; White and opacity for bone:
rgbo[220:255, *] = 50
```

Example 2

Although it is common to use trapezoidal or Gaussian functions when forming the RGBO arrays, this example uses rectangular functions for simplicity.

```
; Set up the axis scaling and default rotation:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute projected image:
C = VOXEL_PROJ(V, rgbo)

; Convert from 24-bit to 8-bit image and display:
TV, COLOR_QUAN(C, 3, R, G, B)

; Load quantized color tables:
TVLCT, R, G, B
```

This example required approximately 27 seconds on a typical workstation to compute the view in a 640- by 512-pixel viewing window. Adding the keyword STEP=[2,2,1] in the call to VOXEL_PROJ decreased the computing time to about 8 seconds, at the expense of slightly poorer resolution.

When viewing a volume with only one constituent, the RGBO array should contain only an intensity/opacity value pair. To illustrate, if in the above example, only muscle was of interest we create the RGBO argument as follows:

```
; Create an empty 256 x 2 array:
rgbo = BYTARR(256,2)
```

```
; Intensity and opacity for muscle:
rgbo[50:70, *] = 20
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute and display the projected image:
TV, VOXEL_PROJ(V, rgbo)

; Create color table array for red:
C = (FINDGEN(256)/255.) # [255., 0., 0]

; Load colors:
TVLCT, C[*,0], C[*,1], C[*,2]
```

Example 3

This example demonstrates combining a volume with the contents of the Z-buffer:

```
; Set plotting to Z-buffer:
SET_PLOT, 'Z'

; Turn on Z buffering:
DEVICE, /Z_BUFFER

; Set scaling:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Draw a polygon at z equal to half the depth:
POLYFILL, [0, Vx-1, Vx-1, 0], [0, 0, Vy-1, Vy-1], Vz/2., /T3D

; Read pixel values from the Z-buffer:
zpix = TVRD()

; Read depth values from the Z-buffer:
zbuff = TVRD(/WORDS,/CHAN)

; Back to display window:
SET_PLOT, 'X'

; Compute the voxel projection and use the ZPIXELS and ZBUFFER
; keywords to combine the volume with the previously-read contents
; of the Z-buffer:
C = VOXEL_PROJ(V, rgbo, ZPIX=zpix, ZBUFF=zbuff)

;Convert from 24-bit to 8-bit image and display.
TV, COLOR_QUAN(C, 3, R, G, B)

; Load the quantized color tables:
TVLCT, R, G, B
```

WAIT

The WAIT procedure suspends execution of an IDL program for a specified period. Note that because of other activity on the system, the duration of program suspension may be longer than requested.

Syntax

WAIT, *Seconds*

Arguments

Seconds

The duration of the wait, specified in seconds. This parameter can be a floating-point value to specify a fractional number of seconds.

Keywords

None.

Examples

To make an IDL program suspend execution for about five and one half seconds, use the command:

```
WAIT, 5.5
```

EXIT, STOP

WARP_TRI

The WARP_TRI function returns an image array with a specified geometric correction applied. Images are warped using control (tie) points such that locations (*Xi*, *Yi*) are shifted to (*Xo*, *Yo*).

The irregular grid defined by (*Xo*, *Yo*) is triangulated using TRIANGULATE. Then the surfaces defined by (*Xo*, *Yo*, *Xi*) and (*Xo*, *Yo*, *Yi*) are interpolated using TRIGRID to get the locations in the input image of each pixel in the output image. Finally, INTERPOLATE is called to obtain the result. Linear interpolation is used by default. Smooth quintic interpolation is used if the QUINTIC keyword is set.

This routine is written in the IDL language. Its source code can be found in the file `warp_tri.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = WARP_TRI(*Xo*, *Yo*, *Xi*, *Yi*, *Image* [, OUTPUT_SIZE=*vector*] [, /QUINTIC] [, /EXTRAPOLATE] [, /TPS])

Return Value

Returns the warped image array.

Arguments

Xo, Yo

Vectors containing the locations of the control (tie) points in the output image.

Xi, Yi

Vectors containing the location of the control (tie) points in the input image. *Xi* and *Yi* must be the same length as *Xo* and *Yo*.

Image

The image to be warped. May be any type of data.

Keywords

OUTPUT_SIZE

Set this keyword equal to a 2-element vector containing the size of the output image. If omitted, the output image is the same size as *Image*.

QUINTIC

Set this keyword to use smooth quintic interpolation. Quintic interpolation is slower but the derivatives are continuous across triangles, giving a more pleasing result than the default linear interpolation.

EXTRAPOLATE

Set this keyword to extrapolate outside the convex hull of the tie points. Setting this keyword implies the use of QUINTIC interpolation.

TPS

Set this keyword to use Thin Plate Spline interpolation, which interpolates a set of irregularly sampled data value over a regular two dimensional grid. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

INTERPOLATE, TRIANGULATE, TRIGRID

WATERSHED

The WATERSHED function applies the morphological watershed operator to a grayscale image. This operator segments images into watershed regions and their boundaries. Considering the gray scale image as a surface, each local minimum can be thought of as the point to which water falling on the surrounding region drains. The boundaries of the watersheds lie on the tops of the ridges. This operator labels each watershed region with a unique index, and sets the boundaries to zero.

Typically, morphological gradients, or images containing extracted edges are used for input to the watershed operator. Noise and small unimportant fluctuations in the original image can produce spurious minima in the gradients, which leads to oversegmentation. Smoothing, or manually marking the seed points are two approaches to overcoming this problem. For further reading, see Dougherty, “An Introduction to Morphological Image Processing”, SPIE Optical Engineering Press, 1992.

Syntax

Result = WATERSHED (*Image* [, CONNECTIVITY={4 | 8}])

Return Value

Returns an image of the same dimensions as the input image. Each pixel of the result will be either zero if the pixel falls along the segmentation between basins, or the identifier of the basin in which that pixel falls.

Arguments

Image

The two-dimensional image to be segmented. *Image* is converted to byte type if necessary.

Keywords

CONNECTIVITY

Set this keyword to either 4 (to select 4-neighbor connectivity) or 8 (to select 8-neighbor connectivity). Connectivity indicates which pixels in the neighborhood of a given pixel are sampled during the segmentation process. 4-neighbor connectivity

samples only the pixels that are immediately adjacent horizontally and vertically. 8-neighbor connectivity samples the diagonally adjacent neighbors in addition to the immediate horizontal and vertical neighbors. The default is 4-neighbor connectivity.

Examples

The following code crudely segments the grains in the data file in the IDL Demo data directory containing an magnified image of grains of pollen. Note that the IDL Demos must be installed in order to read the image used in this example.

It inverts the image, because the watershed operator finds holes, and the grains of pollen are bright. Next, the morphological closing operator is applied with a disc of radius 9, contained within a 19 by 19 kernel, to eliminate holes in the image smaller than the disc. The watershed operator is then applied to segment this image. The borders of the watershed images, which have pixel values of zero, are then merged with the original image and displayed as white.

```
;Radius of disc...
r = 9

;Create a disc of radius r
disc = SHIFT(DIST(2*r+1), r, r) LE r

;Read the image
READ_JPEG, FILEPATH('pollens.jpg', $
   SUBDIR=['examples','demo','demodata']), a

;Invert the image
b = MAX(a) - a

TVSCL, b, 0

;Remove holes of radii less than r
c = MORPH_CLOSE(b, disc, /GRAY)

TVSCL, c, 1

;Create watershed image
d = WATERSHED(c)

;Display it, showing the watershed regions
TVSCL, d, 2

;Merge original image with boundaries of watershed regions
e = a > (MAX(a) * (d EQ 0b))

TVSCL, e, 3
```

Version History

Introduced: 5.3

WDELETE

The WDELETE procedure deletes IDL windows.

Syntax

WDELETE [, *Window_Index* [, ...]]

Arguments

Window_Index

A list of one or more window indices to delete. If this argument is not specified, the current window (as specified by the system variable !D.WINDOW) is deleted. If the window being deleted is not the active window, the value of !D.WINDOW remains unchanged. If the window being deleted is the active window, !D.WINDOW is set to the highest numbered window index or to -1 if no windows remain open.

If this window index is the widget ID of a draw widget, that widget is deleted.

Keywords

None.

Examples

Create IDL graphics window number 5 by entering:

```
WINDOW, 5
```

Delete window 5 by entering:

```
WDELETE, 5
```

Version History

Introduced: Original

WF_DRAW

The WF_DRAW procedure draws weather fronts of various types using parametric spline interpolation to smooth the lines. WF_DRAW uses the POLYFILL routine to make the annotations on the front lines.

This routine is written in the IDL language. Its source code can be found in the file `wf_draw.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WF_DRAW, *X*, *Y* [[, /COLD | , FRONT_TYPE=1] | [, /WARM | , FRONT_TYPE=2] | [, /OCCLUDED | , FRONT_TYPE=3] | [, /STATIONARY | , FRONT_TYPE=4] | [, /CONVERGENCE | , FRONT_TYPE=5]] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, INTERVAL=*value*] [, PSYM=*value*] [, SYM_HT=*value*] [, SYM_LEN=*value*] [, THICK=*value*]

Arguments

X, Y

Vectors of abscissae and ordinates defining the front to be drawn.

Keywords

COLD

Set this keyword to draw a cold front. The default is a plain line with no annotations. A cold front can also be specified by setting the keyword FRONT_TYPE = 1.

COLOR

Use this keyword to specify the color to use. The default = !P.COLOR.

CONVERGENCE

Set this keyword to draw a convergence line. A convergence line can also be specified by setting the keyword FRONT_TYPE = 5.

DATA

Set this keyword if X and Y are specified in data coordinates.

DEVICE

Set this keyword if X and Y are specified in device coordinates.

FRONT_TYPE

Set this keyword equal to the numeric index of type of front to draw. Front type indices are as follows: COLD=1, WARM=2, OCCLUDED=3, STATIONARY=4, CONVERGENCE = 5. Not required if plain line is desired or if an explicit front type keyword is specified.

INTERVAL

Use this keyword to specify the spline interpolation interval, in normalized units. The default = 0.01. Larger values give coarser approximations to curves, smaller values make more interpolated points.

NORMAL

Set this keyword if X and Y are specified in normalized coordinates. This is the default.

OCCLUDED

Set this keyword to draw an occluded front. An occluded front can also be specified by setting the keyword FRONT_TYPE = 3.

PSYM

Set this keyword a standard PSYM value to draw a marker on each actual (*X*, *Y*) data point. See "PSYM" on page 3860 for a list of the symbol types.

STATIONARY

Set this keyword to draw a stationary front. A stationary front can also be specified by setting the keyword FRONT_TYPE = 4.

SYM_HT

Use this keyword to specify the height of front symbols, in normalized units. The default = 0.02.

SYM_LEN

Use this keyword to specify the length and spacing factor for front symbols, in normalized units. The default = 0.15.

THICK

Use this keyword to specify the line thickness. The default = 1.0.

WARM

Set this keyword to draw a warm front. A warm front can also be specified by setting the keyword FRONT_TYPE = 2.

Examples

This example draws various fronts on a map of the United States. Note that this example code is in the file `wf_draw.pro`, and can be run by entering `test_wf_draw` at the IDL command line.

```
PRO test_wf_draw

 MAP_SET, LIMIT = [25, -125, 50, -70], /GRID, /USA
 WF_DRAW, [ -120, -110, -100], [30, 50, 45], /COLD, /DATA, THICK=2

ANNOTATE, XYOUTS

WHERE

The WHERE function returns a vector that contains the one-dimensional subscripts of the nonzero elements of *Array_Expression*. The length of the resulting vector is equal to the number of nonzero elements in *Array_Expression*. Frequently the result of WHERE is used as a vector subscript to select elements of an array using given criteria.

Note: When WHERE Returns –1

If all the elements of *Array_Expression* are zero, WHERE returns a scalar integer with a value of –1. Attempting to use this result as an index into another array results in a "subscripts out of bounds" error. In situations where this is possible, code similar to the following can be used to avoid errors:

```
; Use Count to get the number of nonzero elements:
index = WHERE(array, count)

; Only subscript the array if it's safe:
IF count NE 0 THEN result = array[index]
```

Syntax

Result = WHERE(*Array_Expression* [, *Count*] [, COMPLEMENT=*variable*] [, /L64] [, NCOMPLEMENT=*variable*])

Return Value

Returns a longword vector containing the subscripts of non-zero array elements matching the specified conditions.

Arguments

Array_Expression

The array to be searched. Both the real and imaginary parts of a complex number must be zero for the number to be considered zero.

Count

A named variable that will receive the number of nonzero elements found in *Array_Expression*. This value is returned as a longword integer.

Note

The system variable !ERR is set to the number of nonzero elements. This effect is for compatibility with previous versions of IDL and should *not* be used in new code. Use the COUNT argument to return this value instead.

Keywords

COMPLEMENT

Set this keyword to a named variable that receives the subscripts of the zero elements of *Array_Expression*. These are the subscripts that are not returned in *Result*. Together, *Result* and COMPLEMENT specify every subscript in *Array_Expression*. If there are no zero elements in *Array_Expression*, COMPLEMENT returns a scalar integer with the value -1.

L64

By default, the result of WHERE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

NCOMPLEMENT

Set this keyword to a named variable that receives the number of zero elements found in *Array_Expression*. This value is the number of subscripts that will be returned via the COMPLEMENT keyword if it is specified.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix I, "Thread Pool Keywords" for details.

Examples

Example 1

```
; Create a 10-element integer array where each element is
; set to the value of its subscript:
array = INDGEN(10)
PRINT, 'array = ', array

; Find the subscripts of all the elements in the array that have
; a value greater than 5:
B = WHERE(array GT 5, count, COMPLEMENT=B_C, NCOMPLEMENT=count_c)

; Print how many and which elements met the search criteria:
PRINT, 'Number of elements > 5: ', count
PRINT, 'Subscripts of elements > 5: ', B
PRINT, 'Number of elements <= 5: ', count_c
PRINT, 'Subscripts of elements <= 5: ', B_C
```

IDL prints:

```
array =  0  1  2  3  4  5  6  7  8  9
Number of elements > 5:  4
Subscripts of elements > 5:  6  7  8  9
Number of elements <= 5:  6
Subscripts of elements <= 5:  0  1  2  3  4  5
```

Example 2

The WHERE function behaves differently with different kinds of array expressions. For instance, if a relational operator is used to compare an array, A, with a scalar, B, then every element of A is searched for B. However, if a relational operator is used to compare two arrays, C and D, then a comparison is made between each corresponding element (i.e. C_i & D_i, C_i+1 & D_i+1, etc) of the two arrays. If the two arrays have different lengths then a comparison is only made up to the number of elements for the shorter array. The following example illustrates this behavior:

```
; Compare array, a, and scalar, b:
a = [1,2,3,4,5,5,4,3,2,1]
b = 5
PRINT, 'a = ', a
PRINT, 'b = ', b

result=WHERE(a EQ b)
PRINT,'Subscripts of a that equal b: ', result

; Now compare two arrays of different lengths:
c = [1,2,3,4,5,5,4,3,2,1]
```

```
d = [0,2,4]
PRINT, 'c = ', c
PRINT, 'd = ', d

result=WHERE(c EQ d)
PRINT, 'Subscripts of c that equal d: ', result
```

IDL prints:

```
a =  1  2  3  4  5  5  4  3  2  1
b =  5
Subscripts of a that equal b:  4  5

c =  1  2  3  4  5  5  4  3  2  1
d =  0  2  4
Subscripts of c that equal d: 1
```

Note that WHERE found only one element in the array d that equals an element in array c. This is because only the first three elements of c were searched, since d has only three elements.

Version History

UNIQ

WHILE...DO

The WHILE...DO statement performs its subject statement(s) as long as the expression evaluates to true. The subject is never executed if the condition is initially false.

Note

For information on using WHILE...DO and other IDL program control statements, see Chapter 12, “Program Control” in the *Building IDL Applications* manual.

Syntax

WHILE *expression* DO *statement*

or

WHILE *expression* DO BEGIN

statements

ENDWHILE

Examples

```
i = 0
WHILE (i EQ 1) DO PRINT, i
```

Because the expression (which is false in this case) is evaluated before the subject statement is executed, this code yields no output.

Version History

Introduced: Original

WIDGET_ACTIVEX

The WIDGET_ACTIVEX function is used to incorporate an ActiveX control into an IDL widget hierarchy. IDL provides the same object method and property manipulation facilities for ActiveX controls as it does for COM objects incorporated using the IDLcomIDispatch object interface, but adds the ability to process events generated by the ActiveX control using IDL's widget event handling mechanisms.

Note

IDL can only incorporate ActiveX controls on Windows NT/2000/XP (and later) platforms.

When you use the WIDGET_ACTIVEX routine, IDL automatically creates an IDLcomActiveX object that encapsulates the ActiveX control. You can then call the ActiveX control's methods using IDL object syntax, as discussed in Chapter 5, "Using ActiveX Controls in IDL" in the *External Development Guide* manual. You should be familiar with the material in that chapter before attempting to incorporate ActiveX controls in your IDL programs.

Note

If the COM object you want to use in your IDL application is *not* an ActiveX control, use the IDLcomIDispatch object class.

Syntax

Result = WIDGET_ACTIVEX(*Parent*, *COM_ID*, [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [ID_TYPE=*value*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value is the widget ID of the ActiveX widget. Note that the *widget value* of the ActiveX widget is an object reference to the IDLcomActiveX object that encapsulates the specified ActiveX control.

Arguments

Parent

The widget ID of the parent widget of the new ActiveX control.

COM_ID

A string value specifying the class or program ID of the COM object to create. Note that if you specify a COM program ID via this argument, you must also set the ID_TYPE keyword.

Note

The class or program ID must follow the standard Microsoft naming convention. See Chapter 5, "Using ActiveX Controls in IDL" in the *External Development Guide* manual for more on class and program IDs, and their use with WIDGET_ACTIVEX.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

ID_TYPE

The type of COM object ID specified by the *COM_ID* parameter (class or program). If set to 0 (zero), the value is a class ID (the default). If set to 1 (one), the value is a program ID.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

The GET_VALUE keyword to the WIDGET_CONTROL procedure is used to retrieve an object reference to the IDLcomActiveX object that underlies the ActiveX widget. The object reference returned in this manner can be used to call the ActiveX control's native methods.

Examples

For examples using WIDGET_ACTIVEX, see Chapter 5, “Using ActiveX Controls in IDL” in the *External Development Guide* manual.

Version History

Introduced: 5.5

WIDGET_BASE

The WIDGET_BASE function is used to create base widgets. Base widgets serve as containers for other widgets.

Note

In most cases, you will want let IDL determine the placement of widgets within the base widget. Do this by specifying either the COLUMN keyword or the ROW keyword. See “Positioning Child Widgets Within a Base” in the following section for details.

Exclusive And Non-Exclusive Bases

If the EXCLUSIVE or NONEXCLUSIVE keywords are specified, the base only allows button widget children.

Positioning Child Widgets Within a Base

The standard base widget does not impose any placement constraints on its child widgets. Children of a “bulletin board” base (a base that was created without setting the COLUMN or ROW keywords) have an offset of (0,0) unless an offset is explicitly specified via the XOFFSET or YOFFSET keywords. This means that if you do not specify any of COLUMN, ROW, XOFFSET, or YOFFSET keywords, child widgets will be placed one on top of the other in the upper left corner of the base.

However, laying out widgets using the XSIZE, YSIZE, XOFFSET, and YOFFSET keywords can be both tedious and error-prone. Also, if you want your widget application to display properly on different platforms, you should use the COLUMN and ROW keywords to influence child widget layouts instead of explicitly formatting your interfaces.

When the ROW or COLUMN keywords are specified, the base decides how to lay out its children, and any XOFFSET and YOFFSET keywords specified for such children are ignored.

Positioning Top-Level Bases

When locating a new top level window, some window managers ignore the program’s positioning requests and either choose a position or allow the user to choose. In such cases, the XOFFSET and YOFFSET keywords to WIDGET_BASE will not have an effect. The window manager may provide a way to disable this positioning style. The

Motif window manager (mwm) can be told to honor positioning requests by placing the following lines in your `.Xdefaults` file:

```
Mwm*clientAutoPlace: False
Mwm*interactivePlacement: False
```

Iconizing, Layering, and Destroying Groups of Top-Level Bases

Group membership (defined via the GROUP_LEADER keyword) controls the way top-level base widgets are iconized, layered, and destroyed.

Note

A group can contain sub-groups. Group behavior affects all members of a group and its sub-groups. For example, suppose we create three top-level base widgets with the following group hierarchy:

```
base1 = WIDGET_BASE()
base2 = WIDGET_BASE(GROUP_LEADER=base1)
base3 = WIDGET_BASE(GROUP_LEADER=base2)
```

Effectively, two groups are created. One group has `base2` as its leader and `base3` as its member. The other group has `base1` as its leader and both `base2` and `base3` as members. If `base1` is iconized, both `base2` and `base3` are iconized as well. If `base2` is iconized, `base3` is iconized but `base1` is not.

Widgets behave slightly differently when displayed on different platforms, and depending on whether they are floating or modal bases. The following rules apply to groups of widgets within a group leader/member hierarchy. Widgets that do not belong to the same group hierarchy cannot influence each other.

Iconization and Mapping

Bases and groups of bases can be *iconized* (or *minimized*) by clicking the system minimize control. Bases and groups of bases can also be *mapped* (made visible) and *unmapped* (made invisible).

Motif — Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

Windows — Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

Layering

Layering is the process by which groups of widgets seem to share the same plane on the display screen. Within a layer on the screen, widgets have a *Z-order*, or front-to-back order, that defines which widgets appear to be on top of other widgets.

Motif — All elements on the screen—widgets, the IDLDE, other Motif applications—share a single layer and have an arbitrary Z-order. There is no special layering of IDL widgets.

Windows — All non-floating and non-modal widgets within a group hierarchy share the same layer—that is, when one group member has the input focus, all members of the group hierarchy are displayed in a layer that appears in front of all other groups or applications. Within the layer, the widgets can have an arbitrary Z-order.

Widgets that are floating or modal always float above their group leaders.

Destruction

When a group leader widget is destroyed, either programmatically or by clicking on the system “close” button, all members of the group and all sub-groups are destroyed as well.

If a modal base is on the display, it must be dismissed before any widget can be destroyed.

Syntax

Result = WIDGET_BASE([*Parent*] [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, /MBAR | , /MODAL] [, /BASE_ALIGN_BOTTOM | , /BASE_ALIGN_CENTER | , /BASE_ALIGN_LEFT | , /BASE_ALIGN_RIGHT | , /BASE_ALIGN_TOP] [, /COLUMN | , /ROW] [, /CONTEXT_EVENTS] [, /CONTEXT_MENU] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXCLUSIVE | , /NONEXCLUSIVE] [, /FLOATING] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, /GRID_LAYOUT] [, GROUP_LEADER=*widget_id*{must specify for modal dialogs}]

[, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*] [, /MAP{not for modal bases}] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL{not for modal bases}] [, /SENSITIVE] [, SPACE=*value*{ignored if exclusive or nonexclusive}] [, TITLE=*string*] [, TLB_FRAME_ATTR=*value*{top-level bases only}] [, /TLB_ICONIFY_EVENTS{top-level bases only}] [, /TLB_KILL_REQUEST_EVENTS{top-level bases only}] [, /TLB_MOVE_EVENTS{top-level bases only}] [, /TLB_SIZE_EVENTS{top-level bases only}] [, /TOOLBAR] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*] [, XPAD=*value*{ignored if exclusive or nonexclusive}] [, XSIZE=*value*] [, X_SCROLL_SIZE=*value*] [, YOFFSET=*value*] [, YPAD=*value*{ignored if exclusive or nonexclusive}] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*value*])

X Windows Keywords: [, DISPLAY_NAME=*string*] [, RESOURCE_NAME=*string*] [, RNAME_MBAR=*string*]

Return Value

The returned value of this function is the widget ID of the newly-created base.

Arguments

Parent

The widget ID of the parent widget. To create a *top-level* base, omit the *Parent* argument.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

Warning

You cannot specify both an APP_MBAR and an MBAR for the same top-level base widget. Doing so will cause an error.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the KBRD_FOCUS_EVENTS keyword to keep track of which widget has (or last had) the keyboard focus.

BASE_ALIGN_BOTTOM

Set this keyword to make all children of the new base align themselves with the bottom of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_CENTER

Set this keyword to make all children of the new base align themselves with the center of the base by default. To take effect, you must also set the COLUMN or ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created. In ROW bases, child widgets will be vertically centered. In COLUMN bases, child widgets will be horizontally centered.

BASE_ALIGN_LEFT

Set this keyword to make all children of the new base align themselves with the left side of the base by default. To take effect, you must also set the COLUMN keyword

for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_RIGHT

Set this keyword to make all children of the new base align themselves with the right side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_TOP

Set this keyword to make all children of the new base align themselves with the top of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

COLUMN

If this keyword is included, the base lays out its children in columns. The value of this keyword specifies the number of columns to be used. The number of child widgets in each column is calculated by dividing the number of child widgets created by the number of columns specified. When one column is filled, a new one is started.

Specifying both the COLUMN and ROW keywords causes an error.

Column Width

The width of each column is determined by the width of the widest widget in that column. If the GRID_LAYOUT keyword is set, all columns are as wide as the widest widget in the base.

Horizontal Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its “natural” width, determined either by the value of the widget or by the XSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its “natural” width. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as wide as their column.

Vertical Placement

Child widgets are placed vertically one below the other, with no extra space. If the GRID_LAYOUT keyword is set, each row is as high as its tallest member.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see"Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

CONTEXT_MENU

Set this keyword to create a base widget that can be used as the base for a context-sensitive menu (also known as a pop-up or shortcut menu). A context menu base must have as its parent one of the following types of widgets: WIDGET_BASE, WIDGET_DRAW, WIDGET_TEXT, WIDGET_LIST.

For more on creating context menus, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

DISPLAY_NAME

Set this keyword equal to a string that specifies the name of the X Windows display on which the base should be displayed. This keyword has no effect on Microsoft Windows platforms.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

Note

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the EVENT_HANDLER keyword to XMANAGER.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

Note

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the EVENT_HANDLER keyword to XMANAGER.

EXCLUSIVE

Set this keyword to specify that the base can have only button-widget children and that only one button can be set at a time. These buttons, unlike normal button widgets, have two states—set and unset.

When one exclusive button is pressed, any other exclusive buttons (in the same base) that are currently set are automatically released. Hence, only one button can ever be set at one time.

This keyword can be used to create exclusive button menus. See the CW_BGROUP and CW_PDMENU functions for high-level menu-creation utilities.

Note

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for an exclusive base, the base defaults to COLUMN layout.

FLOATING

Set this keyword—along with the GROUP_LEADER keyword—to create a “floating” top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

The iconizing, layering, and destruction behavior of floating bases and their group leaders is discussed in “Iconizing, Layering, and Destroying Groups of Top-Level Bases” on page 2044.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GRID_LAYOUT

Set this keyword to force the base to have a grid layout, in which all rows have the same height, and all columns have the same width. The row heights and column widths are taken from the largest child widget.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. Widget application hierarchies are defined by group membership relationships between top-level widget bases. When a group leader is killed, for any reason, all widgets in the group are also destroyed. Iconizing and layering behavior is discussed in “Iconizing, Layering, and Destroying Groups of Top-Level Bases” on page 2044.

Note

If you specify a floating base (created with the FLOATING keyword) as a group leader, all member bases must also have either the FLOATING or MODAL keywords set. If you specify a modal base (created with the MODAL keyword) as a group leader, all member bases must have the MODAL keyword set as well.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See the “Events Returned by Base Widgets” section below for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

Note

A procedure specified via the CLEANUP keyword to XMANAGER will override a procedure specified for your application’s top-level base with WIDGET_BASE, KILL_NOTIFY.

MAP

Once a widget hierarchy has been realized, it can be mapped (visible) or unmapped (invisible). This keyword specifies the initial map state for the given base and its descendants. Specifying a non-zero value indicates that the base should be mapped when realized (the default). A zero value indicates that the base should be unmapped initially.

After the base is realized, its map state can be altered using the MAP keyword to the WIDGET_CONTROL procedure.

Note

Modal bases cannot be mapped and unmapped.

Warning

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This “extra” resize event is generated before any manipulation of the base widget by the user.

MBAR

Set this keyword to a named variable to cause a menubar to be placed at the top of the base (the base must be a top-level base). The menubar is itself a special kind of base widget that can only have buttons as children. Upon return, the named variable contains the widget ID of the new menubar base. This widget ID can then be used to fill the menubar with pulldown menus. For example, the following widget creation

commands first create a base with a menubar, then populate the menubar with a simple pulldown menu (CW_PDMENU could also have been used to construct the pulldown menu):

```
base = WIDGET_BASE(TITLE = 'Example', MBAR=bar)
file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
file_bttn1=WIDGET_BUTTON(file_menu, VALUE='Item 1',$
   UVALUE='FILE1')
file_bttn2=WIDGET_BUTTON(file_menu, VALUE='Item 2',$
   UVALUE='FILE2')
```

Note that to set X Window System resources for menubars created with this keyword, you must use the RNAME_MBAR keyword rather than the RESOURCE_NAME keyword.

If you use CW_PDMENU to create a menu for the menubar, be sure to set the MBAR keyword to that function as well.

Note also that the size returned by the GEOMETRY keyword to WIDGET_INFO does not include the size of the menubar.

Warning

You cannot specify both the MBAR and MODAL keywords for the same widget. Doing so will cause an error.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the KBRD_FOCUS_EVENTS keyword to keep track of which widget has (or last had) the keyboard focus.

MODAL

Set this keyword to create a modal dialog. Modal dialogs can have default and cancel buttons associated with them. Default buttons are highlighted by the window system and respond to a press on the “Return” or “Enter” keys as if they had been clicked on. Cancel buttons respond to a press on the “Escape” key as if they had been clicked on. See the DEFAULT_BUTTON and CANCEL_BUTTON keywords to WIDGET_CONTROL for details.

Note

Modal dialogs must have a group leader. Specify the group leader for a modal top-level base via the GROUP_LEADER keyword.

Modal dialogs cannot be scrollable, nor can they support menubars. Setting the SCROLL, MBAR, or APP_MBAR keywords in conjunction with the MODAL

keyword will cause an error. Modal dialogs cannot be mapped or unmapped. Setting the MAP keyword on a modal base will cause an error.

Note

On Windows platforms, the group leader of a modal base must be realized before the modal base itself can be realized. If the group leader has not been realized, it will be realized automatically.

The iconizing, layering, and destruction behavior of modal bases and their group leaders is discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2044.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NONEXCLUSIVE

Set this keyword to specify that the base can only have button widget children. These buttons, unlike normal button widgets, have two states—set and unset. Non-exclusive bases allow any number of the toggle buttons to be set at one time.

Note

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Non-exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for a non-exclusive base, the base defaults to COLUMN layout.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. Once defined, this name can be used in the user's `.Xdefaults` file to customize widget resources not directly supported via the IDL widget routines. This keyword is accepted by all widget creation routines. This keyword only works with the "X" device and is ignored on Microsoft Windows platforms.

RESOURCE_NAME allows unrestricted access to the underlying Motif widgets within the following limitations:

- Users must have the appropriate resources defined in their `.Xdefaults` or application default resource file, or IDL will not see the definitions and they will not take effect.
- Motif resources are documented in the *OSF/Motif Programmer's Reference Manual*. To use them with RESOURCE_NAME, the IDL programmer must determine the type of widget being used by IDL, and then look up the resources that apply to them. Hence, RESOURCE_NAME requires some programmer-level familiarity with Motif.
- Only resources that are not set within IDL can be modified using this mechanism. Although it is not an error to set resources also set by IDL, the IDL settings will silently override user settings. Research Systems does not document the resources used by IDL since the actual resources used may differ from release to release as the IDL widgets evolve. Therefore, you should set only those resources that are obviously not being set by IDL. Among the resources that are not being set by IDL are those that control colors, menu mnemonics, and accelerator keys.

Example

The sample code below produces a pulldown menu named “Menu” with 2 entries named “Item 1” and “Item 2”.

Using the RESOURCE_NAME keyword in conjunction with X resource definitions, we can alter “Item 1” in several ways not possible through the standard IDL widgets interface. We’ll give Item 1 a red background color. We’ll also assign “I” as the keyboard mnemonic. Note that Motif automatically underlines the “I” in the title to indicate this. We’ll also select Meta-F4 as the keyboard accelerator for selecting “Item 1”. If Meta-F4 is pressed while the pointer is anywhere over this application, the effect will be as if the menu was pulled down and “Item 1” was selected with the mouse.

```
; Simple event handler:
PRO test_event, ev
   HELP, /STRUCTURE, ev
END

; Simple widget creation routine:
PRO test

   ; The base gets the resource name "test":
   a = WIDGET_BASE(RESOURCE_NAME = 'test')
   b = WIDGET_BUTTON(a, VALUE='Menu', /MENU)

   ; Assign the Item 1 button the resource name "item1":
   c = WIDGET_BUTTON(b, VALUE='Item 1', $
      RESOURCE_NAME='item1')
   c = WIDGET_BUTTON(b, VALUE='Item 2')
   WIDGET_CONTROL, /REALIZE, a
   XMANAGER, 'test', a
END
```

Note that we gave the overall application the resource name “test”, and the “Item 1” button the resource name “item1”. Now we can use these names in the following `.Xdefaults` file entries:

```
Idl*test*item1*mnemonic: I
Idl*test*item1*accelerator: Meta<Key>F4
Idl*test*item1*acceleratorText: Meta-F4
Idl*test*item1*background: red
```

Note on Specifying Color Resources

If you wish to specify unique colors for your widgets, it is generally a good idea to use a color name (“red” or “lightblue”, for example) rather than specifying an exact color match with a color string (such as “#b1b122222020”). If IDL is not able to

allocate an exact color, the entire operation may fail. Specifying a named color implies “closest color match,” an operation that rarely fails.

If you need an exact color match and IDL fails to allocate the color, try modifying the `Idl.colors` resource in the `$IDL_DIR/resource/X11/lib/app-defaults/Idl` file.

RNAME_MBAR

A string containing an X Window System resource name to be applied to the menubar created by the MBAR keyword. This keyword is identical to the RESOURCE_NAME keyword except that the resource it specifies applies only to the menubar.

ROW

If this keyword is included, the base lays out its children in rows. The value of this keyword specifies the number of rows to be used. The number of child widgets in each row is calculated by dividing the number of child widgets created by the number of rows specified. When one row is filled, a new one is started.

Specifying both the COLUMN and ROW keywords causes an error.

Row Height

The height of each row is determined by the height of the tallest widget in that row. If the GRID_LAYOUT keyword is set, all rows are as tall as the tallest widget in the base.

Vertical Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its “natural” height, determined either by the value of the widget or by the YSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its “natural” height. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as tall as their row.

Horizontal Placement

Child widgets are placed horizontally one next to the other, with no extra space. If the GRID_LAYOUT keyword is set, each column is as wide as its widest member.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

Warning

You cannot specify both the SCROLL and MODAL keywords for the same widget. Doing so will cause an error.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SPACE

The space, in units specified by the UNITS keyword (pixels are the default), between children of a row or column major base. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

TITLE

A string containing the title to be used for the widget. Base widgets use the title only if they are top-level widgets or if they are children of a tab widget. For top-level base widgets, the title appears in the “window dressing” at the top of the base widget; the appearance is platform-specific. For base widgets that have a tab widget as their parent widget, the title is used as the text of the tab.

Note that if the widget base is not wide enough to contain the specified title, the title may appear truncated. If you must be able to see the full title, you have several alternatives:

- Rearrange the widgets in the base so that the base becomes naturally wide enough. This is the best solution.
- Don’t worry about this issue. If the user needs to see the entire label, they can resize the window using the mouse.
- Create the base without using the COLUMN or ROW keywords. Instead, use the XSIZE keyword to explicitly set a usable width. This is an undesirable solution that can lead to strange-looking widget layouts.

For bases that are children of tab widgets, the title may be truncated depending on the width of the largest base that is a child of the tab widget. See the description of the MULTILINE keyword to WIDGET_TAB for additional details.

TLB_FRAME_ATTR

Set this keyword to one of the values shown in the table below to suppress certain aspects of a top-level base’s window frame. This keyword applies only to top-level bases. The settings are merely hints to the window system and may be ignored by some window managers. Valid settings are:

Value	Meaning
1	Base cannot be resized, minimized, or maximized.
2	Suppress display of system menu.
4	Suppress title bar.
8	Base cannot be closed.
16	Base cannot be moved.

Table 133: Valid Values for TLB_FRAME_ATTR Keyword

This keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make a base that has no title bar (value `4`) and cannot be moved (value `16`), set the TLB_FRAME_ATTR keyword to `20` (that is, `4+16`).

TLB_ICONIFY_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is iconified or restored by the user. See the "Events Returned by Base Widgets" section below for more information.

TLB_KILL_REQUEST_EVENTS

Set this keyword, usable only with top-level bases, to send the top-level base a WIDGET_KILL_REQUEST event if a user tries to destroy the widget using the window manager (by default, widgets are simply destroyed). See the "Events Returned by Base Widgets" section below for more information.

Use this keyword to perform complex actions before allowing a widget application to exit. Note that widgets that have this keyword set are responsible for killing themselves after receiving a WIDGET_KILL_REQUEST event—they cannot be destroyed using the usual window system controls.

Use a call to TAG_NAMES with the STRUCTURE_NAME keyword set to differentiate a WIDGET_KILL_REQUEST event from other types of widget events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
   'WIDGET_KILL_REQUEST' THEN ...
```

TLB_MOVE_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is moved on the screen by the user. See the "Events Returned by Base Widgets" section below for more information.

TLB_SIZE_EVENTS

Set this keyword, when creating a top-level base, to make that base return an event when the base is resized by the user. See the "Events Returned by Base Widgets" section below for more information.

TOOLBAR

Set this keyword to indicate that the base is used to hold bitmap buttons that make up a toolbar.

Note

Setting this keyword does not cause any changes in behavior; its only affect is to slightly alter the appearance of the bitmap buttons on the base for cosmetic reasons.

Note

On Motif platforms, if bitmap buttons are on a toolbar base that is also EXCLUSIVE or NONEXCLUSIVE, they will not have a separate “toggle” indicator, they will be grouped closely together, and will have a two-pixel shadow border.

Note

This keyword has no effect on Windows platforms.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer *enters* or *leaves* the region covered by that widget. Widget tracking events are returned as structures with the following definition:

```
{ WIDGET_TRACKING, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID, TOP, and HANDLER are the standard fields found in every widget event. ENTER is 1 if the tracking event is an entry event, and 0 if it is an exit event.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XPAD

The horizontal space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of XPAD is platform dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YPAD

The vertical space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of YPAD is platform-dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

Obsolete Keywords

The following keywords are obsolete:

- APP_MBAR

For information on obsolete keywords, See Appendix O, "Obsolete Features".

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of base widgets. In addition to those keywords that affect all widgets, the following are particularly useful: CANCEL_BUTTON, CONTEXT_EVENTS, DEFAULT_BUTTON, KBRD_FOCUS_EVENTS, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to base widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, MODAL, TLB_ICONIFY_EVENTS, TLB_KILL_REQUEST_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS.

Events Returned by Base Widgets

Resize Events

Top-level widget bases return the following event structure only when they are resized by the user and the base was created with the TLB_SIZE_EVENTS keyword set:

```
{ WIDGET_BASE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The X and Y fields return the new width of the base, not including any frame provided by the window manager.

Move Events

Top-level widget bases return the following event structure when the base is moved and the base was created with the TLB_MOVE_EVENTS keyword set:

```
{ WIDGET_TLB_MOVE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. X and Y are the new location of the top left corner of the base.

Note

On Windows, move events are generated while dragging. On UNIX, move events are generated only on the mouse-up.

Note

If both TLB_SIZE_EVENTS and TLB_MOVE_EVENTS are enabled, a user resize operation that causes the top left corner of the base to move will generate both a move event and a resize event.

Iconify Events

Top-level widget bases return the following event structure when the base is iconified or restored and the base was created with the TLB_ICONIFY_EVENTS keyword set:

```
{ WIDGET_TLB_ICONIFY, ID:0L, TOP:0L, HANDLER:0L, ICONIFIED:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. ICONIFIED is 1 (one) if the user iconified the base and 0 (zero) if the user restored the base.

Keyboard Focus Events

Widget bases return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the base is gaining the keyboard focus, or 0 (zero) if the base is losing the keyboard focus.

Kill Request Events

Top-level widget bases return the following event structure only when a user tries to destroy the widget using the window manager and the base was created with the TLB_KILL_REQUEST_EVENTS keyword set:

```
{ WIDGET_KILL_REQUEST, ID:0L, TOP:0L, HANDLER:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine.

Context Menu Events

Base widgets return the following event structure when the user clicks the right mouse button and the base widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget.

Version History

Introduced: Pre 4.0

TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TOOLBAR keywords; new event structures for inconify and move events: 5.6

See Also

Chapter 24, “Widgets” in the *Building IDL Applications* manual.

WIDGET_BUTTON

The WIDGET_BUTTON function creates button widgets.

Exclusive And Non-Exclusive Bases

Buttons placed into exclusive or non-exclusive bases (created via the EXCLUSIVE or NONEXCLUSIVE keywords to WIDGET_BASE procedure) are created as two-state “toggle” buttons, which are controlled by such bases.

Bitmap Button Labels

Widget buttons can have either a text label (specified as a string value to the VALUE keyword) or a graphic symbol in the form of a bitmap. Bitmap labels are specified in one of the following ways:

1. By setting the VALUE keyword equal to a string containing the name of an image file in BMP format, and setting the BITMAP keyword:

   ```
   button=WIDGET_BUTTON(base, VALUE='mybitmap.bmp', /BITMAP)
   ```

   For 16- and 256-color bitmap files, IDL uses the color of the pixel in the lower left corner as the transparent color. All pixels of this color become transparent, allowing the button color to show through.

   To modify the bitmap after creation, use the /BITMAP keyword with WIDGET_CONTROL:

   ```
   WIDGET_CONTROL, button, SET_VALUE='mybitmap2.bmp', /BITMAP
   ```

2. By setting the VALUE keyword equal to an *n* x *m* bitmap byte array in which each bit represents a pixel with a value of either zero or one. (Arrays of this type can be produced using the CVTTOBM function.) This method creates a black-and-white bitmap label:

   ```
   button=WIDGET_BUTTON(base, VALUE=bw_arr)
   ```

   To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

   ```
   WIDGET_CONTROL, button, SET_VALUE=bw_array2
   ```

3. By setting the VALUE keyword equal to an *n* x *m* x 3 byte array that represents a 24-bit color image, interleaved by plane, with the planes in the order red, green, blue. This method creates a color bitmap label:

   ```
   button=WIDGET_BUTTON(base, VALUE=color_array)
   ```

To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE=color_array2
```

See "Using Button Widgets" in Chapter 26 of the *Building IDL Applications* manual for additional details on creating image files and arrays for use as button bitmaps.

Syntax

Result = WIDGET_BUTTON(*Parent* [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /BITMAP] [, /CHECKED_MENU] [, /DYNAMIC_RESIZE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, /HELP] [, KILL_NOTIFY=*string*] [, /MENU] [, /NO_COPY] [, /NO_RELEASE] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /SEPARATOR] [, TOOLTIP=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, X_BITMAP_EXTRA=*bits*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

X Windows Keywords: [, RESOURCE_NAME=*string*]

Return Value

The returned value of this function is the widget ID of the newly-created button.

Arguments

Parent

The widget ID of the parent for the new button widget.

Keywords

ALIGN_CENTER

Set this keyword to center justify the button's text label.

ALIGN_LEFT

Set this keyword to left justify the button's text label.

ALIGN_RIGHT

Set this keyword to right justify the button's text label.

BITMAP

Set this keyword to specify that the bitmap specified with the VALUE keyword is a color bitmap. The value of a widget button can be a bitmap as described in "Bitmap Button Labels" on page 2067. If you specify a color bitmap with the VALUE keyword, you must also set the /BITMAP keyword.

Note

The use of bitmap values for menu buttons may cause unexpected behavior and is not supported.

CHECKED_MENU

Set this keyword on a menu entry button to enable the ability to place a check (Windows) or selection box (Motif) next to the menu entry. The parent widget of the button must be either a button widget created with the MENU keyword or a base widget created with the CONTEXT_MENU keyword.

On Windows systems, a menu item that has the checked menu feature enabled but which is unselected appears just like a "normal" menu item. On Motif systems, a menu item that has the checked menu feature enabled always displays a selection box, even if the box is not selected.

Note

Setting this keyword does not initially "select" the menu item; selection marks are displayed and removed via the SET_BUTTON keyword to WIDGET_CONTROL.

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

HELP

Set this keyword to tell the widget toolkit that this button is a “help” button for a menubar and should be given that appearance. For example, Motif specifies that the help menubar item is displayed on the far right of the menubar. This keyword is ignored in all other contexts and may be ignored by window managers that have no such special appearance defined.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MENU

The presence of this keyword indicates that the button will be used to activate a pull-down menu. Such buttons can have button children that are then placed into a pull-down menu.

Under Motif, if the value specified for MENU is greater than 1, the button label is enclosed in a box to indicate that this button is a pull-down menu. See the CW_PDMENU function for a high-level pull-down menu creation utility.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would

otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_BUTTON or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_RELEASE

Set this keyword to make exclusive and non-exclusive buttons generate only *select* events. This keyword has no effect on regular buttons.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2055 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SEPARATOR

Set this keyword to tell the widget toolkit that this button is part of a pulldown menu pane and that a separator line should be added directly above this entry. This keyword is ignored in all other contexts.

TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

Note

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

Note

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget button is the label for that button. You can set VALUE to any of the following:

- a string value, which displays as text;
- an *n* x *m* byte array, which displays as a black-and-white bitmap image;
- an *n* x *m* x 3 byte array, which displays as a 24-bit color bitmap image;
- if the BITMAP keyword is also specified, the name of a bitmap image file that displays as a color bitmap image of the same depth as the image in the file.

See “Bitmap Button Labels” on page 2067 for additional details on using bitmap images as button labels.

Note

Under Microsoft Windows, including the ampersand character (&) in the value of a button widget causes the window manager to place an underline under the character

following the ampersand. (This is a feature of Microsoft Windows, and is generally used to indicate which character is used as a keyboard accelerator for the button.) If you are designing an application that will run on different platforms, you should avoid the use of the ampersand in button value strings.

X_BITMAP_EXTRA

When creating a bitmap button that is not of a “byte-aligned” size (i.e., a dimension is not a multiple of 8), this keyword specifies how many bits of the supplied bitmap must be ignored (within the end byte). For example, to create a 10 by 8 bitmap, you need to supply a 2 by 8 array of bytes and ignore the bottom 6 bits. Therefore, you would specify `X_BITMAP_EXTRA = 6`.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of button widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, DYNAMIC_RESIZE, GET_VALUE, INPUT_FOCUS, SET_BUTTON, SET_VALUE, TOOLTIP, X_BITMAP_EXTRA.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to button widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: BUTTON_SET, DYNAMIC_RESIZE, TOOLTIP.

Events Returned by Button Widgets

Pressing the mouse button while the mouse cursor is over a button widget causes the widget to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_BUTTON, ID:0L, TOP:0L, HANDLER:0L, SELECT:0}
```

ID is the widget id of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. SELECT is set to 1 if the button was set, and 0 if released. Normal buttons do not generate events when released, so SELECT will always be 1. However, toggle buttons (created by parenting a button to an exclusive or non-exclusive base) return separate events for the set and release actions.

Version History

Introduced: Pre 4.0

CHECKED_MENU and TOOLTIP keywords added: 5.6

CW_BGROUP, CW_PDMENU

WIDGET_COMBOBOX

The WIDGET_COMBOBOX function creates combobox widgets, which are similar to droplist widgets. The main difference between the combobox widget and the droplist widget is that the combobox widget can be created in such a way that the text field is editable, allowing the user to enter a value that is not on the list.

A combobox widget displays a text field and an arrow button. If the combobox is not editable, selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently-selected option. This action generates an event containing the index of the selected item, which ranges from zero to the number of elements in the list minus one.

If the combobox is editable, text can be entered in the text box without causing the list to drop down. This action causes an event in which the index field is set to -1, allowing you to distinguish this event from list selections.

The text of the current selection is returned in the STR field of the WIDGET_COMBOBOX event structure. See “Widget Events Returned by Combobox Widgets” on page 2085 for details.

Note

WIDGET_COMBOBOX is not currently available on Compaq True64 UNIX platforms due to that platform’s lack of support for the necessary Motif libraries.

Syntax

Result = WIDGET_COMBOBOX(*Parent* [, /DYNAMIC_RESIZE] [, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*value*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created combobox widget.

Arguments

Parent

The widget ID of the parent widget for the new combobox widget.

Keywords

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed.

Note

This keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EDITABLE

Set this keyword to create an editable combobox. If the combobox is editable, users can enter or modify in the text field. Changes in the combobox text field will cause combobox events with the INDEX field of the event structure set to -1. The current text will be ‘ in the STR field of the event structure.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 in the *IDL Reference Guide* for

details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

Note

This keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL

procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_COMBOBOX or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2055 in the *IDL Reference Guide* for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE in the *IDL Reference Guide*.

UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a combobox widget is a scalar string or array of strings that contains the text of the list items (one list item per array element). Combobox widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

Note

Null strings are not allowed in the combobox widget item list.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The desired width of the combobox widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of combobox widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DYNAMIC_RESIZE, GET_VALUE, SET_COMBOBOX_SELECT, SET_VALUE.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO return information that applies specifically to combobox widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: COMBOBOX_GETTEXT, COMBOBOX_NUMBER, DYNAMIC_RESIZE.

Widget Events Returned by Combobox Widgets

Pressing the mouse button while the mouse pointer is over an element of a combobox widget causes the widget to change the text field on the combobox and to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_COMBOBOX, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, STR:""}
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value. If the event was caused by text changes in an editable combobox, the INDEX field will be set to -1. If you are using an editable combobox, it is important to check for the value of -1 prior to using the value of the INDEX field as an index into the array if items. The text of the current selection is returned in the STR field, which may eliminate the need to use the index field in many cases.

Note

Platform-specific UI toolkits behave differently if a combobox widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

Version History

Introduced: 5.6

WIDGET_CONTROL

The WIDGET_CONTROL procedure is used to realize, manage, and destroy widget hierarchies. It is often used to change the default behavior or appearance of previously-realized widgets.

Syntax

WIDGET_CONTROL [, *Widget_ID*]

Keywords that apply to all widgets: [, BAD_ID=*variable*] [, /CLEAR_EVENTS] [, DEFAULT_FONT=*string*{do not specify *Widget_ID*}] [, /DELAY_DESTROY{do not specify *Widget_ID*}] [, /DESTROY] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [, GET_UVALUE=*variable*] [, GROUP_LEADER=*widget_id*] [, /HOURGLASS{do not specify *Widget_ID*}] [, KILL_NOTIFY=*string*] [, /MAP] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, /REALIZE] [, /RESET{do not specify *Widget_ID*}] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, SEND_EVENT=*structure*] [, /SENSITIVE] [, SET_UNAME=*string*] [, SET_UVALUE=*value*] [, /SHOW] [, TIMER=*value*] [, TLB_GET_OFFSET=*variable*] [, TLB_GET_SIZE=*variable*] [, /TLB_KILL_REQUEST_EVENTS] [, TLB_SET_TITLE=*string*] [, TLB_SET_XOFFSET=*value*] [, TLB_SET_YOFFSET=*value*] [, /TRACKING_EVENTS] [, UNITS={0 | 1 | 2}] [, /UPDATE] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*]

Keywords that apply to widgets created with WIDGET_ACTIVEX: [, GET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_BASE: [, BASE_SET_TITLE=*string*] [, CANCEL_BUTTON=*widget_id*{for modal bases}] [, /CONTEXT_EVENTS] [, DEFAULT_BUTTON=*widget_id*{for modal bases}] [, /ICONIFY] [, /KBRD_FOCUS_EVENTS] [, /TLB_ICONIFY_EVENTS] [, /TLB_KILL_REQUEST_EVENTS] [, /TLB_MOVE_EVENTS] [, /TLB_SIZE_EVENTS]

Keywords that apply to widgets created with WIDGET_BUTTON: [, /BITMAP] [, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, /INPUT_FOCUS] [, /SET_BUTTON] [, SET_VALUE=*val*ue] [, TOOLTIP=*string*] [, X_BITMAP_EXTRA=*bits*]

Keywords that apply to widgets created with WIDGET_COMBOBOX:
[, COMBOBOX_ADDITEM=*string*] [, COMBOBOX_DELETEITEM=*integer*]
[, COMBOBOX_INDEX=*integer*] [, ./DYNAMIC_RESIZE]
[, GET_VALUE=*value*] [, SET_COMBOBOX_SELECT=*integer*]
[, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_DRAW:
[, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS]
[, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS]
[, /DRAW_VIEWPORT_EVENTS] [, DRAW_XSIZE=*integer*]
[, DRAW_YSIZE=*integer*] [, GET_DRAW_VIEW=*variable*]
[, GET_UVALUE=*variable*] [, GET_VALUE=*variable*] [, /INPUT_FOCUS]
[, SET_DRAW_VIEW=*[x, y]*] [, TOOLTIP=*string*]

Keywords that apply to widgets created with WIDGET_DROPLIST:
[, /DYNAMIC_RESIZE] [, SET_DROPLIST_SELECT=*integer*]
[, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_LABEL:
[, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_LIST:
[, /CONTEXT_EVENTS] [, SET_LIST_SELECT=*value*]
[, SET_LIST_TOP=*integer*] [, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_SLIDER:
[, GET_VALUE=*value*] [, SET_SLIDER_MAX=*value*]
[, SET_SLIDER_MIN=*value*] [, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_TAB:
[, SET_TAB_CURRENT=*index*] [, SET_TAB_MULTILINE=*value*]

Keywords that apply to widgets created with WIDGET_TABLE:
[, ALIGNMENT={0 | 1 | 2}] [, /ALL_TABLE_EVENTS] [, AM_PM=*[string, string]*] [, COLUMN_LABELS=*string_array*] [, COLUMN_WIDTHS=*array*]
[, DAYS_OF_WEEK=*string_array*{7 names}] [, /DELETE_COLUMNS{not for row_major mode}] [, /DELETE_ROWS{not for column_major mode}]
[, /EDITABLE] [, EDIT_CELL=*[integer, integer]*] [, FORMAT=*value*]
[, GET_VALUE=*variable*] [, INSERT_COLUMNS=*value*]
[, INSERT_ROWS=*value*] [, /KBRD_FOCUS_EVENTS]
[, MONTHS=*string_array*{12 names}] [, ROW_LABELS=*string_array*]
[, ROW_HEIGHTS=*array*] [, SET_TABLE_SELECT=*[left, top, right, bottom]*]
[, SET_TABLE_VIEW=*[integer, integer]*] [, SET_TEXT_SELECT=*[integer, integer]*] [, SET_VALUE=*value*] [, /TABLE_BLANK=*cells*]
[, /TABLE_DISJOINT_SELECTION] [, TABLE_XSIZE=*columns*]

[, TABLE_YSIZE=*rows*] [, /USE_TABLE_SELECT | , USE_TABLE_SELECT=*[left, top, right, bottom]*] [, /USE_TEXT_SELECT]

Keywords that apply to widgets created with WIDGET_TEXT:
[, /ALL_TEXT_EVENTS] [, /APPEND] [, /CONTEXT_EVENTS] [, /EDITABLE] [, GET_VALUE=*variable*] [, /INPUT_FOCUS] [, /KBRD_FOCUS_EVENTS] [, /NO_NEWLINE] [, SET_TEXT_SELECT=*[integer, integer]*] [, SET_TEXT_TOP_LINE=*line_number*] [, SET_VALUE=*value*] [, /USE_TEXT_SELECT]

Keywords that apply to widgets created with WIDGET_TREE:
[, SET_TREE_BITMAP=*array*] [, /SET_TREE_EXPANDED] [, SET_TREE_SELECT={0 | 1 | *widget ID* | *array of widget IDs*}] [, /SET_TREE_VISIBLE]

Arguments

Widget_ID

The widget ID of the widget to be manipulated. This argument is required by all operations, unless the description of the specific keyword states otherwise. Note that if *Widget_ID* is not provided for a keyword that needs it, that keyword is quietly ignored.

Keywords

Not all keywords to WIDGET_CONTROL apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

ALIGNMENT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a scalar, 2-D array, or 1-D array specifying the alignment of the contents of each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell.

If the USE_TABLE_SELECT keyword is not set:

- If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

If the USE_TABLE_SELECT keyword is set:

- In standard selection mode, if ALIGNMENT is set equal to a scalar, all cells in the selection are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each selected cell is governed by the corresponding element of the array.
- In disjoint selection mode, if ALIGNMENT is set equal to a scalar, all cells in the selection are aligned as specified. If ALIGNMENT is set equal to a 1-D array, the alignment of each selected cell is governed by the corresponding element of the array.

ALL_TABLE_EVENTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to cause to the table widget to generate events whenever the user changes the contents of a table cell.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. End-of-line events such as these could be used by the programmer as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between ALL_TABLE_EVENTS and EDITABLE.

Keywords		Effects	
ALL_TABLE_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 134: Effects of using the ALL_TABLE_EVENTS and EDITABLE keywords

ALL_TEXT_EVENTS

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to cause to the text widget to generate events whenever the user changes the contents of the text area.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_TEXT_EVENTS and EDITABLE.

Keywords		Effects	
ALL_TEXT_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 135: Effects of using the ALL_TEXT_EVENTS and EDITABLE keywords

AM_PM

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

APPEND

This keyword applies to widgets created with the WIDGET_TEXT function.

When using the SET_VALUE keyword to set the contents of a text widget (as created with the WIDGET_TEXT procedure), setting this keyword indicates that the supplied text should be appended to the existing contents of the text widget rather than replace it.

BAD_ID

This keyword applies to all widgets.

If *Widget_ID* is not a valid widget identifier, this WIDGET_CONTROL normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

BASE_SET_TITLE

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to a scalar string to change the title of the specified base widget. If the parent of the base widget is a tab widget, the title of the corresponding tab in the tab widget is changed to the provided string. If the parent is not a tab control, this keyword behaves like the keyword TLB_SET_TITLE.

CANCEL_BUTTON

This keyword applies to widgets created with the WIDGET_BASE function using the MODAL keyword.

Set this keyword equal to the widget ID of a button widget that will be the cancel button on a modal base widget.

On Motif and Windows platforms, selecting **Close** from the system menu (generally located at the upper left of the base widget) generates a button event for the **Cancel** button.

CLEAR_EVENTS

This keyword applies to all widgets.

If set, any events generated by the widget hierarchy rooted at *Widget_ID* which have arrived but have not been processed (via the WIDGET_EVENT procedure) are discarded.

COLUMN_LABELS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to an array of strings to be used as labels for the columns of the table. If no label is specified for a column, it receives the default label "*n*" where *n* is the column number. If this keyword is set to the empty string (''), all column labels are set to be empty.

COLUMN_WIDTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a one-dimensional array of widths for the columns of the table widget. The widths are given in the units specified with the UNITS keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If COLUMN_WIDTHS is set to a scalar value, all of the column widths are set to that value.

If the USE_TABLE_SELECT keyword is set (in either standard or disjoint selection mode), the indices of the elements of an array specified as the value of the COLUMN_WIDTHS keyword are interpreted as indices into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from columns `0`, `1`, `2`, `5`, `6`, and `7`, USE_TABLE_SELECT is set equal to one, and the COLUMN_WIDTHS keyword is set equal to a four-element array `[20, 35, 30, 35]`, the widths of columns `0`, `1`, `2`, and `5` would be modified. Similarly, if the table is in standard selection mode and the USE_TABLE_SELECT keyword is set equal to the array `[0, 1, 0, 0]`, and the COLUMN_WIDTHS keyword is set equal to a four-element array `[20, 35, 30, 35]`, only the width of the first column would be altered.

COMBOBOX_ADDITEM

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to a non-null string that specifies a new item to add to the list of the combobox. By default, the item will be added to the end of the list. The item can be added to a specified position in the list by setting the COMBOBOX_INDEX keyword in the same call to WIDGET_CONTROL.

COMBOBOX_DELETEITEM

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the combobox element to be deleted from the list. If the specified element is outside the range of existing elements, no element is deleted.

COMBOBOX_INDEX

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the position at which a new item will be added to the list when using the COMBOBOX_ADDITEM keyword. The value -1 is a special case that indicates the item should be added to the

end of the list. Note that this special case is provided for convenience, and that an item can also be added to the end of the list by omitting the COMBOBOX_INDEX keyword entirely. If the supplied index is not -1, and is outside the range of zero to the length of the existing list, the item is not added to the list.

Note

You can retrieve the length of the existing list using the COMBOBOX_NUMBER keyword to WIDGET_INFO function.

CONTEXT_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function, WIDGET_LIST, and WIDGET_TEXT function.

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

Note

You can also capture right mouse button events generated within draw widgets. See the BUTTON_EVENTS keyword to WIDGET_DRAW function for details.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

DAYS_OF_WEEK

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

DEFAULT_BUTTON

This keyword applies to widgets created with the WIDGET_BASE function using the MODAL keyword.

Set this keyword equal to the widget ID of a button widget that will be the default button on a modal base widget. The default button is highlighted by the window system.

DEFAULT_FONT

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

A string containing the name of the default font to be used.

If the font to be used for a given widget is not explicitly specified (via the FONT keyword to the widget creation function), a default supplied by the window system or server is used. Use this keyword to change the default. See "About Device Fonts" on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

DELAY_DESTROY

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Normally, when the user destroys a widget hierarchy using the window manager, it is immediately removed. This can cause problems for applications that use the background task facility provided by the XMANAGER procedure if the hierarchy is destroyed while a background task is using it.

If DELAY_DESTROY is set, attempts to destroy the hierarchy are delayed until the next attempt to obtain an event for it. Setting DELAY_DESTROY to zero restores the default behavior.

XMANAGER uses this keyword automatically when managing background tasks. It is not expected that applications will need to use it directly.

DELETE_COLUMNS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to delete columns that contain selected cells. If a selection is specified via the USE_TABLE_SELECT keyword (in either standard or disjoint mode), the columns that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

Warning

You cannot delete columns from a table which displays structure data in /ROW_MAJOR mode (the default).

DELETE_ROWS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to delete rows that contain selected cells. If a selection is specified via the USE_TABLE_SELECT keyword (in either standard or disjoint mode), the rows that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

Warning

You cannot delete rows from a table which displays structure data in /COLUMN_MAJOR mode.

DESTROY

This keyword applies to all widgets.

Set this keyword to destroy the widget and any child widgets in its hierarchy. Any further attempts to use the IDs for these widgets will cause an error.

DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable button press events for draw widgets. Setting a zero value disables such events.

Note

You can use button events generated by draw widgets to simulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. See the BUTTON_EVENTS keyword to WIDGET_DRAW for details.

DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable viewport expose events for draw widgets. Setting a zero value disables such events.

Note

You must explicitly disable backing store (by setting the RETAIN keyword to WIDGET_DRAW equal to zero) in order to generate expose events.

DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with WIDGET_DRAW.

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See "Widget Events Returned by Draw Widgets" on page 2138 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a "normal" key is pressed. "Normal" keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

Note

Keyboard events are never generated for function keys.

DRAW_MOTION_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable motion events for draw widgets. Setting a zero value disables such events.

DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable viewport motion events for draw widgets. Setting a zero value disables such events.

DRAW_XSIZE

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to an integer that specifies the new horizontal size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_XSIZE or XSIZE. However, for scrolling draw widgets DRAW_XSIZE is the only way to change the width of the drawable area (XSIZE sets the viewport size).

DRAW_YSIZE

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to an integer that specifies the new vertical size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_YSIZE or YSIZE. However, for scrolling draw widgets DRAW_YSIZE is the only way to change the height of the drawable area (YSIZE sets the viewport size).

DYNAMIC_RESIZE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, and WIDGET_LABEL functions.

Set this keyword to activate (if set to 1) or deactivate (if set to 0) dynamic resizing of the specified WIDGET_BUTTON, WIDGET_LABEL, or WIDGET_DROPLIST widget (see the documentation for the DYNAMIC_RESIZE keyword to those procedures for more information about dynamic widget resizing).

EDITABLE

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Set this keyword to allow direct user editing of the contents of a text or table widget. Normally, the text in text and table widgets is read-only. See the descriptions of the ALL_TABLE_EVENTS and ALL_TEXT_EVENTS keywords for additional details.

EDIT_CELL

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a two-element integer array containing the y (row) and x (column) coordinates of a table cell to put that cell into edit mode. For example, to put the top cell in the third column (x index=2) into edit mode, use the following commands:

```
row=0
col=2
WIDGET_CONTROL, table, EDIT_CELL=[row, col]
```

where *table* is the Widget ID of the table widget.

EVENT_FUNC

This keyword applies to all widgets.

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the EVENT_FUNC or EVENT_PRO keywords. To specify no event routine, set this keyword to a null string (`''`).

EVENT_PRO

This keyword applies to all widgets.

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the EVENT_FUNC or EVENT_PRO keywords. To specify no event routine, set this keyword to a null string (`''`).

FORMAT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a single string or a one- or two-dimensional array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT/PRINTF procedures.

If the USE_TABLE_SELECT keyword is set equal to one, the format is changed only for the currently selected cells. If USE_TABLE_SELECT is set equal to an array, the format is changed for the specified cells.

- In standard selection mode, FORMAT can be set either to a single string or to a two-dimensional array of strings of the same size as the selected area.
- In disjoint selection mode, FORMAT can be set either to a single string or to a one-dimensional array of strings with the same number of elements as the selected area.

FUNC_GET_VALUE

This keyword applies to all widgets.

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. The function specified by FUNC_GET_VALUE is called with the widget ID as an argument. The function specified by FUNC_GET_VALUE should return a value for a widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GET_DRAW_VIEW

This keyword applies to widgets created with the WIDGET_DRAW function.

Specifies a named variable which will be assigned the current position of a draw widget viewport. The position is returned as a 2-element integer array giving the X and Y position relative to the lower left corner of the graphics area.

GET_UVALUE

This keyword applies to all widgets.

Set this keyword to a named variable to contain the current user value of the widget.

Each widget can contain a user set value of any data type and organization. This value is not used by the widget in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to obtain the current user value.

The user value of a widget can be set with the SET_UVALUE keyword to this routine, or with the UVALUE keyword to the routine that created it.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword (described below) with GET_UVALUE.

GET_VALUE

This keyword applies to widgets created with the WIDGET_ACTIVEX, WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DRAW,

WIDGET_LABEL, WIDGET_SLIDER, WIDGET_TABLE, and WIDGET_TEXT functions.

Note

If you would like information about the values returned for a specific compound widget—beginning with the prefix “CW_”—please refer to the description of the compound widget, which may also include a section titled, “Keywords to WIDGET_CONTROL and WIDGET_INFO”. Compound widgets are described in the *Reference Guide*.

Set this keyword to a named variable to contain the current value of the widget. The type of value returned depends on the widget type:

- ActiveX: An object reference to the IDLcomActiveX object that underlies the ActiveX widget. See Chapter 5, “Using ActiveX Controls in IDL” in the *External Development Guide* manual for details.
- Button: If the button label is text, it is returned as a string. Attempts to obtain the value of a button with a bitmap label is an error.
- Combobox: The contents of the list of the combobox widget are returned as a string or string array.
- Draw: The value of a draw widget depends on whether the draw widget uses IDL Direct Graphics or IDL Object Graphics. (The type of graphics used is specified by the GRAPHICS_LEVEL keyword to WIDGET_DRAW.) The two possibilities are:

  A. By default, draw widgets use IDL Direct Graphics. In this case, the value of a draw widget is the IDL window ID for the drawing area. This ID is used with procedures such as WSET, WSHOW, etc., to direct graphics to the widget. The window ID is assigned to drawing area widgets at the time they are realized. If the widget has not yet been realized, a value of -1 is returned.

  B. If the draw widget uses IDL Object Graphics (that is, if the GRAPHICS_LEVEL keyword to WIDGET_DRAW is set equal to 2), the value of the draw widget is the object reference of the window object used in the draw widget.
- Label: The label text is returned as a string.
- Slider: The current value of the slider is returned as an integer.
- Table: Normally, the data for the whole table are returned as a two dimensional array or a vector of structures.

If the USE_TABLE_SELECT keyword is set, the value returned is a subset of the whole data.

- If the table is in standard selection mode and the table data is of a single type, the value returned is a two dimensional array. If the table contains structure data, the value returned is a vector of (possibly anonymous) structures.
- If the table is in disjoint selection mode and the table data is a single type, the value returned is a one-dimensional array of values. If the table contains structure data, the value returned is a single structure in which each field corresponds to a selected cell. In either case, use the TABLE_SELECT keyword to WIDGET_INFO to get the row and column indices of the disjoint values.

If the USE_TEXT_SELECT keyword is set, the value returned is a string corresponding to the currently-selected text in the currently-selected cell.

- Text: The current contents of the text widget are returned as a string array. If the USE_TEXT_SELECT keyword is also specified, only the contents of the current selection are returned.
- Widget types not listed above do not return a value. Attempting to retrieve the value of such a widget causes an error.

The value of a widget can be set with the SET_VALUE keyword to this routine, or with the VALUE keyword to the routine that created it.

GROUP_LEADER

This keyword applies to all widgets.

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

HOURGLASS

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Set this keyword to turn on an “hourglass-shaped” cursor for all IDL widgets and graphics windows. The hourglass remains in place until the WIDGET_EVENT

function attempts to process the next event. Then the previous cursor is reinstated. If an application starts a time-intensive calculation inside an event-handling routine, the hourglass cursor should be used to indicate that the system is not currently responding to events.

ICONIFY

This keyword applies to all widgets.

Set this keyword to a non-zero value to cause the specified widget to become iconified. Set this keyword to zero to open an iconified widget.

INPUT_FOCUS

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_DRAW, and WIDGET_TEXT functions.

If *Widget_ID* is a text widget, you can set this keyword to cause the widget to receive the keyboard focus. If *Widget_ID* is a button widget, set this keyword to position the mouse pointer over the button (on Motif), or set the focus to the button so that it can be “pushed” with the spacebar (on Windows). This keyword has no effect for other widget types.

Note

You cannot assign the input focus to an unrealized widget.

INSERT_COLUMNS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the number of columns to be added to the right of the rightmost column of the table. If the USE_TABLE_SELECT keyword is set equal to one, the columns are inserted to the left of the current selection. If USE_TABLE_SELECT is set equal to an array, the columns are inserted to the left of the specified selection.

Warning

You cannot insert columns into a table which displays structure data in /ROW_MAJOR (default) mode because it would change the structure.

INSERT_ROWS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the number of rows to be added below the bottommost row of the table. If the USE_TABLE_SELECT keyword is set equal to one, the rows are

inserted above the current selection. If USE_TABLE_SELECT is set equal to an array, the rows are inserted above the specified selection.

Warning

You cannot insert rows into a table which displays structure data in /COLUMN_MAJOR mode because it would change the structure.

KBRD_FOCUS_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_TABLE, and WIDGET_TEXT functions.

Set this keyword to cause widget keyboard focus events to be issued for the widget whenever the keyboard focus of that widget changes. See the KBRD_FOCUS_EVENTS keywords to WIDGET_BASE, WIDGET_TABLE, and WIDGET_TEXT for details.

KILL_NOTIFY

This keyword applies to all widgets.

Use this keyword to change or remove a previously-specified callback procedure for *Widget_ID*. A previously-defined callback can be removed by setting this keyword to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

For a top-level base widget in a widget application, the CLEANUP keyword to XMANAGER can also be used to specify a procedure that will be called when the base widget dies. Note that the *last* call to any of:

- WIDGET_BASE, KILL_NOTIFY
- XMANAGER, CLEANUP
- WIDGET_CONTROL, KILL_NOTIFY

determines the procedure that is executed when the specified top-level base widget dies. Calling XMANAGER with the CLEANUP keyword overrides any previous setting of KILL_NOTIFY. Similarly, calling WIDGET_CONTROL with KILL_NOTIFY overrides any previous setting of CLEANUP.

MANAGED

This keyword applies to all widgets.

This keyword is used by the XMANAGER procedure to mark those widgets that it is currently managing. User applications should not use this keyword directly.

MAP

This keyword applies to all widgets.

Set this keyword to zero to unmap the widget hierarchy rooted at the widget specified by *Widget_ID*. The hierarchy disappears from the screen, but still exists.

The mapping operation applies only to base widgets. If the specified widget is not a base, IDL searches upward in the widget hierarchy until it finds the closest base widget. The map operation is applied to that base.

Set MAP to a nonzero value to re-map the widget hierarchy and make it visible. Normally, the widget is automatically mapped when it is realized, so use of the MAP keyword is not required.

MONTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

NO_COPY

This keyword applies to all widgets.

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get”

operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

Note

The NO_COPY keyword increases efficiency when sending event structures using the SEND_EVENT keyword to WIDGET_CONTROL.

NO_NEWLINE

This keyword applies to widgets created with the WIDGET_TEXT function.

When setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. The NO_NEWLINE keyword suppresses this action.

NOTIFY_REALIZE

This keyword applies to all widgets.

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. A previously-set callback routine can be removed by setting this keyword to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

This keyword applies to all widgets.

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. The procedure specified by PRO_SET_VALUE is called with 2 arguments— a widget ID and a value. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

REALIZE

This keyword applies to all widgets.

If set, the widget hierarchy is realized. Until the realization step, the widget hierarchy exists only within IDL. Realization is the step of actually creating the widgets on the screen (and mapping them if necessary).

When a previously-realized widget gets a new child widget, the new child is automatically realized.

Tip

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This “extra” resize event is generated before any manipulation of the base widget by the user.

RESET

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword. Set the RESET keyword to destroy every currently active widget. This keyword should be used with caution.

ROW_LABELS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label “*n*” where *n* is the row number. If this keyword is set to the empty string (''), all row labels are set to be empty.

ROW_HEIGHTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Note

This keyword is not supported under Microsoft Windows.

Set this keyword equal to a one-dimensional array of heights for the rows of the table widget. The heights are given in the units specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

If the USE_TABLE_SELECT keyword is set (in either standard or disjoint selection mode), the indices of the elements of the specified array are interpreted as indices into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from rows `0`, `1`, `2`, `5`, `6`, and `7`, USE_TABLE_SELECT is set equal to one, and the ROW_HEIGHTS keyword is set equal to a four-element array `[20, 35, 30, 35]`, the height of rows `0`, `1`, `2`, and `5` would be modified. Similarly, if the table is in standard selection mode and the USE_TABLE_SELECT keyword is set equal to the array `[0, 1, 0, 0]`, and the

ROW_HEIGHTS keyword is set equal to a four-element array `[20, 35, 30, 35]`, only the height of the first row would be altered.

SCR_XSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new horizontal size, in units specified by the UNITS keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area).

SCR_YSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new vertical size, in units specified by the UNITS keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area).

SEND_EVENT

This keyword applies to all widgets.

Set this keyword to a structure containing a valid widget event to be sent to the specified widget. The value of SEND_EVENT *must* be a structure and the first three fields must be ID, TOP, and HANDLER (all of LONG type). Additional fields can be of any type.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SEND_EVENT.

SENSITIVE

Set this keyword to control the sensitivity state of a widget after creation. This keyword applies to all widgets. Use the SENSITIVE keyword with the widget creation function to control the initial sensitivity state.

When a widget is sensitive, it has normal appearance and can receive user input. For instance, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by

changing its appearance, and ignores any input directed at it. If SENSITIVE is zero, the widget hierarchy becomes insensitive. If nonzero, it becomes sensitive.

Sensitivity can be used to control when a user is allowed to manipulate a widget. It should be noted that some widgets do not change their appearance when they are made insensitive, and simply cease generating events.

SET_BUTTON

This keyword applies to widgets created with the WIDGET_BUTTON function.

This keyword changes the current state of toggle buttons. If set equal to zero, every toggle button in the hierarchy specified by *Widget_ID* is set to the unselected state. If set to a nonzero value, the action depends on the type of base holding the buttons:

- For a non-exclusive base:
  - If a single button is specified by *Widget_ID*, that button is set to the selected state, leaving the state of other buttons in the base unchanged.
  - If the base itself is specified by *Widget_ID*, all buttons are set to the selected state.
- For an exclusive base:
  - If a single button is specified by *Widget_ID*, that button is set to the selected state, and all other buttons in the base are set to the unselected state.
  - If the base itself is specified by *Widget_ID*, IDL generates an error, since an exclusive base can contain at most one selected button.

If the specified *Widget_ID* is a button widget that was created using the CHECKED_MENU keyword, the checked state of the menu item is modified. If the keyword value is nonzero, the menu button is placed in a checked state. If the keyword value is zero, the button is placed in a un-checked state.

SET_COMBOBOX_SELECT

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the combobox list element to be displayed. If the specified element is outside the range of existing elements, the selection remains unchanged.

SET_DRAW_VIEW

This keyword applies to widgets created with the WIDGET_DRAW function.

A scrollable draw widget provides a large graphics area which is viewed through a smaller viewport. This keyword allows changing the current position of the viewport. The desired position is specified as a 2-element integer array giving the X and Y position in units specified by the UNITS keyword (pixels are the default) relative to the lower left corner of the graphics area. For example, to position the viewport to the lower left corner of the image:

```
WIDGET_CONTROL, widget, SET_DRAW_VIEW=[0, 0]
```

SET_DROPLIST_SELECT

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to an integer that specifies the droplist element to be current (i.e., the element that is displayed on the droplist button). Positions start at zero. If the specified element is outside the possible range, no new selection is set.

SET_LIST_SELECT

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to an integer scalar or vector that specifies the list element or elements to be highlighted. The previous selection (if there is a selection) is cleared. Positions start at zero. If the specified element is outside the possible range, no new selection in set. Note that the MULTIPLE keyword to WIDGET_LIST must have been set in more than a single list element is specified.

If the selected position is not currently on the screen, the list widget automatically move the current scrolling viewport to make it visible. The resulting topmost visible element is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the SET_LIST_TOP keyword (described below) to explicitly set the viewport.

SET_LIST_TOP

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to an integer that specifies the element of the list widget to the positioned at the top of the scrolling list. If the specified element is outside the range of list elements, nothing happens.

SET_SLIDER_MAX

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to a new maximum value for the specified slider widget.

Note

This keyword does not apply to floating-point sliders created with the CW_FSLIDER function.

SET_SLIDER_MIN

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to a new minimum value for the specified slider widget.

Note

This keyword does not apply to floating-point sliders created with the CW_FSLIDER function.

SET_TAB_CURRENT

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword equal to the zero-based index of the tab to be set as the current (visible) tab. If the index value is invalid, the value is quietly ignored.

SET_TAB_MULTILINE

This keyword applies to widgets created with the WIDGET_TAB function.

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and UNIX systems.

Windows

Set this keyword to cause tabs to be organized in a multi-line display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE=0 and LOCATION=0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION=1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab

widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

UNIX

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. (Tab text may be truncated if the text of a single tab exceeds the space available, however.) This means that if MULTILINE is set to any value other than one, some tabs may not be displayed.

SET_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

- In standard selection mode, specify a four-element array, of the form [*left*, *top*, *right*, *bottom*] specifying the of cells to act upon.
- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). The value -1 is used to refer to the title row or title column.

See "USE_TABLE_SELECT" on page 2121 for details on the selection modes.

Note

To remove a table selection programmatically, set this keyword to either `[-1, -1, -1, -1]` (in standard selection mode) or `[[-1, -1]]` (in disjoint selection mode).

If the selected position is not currently on the screen, the table widget automatically moves the current scrolling viewport to make a portion of it visible. The resulting top-left visible cell is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the SET_TABLE_VIEW keyword to explicitly set the viewport.

SET_TABLE_VIEW

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to a two-element array of zero-based cell indices that specifies the cell of the table widget to the positioned at the top-left of the widget. If the specified cell is outside the range of valid cells, nothing happens.

SET_TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Use this keyword to clear any current selection in the specified table cell or text widget, and either set a new selection, or simply set the text insertion point. To set a selection, specify a two-element integer array containing the starting position and the length of the selection. For example, to set a selection covering characters 3 though 23:

```
WIDGET_CONTROL, widgetID, SET_TEXT_SELECT=[3, 20]
```

To move the text insertion point without setting a selection, omit the second element, or set it to zero.

SET_TEXT_TOP_LINE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to the zero-based line number of the line to be positioned on the topmost visible line in the text widget's viewport. No horizontal scrolling is performed. Note that this is a line number, not a character offset.

SET_TREE_BITMAP

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

Set this keyword equal to zero to revert to the appropriate default system bitmap.

SET_TREE_EXPANDED

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword equal to a nonzero value to expand the specified tree widget folder. Set this keyword equal to zero to collapse the specified tree widget folder.

SET_TREE_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

This keyword has two modes of operation, depending on the widget ID passed to WIDGET_CONTROL:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget):
  - If the tree widget is in multiple-selection mode and SET_TREE_SELECT is set to an array of widget IDs corresponding to tree widgets that are nodes in the tree, those nodes are selected.
  - If the tree widget is *not* in multiple-selection mode and SET_TREE_SELECT is set to a single widget ID corresponding to a tree widget that is a node in the tree, that node is selected.
  - If the keyword is set to zero, all selections in the tree widget are cleared.
- If the specified widget ID is a tree widget that is a node in a tree:
  - If the keyword is set to a nonzero value, the specified node is selected.
  - If the keyword is set to zero, the specified node is deselected.

Note

If the tree widget is in multiple-selection mode, the selection changes made to the tree widget via this keyword are additive — that is, the current selections are retained and any additional nodes specified by SET_TREE_SELECT are also selected.

SET_TREE_VISIBLE

This keyword applies to widgets created with the WIDGET_TREE function and whose parent widget was also created using the WIDGET_TREE function (that is, tree widgets that are nodes of another tree).

Set this keyword to make the specified tree node *visible* to the user. Setting this keyword has two possible effects:

1. If the specified node is inside a collapsed folder, the folder and all folders above it are expanded to reveal the node.
2. If the specified node is in a portion of the tree that is not currently visible because the tree has scrolled within the parent base widget, the tree view scrolls so that the selected node is at the top of the base widget.

Note

Use of this keyword does not affect the tree widget selection state.

SET_UNAME

This keyword applies to all widgets.

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID. You can set the name at creation time, using the UNAME keyword with the creation function.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

SET_UVALUE

This keyword applies to all widgets.

Each widget can contain a user-set value. This value is not used by IDL in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SET_UVALUE.

SET_VALUE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, WIDGET_LABEL, WIDGET_LIST, WIDGET_SLIDER, WIDGET_TABLE, and WIDGET_TEXT functions.

Sets the value of the specified widget. The meaning of the value differs between widget types:

- Button: The label to be used for the button. This value can be either a scalar string, or a 2D byte array containing a bitmap.
- Combobox: The contents of the combobox widget (string or string array).
- Droplist: The contents of the droplist widget (string or string array).
- Label: The text to be displayed by the label widget.

- List: The contents of the list widget (string or string array).
- Slider: The current position of the slider (integer).
- Table: Normally, the data for the whole table is changed to the specified data, which must be of the form of a two dimensional array or a vector of structures. In this form, the table is resized to fit the given data (unless the TABLE_XSIZE or TABLE_YSIZE keywords are given).

  If the USE_TABLE_SELECT keyword is set, the value given is treated as a subset of the whole data, and only the given range of cells are updated. Used in this form, the type of data stored in the table cannot be changed. The data passed in is converted, as appropriate, to the type of the selected cells. If less data is passed in than fits in the current selection, the cells outside the range of data (but inside the selection) are left unchanged. If more data is passed in than fits in the current selection, the extra data is ignored.

  - If the table is in standard selection mode, the data should be a two-dimensional array of values for a single-type table, or a vector of structures for a table that contains structure data.
  - If the table is in disjoint selection mode, the data should be a one-dimensional array of values for a single-type table, or a single structure with each field corresponding to a cell for a table that contains structure data.

  If the USE_TEXT_SELECT keyword is present, the value must be a string, which replaces the currently-selected text in the currently-selected cell.
- Text: The text to be displayed. If the APPEND keyword is also specified, the text is appended to the current contents instead of instead of completely replacing it (string or string array). If the USE_TEXT_SELECT keyword is specified, the new string replaces only the currently-selected text in the text widget.
- Widget types not listed above do not allow the setting of a value. Attempting to set the value of such a widget causes an error.

The value of a widget can also be set with the VALUE keyword to the routine that created it.

SHOW

This keyword applies to all widgets.

Controls the visibility of a widget hierarchy. If set to zero, the hierarchy containing *Widget_ID* is pushed behind any other windows on the screen. If nonzero, the hierarchy is pulled in front.

TABLE_BLANK

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a nonzero value to cause the specified cells to be blank. Set this keyword equal to zero to cause the specified cells to display values as usual.

Note

Hiding cell contents using this keyword is a *display-only operation*. The cell contents are not actually removed from the table, they are simply hidden from view. Any operation that evaluates or changes the value of a cell will operate in the same way on a cell whose contents are hidden as it will on a cell whose contents are visible.

If the USE_TABLE_SELECT keyword is set equal to one, the currently selected cells are blanked or restored. If USE_TABLE_SELECT is set equal to an array, the specified cells are blanked or restored. If USE_TABLE_SELECT is not set, the entire table is hidden or displayed.

TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to enable the ability to select multiple rectangular regions of cells.

TABLE_XSIZE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to the number of data columns in the table widget. Note that if the table widget was created with row titles enabled (that is, if the NO_HEADERS keyword to WIDGET_TABLE was *not* set), the table will contain one column more than the number specified by TABLE_XSIZE.

If the table is made smaller as a result of the application of the TABLE_XSIZE keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new columns is set according to the following rules:

1. If the table was not created with either the ROW_MAJOR or COLUMN_MAJOR keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.

2. If the SET_VALUE keyword is given, the types of all columns are set according to the new structure.
3. If the table was created with the ROW_MAJOR keyword set, and the SET_VALUE keyword is not specified, the cells in the new columns inherit their type from the cells to their left.
4. [2]If the table was created with the COLUMN_MAJOR keyword set, and the SET_VALUE keyword is not specified, any new columns default to type INT.

TABLE_YSIZE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to the number of data rows in the table widget. Note that if the table widget was created with column titles enabled (that is, if the NO_HEADERS keyword to WIDGET_TABLE was *not* set), the table will contain one row more than the number specified by TABLE_YSIZE.

If the table is made smaller as a result of the application of the TABLE_YSIZE keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new rows is set according to the following rules:

1. If the table was not created with either the ROW_MAJOR or COLUMN_MAJOR keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.
2. If the SET_VALUE keyword is given, the types of all rows are set according to the new structure.
3. If the table was created with the COLUMN_MAJOR keyword set, and the SET_VALUE keyword is not specified, the cells in the new rows inherit their type from the cells above.
4. If the table was created with the ROW_MAJOR keyword set, and the SET_VALUE keyword is not specified, any new rows default to type INT.

TIMER

This keyword applies to all widgets.

If this keyword is present, a WIDGET_TIMER event is generated. Set this keyword to a floating-point value that represents the number of seconds before the timer event arrives. Note that this event is identical to any other widget event except that it contains only the 3 standard event tags. These event structures are defined as:

```
{ WIDGET_TIMER, ID:0L, TOP:0L, HANDLER:0L }
```

It is left to the caller to tell the difference between standard widget events and timer events. The standard way to do this is to use a widget that doesn't normally generate events (e.g., a base or label). Alternately, the TAG_NAMES function can be called with the STRUCTURE_NAME keyword to differentiate a WIDGET_TIMER event from other types of events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
   'WIDGET_TIMER' THEN ...
```

Using the TIMER keyword is more efficient than the background task functionality found in the XMANAGER procedure because it doesn't "poll" like the original background task code. Research Systems will eventually eliminate the background task functionality from XMANAGER. We encourage all users to modify their code to use the TIMER keyword instead.

TLB_GET_OFFSET

This keyword applies to all widgets.

Set this keyword to a named variable in which the offset of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The offset is measured in device coordinates relative to the upper-left corner of the screen.

TLB_GET_SIZE

This keyword applies to all widgets.

Set this keyword to a named variable in which the size of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The size is returned as a two-element vector that contains the horizontal and vertical size of the base in device coordinates.

TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is iconified or restored by the user.

TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Use this keyword to set or clear kill request events for the specified top-level base. For more information on these events see "TLB_KILL_REQUEST_EVENTS" on page 2060.

TLB_MOVE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is moved by the user. Note that if TLB_SIZE_EVENTS are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

TLB_SET_TITLE

This keyword applies to all widgets.

Set this keyword to a scalar string to change the title of the specified top-level base after it has been created.

TLB_SET_XOFFSET

This keyword applies to all widgets.

Use this keyword to set the horizontal position of the top level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

TLB_SET_YOFFSET

This keyword applies to all widgets.

Use this keyword to set the vertical position of the top-level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

TLB_SIZE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is resized by the user. Note that if TLB_MOVE_EVENTS are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

TOOLTIP

This keyword applies to widgets created with the WIDGET_BUTTON and WIDGET_DRAW functions.

Set this keyword to a string that will be displayed when the cursor hovers over the specified widget. For UNIX platforms, this string must be non-zero in length, which means that a tooltip can be modified but not be removed on UNIX versions of IDL.

Note

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

Note

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to a non-zero value to enable tracking events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable tracking events for the specified widget. For a description of tracking events, see "TRACKING_EVENTS" on page 2061.

UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used for most widget sizing operations. Set UNITS equal to 0 to specify that all measurements are in pixels (this is the default), to 1 to specify that all measurements are in inches, or to 2 to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_LIST, WIDGET_TABLE, or WIDGET_TEXT functions.

UPDATE

This keyword applies to all widgets.

Use this keyword to enable (if set to 1) or disable (if set to 0) screen updates for the widget hierarchy to which the specified widget belongs. This keyword is useful for preventing unwanted intermediate screen updates when changing the values of many

widgets at once or when adding several widgets to a previously-realized widget hierarchy. When first realized, widget hierarchies are set to update.

Note

Do not attempt to resize a widget on the Windows platform while UPDATE is turned off. Doing so may prevent IDL from updating the screen properly when UPDATE is turned back on.

USE_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to modify the behavior of the ALIGNMENT, COLUMN_WIDTHS, DELETE_COLUMNS, DELETE_ROWS, FORMAT, GET_VALUE, INSERT_COLUMNS, INSERT_ROWS, ROW_HEIGHTS, SET_VALUE, and TABLE_BLANK keywords. If USE_TABLE_SELECT is set, these other keywords only apply to the currently-selected cells. Normally, these keywords apply to the entire contents of a table widget.

Note

If either the title row or the title column of the table is selected, this keyword only modifies the behavior of the ROW_HEIGHTS or COLUMN_WIDTHS keywords.

Warning

The Microsoft Windows platform does not support the ROW_HEIGHTS keyword. Selecting the title row of a table via USE_TABLE_SELECT has no effect.

Selection Modes

The table widget supports two *selection modes*:

- In *standard selection mode*, only a single selection can be created at a given time. Creating a new selection causes the existing selection to disappear.
- In *disjoint selection mode*, multiple selections can be created at one time. Creating a new selection does not cause the existing selection(s) to disappear. A table can be created in disjoint selection mode using either the DISJOINT_SELECTION keyword to WIDGET_TABLE or the TABLE_DISJOINT_SELECTION keyword to WIDGET_CONTROL.

The keywords listed above to generate different output or expect different input based on the selection mode. See the description of each keyword for details. For more information on table selection modes, see “Selection Modes” in Chapter 26 of the *Building IDL Applications* manual

Specifying Selections Programmatically

In many cases, your code will use a selection created by the user manually, with the mouse. You can also create selections programmatically, by setting USE_TABLE_SELECT equal to an array.

- In standard selection mode, specify a four-element array, of the form [*left, top, right, bottom*] specifying the of cells to act upon.
- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). The value -1 is used to refer to the title row or title column.

Note

Setting USE_TABLE_SELECT equal to an array does *not* change the current table selection. Operations affect the specified cells without changing the current selection.

is equivalent to first calling WIDGET_CONTROL and setting the SET_TABLE_SELECT keyword equal to an array, and then calling WIDGET_CONTROL with USE_TABLE_SELECT set equal to one.

Example

To change the column widths of the title column and the first five data columns of a table widget named `wTable`, leaving the widths of the other columns unchanged:

```
WIDGET_CONTROL, wTable, USE_TABLE_SELECT=[-1,0,4,0], $
    COLUMN_WIDTHS=50
```

For additional examples, see “Using Table Widgets” in Chapter 26 of the *Building IDL Applications* manual.

USE_TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Set this keyword to modify the behavior of the GET_VALUE and SET_VALUE keywords. If USE_TEXT_SELECT is set, GET_VALUE and SET_VALUE apply only to the current text selection. Normally, these keywords apply to the entire contents of a text widget.

X_BITMAP_EXTRA

This keyword applies to widgets created with the WIDGET_BUTTON function.

When the value of a button widget is a bitmap, the usual width is taken to be 8 times the number of columns in the source byte array. This keyword can be used to indicate the number of bits in the last byte of each row that should be ignored. The value can range between 0 and 7.

XOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new horizontal offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

XSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new horizontal size.

- Text and List widgets: Size is specified in characters. The UNITS keyword is ignored.
- Table widgets: Size is specified in columns. The width of the row labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw widgets), this keyword adjusts the *viewport* size. Use the DRAW_XSIZE keyword to change the width of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

YOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new vertical offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change

the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

YSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new vertical size

- Text and List widgets: Size is specified in lines. The UNITS keyword is ignored.
- Table widgets: Size is specified in rows. The height of the column labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw and table widgets), this keyword adjusts the *viewport* size. Use the DRAW_YSIZE keyword to change the height of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

Version History

Introduced: Pre 4.0

COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DRAW_KEYBOARD_EVENTS, SET_BUTTON, SET_COMBOBOX_SELECT, SET_TAB_CURRENT, SET_TAB_MULTILINE, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP keywords added: 5.6

Chapter 26, "Widget Application Techniques" in the *Building IDL Applications* manual.

WIDGET_DISPLAYCONTEXTMENU

The WIDGET_DISPLAYCONTEXTMENU procedure displays a *context-sensitive menu* (also known as a *pop-up* or *shortcut* menu). Context-sensitive menus appear when the user clicks the right mouse button over a widget for which a context menu is defined. Because the widget programmer must explicitly detect the right-mouse button click and call WIDGET_DISPLAYCONTEXTMENU to display the context menu, a widget can have any number of associated context menus, which can be displayed under different circumstances.

Context menus are created by placing one or more button widgets on a base widget constructed with the CONTEXT_MENU keyword set. The context menu's base widget must have as its parent a base, draw, list, or text widget; in the case of all but draw widgets, the parent widget must be configured to generate context menu events via the CONTEXT_EVENTS keyword. Draw widgets that support context menus must have the BUTTON_EVENTS keyword set.

The widget application's event handler routine must detect the presence of a context menu event (base, list, and text widgets) or the right mouse-button event (draw widgets) and call WIDGET_DISPLAYCONTEXTMENU to display the context menu. Events generated when the user clicks on the context menu's buttons are handled in the normal way. If the user clicks outside the context menu, it is dismissed and no event is generated.

Syntax

WIDGET_DISPLAYCONTEXTMENU, *Parent, X, Y, ContextBase_ID*

Arguments

Parent

The widget ID of the parent widget of the context menu widget.

Note

The parent widget must be either a base, list, or text widget with the CONTEXT_EVENTS keyword set or a draw widget with the BUTTON_EVENTS keyword set. In most cases the parent widget can be identified via the ID field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.

X

The x location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the x location of the user's right mouse-button click, as reported in the X field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

Y

The y location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the y location of the user's right mouse-button click, as reported in the Y field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

ContextBase_ID

The widget ID of the context menu base widget that contains the context menu to be displayed. Use the CONTEXT_MENU keyword to WIDGET_BASE to create a context menu base.

Note

The context menu base must be a child of the widget specified by the *Parent* argument.

Keywords

None.

Examples

For examples using WIDGET_DISPLAYCONTEXTMENU, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

Version History

Introduced: 5.5

WIDGET_DRAW

The WIDGET_DRAW function is used to create draw widgets. Draw widgets are rectangular areas that IDL treats as standard graphics windows. Draw widgets can use either IDL Direct graphics or IDL Object graphics, depending on the value of the GRAPHICS_LEVEL keyword. Any graphical output that can be produced by IDL can be directed to a draw widget. Draw widgets can have optional scroll bars to allow viewing a larger graphics area than could otherwise be displayed in the widget's visible area.

The returned value of this function is the widget ID of the newly-created draw widget.

Note

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD( ) may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly.

For a more detailed discussion of the draw widget, along with examples, see "Using Draw Widgets" in Chapter 26 of the *Building IDL Applications* manual.

Syntax

Result = WIDGET_DRAW(*Parent* [, /APP_SCROLL] [, /BUTTON_EVENTS] [, /COLOR_MODEL] [, COLORS=*integer*] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXPOSE_EVENTS] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GRAPHICS_LEVEL=2] [, GROUP_LEADER=*widget_id*] [, KEYBOARD_EVENTS={1 | 2}] [, KILL_NOTIFY=*string*] [, /MOTION_EVENTS] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RENDERER={0 | 1}] [, RESOURCE_NAME=*string*] [, RETAIN={0 | 1 | 2}] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL] [, /SENSITIVE] [, TOOLTIP=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, /VIEWPORT_EVENTS] [, XOFFSET=*value*] [, XSIZE=*value*] [, X_SCROLL_SIZE=*width*] [, YOFFSET=*value*] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*height*])

Arguments

Parent

The widget ID of the parent widget of the new draw widget.

Keywords

APP_SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

The drawable area of a draw widget created with the APP_SCROLL keyword is the same size as the viewable area (the *viewport*). This is useful for displaying very large images, because the memory used by a draw widget is directly related to the size of the drawable area. A draw widget created with the APP_SCROLL keyword also has the concept of a *virtual drawable area*, which is the size of the entire image. The fact that only a portion of the entire image is held in memory means that you must capture events generated when the user adjusts the scroll bars and display the correct portion of the image in your event-handling code.

Note

If the image you are displaying is relatively small or memory is not a concern, consider using the SCROLL keyword rather than APP_SCROLL. With SCROLL, the drawable area is the size of the entire image; this allows IDL to display the appropriate portions of the image automatically when the user adjusts the scroll bars. See "SCROLL" on page 2134 and "Scrolling Draw Widgets" in Chapter 26 of the *Building IDL Applications* manual for details.

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the virtual drawable area using the XSIZE and YSIZE keywords. If APP_SCROLL is set, the application generates viewport events even if the VIEWPORT_EVENTS keyword is not set.

If the drawable area uses Direct Graphics (that is, if GRAPHICS_LEVEL is *not* set equal to 2), system backing store is used by default and the viewport is automatically restored after it has been obscured. If you prefer to manually restore the viewport in an event-handling routine, set RETAIN=0 and EXPOSE_EVENTS=1; this allows you to redraw the virtual canvas when your application receives expose events.

If the drawable area uses Object Graphics (that is, if the GRAPHICS_LEVEL keyword is set equal to 2), the application will *not* automatically restore the viewport, and will generate expose events as if RETAIN=0 and EXPOSE_EVENTS=1 had been set.

BUTTON_EVENTS

Set this keyword to make the draw widget generate events when the mouse buttons are pressed or released (and the mouse pointer is in the draw widget). Normally, draw widgets do not generate events.

You can use the event structure generated when the BUTTON_EVENTS keyword is set to emulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. To determine whether the user clicked the right mouse button, use the test:

```
IF (event.release EQ 4)
```

where `event` holds the widget event structure.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

COLOR_MODEL

Set this keyword equal to 1 (one) to cause the draw widget's associated IDLgrWindow object to use indexed color. If the COLOR_MODEL keyword is not set, or is set to a value other than one, the draw widget will use RGB color.

This keyword is only valid when the draw widget uses IDL Object Graphics. (The graphics type used by a draw widget is determined by setting the GRAPHICS_LEVEL keyword to WIDGET_DRAW.)

COLORS

The maximum number of color table indices to be used. This parameter has effect *only* if it is supplied when the *first* IDL graphics window is created.

If COLORS is not specified when the first window is created, all or most of the available color indices are allocated, depending upon the window system in use.

To use monochrome windows on a color display, set COLORS equal to 2 when creating the first window. One color table is maintained for all IDL windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be used.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EXPOSE_EVENTS

Set this keyword to make the draw widget generate event when the visibility of the draw widget changes. This may occur when the widget is hidden behind something else on the screen, brought to the foreground, or when the scroll bars are moved. Normally, draw widgets do not generate events.

If this keyword is set, expose events will be generated only when IDL is unable to restore the contents of the window itself. After the initial draw, expose events are not issued when GRAPHICS_LEVEL=2 and the software renderer is being used (RENDERER=1). In such cases, expose events are not issued because IDL can internally refresh the window itself. On platforms for which OpenGL support is not offered, the software renderer is always being used, and therefore, expose events are not issued after the initial draw.

Note

When using hardware rendering, you must explicitly disable backing store (by setting RETAIN=0) in order to generate expose events. Additional expose events may be generated if both EXPOSE_EVENTS and RETAIN=1 are turned on.

Warning

Large numbers of events may be generated when EXPOSE_EVENTS is specified. You may wish to compress the events (perhaps using a timer) and only act on a subset.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GRAPHICS_LEVEL

Set this keyword equal to 2 (two) to use IDL Object Graphics in the draw widget. If the GRAPHICS_LEVEL keyword is not set, or is set to a value other than two, the draw widget will use IDL Direct Graphics.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KEYBOARD_EVENTS

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See “Widget Events Returned by Draw Widgets” on page 2138 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

Note

Keyboard events are never generated for function keys.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MOTION_EVENTS

Set this keyword to make the draw widget generate events when the mouse cursor moves across the widget. Normally, draw widgets do not generate events.

Draw widgets that return motion events can generate a large number of events that can result in poor performance on slower machines.

Note that it is possible to generate motion events with coordinates outside the draw widget. If you position the mouse cursor inside the draw widget, press the mouse button, and drag the cursor out of the draw widget, the X and Y fields of the widget event will specify coordinates outside the draw widget.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_DRAW or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE

keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of a draw widget. See "IDLgrWindow" on page 3015 for details.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2055 for a complete discussion of this keyword.

RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the draw widget. RETAIN=0 specifies no backing store. RETAIN=1 requests that the server or window system provide backing store. RETAIN=2 specifies that IDL provide backing store directly. See "Backing Store" on page 2142 for details on the

use of RETAIN with Direct Graphics. For more information on the use of RETAIN with Object Graphics, see “IDLgrWindow::Init” on page 3030.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the entire drawable area using the XSIZE and YSIZE keywords.

Note

While the viewport of a draw widget created with the SCROLL keyword may be smaller than the entire image, the drawable area itself is the same size as the image, and uses memory commensurately. If you want to display a portion of a very large image, consider using the APP_SCROLL keyword rather than SCROLL. The drawable area of a draw widget created with APP_SCROLL is the same size as the viewport. This saves memory when the displayed image is large, but requires extra work on the programmer’s part to handle viewport events and display the appropriate portion of the image. See “APP_SCROLL” on page 2128 and “Scrolling Draw Widgets” in Chapter 26 of the *Building IDL Applications* manual for details.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse

cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

Note

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a draw widget is the IDL window number for use with Direct Graphics routines, such as WSET. For Object Graphics routines, it is the draw window object reference. This value cannot be set or modified by the user.

To obtain the window number for a newly-created draw widget, use the GET_VALUE keyword to WIDGET_CONTROL *after* the draw widget has been realized. Draw widgets do not have a window number assigned to them until they are realized. For example, to return the window number of a draw widget in the variable *win_num*, use the command:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE = win_num
```

where *my_drawwidget* is the widget ID of the desired draw widget.

When using Object Graphics for the widget draw, the following command returns an object reference to the draw window:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE = oWindow
```

where *oWindow* is a window object.

VIEWPORT_EVENTS

Set this keyword to enable viewport motion events for draw widgets.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the X_SCROLL_SIZE keyword implies SCROLL.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the Y_SCROLL_SIZE keyword implies SCROLL.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of draw widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DRAW_BUTTON_EVENTS, DRAW_EXPOSE_EVENTS, DRAW_KEYBOARD_EVENTS, DRAW_MOTION_EVENTS, DRAW_VIEWPORT_EVENTS, DRAW_XSIZE, DRAW_YSIZE, GET_DRAW_VIEW, GET_VALUE, INPUT_FOCUS, SET_DRAW_VIEW, TOOLTIP.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to draw widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DRAW_BUTTON_EVENTS, DRAW_EXPOSE_EVENTS, DRAW_KEYBOARD_EVENTS, DRAW_MOTION_EVENTS, DRAW_VIEWPORT_EVENTS, TOOLTIP.

Widget Events Returned by Draw Widgets

By default, draw widgets do not generate events. If the BUTTON_EVENTS keyword is set when the widget is created, pressing or releasing any mouse button while the mouse cursor is over the draw widget causes events to be generated. Specifying the MOTION_EVENTS keyword causes events to be generated *continuously* as the mouse cursor moves across the draw widget. Specifying the EXPOSE_EVENTS keyword causes events to be generated whenever the visibility of any portion of the draw window (or viewport) changes. Specifying the KEYBOARD_EVENTS keyword causes events to be generated when the draw widget has keyboard focus and a keyboard key is pressed.

The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
   PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.3 release before the structure was defined by an internal call, the MODIFIERS field will break the existing user code.

Note

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.6 release before the structure was defined by an internal call, the CH and KEY fields will break the existing user code.

ID, TOP, and HANDLER are the three standard fields found in every widget event. TYPE returns a value that describes the type of draw widget interaction that generated an event. The values for TYPE are shown in the table below.

Value	Meaning
0	Button Press
1	Button Release
2	Motion
3	Viewport Moved (Scrollbars)
4	Visibility Changed (Exposed)
5	Key Press (ASCII character value reported in CH field)
6	Key Press (Non-ASCII key value reported in KEY field)

Table 136: Values for the TYPE field

The X and Y fields give the device coordinates at which the event occurred, measured from the lower left corner of the drawing area.

For button and “viewport moved” events (that is, when the TYPE field contains 0, 1, or 3), PRESS and RELEASE are bitmasks that represent which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 137: Bitmask for the PRESS and RELEASE Fields during Button Events

For motion events, both PRESS and RELEASE are zero. For keyboard events, PRESS contains 1 (one) if the key is down and 0 (zero) if it is up; RELEASE contains 0 (zero) if the key is down and 1 (one) if it is up.

Note

IDL obtains information about which mouse button was pressed from the operating system, not from the mouse hardware itself. This means that if the operating system or some extension thereof remaps the mouse buttons, IDL may receive information that one button was pressed even if a different physical button was pressed. For example, if a user remaps the mouse buttons to reverse left and right, and then presses the right physical mouse button, the widget event structure will reflect a left mouse button press.

The CLICKS field returns either 1 or 2. If the time interval between two button-press events is less than the time interval for a double-click event for the platform, the CLICKS field returns 2. If the time interval between button-press events is greater than the time interval for a double-click event for the platform, the CLICKS field returns 1. This means that if you are writing a widget application that requires the user to double-click on a draw widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.

The MODIFIERS field is valid for button press, button release, motion, and “normal” keyboard events. It is a bitmask which returns the current state of several keyboard modifier keys at the time the event was generated. If a bit is zero, the key is up. If the bit is set, the key is depressed.

Note

“Normal” keyboard events are generated when the KEYBOARD_EVENTS keyword is set equal to one. If KEYBOARD_EVENTS is set equal to two, the keypress event for a modifier key contains zero in the `MODIFIERS` field and the key value is reported in the `KEY` field; see below.

The value in the MODIFIERS field is generated by OR-ing the following values together if a key is depressed.

Bitmask	Modifier Key
1	Shift
2	Control

Table 138: Bitmask for the MODIFIERS Field

Bitmask	Modifier Key
4	Caps Lock
8	Alt (See Note following this table.)

Table 138: Bitmask for the MODIFIERS Field

Note

Under UNIX, the Alt key is the currently mapped MOD1 key.

Keyboard events are generated with the value of the TYPE field equal to 5 or 6. If the event was generated by an ASCII keyboard character, the TYPE field will be set to 5 and the ASCII value of the key will be returned in the CH field. (Note that ASCII values can be converted to the string representing the character using the IDL STRING routine.) If the event was generated due to a non-ASCII keyboard character, the type of the event will be set to 6 and a numeric value representing the key will be returned in the KEY field. The following table lists the possible values of the KEY field.

Note that for the key values reported in the KEY field for the SHIFT, CONTROL, CAPS LOCK, and ALT keys are not the same as those reported in the MODIFIER field bit mask, since the KEY field is not a bitmask.

Key Field Value	Keyboard Key
1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up

Table 139: Modifier key values reported in the KEY field.

Key Field Value	Keyboard Key
10	Page Down
11	Home
12	End

Table 139: Modifier key values reported in the KEY field. (Continued)

Note on using CURSOR

Note that the CURSOR procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, examine the X, Y, PRESS, and RELEASE fields in the structures returned by the draw widget in response to cursor events.

Backing Store

Draw widgets with scroll bars rely on backing store to repaint the visible area of the window as it is moved. Their performance is best on systems that provide backing store. However, if your system does not automatically provide backing store, you can make IDL supply it with the statement:

```
DEVICE, RETAIN=2
```

or by using the RETAIN keyword to WIDGET_DRAW.

Note

If you are using graphics acceleration, you may wish to turn off backing store entirely and enable expose events (via the EXPOSE_EVENTS keyword) and redraw the draw widget's contents manually. However, because the number of events generated may be quite high, you may wish to enable a timer as well and only redraw the draw widget periodically.

SLIDE_IMAGE, WINDOW

WIDGET_DROPLIST

The WIDGET_DROPLIST function creates “droplist” widgets. A droplist widget displays a text field and an arrow button. Selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently-selected option. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

Note

The WIDGET_COMBOBOX function creates a similar widget that optionally allows users to edit the text displayed by the droplist. The combobox widget is intended to replace the droplist widget; Research Systems recommends that new code use WIDGET_COMBOBOX rather than WIDGET_DROPLIST.

Syntax

Result = WIDGET_DROPLIST(*Parent* [, /DYNAMIC_RESIZE]
[, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
[, FRAME=*value*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SENSITIVE] [, TITLE=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*]
[, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created droplist widget.

Arguments

Parent

The widget ID of the parent widget for the new droplist widget.

Keywords

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_DROPLIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation

(GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2055 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TITLE

Set this keyword to a string to be used as the title for the droplist widget.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a droplist widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The desired width of the droplist widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of droplist widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, SET_DROPLIST_SELECT, SET_VALUE.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to droplist widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DROPLIST_NUMBER, DROPLIST_SELECT, DYNAMIC_RESIZE.

Widget Events Returned by Droplist Widgets

Pressing the mouse button while the mouse cursor is over an element of a droplist widget causes the widget to change the label on the droplist button and to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{ WIDGET_DROPLIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L }
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value.

Note

Platform-specific UI toolkits behave differently if a droplist widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

CW_PDMENU, WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_LIST

WIDGET_EVENT

The WIDGET_EVENT function returns events for the widget hierarchy rooted at *Widget_ID*. Widgets communicate information by generating events. Events are generated when a button is pressed, a slider position is changed, and so forth.

Note

Widget applications should use the XMANAGER procedure in preference to calling WIDGET_EVENT directly. See "Widget Event Processing" in Chapter 25 of the *Building IDL Applications* manual.

Event Processing

Events for a given widget are processed in the order that they are generated. The event processing performed by WIDGET_EVENT consists of the following steps, applied iteratively:

1. Wait for an event from one of the specified widgets to arrive.
2. Starting with the widget that generated the event, move up the widget hierarchy looking for a widget that has an associated event-handling procedure or function. Event-handling routines are associated with a widget via the EVENT_PRO and EVENT_FUNC keywords to the widget creation functions or the WIDGET_CONTROL procedure.
3. If an event-handling *procedure* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling procedure. When the procedure returns, WIDGET_EVENT returns to the first step above and starts searching for events. Hence, event-handling procedures are said to "swallow" events.
4. If an event-handling *function* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling function.

   When the function returns, its value is examined. If the value is not a structure, it is discarded and WIDGET_EVENT returns to the first step. This behavior allows event-handling functions to selectively act like event-handling procedures and "swallow" events.

   If the returned value is a structure, it is checked to ensure that it has the standard first three fields: `ID`, `TOP`, and `HANDLER`. If any of these fields is missing, IDL issues an error. Otherwise, the returned value replaces the event found in the first step and WIDGET_EVENT continues moving up the widget

hierarchy looking for another event handler routine, as described in step 2, above.

In situations where an event structure is returned, event functions are said to "rewrite" events. This ability to rewrite events is the basis of *compound widgets*, which combine several widgets to give the appearance of a single, more complicated widget. Compound widgets are an important widget programming concept. For more information, see "Compound Widgets" in Chapter 25 of the *Building IDL Applications* manual.

5. If an event reaches the top of a widget hierarchy without being swallowed by an event handler, it is returned as the value of WIDGET_EVENT.
6. If WIDGET_EVENT was called without an argument, and there are no widgets left on the screen that are being managed (as specified via the MANAGED keyword to the WIDGET_CONTROL procedure) and could generate events, WIDGET_EVENT ends the search and returns an *empty event* (a standard widget event structure with the top three fields set to zero).

Note

Do not interrupt the event loop by placing a STOP or EXIT command in the event-handler or other callback routine. The presence of either command will cause the widget routine to exit with an error.

Syntax

Result = WIDGET_EVENT([*Widget_ID*]) [, BAD_ID=*variable*] [, /NOWAIT] [, /SAVE_HOURGLASS]

UNIX Keywords: [, /YIELD_TO_TTY]

Return Value

A widget event is returned in a structure. The exact contents of this structure vary depending upon the type of widget involved. The first three elements of this structure, however, are always the same.

```
{ WIDGET, ID:0L, TOP:0L, HANDLER:0L, ... }
```

Any other elements vary from widget type to type. The three fixed elements are:

Value	Meaning
ID	The widget ID of the widget that generated the event.
TOP	The widget ID of the top level base for the widget hierarchy containing `ID`.
HANDLER	When an event is passed as the argument to an event handling procedure or function, as discussed in the previous section, this field contains the identifier of the widget associated with the handler routine. When an event is returned from WIDGET_EVENT, this value is always zero to indicate that no handler routine was found.

Table 140: Common Event Structure Fields

Arguments

Widget_ID

Widget_ID specifies the widget hierarchy for which events are desired. The first available event for the specified widget or any of its children is returned. If this argument is not specified, WIDGET_EVENT processes events for all existing widgets.

Widget_ID can also be an array of widget identifiers, in which case all of the specified widget hierarchies are searched.

Note

Attempting to obtain events for a widget hierarchy which is not producing events will hang IDL, unless the NOWAIT keyword is used.

Keywords

BAD_ID

If one of the values supplied via *Widget_ID* is not a valid widget identifier, this function normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

This keyword can be used to handle the situation in which IDL is waiting within WIDGET_EVENT when the user kills the widget hierarchy.

This keyword has meaning only if *Widget_ID* is explicitly specified.

NOWAIT

When no events are currently available for the specified widget hierarchy, WIDGET_EVENT normally waits until one is available and then returns it. However, if NOWAIT is set and no events are present, it immediately returns. In this case, the ID field of the returned structure will be zero.

SAVE_HOURGLASS

Set this keyword to prevent the hourglass cursor from being cleared by WIDGET_EVENT. This keyword can be of use if a program has to poll a widget periodically during a long computation.

YIELD_TO_TTY (UNIX Only)

Unless the NOWAIT keyword is specified, WIDGET_EVENT does not return until the asked for event is available. If the user should enter a line of input from the keyboard, it cannot be processed until WIDGET_EVENT returns. If the YIELD_TO_TTY keyword is specified and the user enters a line of input, WIDGET_EVENT returns immediately. In this case, the ID field of the returned structure will be zero.

Note

This keyword is supported under UNIX only, and there are no plans to extend it to other operating systems. Do not use it if you intend to use non-UNIX systems.

XMANAGER

WIDGET_INFO

The WIDGET_INFO function is used to obtain information about the widget subsystem and individual widgets. The specific area for which information is desired is selected by setting the appropriate keyword.

Syntax

Result = WIDGET_INFO([*Widget_ID*])

Keywords that apply to all widgets: [, /ACTIVE] [, /CHILD] [, /EVENT_FUNC] [, /EVENT_PRO] [, FIND_BY_UNAME=*string*] [, /FONTNAME] [, /GEOMETRY] [, /KBRD_FOCUS_EVENTS] [, /MANAGED] [, /MAP] [, /NAME] [, /PARENT] [, /REALIZED] [, /SENSITIVE] [, /SIBLING] [, /SYSTEM_COLORS] [, /TRACKING_EVENTS] [, /TYPE] [, UNITS={0 | 1 | 2}] [, /UNAME] [, /UPDATE] [, /VALID_ID] [, /VERSION] [, /VISIBLE]

Keywords that apply to widgets created with WIDGET_BASE: [, /CONTEXT_EVENTS] [, /MODAL] [, /TLB_ICONIFY_EVENTS] [, /TLB_KILL_REQUEST_EVENTS] [, /TLB_MOVE_EVENTS] [, /TLB_SIZE_EVENTS]

Keywords that apply to widgets created with WIDGET_BUTTON: [, /BUTTON_SET] [, /DYNAMIC_RESIZE] [, /TOOLTIP]

Keywords that apply to widgets created with WIDGET_COMBOBOX: [, /COMBOBOX_GETTEXT] [, /COMBOBOX_NUMBER] [, /DYNAMIC_RESIZE]

Keywords that apply to widgets created with WIDGET_DRAW: [, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS] [, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS] [, /DRAW_VIEWPORT_EVENTS] [, /TOOLTIP]

Keywords that apply to widgets created with WIDGET_DROPLIST: [, /DROPLIST_NUMBER] [, /DROPLIST_SELECT] [, /DYNAMIC_RESIZE]

Keywords that apply to widgets created with WIDGET_LABEL: [, /DYNAMIC_RESIZE]

Keywords that apply to widgets created with WIDGET_LIST: [, /CONTEXT_EVENTS] [, /LIST_MULTIPLE] [, /LIST_NUMBER] [, /LIST_NUM_VISIBLE] [, /LIST_SELECT] [, /LIST_TOP]

Keywords that apply to widgets created with WIDGET_SLIDER:
[, /SLIDER_MIN_MAX]

Keywords that apply to widgets created with WIDGET_TAB:
[, /TAB_CURRENT] [, /TAB_MULTILINE] [, /TAB_NUMBER]

Keywords that apply to widgets created with WIDGET_TABLE:
[, /COLUMN_WIDTHS] [, /ROW_HEIGHTS{not supported in Windows}]
[, /TABLE_ALL_EVENTS] [, /TABLE_DISJOINT_SELECTION]
[, /TABLE_EDITABLE] [, /TABLE_EDIT_CELL] [, /TABLE_SELECT]
[, /TABLE_VIEW] [, /USE_TABLE_SELECT]

Keywords that apply to widgets created with WIDGET_TEXT:
[, /CONTEXT_EVENTS] [, /TEXT_ALL_EVENTS] [, /TEXT_EDITABLE]
[, /TEXT_NUMBER] [, TEXT_OFFSET_TO_XY=*integer*] [, /TEXT_SELECT]
[, /TEXT_TOP_LINE] [, TEXT_XY_TO_OFFSET=*[column, line]*]

Keywords that apply to widgets created with WIDGET_TREE:
[, /TREE_EXPANDED] [, /TREE_ROOT] [, /TREE_SELECT]

Return Value

Returns the specified information for the given widget ID. If the SYSTEM_COLORS keyword is specified, a structure is returned. See "The WIDGET_SYSTEM_COLORS Structure" on page 2170 for details.

Arguments

Widget_ID

Usually this argument should be the widget ID of the widget for which information is desired. If the ACTIVE or VERSION keywords are specified, this argument is not required.

Widget_ID can also be an array of widget identifiers, in which case the result is an array with the same structure in which information on all the specified widgets is returned.

Keywords

Not all keywords to WIDGET_INFO apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

ACTIVE

This keyword applies to all widgets.

Set this keyword to return 1 if there is at least one realized, managed, top-level widget on the screen. Otherwise, 0 is returned.

BUTTON_SET

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to return the “set” state of a widget button. If the button is currently set, 1 (one) is returned. If the button is currently not set, 0 (zero) is returned. This keyword is intended for use with exclusive, non-exclusive and checked menu buttons.

CHILD

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first child of the widget specified by *Widget_ID*. If the widget has no children, 0 is returned.

COLUMN_WIDTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return an array of long integers giving the width of each column in the table. If USE_TABLE_SELECT is set equal to one, only the column widths for columns that contain currently-selected cells are returned. If USE_TABLE_SELECT is set equal to an array, only the column widths for columns that contain specified cells are returned.

COMBOBOX_GETTEXT

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to return the current text from the text box of the specified combobox widget. Note that when using an editable combobox, the text displayed in the text box may not be an item from the list of values in the combobox list. To obtain the index of the selected item, inspect the INDEX field of the event structure returned by the combobox widget.

COMBOBOX_NUMBER

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to return the number of elements currently contained in the list of the specified combobox widget.

CONTEXT_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_LIST, or WIDGET_TEXT functions.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* is configured to generate context events (that is, the widget was created with the CONTEXT_EVENTS keyword). Otherwise, 0 (zero) is returned.

DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the BUTTON_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the EXPOSE_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return an integer specifying the type of keyboard events currently generated by the draw widget specified by *Widget_ID*. Possible values are:

- 0: No keyboard events are generated
- 1: Keyboard events are generated for “normal” keys (all keys except function keys and modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT).
- 2: Keyboard events are generated for “normal” keys and modifier keys.

Note

Keyboard events are never generated for function keys.

DRAW_MOTION_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the MOTION_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the VIEWPORT_EVENTS attribute set. Otherwise, 0 is returned.

DROPLIST_NUMBER

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to return the number of elements currently contained in the specified droplist widget.

DROPLIST_SELECT

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to return the zero-based number of the currently-selected element (i.e., the currently-displayed element) in the specified droplist widget.

DYNAMIC_RESIZE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, and WIDGET_LABEL functions.

Set this keyword to return a True value (1) if the widget specified by *Widget_ID* is a button, droplist, or label widget that has had its DYNAMIC_RESIZE attribute set. Otherwise, False (0) is returned.

EVENT_FUNC

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler function associated with *Widget_ID*. A null string is returned if no event handler function exists.

EVENT_PRO

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler procedure associated with *Widget_ID*. A null string is returned if no event handler procedure exists.

FIND_BY_UNAME

This keyword applies to all widgets.

Set this keyword to a UNAME value that will be searched for in the widget hierarchy, and if a widget with the given UNAME is in the hierarchy, its ID is returned. The search starts in the hierarchy with the given widget ID and travels down, and this keyword returns the widget ID of the first widget that has the specified UNAME value.

If a widget is not found, 0 is returned.

FONTNAME

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the font being used by the specified widget. The returned name can then be used when creating other widgets or with the SET_FONT keyword to the DEVICE procedure. If fonts are not supported by the specified widget, an empty string is returned.

Note that you can use this keyword to retrieve the name of the *default* font used by one type of widget and use the same font in other contexts. For example, the following code retrieves the default font used for buttons and writes into the drawable area of a draw widget using the same font:

```
wBase = WIDGET_BASE(/ROW)
wButton = WIDGET_BUTTON(wBase, VALUE="Button")
wDraw = WIDGET_DRAW(wBase, XSIZE=200, YSIZE=100)
WIDGET_CONTROL, wBase, /REALIZE
strFont = WIDGET_INFO(wButton, /FONTNAME)
DEVICE, SET_FONT=strFont
WIDGET_CONTROL, wDraw, GET_VALUE=iWindow
WSET, iWindow
XYOUTS, 100, 50, 'Same Font as Button', FONT=0, /DEVICE, $
   ALIGNMENT=.5
```

This method allows you to synchronize the fonts in several widgets without knowing in advance which font is in use.

The format of the returned font name is platform dependent. See “About Device Fonts” on page 3940 for additional details.

GEOMETRY

This keyword applies to all widgets.

Set this keyword to return a WIDGET_GEOMETRY structure that describes the offset and size information for the widget specified by *Widget_ID*. This structure has the following definition:

```
{ WIDGET_GEOMETRY,
   XOFFSET:0.0,
   YOFFSET:0.0,
   XSIZE:0.0,
   YSIZE:0.0,
   SCR_XSIZE:0.0,
   SCR_YSIZE:0.0,
   DRAW_XSIZE:0.0,
   DRAW_YSIZE:0.0,
   MARGIN:0.0,
   XPAD:0.0,
   YPAD:0.0,
   SPACE:0.0 }
```

With the exception of MARGIN, all of the structure's fields correspond to the keywords of the same name to the various widget routines. MARGIN is the width of any frame added to the widget, in units specified by the UNITS keyword (pixels are the default). Therefore, the actual width of any widget is:

```
SCR_XSIZE + (2* MARGIN)
```

The actual height of any widget is:

```
SCR_YSIZE + (2 * MARGIN)
```

Note

Different window managers may use different *window dressing* (borders, margins, scrollbars, *etc*.). As a result, running a given segement of widget code on different platforms may yield different geometry.

KBRD_FOCUS_EVENTS

This keyword applies to all widgets.

Set this keyword to return the keyboard focus events status of the widget specified by *Widget ID*. WIDGET_INFO returns 1 (one) if keyboard focus events are currently enabled for the widget, or 0 (zero) if they are not. Only base, table, and text widgets can generate keyboard focus events.

LIST_MULTIPLE

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword equal to a named variable that will contain a non-zero value if the list widget supports multiple item selections. See the MULTIPLE keyword to WIDGET_LIST for more on multiple item selections.

LIST_NUMBER

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the number of elements currently contained in the specified list widget.

LIST_NUM_VISIBLE

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the number of elements that can be visible in the scrolling viewport of the specified list widget. Note that this value can be larger than the total number of elements actually in the list.

LIST_SELECT

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the index or indices of the currently-selected (highlighted) element or elements in the specified list widget. Note that this offset is zero-based. If no element is currently selected, -1 is returned.

LIST_TOP

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the zero-based offset of the topmost element currently visible in the specified list widget.

MANAGED

This keyword applies to all widgets.

Set this keyword to return 1 if the specified widget is managed, or 0 otherwise. If no widget ID is specified in the call to WIDGET_INFO, the return value will be an array containing the widget IDs of all currently-managed widgets.

MAP

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is mapped (visible), or False (0) otherwise. Note that when a base widget is unmapped, all of its

children are unmapped. If WIDGET_INFO reports that a particular widget is unmapped, it may be because a parent in the widget hierarchy has been unmapped.

MODAL

This keyword applies to widgets created with the WIDGET_BASE function and the MODAL keyword.

If this keyword is set, WIDGET_INFO will return True (1) if the base widget specified by *Widget_ID* is a modal base widget, or False (0) otherwise.

NAME

This keyword applies to all widgets.

Set this keyword to return the widget type name of the widget specified by *Widget_ID*. The returned value will be one of the following strings: “BASE”, “BUTTON”, “COMBOBOX”, “DRAW”, “DROPLIST”, “LABEL”, “LIST”, “SLIDER”, “TAB”, “TABLE”, “TEXT”, or “TREE”. Set the TYPE keyword to return the widget’s type code.

PARENT

This keyword applies to all widgets.

Set this keyword to return the widget ID of the parent of the widget specified by *Widget_ID*. If the widget is a top-level base (i.e., it has no parent), 0 is returned.

REALIZED

This keyword applies to all widgets.

Set this keyword to return 1 if the widget specified by *Widget_ID* has been realized. If the widget has not been realized, 0 is returned.

ROW_HEIGHTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Note

This keyword is not supported under Microsoft Windows.

Set this keyword to return an array of long integers giving the height of each row in the table. If USE_TABLE_SELECT is set equal to one, only the row heights for rows that contain currently-selected cells are returned. If USE_TABLE_SELECT is set

equal to an array, only the row heights for rows that contain specified cells are returned.

SENSITIVE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is sensitive (enabled), or False (0) otherwise. Note that when a base is made insensitive, all its children are made insensitive. If WIDGET_INFO reports that a particular widget is insensitive, it may be because a parent in the widget hierarchy has been made insensitive.

SIBLING

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first sibling of the widget specified by *Widget_ID*. If the widget is the last sibling in the chain, 0 is returned.

SLIDER_MIN_MAX

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to return the current minimum and maximum values of the specified slider as a two-element integer array. Element 0 is the minimum value and element 1 is the maximum value.

SYSTEM_COLORS

This keyword applies to all widgets.

Set this keyword and supply the widget ID of any widget to cause WIDGET_INFO to return an IDL structure that contains RGB values used for 25 IDL display elements.

For more detailed information on the WIDGET_SYSTEM_COLORS structure fields and their meaning see the "The WIDGET_SYSTEM_COLORS Structure" on page 2170.

TAB_CURRENT

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the zero-based index of the current tab in the tab widget.

TAB_MULTILINE

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the current setting of the multi-line mode for the tab widget.

TAB_NUMBER

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the number of tabs contained in the tab widget.

TABLE_ALL_EVENTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if *Widget_ID* is a table widget with the ALL_EVENTS attribute set. Otherwise, 0 (zero) is returned.

TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* has disjoint selection enabled. Otherwise, 0 (zero) is returned.

TABLE_EDITABLE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if *Widget_ID* is a table widget that allows user editing of its contents. Otherwise, 0 (zero) is returned.

TABLE_EDIT_CELL

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return a two-element integer array containing the row and column coordinates of the currently editable cell. If none of the cells in the table widget is currently editable, the array [-1, -1] is returned.

TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the currently-selected (highlighted) cells in the specified table widget.

- In standard selection mode, this keyword returns an array of the form [*left*, *top*, *right*, *bottom*] containing the zero-based indices of the columns and rows that define the selection.

- In disjoint selection mode (enabled by setting the DISJOINT_SELECTION keyword to WIDGET_TABLE), this keyword returns a 2 x *n* array of column/row pairs containing the zero-based indices the selected cells.

TABLE_VIEW

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return a two-element array of the form [*left*, *top*] containing the zero-based offsets of the top-left cell currently visible in the specified table widget.

TEXT_ALL_EVENTS

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return 1 if *Widget_ID* is a text widget with the ALL_EVENTS attribute set. Otherwise, 0 is returned.

TEXT_EDITABLE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return 1 if *Widget_ID* is a text widget that allows user editing of its contents. Otherwise, 0 is returned.

TEXT_NUMBER

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the number of characters currently contained in the specified text widget.

TEXT_OFFSET_TO_XY

This keyword applies to widgets created with the WIDGET_TEXT function.

Use this keyword to translate a text widget character offset into column and line form. The value of this keyword should be set to the character offset (an integer) to be translated. WIDGET_INFO returns a two-element integer array giving the column (element 0) and line (element 1) corresponding to the offset. If the offset specified is out of range, the array [-1,-1] is returned.

TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the starting character offset and length (in characters) of the selected (highlighted) text in the specified text widget. WIDGET_INFO returns a

two-element integer array containing the starting position of the highlighted text as an offset from character zero of the text in the widget (element 0), and length of the current selection (element 1).

TEXT_TOP_LINE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the zero-based line number of the line currently at the top of a text widget's display viewport. Note that this value is different from the zero-based character offset of the characters in the line. The character offset can be calculated from the line offset via the TEXT_XY_TO_OFFSET keyword.

TEXT_XY_TO_OFFSET

This keyword applies to widgets created with the WIDGET_TEXT function.

Use this keyword to translate a text widget position given in line and column form into a character offset. The value of this keyword should be set to a two-element integer array specifying the column (element 0) and line (element 1) position. WIDGET_INFO returns the character offset (as a longword integer) corresponding to the position. If the position specified is out of range, -1 is returned.

TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return iconify events. Otherwise, 0 is returned.

TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return kill request events. Otherwise, 0 is returned.

TLB_MOVE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return move events. Otherwise, 0 is returned.

TLB_SIZE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return resize events. Otherwise, 0 is returned.

TOOLTIP

This keyword applies to widgets created with the WIDGET_BUTTON and WIDGET_DRAW functions.

Set this keyword to have the WIDGET_INFO function return the text of the tooltip of the widget. If the widget does not have a tooltip, a null string will be returned.

TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to return the tracking events status for the widget specified by *Widget_ID*. WIDGET_INFO returns 1 if tracking events are currently enabled for the widget. Otherwise, 0 is returned.

TREE_EXPANDED

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return 1 (one) if the specified tree widget node is a folder that is expanded, or 0 (zero) if the specified node is a folder that is collapsed.

Note

Only tree widget nodes created with the FOLDER keyword can be expanded or collapsed. This keyword will always return 0 (zero) if the specified tree widget node is not a folder.

TREE_ROOT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return the widget ID of the *root node* of the tree widget hierarchy of which *Widget ID* is a part. The root node is the tree widget whose parent is a base widget.

TREE_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return information about the nodes selected in the specified tree widget. This keyword has two modes of operation, depending on the widget ID passed to WIDGET_INFO:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget), this keyword returns either the widget ID of the selected node or (if multiple nodes are selected) an array of widget IDs of the selected nodes. If no nodes are selected, -1 is returned.
- If the specified widget ID is a tree widget that is a node in a tree, this keyword returns 1 (one) if the node is selected or 0 (zero) if it is not selected.

TYPE

This keyword applies to all widgets.

Set this keyword to return the type code of the specified *Widget_ID*. Possible values are given the following table. Note that you can set the NAME keyword to return string names instead.

Value	Type
0	Base
1	Button
2	Slider
3	Text
4	Draw
5	Label
6	List
8	Droplist
9	Table
10	Tab
11	Tree
12	Combobox

Table 141: Widget Type Codes

UNAME

This keyword applies to all widgets.

Set this keyword to have the WIDGET_INFO function return the user name of the widget.

UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used when returning dimensions for most widget types. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when retrieving the XSIZE or YSIZE of a WIDGET_LIST, WIDGET_TABLE, or WIDGET_TEXT functions.

UPDATE

This keyword applies to all widgets.

Set this keyword to return 1 if the widget hierarchy that contains *Widget_ID* is set to display updates. Otherwise, 0 is returned. See "UPDATE" on page 2120.

USE_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to modify the behavior of the COLUMN_WIDTHS and ROW_HEIGHTS keywords. If USE_TABLE_SELECT is set, the COLUMN_WIDTHS and ROW_HEIGHTS keywords only apply to the currently-selected cells. Normally, these keywords apply to the entire contents of a table widget.

The USE_TABLE_SELECT keyword can also be specified as a four-element array, of the form [*left*, *top*, *right*, *bottom*], giving the group of cells to act on. In this usage, the value -1 is used to refer to the row or column titles.

VALID_ID

This keyword applies to all widgets.

Set this keyword to return 1 if *Widget_ID* represents a currently-valid widget. Otherwise, 0 is returned.

VERSION

This keyword applies to all widgets.

Set this keyword to return a structure that gives information about the widget implementation. This structure has the following definition:

```
{ WIDGET_VERSION, STYLE:'', TOOLKIT:'', RELEASE:'' }
```

`STYLE` is the style of widget toolkit used. `TOOLKIT` is the implementation of the toolkit. `RELEASE` is the version level of the toolkit. This field can be used to distinguish between different releases of a given toolkit, such as Motif 1.0 and Motif 1.1.

VISIBLE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is visible, or False (0) otherwise. A widget is visible if:

- it has been realized,
- it and all of its ancestors are mapped.

Note

The value returned by WIDGET_INFO when this keyword is set is not affected if the widget is minimized or obscured by another window. Widgets that are visible in the sense of this keyword may not be immediately apparent to a person viewing a particular display device.

The WIDGET_SYSTEM_COLORS Structure

When the SYSTEM_COLORS keyword is specified in a call to WIDGET_INFO, IDL returns a WIDGET_SYSTEM_COLORS structure. This allows application developers to determine what colors are used in IDL application widgets, so they can design widgets for their application with the same look and feel as the supplied IDL widgets.

The WIDGET_SYSTEM_COLORS structure consists of 25 fields, each containing a three-element vector corresponding to the Red, Green, and Blue color values used for various widget elements. The vector elements are integers ranging between 0 and 255 if a color value is available (vector elements contain –1 if the color value is

unavailable). The field names and meaning on the Windows and UNIX operating systems are shown in the following table.

Field Names	Windows Platform	UNIX Platform
DARK_SHADOW_3D	Dark shadow color for 3D display elements.	N/A
FACE_3D	Face color for 3D display elements and dialog boxes.	Base background color for all widgets.
LIGHT_EDGE_3D	Highlight color for 3D edges that face the light source.	Color of top and left edges of 3D widgets.
LIGHT_3D	Light color for 3D display elements.	Color of highlight rectangle around widgets with the keyboard focus.
SHADOW_3D	Color for 3D edges that face away from the light source.	Color of bottom and right edges of 3D widgets.
ACTIVE_BORDER	Active window's border color.	Push button background color when button is armed.
ACTIVE_CAPTION	Active window's caption color.	N/A
APP_WORKSPACE	Background color of MDI applications.	N/A
DESKTOP	Desktop color.	N/A
BUTTON_TEXT	Text color on push buttons.	Widget text color.
CAPTION_TEXT	Color of text in caption, size box, and scroll bar arrow box.	Widget text color.

Table 142: WIDGET_SYSTEM_COLORS Structure Fields

Field Names	Windows Platform	UNIX Platform
GRAY_TEXT	Color of disabled text.	N/A
HIGHLIGHT	Color of item(s) selected in a widget.	Toggle button fill color.
HIGHLIGHT_TEXT	Color of text of item(s) selected in a widget.	N/A
INACTIVE_BORDER	Inactive window's border color.	N/A
INACTIVE_CAPTION	Inactive window's caption color.	N/A
INACTIVE_CAPTION_TEXT	Inactive window's caption text color.	N/A
TOOLTIP_BK	Background color for tooltip controls.	N/A
TOOLTIP_TEXT	Text color for tooltip controls.	N/A
MENU	Menu background color.	N/A
MENU_TEXT	Menu text color.	N/A
SCROLLBAR	Color of scroll bar "gray" area.	Color of scroll bar "gray" area.
WINDOW_BK	Window background color.	Base background color for all widgets.
WINDOW_FRAME	Window frame color.	Widget border color.
WINDOW_TEXT	Text color in windows.	Widget text color.

Table 142: WIDGET_SYSTEM_COLORS Structure Fields (Continued)

Version History

Introduced: Pre 4.0

BUTTON_SET, COMBOBOX_GETTEXT, COMBOBOX_NUMBER, FONTNAME, MAP, SENSITIVE, TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS,

TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP, TREE_EXPANDED, TREE_ROOT, TREE_SELECT, and VISIBLE keywords added: 5.6

See Also

Chapter 25, “Creating Widget Applications” in the *Building IDL Applications* manual.

WIDGET_LABEL

The WIDGET_LABEL function is used to create label widgets.

Syntax

Result = WIDGET_LABEL(*Parent* [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /DYNAMIC_RESIZE] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created label widget.

Arguments

Parent

The widget ID of the parent widget for the new label widget.

Keywords

ALIGN_CENTER

Set this keyword to center justify the label text.

ALIGN_LEFT

Set this keyword to left justify the label text.

ALIGN_RIGHT

Set this keyword to right justify the label text.

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword cannot be used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_LABEL or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2055 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SUNKEN_FRAME

Set this keyword to create a three dimensional, bevelled border around the label widget. The resulting frame gives the label a “sunken” appearance, similar to what is often seen in application status bars.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget label is a string containing the text for the label.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of label widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, GET_VALUE, SET_VALUE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to label widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DYNAMIC_RESIZE.

Widget Events Returned by Label Widgets

Label widgets do not return an event structure.

Version History

Introduced: Pre 4.0

SUNKEN_FRAME keyword added: 5.6

CW_FIELD, WIDGET_TEXT

WIDGET_LIST

The WIDGET_LIST function is used to create list widgets. A list widget offers the user a list of text elements from which to choose. The user can select an item by pointing at it with the mouse cursor and pressing a button. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

The returned value of this function is the widget ID of the newly-created list widget.

Syntax

Result = WIDGET_LIST(*Parent* [, /CONTEXT_EVENTS]
[, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
[, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /MULTIPLE]
[, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*]
[, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created list widget.

Arguments

Parent

The widget ID of the parent widget for the new list widget.

Keywords

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID

to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MULTIPLE

Set this keyword to allow the user to select more than one item from the list in a single operation. Multiple selections are handled using the platform’s native mechanism:

Motif

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the mouse button when selecting items also selects a range. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

Windows

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL

makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_LIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2055 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_LIST.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a list widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

Note that the value of a list widget can only be set. It cannot be retrieved using WIDGET_CONTROL.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The desired width of the widget, in characters. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The desired height of the widget, in number of list items visible. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of list widgets. In addition to those keywords that affect all widgets, the following are particularly useful: CONTEXT_EVENTS, SET_LIST_SELECT, SET_LIST_TOP, SET_VALUE.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to list widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, LIST_MULTIPLE, LIST_NUMBER, LIST_NUM_VISIBLE, LIST_SELECT, LIST_TOP.

Widget Events Returned by List Widgets

Pressing the mouse button while the mouse cursor is over an element of a list widget causes the widget to highlight the appearance of that element and to generate an event. The appearance of any previously selected element is restored to normal at the same time. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_LIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, CLICKS:0L}
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This index can be used to subscript the array of names originally used to set the widget's value. The CLICKS field returns either 1 or 2, depending upon how the list item was selected. If the list item is double-clicked, CLICKS is set to 2.

Note

If you are writing a widget application that requires the user to double-click on a list widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.

Context Menu Events

List widgets return the following event structure when the user clicks the right mouse button and the list widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the list widget.

Version History

Introduced: Pre 4.0

See Also

CW_BGROUP, WIDGET_COMBOBOX, WIDGET_DROPLIST

WIDGET_SLIDER

The WIDGET_SLIDER function is used to create slider widgets. Slider widgets are used to indicate an integer value from a range of possible values. They consist of a rectangular region which represents the possible range of values. Inside this region is a sliding pointer that displays the current value. This pointer can be manipulated by the user via the mouse, or from within IDL via the WIDGET_CONTROL procedure.

To indicated floating-point values, see CW_FSLIDER.

Syntax

Result = WIDGET_SLIDER(*Parent* [, /DRAG] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, MAXIMUM=*value*] [, MINIMUM=*value*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, SCROLL=*units*] [, /SENSITIVE] [, /SUPPRESS_VALUE] [, /TRACKING_EVENTS] [, TITLE=*string*] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, /VERTICAL] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created slider widget.

Arguments

Parent

The widget ID of the parent for the new slider widget.

Keywords

DRAG

Set this keyword to cause events to be generated continuously while the slider is being dragged by the user. Normally, slider widgets generate position events only when the slider comes to rest at its final position and the mouse button is released.

Note

Under Microsoft Windows, this keyword has no effect. IDL sliders only generate events when the mouse button is released.

When a slider widget is set to return drag events, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MAXIMUM

The maximum value of the range encompassed by the slider. If this keyword is not supplied, a default of 100 is used.

MINIMUM

The minimum value of the range encompassed by the slider. If this keyword is not supplied, a default of 0 is used.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would

otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_SLIDER or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2055 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set the SCROLL keyword to an integer value specifying the number of integer units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The

default on both platforms is 0.1 x (MAXIMUM - MINIMUM), which is 10% of the slider range.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SUPPRESS_VALUE

Set this keyword to inhibit the display of the current slider value.

Sliders work only with integer units. This keyword can be used to suppress the actual value of a slider so that a program can present the user with a slider that seems to work in other units (such as floating-point) or with a non-linear scale.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

TITLE

A string containing the title to be used for the slider widget.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget

hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget slider is the current position of the slider.

VERTICAL

Set this keyword to create a vertical slider. If this keyword is omitted, the slider is horizontal.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Note

Setting XSIZE for a vertical slider (created with the VERTICAL keyword) does not change the visible width of the slider itself, but does change the amount of horizontal space occupied by the widget within its parent base.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Note

Setting YSIZE for a horizontal slider does not change the visible height of the slider itself, but does change the amount of vertical space occupied by the widget within its parent base.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of slider widgets. In addition to those keywords that affect all widgets, the following are particularly useful: GET_VALUE, SET_SLIDER_MAX, SET_SLIDER_MIN, SET_VALUE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to slider widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: SLIDER_MIN_MAX.

Widget Events Returned by Slider Widgets

Slider widgets generate events when the mouse is used to change their value. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_SLIDER, ID:0L, TOP:0L, HANDLER:0L, VALUE:0L, DRAG:0}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. VALUE returns the new value of the slider. DRAG returns integer 1 if the slider event was generated as part of a drag operation, or zero if the event was generated when the user had finished positioning the slider. Note that the slider widget only generates events during the drag operation if the DRAG keyword is set. When the DRAG keyword is set, the DRAG field can be used to avoid computationally expensive operations until the user releases the slider.

Known Implementation Problems

Under Motif 1.0, vertical sliders with a title organized in row bases get horizontally truncated and the slider doesn’t show (the title does). Use the XSIZE keyword to work around this.

Version History

Introduced: Pre 4.0

CW_FSLIDER

WIDGET_TAB

The WIDGET_TAB function is used to create a tab widget. Tab widgets present a display area on which different pages (base widgets and their children) can be displayed by selecting the appropriate tab. The titles of the tabs are supplied as the values of the TITLE keyword for each of the tag widget's child base widgets.

For a more detailed discussion of the tab widget, along with examples, see "Using Tab Widgets" in Chapter 26 of the *Building IDL Applications* manual.

Syntax

Result = WIDGET_TAB(*Parent* [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, LOCATION={0 | 1 | 2 | 3}] [, MULTILINE=0 | 1 (Windows) or *num* tabs per row (Motif)] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created tab widget.

Arguments

Parent

The widget ID of the parent for the new tab widget.

Note

Only base widgets can be the parent of a tab widget.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). Note that the procedure specified is used only if you are not using the XMANAGER procedure to manage your widgets.

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

If you use the XMANAGER procedure to manage your widgets, the value of this keyword is overwritten. Use the CLEANUP keyword to XMANAGER to specify a procedure to be called when a managed widget dies.

LOCATION

Set this keyword equal to an integer that specifies which edge of the tab widget will contain the tabs. The possible values are:

Value	Description
0	The tabs are placed along the top of the widget, which is the default behavior.
1	The tabs are placed along the bottom of the widget.

Table 143: LOCATION Keyword Values

Value	Description
2	The tabs are placed along the left edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.
3	The tabs are placed along the right edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.

Table 143: LOCATION Keyword Values (Continued)

MULTILINE

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and Motif systems.

Windows

Set this keyword to cause tabs to be organized in a multiline display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE = 0 and LOCATION = 0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION = 1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

Motif

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. However, tab text may be truncated if the text of a single tab exceeds the space available. If MULTILINE is set to any value other than one, some tabs may not be displayed.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_TAB or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (which is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of tab widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: BASE_SET_TITLE, SET_TAB_CURRENT, SET_TAB_MULTILINE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO return information that applies specifically to tab widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER.

Widget Events Returned by Tab Widgets

Tab widgets generate events when a new tab is selected. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_TAB, ID:0L, TOP:0L, HANDLER:0L, TAB:0L}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. TAB returns the zero-based index of the tab selected.

Version History

Introduced: 5.6

See Also

"Using Tab Widgets" in Chapter 26 of the *Building IDL Applications* manual

WIDGET_TABLE

The WIDGET_TABLE function creates table widgets. Table widgets display two-dimensional data and allow in-place data editing. They can have one or more rows and columns, and automatically create scroll bars when viewing more data than can otherwise be displayed on the screen.

For a more detailed discussion of the table widget, along with examples, see "Using Table Widgets" in Chapter 26 of the *Building IDL Applications* manual.

Note on Table Sizing

Table widgets are sized according to the value of the following pairs of keywords to WIDGET_TABLE, in order of precedence: SCR_XSIZE/SCR_YSIZE, XSIZE/YSIZE, X_SCROLL_SIZE/Y_SCROLL_SIZE, VALUE. If either dimension remains unspecified by one of the above keywords, the default value of six (columns or rows) is used when the table is created. If the width or height specified is less than the size of the table, scroll bars are added automatically.

Syntax

Result = WIDGET_TABLE(*Parent* [, ALIGNMENT={0 | 1 | 2}] [, /ALL_EVENTS] [, AM_PM=*[string, string]*] [, COLUMN_LABELS=*string_array*] [, /COLUMN_MAJOR | , /ROW_MAJOR] [, COLUMN_WIDTHS=*array*] [, DAYS_OF_WEEK=*string_array*{7 names}] [, /DISJOINT_SELECTION] [, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FORMAT=*value*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*] [, MONTHS=*string_array*{12 names}] [, /NO_COPY] [, /NO_HEADERS] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, /RESIZEABLE_COLUMNS] [, /RESIZEABLE_ROWS{not supported in Windows}] [, RESOURCE_NAME=*string*] [, ROW_HEIGHTS=*array*{not supported in Windows}] [, ROW_LABELS=*string_array*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, X_SCROLL_SIZE=*width*] [, YOFFSET=*value*] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*height*])

Return Value

The returned value of this function is the widget ID of the newly-created table widget.

Arguments

Parent

The widget ID of the parent widget for the new table widget.

Keywords

ALIGNMENT

Set this keyword equal to a scalar or 2-D array specifying the alignment of the text within each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell. If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

ALL_EVENTS

Set this keyword to cause to the text widget to generate events whenever the user changes the contents of a table cell.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

Keywords		Effects	
ALL_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated.**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 144: Effects of using the ALL_EVENTS and EDITABLE keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

COLUMN_LABELS

Set this keyword equal to an array of strings used as labels for the columns of the table widget. The default labels are of the form “Column *n*”, where *n* is the column number. If this keyword is set to the empty string (' '), all column labels are set to be empty.

COLUMN_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the VALUE keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one column’s data. Note that the structures must all be of the same type, and must have one field for each row in the table. If this keyword is not set, the table widget behaves as if the ROW_MAJOR keyword were set.

COLUMN_WIDTHS

Set this keyword equal to an array of widths for the columns of the table widget. The widths are given in any of the units as specified with the UNITS keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If COLUMN_WIDTHS is set to a scalar value, all columns are set to that width.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

DISJOINT_SELECTION

Set this keyword to enable the ability to select multiple rectangular regions of cells. The regions can be overlapping, touching, or entirely distinct.

Setting this keyword changes the data structures returned by the TABLE_SELECT keyword to WIDGET_INFO and the GET_VALUE keyword to WIDGET_CONTROL.

Similarly, the data structures you supply via the SET_TABLE_SELECT and SET_VALUE keywords to WIDGET_CONTROL are different in disjoint mode.

See "Selection Modes" in Chapter 26 of the *Building IDL Applications* manual for additional details.

EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See ALL_EVENTS for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

Note

The method by which text widgets are placed into edit mode is dependent upon the windowing system. See "Edit Mode" in the *Building IDL Applications* manual

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

A single font is shared by the row and column labels and by all of the cells in the widget.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FORMAT

Set this keyword equal to a single string or array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT procedure.

Warning

If the format specified is incompatible with the data displayed in a table cell, an error message is generated. Since the error is generated *for each cell displayed*, the number of messages printed is potentially large, and can slow execution significantly. Note also that each time a new cell is displayed (when scroll bars are repositioned, for example), a new error is generated *for each cell displayed*.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “Widget Events Returned by Table Widgets” on page 2216 for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_TABLE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_HEADERS

Set this keyword to disable the display of the table widget’s header area (where row and column labels are normally displayed).

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once

(because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESIZEABLE_COLUMNS

Set this keyword to allow the user to change the size of columns using the mouse. Note that if the NO_HEADERS keyword was set, the columns cannot be resized interactively.

RESIZEABLE_ROWS

Set this keyword to allow the user to change the size of rows using the mouse. Note that if the NO_HEADERS keyword was set, the rows cannot be resized interactively.

Under Microsoft Windows, the row size cannot be changed.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2055 for a complete discussion of this keyword.

ROW_HEIGHTS

Set this keyword equal to an array of heights for the rows of the table widget. The heights are given in any of the units as specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

Note

This keyword is not supported under Microsoft Windows.

ROW_LABELS

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label "Row *n*", where *n*

is the row number. If this keyword is set to the empty string (''), all row labels are set to be empty.

ROW_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the VALUE keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one row's data. Note that the structures must all be of the same type, and must have one field for each column in the table. This is the default behavior if neither the COLUMN_MAJOR or ROW_MAJOR keyword is set.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen width of the widget *includes* the width of scroll bars, if any are present. Setting SCR_XSIZE overrides values set for the XSIZE or X_SCROLL_SIZE keywords. See "Note on Table Sizing" on page 2205.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen height of the widget *includes* the height of scroll bars, if any are present. Setting SCR_YSIZE overrides values set for the YSIZE or Y_SCROLL_SIZE keywords. See "Note on Table Sizing" on page 2205.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. See "Note on Table Sizing" on page 2205

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a table widget is either a two-dimensional array or a vector of structures.

If the value is specified as a two-dimensional array, all data must be of the same data type.

If the value is specified as a vector of structures, it can be displayed either in column-major or row-major format by setting either the COLUMN_MAJOR keyword or the ROW_MAJOR keyword. All of the structures must be of the same type, and must contain one field for each row (if COLUMN_MAJOR is set) or column (if ROW_MAJOR is set) in the table. If neither keyword is set, the data is displayed in row major format.

Note

If the VALUE keyword is not specified, the data in the created table will be of type STRING.

If none of [XY]SIZE, SCR_[XY]SIZE, or [XY]_SCROLL_SIZE is present, the size of the table is determined by the size of the array or vector of structures specified by VALUE. See "Note on Table Sizing" on page 2205.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in columns. If row labels are present, one column is automatically added to this value. See "Note on Table Sizing" on page 2205.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget, in columns. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the

scrolling viewport independently of the actual width of the widget. See “Note on Table Sizing” on page 2205.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in rows. If column labels are present, one row is automatically added to this value. See “Note on Table Sizing” on page 2205.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. in rows. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual width of the widget. See “Note on Table Sizing” on page 2205.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of table widgets. In addition to those keywords that affect all widgets, the following are particularly useful: ALIGNMENT, ALL_TABLE_EVENTS, COLUMN_LABELS,

COLUMN_WIDTHS, DELETE_COLUMNS, DELETE_ROWS, EDITABLE, EDIT_CELL, FORMAT, GET_VALUE, INSERT_COLUMNS, INSERT_ROWS, KBRD_FOCUS_EVENTS, ROW_LABELS, ROW_HEIGHTS, SET_TABLE_SELECT, SET_TABLE_VIEW, SET_TEXT_SELECT, SET_VALUE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TABLE_XSIZE, TABLE_YSIZE, USE_TABLE_SELECT, USE_TEXT_SELECT.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to table widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: COLUMN_WIDTHS, KBRD_FOCUS_EVENTS, ROW_HEIGHTS, TABLE_ALL_EVENTS, TABLE_DISJOINT_SELECTION, TABLE_EDITABLE, TABLE_EDIT_CELL, TABLE_SELECT, TABLE_VIEW, USE_TABLE_SELECT.

Widget Events Returned by Table Widgets

There are several variations of the table widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the field type before referencing fields that are not present in all table event structures. The different table widget event structures are described below.

Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed into a cell of a table widget by a user.

```
{WIDGET_TABLE_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
   CH:0B, X:0L, Y:0L }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character. X and Y give the zero-based address of the cell within the table.

Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a cell by the window system.

```
{WIDGET_TABLE_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
   STR:'', X:0L, Y:0L}
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted. X and Y give the zero-based address of the cell within the table.

Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a cell of a table widget.

```
{WIDGET_TABLE_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
   LENGTH:0L, X:0L, Y:0L}
```

OFFSET is the (zero-based) character position of the first character deleted. It is also the insertion position that will result when the next character is inserted. LENGTH gives the number of characters involved. X and Y give the zero-based address of the cell within the table.

Text Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{WIDGET_TABLE_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3,
   OFFSET:0L, LENGTH:0L, X:0L, Y:0L}
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that the widget has no selection, and that the insertion position is given by OFFSET. X and Y give the zero-based address of the cell within the table.

Note

Text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is not sent.

Cell Selection (TYPE = 4)

This is the type of structure returned when range of cells is selected (highlighted) or deselected by the user.

```
{WIDGET_TABLE_CELL_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:4,
   SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The event announces a change in the currently selected cells. The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

Note

If the table is in disjoint selection mode, selecting an additional region will result in a new WIDGET_TABLE_CELL_SEL event that reflects only the newly-selected cells. Use WIDGET_INFO, /TABLE_SELECT to obtain the entire selected region in disjoint selection mode.

When cells are deselected (either by changing the selection or by clicking in the upper left corner of the table) an event is generated in which the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields contain the value -1. This means that two WIDGET_TABLE_CELL_SEL events are generated when an existing selection is changed to a new selection. If your code pays attention to WIDGET_TABLE_CELL_SEL events, be sure to differentiate between select and deselect events.

Note

If the table is in disjoint selection mode and a new cell range is selected *starting on a previously-selected cell*, the previously selected cells are deselected but a WIDGET_TABLE_CELL_DESEL event is generated for the deselection rather than a WIDGET_TABLE_CELL_SEL event. See “Cell Deselection (Disjoint Mode) (TYPE = 9)” on page 2219 for details.

Row Height Changed (TYPE = 6)

This is the type of structure returned when a row height is changed by the user.

```
{WIDGET_TABLE_ROW_HEIGHT, ID:0L, TOP:0L, HANDLER:0L, TYPE:6,
    ROW:0L, HEIGHT:0L}
```

The event announces that the height of the given row has been changed by the user. The ROW field contains the zero-based row number, and the HEIGHT field contains the new height.

Column Width Changed (TYPE = 7)

This is the type of structure returned when a column width is changed by the user.

```
{WIDGET_TABLE_COL_WIDTH, ID:0L, TOP:0L, HANDLER:0L, TYPE:7,
   COL:0L, WIDTH:0L}
```

The event announces that the width of the given column has been changed by the user. The COL field contains the zero-based column number, and the WIDTH field contains the new width.

Invalid Data (TYPE = 8)

This is the type of structure returned when the text entered by the user does not pass validation, and the user has finished editing the field (by hitting TAB or ENTER).

```
{WIDGET_TABLE_INVALID_ENTRY, ID:0L, TOP:0L, HANDLER:0L, TYPE:8,
   STR:'', X:0L, Y:0L}
```

When this event is generated, the cell's data is left unchanged. The invalid contents entered by the user is given as a text string in the STR field. The cell location is given by the X and Y fields.

Cell Deselection (Disjoint Mode) (TYPE = 9)

This is the type of structure returned when selected cells are de-selected by the user *and the table is in disjoint selection mode*. It is identical to the (TYPE = 4) WIDGET_TABLE_CELL_SEL event structure except for the name and type value.

This event occurs when the user holds down the control key when starting a selection and the cell used to start the selection was already selected. In contrast, if the user starts a selection with the control key down but starts on a cell that was not selected, the normal WIDGET_TABLE_CELL_SEL is generated.

```
{WIDGET_TABLE_CELL_DESEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:9,
   SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

Keyboard Focus Events

Table widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the table widget generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the table widget is gaining the keyboard focus, or 0 (zero) if the table widget is losing the keyboard focus.

Version History

Introduced: 5.0

DISJOINT_SELECTION keyword, Cell deselection (type 9) event added: 5.6

WIDGET_CONTROL

WIDGET_TEXT

The WIDGET_TEXT function creates text widgets. Text widgets display text and optionally get textual input from the user. They can have 1 or more lines, and can optionally contain scroll bars to allow viewing more text than can otherwise be displayed on the screen.

Syntax

Result = WIDGET_TEXT(*Parent* [, /ALL_EVENTS] [, /CONTEXT_EVENTS]
[, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
[, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, /KBRD_FOCUS_EVENTS]
[, KILL_NOTIFY=*string*] [, /NO_COPY] [, /NO_NEWLINE]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SCROLL] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, /WRAP]
[, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created text widget.

Arguments

Parent

The widget ID of the parent widget for the new text widget.

Keywords

ALL_EVENTS

Set this keyword to cause to the text widget to generate events whenever the user changes the contents of the text area.

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

Keywords		Effects	
ALL_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated.**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 145: Effects of using the ALL_EVENTS and EDITABLE keywords

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See ALL_EVENTS for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

See "ALL_TEXT_EVENTS" on page 2090 for a description of how EDITABLE interacts with the ALL_TEXT_EVENTS keyword.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

Note

This keyword is only a “hint” to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets *always* have frames.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “Widget Events Returned by Text Widgets” on page 2228 for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_TEXT or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_NEWLINE

Normally, when setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. Set this keyword to suppress this action.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2055 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse

cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2061 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_TEXT.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a text widget is the current text displayed by the widget.

VALUE can be either a string or an array of strings. Note that variables returned by the GET_VALUE keyword to WIDGET_CONTROL are always string arrays, even if a scalar string is specified in the call to WIDGET_TEXT.

WRAP

Set this keyword to indicate that scrolling or multi-line text widgets should automatically break lines between words to keep the text from extending past the right edge of the text display area. Note that carriage returns are *not* automatically entered when lines wrap; the value of the text widget will remain a single-element array unless you explicitly enter a carriage return.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in characters. Note that the physical width of the text widget depends on both the value of XSIZE and on the size of the font used. The default value of XSIZE varies according to your windowing system. On Windows, the default size is roughly 20 characters. On Motif, the default size depends on the width of the text widget.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in text lines. Note that the physical height of the text widget depends on both the value of YSIZE and on the size of the font used. The default value of YSIZE is one line.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of text widgets. In addition to those keywords that affect all widgets, the following are particularly useful: ALL_TEXT_EVENTS, APPEND, CONTEXT_EVENTS, EDITABLE, GET_VALUE, KBRD_FOCUS_EVENTS, INPUT_FOCUS, NO_NEWLINE, SET_TEXT_SELECT, SET_TEXT_TOP_LINE, SET_VALUE, USE_TEXT_SELECT.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to text widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, TEXT_ALL_EVENTS, TEXT_EDITABLE, TEXT_NUMBER, TEXT_OFFSET_TO_XY, TEXT_SELECT, TEXT_TOP_LINE, TEXT_XY_TO_OFFSET.

Widget Events Returned by Text Widgets

There are several variations of the text widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all text event structures. The different text widget event structures are described below.

Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed or pasted into a text widget by a user.

```
{ WIDGET_TEXT_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
   CH:0B }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character.

Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a text widget by the window system.

```
{ WIDGET_TEXT_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
   STR:'' }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted.

Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a text widget.

```
{ WIDGET_TEXT_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
   LENGTH:0L }
```

OFFSET is the (zero-based) character position of the first character to be deleted. It is also the insertion position that will result when the characters have been deleted. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters were deleted.

Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{ WIDGET_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3, OFFSET:0L,
   LENGTH:0L }
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters are selected, and the new insertion position is given by OFFSET.

Note that text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is *not* sent.

Keyboard Focus Events

Text widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

The first three fields are the standard fields found in every widget event. The ENTER field returns 1 (one) if the text widget is gaining the keyboard focus, or 0 (zero) if the text widget is losing the keyboard focus.

Context Menu Events

Text widgets return the following event structure when the user clicks the right mouse button and the text widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the text widget.

Version History

Introduced: Pre 4.0

CW_FIELD, XDISPLAYFILE

WIDGET_TREE

The WIDGET_TREE function is used to create and populate a tree widget. The tree widget presents a hierarchical view that can be used to organize a wide variety of data structures and information.

The WIDGET_TREE function performs two separate tasks: creating the tree widget and populating the tree widget with *nodes* (branches and leaves).

For a more detailed discussion of the tree widget, along with examples, see "Using Tree Widgets" in Chapter 26 of the *Building IDL Applications* manual.

Syntax

Result = WIDGET_TREE(*Parent* [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, BITMAP=*array*] [, /CONTEXT_EVENTS] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXPANDED] [, /FOLDER] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /MULTIPLE] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /TOP] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*string*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created tree widget.

Arguments

Parent

The widget ID of the parent for the new tree widget. *Parent* can be either a base widget or a tree widget.

- If *Parent* is a base widget, WIDGET_TREE will create a tree widget that contains no other tree widgets. This type of tree widget is referred to as a *root node*.
- If *Parent* is a tree widget, WIDGET_TREE will create a new tree widget (called a *node*) in the specified tree widget.

Note

With the exception of the first tree widget created (the *root node*, whose *Parent* is a base widget), a tree widget (or *node*) must be created with the FOLDER keyword in order to serve as the *Parent* for other tree widgets.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

BITMAP

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-

sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 26 of the *Building IDL Applications* manual.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EXPANDED

If the tree node being created is a *folder* (specified by the FOLDER keyword), set this keyword to cause the folder to be initially displayed expanded, showing all of its immediate child entries. By default, folders are initially displayed collapsed.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

FOLDER

Set this keyword to cause the tree node being created to act as a *folder* (that is, as a branch of the tree rather than a leaf).

Note

With the exception of the root node (the tree widget whose *Parent* widget is a base widget), only tree nodes that have the FOLDER keyword set can act as the parent for other tree widgets.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). Note that the procedure specified is used only if you are not using the XMANAGER procedure to manage your widgets.

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

If you use the XMANAGER procedure to manage your widgets, the value of this keyword is overwritten. Use the CLEANUP keyword to XMANAGER to specify a procedure to be called when a managed widget dies.

MULTIPLE

Set this keyword to enable multiple selection operations in the tree widget. If enabled, multiple elements in the tree widget can be selected at one time by holding down the **Control** or **Shift** key while clicking the left mouse button.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_TAB or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

TOP

Set this keyword to cause the tree node being created to be inserted as the parent node's top entry. By default, new nodes are inserted as the parent node's bottom entry.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (which is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

Set this keyword equal to a string containing the text that will be displayed next to the tree node. If this keyword is not set, the default value `Tree` is used.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of tree widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO return information that applies specifically to tree widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: TREE_EXPANDED, TREE_SELECT, and TREE_ROOT.

Widget Events Returned by Tree Widgets

Several variations of the tree widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all tree event structures. The different tree widget event structures are described below.

Select (TYPE = 0)

This structure is returned when the currently selected node in the tree widget changes:

```
{WIDGET_TREE_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, CLICKS:0L}
```

The CLICKS field indicates the number of mouse-button clicks that occurred when the event took place. This field contains 1 (one) when the item is selected, or 2 when the user double-clicks on the item.

Expand (TYPE = 1)

This structure is returned when a folder in the tree widget expands or collapses:

```
{WIDGET_TREE_EXPAND, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, EXPAND:0L}
```

The EXPAND field contains 1 (one) if the folder expanded or 0 (zero) if the folder collapsed.

Context Menu Events

Tree widgets return the following event structure when the user clicks the right mouse button and the tree widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, and are measured from the upper left corner of the tree widget.

Version History

Introduced: 5.6

See Also

"Using Tree Widgets" in Chapter 26 of the *Building IDL Applications* manual

WINDOW

The WINDOW procedure creates a window for the display of graphics or text. It is only necessary to use WINDOW if more than one simultaneous window or a special size window is desired because a window is created automatically the first time any display procedure attempts to access the window system. The newly-created window becomes the current window, and the system variable !D.WINDOW is set to that window's window index. (See the description of the WSET procedure for a discussion of the current IDL window.)

The behavior of WINDOW varies slightly depending on the window system in effect. See the discussion of IDL graphics devices in Appendix G, "IDL Graphics Devices" for additional details.

Syntax

WINDOW [, *Window_Index*] [, COLORS=*value*] [, /FREE] [, /PIXMAP] [, RETAIN={0 | 1 | 2}] [, TITLE=*string*] [, XPOS=*value*] [, YPOS=*value*] [, XSIZE=*pixels*] [, YSIZE=*pixels*]

Arguments

Window_Index

The window index for the newly-created window. A window index is an integer value between 0 and 31 that is used to refer to the window. If this parameter is omitted, window index 0 is used. If the value of *Window_Index* specifies an existing window, the existing window is deleted and a new one is created. If you need to create more than 32 windows, use the FREE keyword described below.

Keywords

COLORS

Note

This keyword is ignored under Microsoft Windows.

The maximum number of color table indices to be used when drawing. This keyword has an effect only if supplied when the first window is created. If COLORS is not present when the first window is created, all or most of the available color indices are allocated depending upon the window system in use.

To use monochrome windows on a color display in X Windows, use COLORS = 2 when creating the first window. One color table is maintained for all windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be allocated.

Although this keyword is ignored under Microsoft Windows, we could use the following code to use a monochrome window on all platforms:

```
WINDOW, COLORS=2 ; ignored on Windows
white=!D.N_COLORS-1
PLOT, FINDGEN(20), COLOR=white
```

FREE

Set this keyword to create a window using the smallest unused window index above 32. If this keyword is present, the *Window_Index* argument can be omitted. The default position of the new window is opposite that of the current window. Using the FREE keyword allows the creation of a large number of windows. The system variable !D.WINDOW is set to the index of the newly-created window.

PIXMAP

Set the PIXMAP keyword to specify that the window being created is actually an invisible portion of the display memory called a pixmap.

RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the window:

- 0 = no backing store
- 1 = requests that the server or window system provide backing store
- 2 = specifies that IDL provide backing store directly

See “Backing Store” on page 3806 for details.

TITLE

A scalar string that contains the window’s label. If not specified, the window is given a label of the form “IDL *n*”, where *n* is the index number of the window. For example, to create a window with the label “IDL Graphics”, enter:

```
WINDOW, TITLE='IDL Graphics'
```

XPOS

The X position of the window, specified in device coordinates. On Motif platforms, XPOS specifies the X position of the *lower* left corner and is measured from the lower left corner of the screen. On Windows platforms, XPOS specifies the X position of the *upper* left corner and is measured from the upper left corner of the screen. That is, specifying

```
WINDOW, XPOS = 0, YPOS = 0
```

will create a window in the lower left corner on Motif machines and in the upper left corner on Windows machines.

If no position is specified, the position of the window is determined from the value of Window Index using the following rules:

- Window 0 is placed in the upper right hand corner.
- Even numbered windows are placed on the top half of the screen and odd numbered windows are placed on the bottom half.
- Windows 0,1,4,5,8, and 9 are placed on the right side of the screen and windows 2,3,6, and 7 are placed on the left.

Note

The order of precedence (highest to lowest) for positioning windows is: XPOS/YPOS keywords to WINDOW, Tile/Cascade IDE graphics (user system) preferences, optional index argument to WINDOW. Also realize that setting LOCATION is only a request to the Window manager and may not always be honored due to system peculiarities.

YPOS

The Y position of the window, specified in device coordinates. See the description of XPOS for details.

XSIZE

The width of the window in pixels.

YSIZE

The height of the window in pixels.

Examples

Create graphics window number 0 with a size of 400 by 400 pixels and a title that reads “Square Window” by entering:

```
WINDOW, 0, XSIZE=400, YSIZE=400, TITLE='Square Window'
```

Version History

Introduced: Original

WDELETE, WSET, WSHOW

WRITE_BMP

The WRITE_BMP procedure writes an image and its color table vectors to a Microsoft Windows Version 3 device independent bitmap file (.BMP).

WRITE_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file `write_bmp.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_BMP, *Filename*, *Image*[, *R*, *G*, *B*] [, /FOUR_BIT] [, IHDR=*structure*] [, HEADER_DEFINE=*h*{define *h* before call}] [, /RGB]

Arguments

Filename

A scalar string containing the full pathname of the bitmap file to write.

Image

The array to write into the new bitmap file. The array should be scaled into a range of bytes for 8- and 24-bit deep images. Scale to 0-15 for 4-bit deep images. If the image has 3 dimensions and the first dimension is 3, a 24-bit deep bitmap file is created.

Note

For 24-bit images, color interleaving is blue, green, red: *Image*[0, *i*, *j*] = blue, *Image*[1, *i*, *j*] = green, *Image*[2, *i*, *j*] = red.

R, G, B

Color tables. If omitted, the colors loaded in the COLORS common block are used.

Keywords

FOUR_BIT

Set this keyword to write as a 4-bit device independent bitmap. If omitted or zero, an 8-bit deep bitmap is written.

IHDR

Set this keyword to a BITMAPINFOHEADER structure containing the file header fields that are not obtained from the image itself. The fields in this structure that can be set are: `bi{XY}PelsPerMeter`, `biClrUsed`, and `biClrImportant`.

HEADER_DEFINE

If this keyword is set, WRITE_BMP returns an empty BITMAPINFOHEADER structure, containing zeros. No other actions are performed. This structure may be then modified with the pertinent fields and passed in via the IHDR keyword parameter. See the Microsoft Windows Programmers Reference Guide for a description of each field in the structure.

Note: this parameter must be defined *before* the call. For example:

```
H = 0
WRITE_BMP, HEADER_DEFINE = H
```

RGB

Set this keyword to reverse the color interleaving for 24-bit images to red, green, blue: *Image*[0, *i*, *j*] = red, *Image*[1, *i*, *j*] = green, *Image*[2, *i*, *j*] = blue. By default, 24-bit images are written with color interleaving of blue, green, red.

Examples

The following command captures the contents of the current IDL graphics window and saves it to a Microsoft Windows Bitmap file with the name `test.bmp`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_BMP, 'test.bmp', TVRD()
```

The following commands scale an image to 0-15, and then write a 4-bit BMP file, using a grayscale color table:

```
; Create a ramp from 0 to 255:
r = BYTSCL(INDGEN(16))

WRITE_BMP, 'test.bmp', BYTSCL(Image, MAX=15), r, r, r, /FOUR
```

Version History

Introduced: Pre 4.0

READ_BMP, QUERY_* Routines

WRITE_IMAGE

The WRITE_IMAGE procedure writes an image and its color table vectors, if any, to a file of a specified type. WRITE_IMAGE can write most types of image files supported by IDL.

Syntax

WRITE_IMAGE, *Filename*, *Format*, *Data* [, *Red*, *Green*, *Blue*] [, /APPEND]

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. The following are the supported formats:

- BMP
- JPEG
- PNG
- PPM
- SRF
- TIFF

Data

An IDL variable containing the image data to write to the file.

Red

An optional vector containing the red channel of the color table if a colortable exists.

Green

An optional vector containing the green channel of the color table if a colortable exists.

Blue

An optional vector containing the blue channel of the color table if a colortable exists.

Keywords

APPEND

Set this keyword to force the image to be appended to the file instead of overwriting the file. APPEND may be used with image formats that supports multiple images per file and is ignored for formats that support only a single image per file.

Version History

Introduced: 5.3

WRITE_JPEG

The WRITE_JPEG procedure writes compressed images to files. JPEG (Joint Photographic Experts Group) is a standardized compression method for full-color and gray-scale images. This procedure is based in part on the work of the Independent JPEG Group.

As the Independent JPEG Group states, JPEG is intended for real-world scenes (such as digitized photographs). Line art, such as drawings or IDL plots, and other unrealistic images are not its strong suit. Note also that JPEG is a lossy compression scheme. That is, the output image is *not* identical to the input image. Hence you cannot use JPEG if you must have identical output bits. On typical images of real-world scenes, however, very good compression levels can be obtained with no visible change, and amazingly high compression levels are possible if you can tolerate a low-quality image. You can trade off output image quality against compressed file size by adjusting a compression parameter. Files are encoded in JFIF, the JPEG File Interchange Format; however, such files are usually simply called JPEG files.

If you need to store images in a format that uses lossless compression, consider using the WRITE_PNG procedure. This procedure writes a Portable Network Graphics (PNG) file using lossless compression with either 8 or 16 data bits per channel. To store 8-bit or 24-bit images without compression, consider using WRITE_BMP (for Microsoft Bitmap format files) or WRITE_TIFF (to write Tagged Image Format Files).

For a short technical introduction to the JPEG compression algorithm, see: Wallace, Gregory K. “The JPEG Still Picture Compression Standard”, *Communications of the ACM*, April 1991 (vol. 34, no. 4), pp. 30-44.

Note

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

Syntax

WRITE_JPEG [, *Filename* | , UNIT=*lun*] , *Image* [, /ORDER] [, /PROGRESSIVE] [, QUALITY=*value*{0 to 100}] [, TRUE={1 | 2 | 3}]

Arguments

Filename

A string containing the name of file to be written in JFIF (JPEG) format. If this parameter is not present, the UNIT keyword must be specified.

Image

A byte array of either two or three dimensions, containing the image to be written. Grayscale images must have two dimensions. TrueColor images must have three dimensions with the index of the dimension that contains the color specified with the TRUE keyword.

Keywords

ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image array is in the standard IDL order (i.e., from bottom-to-top) set ORDER to 0, its default value. If the image array is in top-to-bottom order, ORDER must be set to 1.

PROGRESSIVE

Set this keyword to write the image as a series of scans of increasing quality. When used with a slow communications link, a decoder can generate a low-quality image very quickly, and then improve its quality as more scans are received.

Warning

Not all JPEG applications can handle progressive JPEG files, and it is up the JPEG reader to progressively display the JPEG image. For example, IDL's READ_JPEG routine ignores the progressive readout request and reads the entire image in at the first reading.

QUALITY

This keyword specifies the quality index, in the range of 0 (terrible) to 100 (excellent) for the JPEG file. The default value is 75, which corresponds to very good quality. Lower values of QUALITY produce higher compression ratios and smaller files.

TRUE

This keyword specifies the index, starting at 1, of the dimension over which the color is interleaved. For example, for an image that is pixel interleaved and has dimensions of (3, *m*, *n*), set TRUE to 1. Specify 2 for row-interleaved images (*m*, 3, *n*); and 3 for band-interleaved images (*m*, *n*, 3). If TRUE is not set, the image is assumed to have no interleaving (it is not a TrueColor image).

UNIT

This keyword designates the logical unit number of an already open file to receive the output, allowing multiple JFIF images per file or the embedding of JFIF images in other data files. If this keyword is used, *Filename* should not be specified.

Note

When opening a file intended for use with the UNIT keyword, if the filename does not end in `.jpg`, or `.jpeg`, you must specify the STDIO keyword to OPEN in order for the file to be compatible with WRITE_JPEG.

Examples

Write the image contained in the array A, using JPEG compression with a quality index of 25. The image is stored in bottom-to-top order:

```
image = DIST(100)
WRITE_JPEG, 'test1.jpg', image, QUALITY=25
```

Write a TrueColor image to a JPEG file. The image is contained in the band-interleaved array A with dimensions (*m*, *n*, 3). Assume it is stored in top-to-bottom order:

```
WRITE_JPEG, 'test2.jpg', image, TRUE=3, /ORDER
```

Version History

Introduced: Pre 4.0

See Also

READ_JPEG, QUERY_* Routines

WRITE_NRIF

The WRITE_NRIF procedure writes an image and its color table vectors to an NCAR Raster Interchange Format (NRIF) rasterfile.

WRITE_NRIF only writes 8- or 24-bit deep rasterfiles of types “Indexed Color” (8-bit) and “Direct Color integrated” (24-bit). The color map is included only for 8-bit files.

See the document “NCAR Raster Interchange Format and TAGS Raster Reference Manual,” available from the Scientific Computing Division, National Center for Atmospheric Research, Boulder, CO, 80307-3000, for information on the structure of NRIF files.

This routine is written in the IDL language. Its source code can be found in the file `write_nrif.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_NRIF, *File*, *Image* [, *R*, *G*, *B*]

Arguments

File

A scalar string containing the full path name of the NRIF file to write.

Image

The byte array to be written to the NRIF file. If *Image* has the dimensions (*n*,*m*), an 8-bit NRIF file with color tables is created. If *Image* has the dimensions (3,*n*,*m*), a 24-bit NRIF file is created, where each byte triple represents the red, green, and blue intensities at (*n*,*m*) on a scale from 0 to 255. The NRIF image will be rendered from bottom to top, in accordance with IDL standards.

R, G, B

The Red, Green, and Blue color vectors to be used as a color table with 8-bit images. If color vectors are supplied, they are included in the output (8-bit images only). If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_NRIF calls LOADCT to load the grayscale entry (table 0).

Note

WRITE_NRIF does not recognize color vectors loaded directly using TVLCT, so if a custom color table is desired and it is not convenient to use XPALETTE, include the R, G, and B vectors that were used to create the color table.

Version History

Introduced: Pre 4.0

WRITE_PICT

The WRITE_PICT procedure writes an image and its color table vectors to a PICT (version 2) format image file. The PICT format is used by Apple Macintosh computers.

Note: WRITE_PICT only works with 8-bit displays

This routine is written in the IDL language. Its source code can be found in the file `write_pict.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_PICT, *Filename* [, *Image*, *R*, *G*, *B*]

Arguments

Filename

A scalar string containing the full pathname of the PICT file to write.

Image

The byte array to be written to the PICT file. If *Image* is omitted, the entire current graphics window is read into an array and written to the PICT file.

R, G, B

The Red, Green, and Blue color vectors to be written to the PICT file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_PICT calls LOADCT to load the grayscale entry (table 0).

Examples

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_PICT, 'test.pict', TVRD()
```

Version History

Introduced: Pre 4.0

See Also

READ_PICT, QUERY_* Routines

WRITE_PNG

The WRITE_PNG procedure writes a 2-D or 3-D IDL variable into a Portable Network Graphics (PNG) file. The data in the file is stored using lossless compression with either 8 or 16 data bits per channel, based on the input IDL variable type. 3-D IDL variables must have the number of channels as their leading dimension (pixel interleaved). For BYTE format 2-D IDL variables, an optional palette may be stored in the image file along with a list of pixel values which are to be considered transparent by a reading program.

Note

IDL supports version 1.0.5 of the PNG Library.

Syntax

WRITE_PNG, *Filename*, *Image*[, *R*, *G*, *B*] [, /ORDER] [, /VERBOSE] [, TRANSPARENT=*array*]

Arguments

Filename

A scalar string containing the full pathname of the PNG file to write.

Image

The array to write into the new PNG file. If *Image* is one of the integer data types, it is converted to type unsigned integer (UINT) and written out at 16 data bits per channel. All other data types are converted to bytes and written out at 8-bits per channel.

Note

If *Image* is two-dimensional (single-channel) and *R*, *G*, and *B* are provided, all input data types (including integer) are converted to bytes and written out as 8-bit data.

R, G, B

For single-channel images, *R*, *G*, and *B* should contain the red, green, and blue color vectors, respectively. For multi-channel images, these arguments are ignored.

Keywords

ORDER

Set this keyword to indicate that the rows of the image should be written from bottom to top. The rows are written from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

VERBOSE

Produces additional diagnostic output during the write.

TRANSPARENT

Set this keyword to an array of pixel index values which are to be treated as “transparent” for the purposes of image display. This keyword is valid only if *Image* is a single-channel (color indexed) image and the R, G, B palette is provided.

Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bits/channel) image with a palette.

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = INDGEN(256)
green = INDGEN(256)
blue = INDGEN(256)
WRITE_PNG,'rgb_image.png',rgbdata
WRITE_PNG,'ci_image.png',cidata,red,green,blue

; Query and Read the data:
names = ['rgb_image.png','ci_image.png','unknown.png']
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
   ok = QUERY_PNG(names[i],s)
   IF (ok) THEN BEGIN
      HELP,s,/STRUCTURE
      IF (s.HAS_PALETTE) THEN BEGIN
         img = READ_PNG(names[i],rpal,gpal,bpal)
         HELP,img,rpal,gpal,bpal
      ENDIF ELSE BEGIN
         img = READ_PNG(names[i])
         HELP,img
      ENDELSE
   ENDIF ELSE BEGIN
```

```
      PRINT,names[i],' is not a PNG file'
    ENDELSE
  ENDFOR
```

Version History

Introduced: 5.2

See Also

READ_PNG, QUERY_* Routines

WRITE_PPM

The WRITE_PPM procedure writes an image to a PPM (TrueColor) or PGM (gray scale) file. This routine is written in the IDL language. Its source code can be found in the file `write_ppm.pro` in the `lib` subdirectory of the IDL distribution.

Note

WRITE_PPM only writes 8-bit deep PGM/PPM files of the standard type. Images should be ordered so that the first row is the top row.

PPM/PGM format is supported by the PBMPLUS toolkit for converting various image formats to and from portable formats, and by the Netpbm package.

Syntax

WRITE_PPM, *Filename*, *Image* [, /ASCII]

Arguments

Filename

A scalar string specifying the full pathname of the PPM or PGM file to write.

Image

The 2D (gray scale) or 3D (TrueColor) array to be written to a file.

Keywords

ASCII

Set this keyword to force WRITE_PPM to use formatted ASCII input/output to write the image data. The default is to use the far more efficient binary input/output (RAWBITS) format.

Examples

```
image = DIST(100)
WRITE_PPM, 'file.ppm', image
```

Version History

Introduced: 4.0

See Also

READ_PPM, QUERY_* Routines

WRITE_SPR

The WRITE_SPR procedure writes a row-indexed sparse array structure to a specified file. Row-indexed sparse arrays are created using the SPRSIN function.

Syntax

WRITE_SPR, *AS*, *Filename*

Arguments

AS

A row-indexed sparse array created by SPRSIN.

Filename

The name of the file that will contain AS.

Keywords

None.

Examples

```
; Create an array:
A = [[3.,0., 1., 0., 0.],$
     [0.,4., 0., 0., 0.],$
     [0.,7., 5., 9., 0.],$
     [0.,0., 0., 0., 2.],$
     [0.,0., 0., 6., 5.]]

; Convert it to sparse storage format:
A = SPRSIN(A)

; Store it in the file sprs.as:
WRITE_SPR, A, 'sprs.as'
```

Version History

Introduced: Pre 4.0

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSIN, READ_SPR

WRITE_SRF

The WRITE_SRF procedure writes an image and its color table vectors to a Sun Raster File (SRF).

WRITE_SRF only writes 32-, 24-, and 8-bit-deep rasterfiles of type RT_STANDARD. Use the UNIX command `rasfilter8to1` to convert these files to 1-bit deep files. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `write_srf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_SRF, *Filename* [, *Image*, *R*, *G*, *B*] [, /ORDER] [, /WRITE_32]

Arguments

Filename

A scalar string containing the full pathname of the SRF to write.

Image

The array to be written to the SRF. If *Image* has dimensions (3,*n*,*m*), a 24-bit SRF is written. If *Image* is omitted, the entire current graphics window is read into an array and written to the SRF file. *Image* should be of byte type, and in top to bottom scan line order.

R, G, B

The Red, Green, and Blue color vectors to be written to the file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_SRF calls LOADCT to load the grayscale entry (table 0).

Keywords

ORDER

Set this keyword to write the image from the top down instead of from the bottom up. This setting is only necessary when writing a file from the current IDL graphics window; it is ignored when writing a file from a data array passed as a parameter.

WRITE_32

Set this keyword to write a 32-bit file. If the input image is a TrueColor image, dimensioned (3, *n*, *m*), it is normally written as a 24-bit raster file.

Examples

Create a pseudo screen dump from the current window:

```
WRITE_SRF, 'test.srf', TVRD()
```

Version History

Introduced: Original

READ_SRF, QUERY_* Routines

WRITE_SYLK

The WRITE_SYLK function writes the contents of an IDL variable to a SYLK (Symbolic Link) format spreadsheet data file.

Note

This routine writes only numeric and string SYLK data. It cannot handle spreadsheet and cell formatting information (cell width, text justification, font type, date, time, monetary notations, etc.). A given SYLK data file cannot be appended with data blocks through subsequent calls.

This routine is written in the IDL language. Its source code can be found in the file `write_sylk.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = WRITE_SYLK(*File*, *Data* [, STARTCOL=*column*] [, STARTROW=*row*])

Return Value

The function returns TRUE if the write operation was successful.

Arguments

File

A scalar string specifying the full path name of the SYLK file to write.

Data

A scalar, vector, or 2D array to be written to *File*.

Keywords

STARTCOL

Set this keyword to the first column of spreadsheet cells to write. If not specified, the write operation begins with the first column found in the file (column 0).

STARTROW

Set this keyword to the first row of spreadsheet cells to write. If not specified, the write operation begins with the first row of cells found in the file (row 0).

Examples

Suppose you wish to write the contents of a 2 by 2 floating-point array, `data`, to a SYLK data file called “bar.slk” such that the matrix would appear with it’s upper left data at the cell in the 10th row and the 20th column. Use the following command:

```
status = WRITE_SYLK('bar.slk', data, STARTROW = 9, STARTCOL = 19)
```

The IDL variable `status` will contain the value 1 if the operation was successful.

Version History

Introduced: 4.0

READ_SYLK

WRITE_TIFF

The WRITE_TIFF procedure can write TIFF files with one or more channels, where each channel can contain 1, 4, 8, 16, or 32-bit integer pixels, or floating-point values.

Syntax

WRITE_TIFF, *Filename [, Image]* [, /APPEND]
[, BITS_PER_SAMPLE={1 | 4 | 8}] [, RED=*value*] [, GREEN=*value*]
[, BLUE=*value*] [, COMPRESSION={0 | 2 | 3}] [, GEOTIFF=*structure*]
[, /LONG | , /SHORT | , /FLOAT] [, ORIENTATION=*value*]
[, PLANARCONFIG={1 | 2}] [, UNITS={1 | 2 | 3}] [, /VERBOSE]
[, XRESOL=*pixels/inch*] [, YRESOL=*pixels/inch*]

Arguments

Filename

A scalar string containing the full pathname of the TIFF to write.

Image

The array to be written to the TIFF. If *Image* has dimensions (k,n,m), a k-channel TIFF is written. Image should be in top to bottom scan line order. By default, this array is converted to byte format before being written (see the LONG, SHORT and FLOAT keywords below). Note that many TIFF readers can read only one- or three-channel images.

Note

The Image argument is optional if PLANARCONFIG is set to 2 and the RED, GREEN, and BLUE keywords have been set to 2D arrays.

Note

Grayscale TIFF images are written out with the PhotometricInterpretation tag set to BlackIsZero, implying that values of 0 should correspond to black. If you want values of 0 to correspond to white, you should invert your pixel values before calling WRITE_TIFF.

Order

This argument is obsolete. The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead.

Keywords

APPEND

Set this keyword to specify that the image should be added to the existing file, creating a multi-image TIFF file.

BITS_PER_SAMPLE

Set this keyword to either 1, 4, or 8 to create a grayscale image file with the specified number of bits per pixel. For 1-bit (bi-level) images, an output pixel is assigned the value 1 (one) if the corresponding input pixel is nonzero. For 4-bit grayscale images, the input pixel values *must* be in the range 0 through 15, or the image will be garbled. The default is BITS_PER_SAMPLE=8. This keyword is ignored if an RGB image or color palette is present, or if one of the FLOAT, LONG, or SHORT keywords is set.

COMPRESSION

Set this keyword to select the type of compression to be used:

- 0 = none (default)
- 2 = PackBits
- 3 = JPEG (ITIFF files)

Note

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and the ORIENTATION keyword should not be specified. If your input image is not in top-to-bottom order, you should use REVERSE(*image*, 2) to flip the order before calling WRITE_TIFF.

FLOAT

Set this keyword to write the pixel components as floating-point entities (the default is 8-bit).

GEOTIFF

Set this keyword to an anonymous structure containing one field for each of the GeoTIFF tags and keys to be written into the file. The GeoTIFF structure is formed using fields named from the following table.

Anonymous Structure Field Name	IDLDatatype
TAGS:	
"MODELPIXELSCALETAG"	DOUBLE[3]
"MODELTRANSFORMATIONTAG"	DOUBLE[4,4]
"MODELTIEPOINTTAG"	DOUBLE[6,*]
KEYS:

"VERTICALCSTYPEGEOKEY"	INT
"VERTICALCITATIONGEOKEY"	STRING
"VERTICALDATUMGEOKEY"	INT
"VERTICALUNITSGEOKEY"	INT

Table 146: GEOTIFF Structures (Continued)

Note

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

LONG

Set this keyword to write the pixel components as unsigned 32-bit entities (the default is 8-bit).

ORIENTATION

Set this keyword to an integer value to specify the orientation of the TIFF image. The default is ORIENTATION=1.

Note

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and this keyword should not be specified.

Possible values are:

Value	Description
0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.

Table 147: ORIENTATION Keyword Values

Value	Description
2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

Table 147: ORIENTATION Keyword Values (Continued)

Warning

Not all TIFF readers honor the value of the ORIENTATION field. IDL writes the value into the file, but some readers are known to ignore this value. In such cases, we recommend that you convert the image to top-to-bottom order with the REVERSE function and then set ORIENTATION to 1.

PLANARCONFIG

This keyword determines the order in which a multi-channel image is stored and written. It has no effect with a single-channel image. Set this keyword to 2 to if the Image parameter is interleaved by “plane”, or band, and its dimensions are (*Columns*, *Rows*, *Channels*). The default value is 1, indicating that multi-channel images are interleaved by color, also called channel, and its dimensions are (*Channels*, *Columns*, *Rows*).

As a special case, this keyword may be set to 2 to write an RGB image that is contained in three separate arrays (color planes), stored in the variables specified by the RED, GREEN, and BLUE keywords. Otherwise, omit this parameter (or set it to 1).

Note

Many TIFF readers can read only one- or three-channel images.

RED, GREEN, BLUE

If you are writing a Palette color image, set these keywords equal to the color table vectors, scaled from 0 to 255.

If you are writing an RGB interleaved image (i.e., if the PLANARCONFIG keyword is set to 2), set these keywords to the names of the variables containing the three image components.

SHORT

Set this keyword to write the pixel components as unsigned 16-bit entities (the default is 8-bit).

UNITS

Set this keyword to one of the following values to specify the units used for the values specified by the XRESOL and YRESOL keywords:

Value	Description
1	No units
2	Inches (the default)
3	Centimeters

Table 148: UNITS Keyword Values

VERBOSE

Set this keyword to produce additional diagnostic output during the write.

XRESOL

Set this keyword to the horizontal resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of XRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

YRESOL

Set this keyword to the vertical resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of YRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

Examples

Example 1

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_TIFF, 'test.tiff', TVRD()
```

Example 2

Write a three-channel image from three one-channel (two-dimensional) arrays, contained in the variables Red, Green, and Blue:

```
WRITE_TIFF, 'test.tif', Red, Green, Blue, PLANARCONFIG=2
```

Example 3

Write and read a multi-image TIFF file. The first image is a 16-bit single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND
; Read the image data back
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
   FOR i=0,s.NUM_IMAGES-1 DO BEGIN
      imp = QUERY_TIFF('multi.tif',t,IMAGE_INDEX=i)
      img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
      HELP,t,/STRUCTURE
      HELP,img
   ENDFOR
ENDIF
```

Version History

Introduced: 5.0

ITIFF support added: 5.6

READ_TIFF, QUERY_* Routines

WRITE_WAV

The WRITE_WAV procedure writes the audio stream to the named .WAV file.

Syntax

WRITE_WAV, *Filename*, *Data*, *Rate*

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to write.

Data

The array to write into the new .WAV file. The array can be a one- or two-dimensional array. A two-dimensional array is written as a multi-channel audio stream where the leading dimension of the IDL array is the number of channels. If the input array is in BYTE format, the data is written as 8-bit samples, otherwise, the data is written as signed 16-bit samples.

Rate

The sampling rate for the data array in samples per second.

Keywords

None.

Version History

Introduced: 5.3

WRITE_WAVE

The WRITE_WAVE procedure writes a three dimensional IDL array to a `.wave` or `.bwave` file for use with the Wavefront Advanced Data Visualizer. Note that this routine only writes one scalar field for each Wavefront file that it creates.

This routine is written in the IDL language. Its source code can be found in the file `write_wave.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_WAVE, *File*, *Array* [, /BIN] [, DATANAME=*string*] [, MESHNAME=*string*] [, /NOMESHDEF] [, /VECTOR]

Arguments

File

A scalar string containing the full path name of the Wavefront file to write.

Array

A 3D array to be written to the file.

Keywords

BIN

Set this keyword to create a binary file. By default, text files are created.

DATANAME

Set this keyword to the name of the data inside of the Wavefront file. If not specified, the name used is “idldata”.

MESHNAME

Set this keyword to the name of the mesh used in the Wavefront file. If not specified, the name used is “idlmesh”.

NOMESHDEF

Set this keyword to *omit* the mesh definition from the Wavefront file.

VECTOR

Set this keyword to write the variable as a vector. The data is written as an array of 3-space vectors. The array may contain any number of dimensions but must have a leading dimension of 3. If the leading array dimension is not 3, this keyword is ignored.

Version History

Introduced: Pre 4.0

See Also

READ_WAVE

WRITEU

The WRITEU procedure writes unformatted binary data from an expression into a file. This procedure performs a direct transfer with no processing of any kind being done to the data.

Syntax

WRITEU, *Unit*, $Expr_1$ ..., $Expr_n$ [, TRANSFER_COUNT=*variable*]

Arguments

Unit

The IDL file unit to which the output is sent.

$Expr_i$

The expressions to be output. For non-string variables, the number of bytes implied by the data type is output. When WRITEU is used with a variable of type string, IDL outputs exactly the number of bytes contained in the existing string.

Keywords

TRANSFER_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the output operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, writing more data than an output device will accept causes an error. Files opened with the RAWIO keyword will not generate such an error. Instead, the programmer must keep track of the transfer count to judge the success or failure of a WRITEU operation.

Obsolete Keywords

The following keywords are obsolete:

- REWRITE

For information on obsolete keywords, See Appendix O, “Obsolete Features”.

Examples

```
; Create some data to store in a file:
D = BYTSCL(DIST(200))
; Open a new file for writing as IDL file unit number 1:
OPENW, 1, 'newfile'
; Write the data in D to the file:
WRITEU, 1, D
; Close file unit 1:
CLOSE, 1
```

Version History

Introduced: Original

See Also

OPEN, READU, Chapter 10, “Files and Input/Output” in the *Building IDL Applications* manual, and “Unformatted Input/Output with Structures” in Chapter 7 of the *Building IDL Applications* manual.

WSET

The WSET procedure selects the current window. Most IDL graphics routines do not explicitly require the IDL window to be specified. Instead, they use the window known as the current window. The window index number of the current window is contained in the read-only system variable !D.WINDOW. WSET only works with devices that have windowing systems.

Syntax

WSET [, *Window_Index*]

Arguments

Window_Index

This argument specifies the window index of the window to be made current. If this argument is not specified, a default of 0 is used.

If you set *Window_Index* equal to -1, IDL will try to locate an existing window to make current, ignoring any managed draw widgets that may exist. If there is no window to make current, WSET changes the value of the WINDOW field of the !D system variable to -1, indicating that there are no current windows.

If there are no existing IDL windows, and you call WSET without the *Window_Index* argument or with a *Window_Index* of 0, a new window with the index 0 is opened. Calling WSET with a *Window_Index* for a window that does not exist, except for window 0, results in a “Window is closed and unavailable” error message.

Keywords

None.

Examples

Create IDL windows 1 and 2 by entering:

```
WINDOW, 1 & WINDOW, 2
```

Set the current window to window 1 and display an image by entering:

```
WSET, 1 & TVSCL, DIST(100)
```

Set the current window to window 2 and display an image by entering:

```
WSET, 2 & TVSCL, DIST(100)
```

Version History

Introduced: Original

See Also

WDELETE, WINDOW, WSHOW

WSHOW

The WSHOW procedure exposes or hides the designated window.

Syntax

WSHOW [, *Window_Index* [, *Show*]] [, /ICONIC]

Arguments

Window_Index

The window index of the window to be hidden or exposed. If this argument is not specified, the current window is assumed. If this index is the window ID of a draw widget, the widget base associated with that drawable is brought to the front of the screen.

Show

Set *Show* to 0 to hide the window. Omit this argument or set it to 1 to expose the window.

Keywords

ICONIC

Set this keyword to iconify the window. Set ICONIC to 0 to de-iconify the window.

Under windowing systems, iconification is the task of the window manager, and client applications such as IDL have no direct control over it. The ICONIC keyword serves as a hint to the window manager, which is free to iconify the window or ignore the request as it sees fit.

Examples

To bring IDL window number 0 to the front, enter:

```
WSHOW, 0
```

Version History

Introduced: Original

WDELETE, WINDOW, WSET

WTN

The WTN function returns a multi-dimensional discrete wavelet transform of the input array A. The transform is based on a Daubechies wavelet filter.

WTN is based on the routine `wtn` described in section 13.10 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = WTN(*A*, *Coef* [, /COLUMN] [, /DOUBLE] [, /INVERSE] [, /OVERWRITE])

Return Value

Arguments

A

The input vector or array. The dimensions of *A* must all be powers of 2.

Coef

An integer that specifies the number of wavelet filter coefficients. The allowed values are 4, 12, or 20. When *Coef* is 4, the `daub4()` function (see *Numerical Recipes*, section 13.10) is used. When *Coef* is 12 or 20, `pwt()` is called, preceded by `pwtset()` (see *Numerical Recipes*, section 13.10).

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

INVERSE

If the INVERSE keyword is set, the inverse transform is computed. By default, WTN performs the forward wavelet transform.

OVERWRITE

Set the OVERWRITE keyword to perform the transform “in place.” The result overwrites the original contents of the array.

Examples

This example demonstrates the use of IDL’s discrete wavelet transform and sparse array storage format to compress and store an 8-bit gray-scale digital image. First, an image selected from the `people.dat` data file is transformed into its wavelet representation and written to a separate data file using the WRITEU procedure.

Next, the transformed image is converted, using the SPRSIN function, to row-indexed sparse storage format retaining only elements with an absolute magnitude greater than or equal to a specified threshold. The sparse image is written to a data file using the WRITE_SPR procedure.

Finally, the transformed image is reconstructed from the storage file and displayed alongside the original.

```
; Begin by choosing the number of wavelet coefficients to use and a
; threshold value:
coeffs = 12 & thres = 10.0

; Open the people.dat data file, read an image using associated
; variables, and close the file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
images = assoc(1, bytarr(192, 192))
image_1 = images[0]
close, 1

; Expand the image to the nearest power of two using cubic
; convolution, and transform the image into its wavelet
; representation using the WTN function:
pwr = 256
image_1 = CONGRID(image_1, pwr, pwr, /CUBIC)
wtn_image = WTN(image_1, coeffs)

; Write the image to a file using the WRITEU procedure and check
; the size of the file (in bytes) using the FSTAT function:
OPENW, 1, 'original.dat'
WRITEU, 1, wtn_image
```

```
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the file is ', status.size, ' bytes.'

; Now, we convert the wavelet representation of the image to a
; row-indexed sparse storage format using the SPRSIN function,
; write the data to a file using the WRITE_SPR procedure, and check
; the size of the "compressed" file:
sprs_image = SPRSIN(wtn_image, THRES = thres)
WRITE_SPR, sprs_image, 'sparse.dat'
OPENR, 1, 'sparse.dat'
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the compressed file is ', status.size, ' bytes.'

; Determine the number of elements (as a percentage of total
; elements) whose absolute magnitude is less than the specified
; threshold. These elements are not retained in the row-indexed
; sparse storage format:
PRINT, 'Percentage of elements under threshold: ',$
   100.*N_ELEMENTS(WHERE(ABS(wtn_image) LT thres, $
   count)) / N_ELEMENTS(image_1)

; Next, read the row-indexed sparse data back from the file
; sparse.dat using the READ_SPR function and reconstruct the
; image from the non-zero data using the FULSTR function:
sprs_image = READ_SPR('sparse.dat')
wtn_image = FULSTR(sprs_image)

; Apply the inverse wavelet transform to the image:
image_2 = WTN(wtn_image, COEFFS, /INVERSE)

; Calculate and print the amount of data used in reconstruction of
; the image:
PRINT, 'The image on the right is reconstructed from:', $
   100.0 - (100.* count/N_ELEMENTS(image_1)),$
   '% of original image data.'

; Finally, display the original and reconstructed images side by
; side:
WINDOW, 1, XSIZE = pwr*2, YSIZE = pwr, $
   TITLE = 'Wavelet Image Compression and File I/O'
TV, image_1, 0, 0
TV, image_2, pwr - 1, 0
```

IDL Output

```
Size of the file is   262144 bytes.
Size of the compressed file is   69600 bytes.
```

```
Percentage of elements under threshold:   87.0331
The image on the right is reconstructed from: 12.9669% of original
image data.
```

The sparse array contains only 13% of the elements contained in the original array. The following figure is created from this example. The image on the left is the original 256 by 256 image. The image on the right was compressed by the above process and was reconstructed from 13% of the original data. The size of the compressed image's data file is 26.6% of the size of the original image's data file. Note that due to limitations in the printing process, differences between the images may not be as evident as they would be on a high-resolution printer or monitor.

Figure 34: Original image (left) and image reconstructed from 13% of the data (right).

FFT

XBM_EDIT

The XBM_EDIT procedure is a utility for creating and editing icons for use with IDL widgets as bitmap labels for widget buttons.

The icons created with XBM_EDIT can be saved in two different file formats. IDL "array definition files" are text files that can be inserted into IDL programs. "Bitmap array files" are data files that can be read into IDL programs. Bitmap array files should be used temporarily until the final icon design is determined and then they can be saved as IDL array definitions for inclusion in the final widget code. This routine does not check the file types of the files being read and assumes that they are of the correct size and type for reading. XBM_EDIT maintains its state in a common block so it is restricted to one working copy at a time.

This routine is written in the IDL language. Its source code can be found in the file `xbm_edit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XBM_EDIT [, /BLOCK] [, FILENAME=*string*] [, GROUP=*widget_id*] [, XSIZE=*pixels*] [, YSIZE=*pixels*]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XBM_EDIT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

FILENAME

Set this keyword to a scalar string that contains the filename to be used for the new icon. If this argument is not specified, the name “idl.bm” is used. The filename can be changed in XBM_EDIT by editing the “Filename” field before selecting a file option.

GROUP

The widget ID of the widget that calls XBM_EDIT. When this ID is specified, the death of the caller results in the death of XBM_EDIT.

XSIZE

The number of pixels across the bitmap is in the horizontal direction. The default value is 16 pixels.

YSIZE

The number of pixels across the bitmap is in the vertical direction. The default value is 16 pixels.

Version History

Introduced: Pre 4.0

WIDGET_BUTTON

XDISPLAYFILE

The XDISPLAYFILE procedure is a utility for displaying ASCII text files using a widget interface.

This routine is written in the IDL language. Its source code can be found in the file `xdisplayfile.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XDISPLAYFILE, *Filename* [, /BLOCK] [, DONE_BUTTON=*string*]
[, /EDITABLE] [, FONT=*string*] [, GROUP=*widget_id*] [, HEIGHT=*lines*]
[, /MODAL] [, TEXT=*string or string array*] [, TITLE=*string*]
[, WIDTH=*characters*] [, WTEXT=*variable*]

Arguments

Filename

A scalar string that contains the filename of the file to display. *Filename* can include a path to that file.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XDISPLAYFILE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

DONE_BUTTON

Set this keyword to a string containing the text to use for the Done button label. If omitted, the text “Done with <filename>” is used.

EDITABLE

Set this keyword to allow modifications to the text displayed in XDISPLAYFILE. Setting this keyword also adds a “Save” button in addition to the Done button.

FONT

A string containing the name of the font to use. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3940 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

GROUP

The widget ID of the widget that calls XDISPLAYFILE. If this keyword is specified, the death of the group leader results in the death of XDISPLAYFILE.

HEIGHT

The number of text lines that the widget should display at one time. If this keyword is not specified, 24 lines is the default.

MODAL

Set this keyword to create the XDISPLAYFILE dialog as a modal dialog. Setting the MODAL keyword allows you to call XDISPLAYFILE from another modal dialog.

TEXT

A string or string array to be displayed in the widget instead of the contents of a file. If this keyword is present, the *Filename* input argument is ignored (but is still required). String arrays are displayed one element per line.

TITLE

A string to use as the widget title rather than the file name or “XDisplayFile”.

WIDTH

The width of the widget display in characters. If this keyword is not specified, 80 characters is the default.

WTEXT

Set this keyword to a named variable that will contain the widget ID of the text widget. This allows setting text selections and cursor positions programmatically. For example, the following code opens the XDISPLAYFILE widget and selects the first 10 characters of the file displayed in the text widget:

```
XDISPLAYFILE, 'myfile.txt', /EDITABLE, WTEXT=w
WIDGET_CONTROL, w, SET_TEXT_SELECT=[0, 10]
```

XDXF

The XDXF procedure is a utility for displaying and interactively manipulating DXF objects.

Using XDXF

XDXF displays a resizeable top-level base with a menu and draw widget used to display and manipulate the orientation of a DXF object.

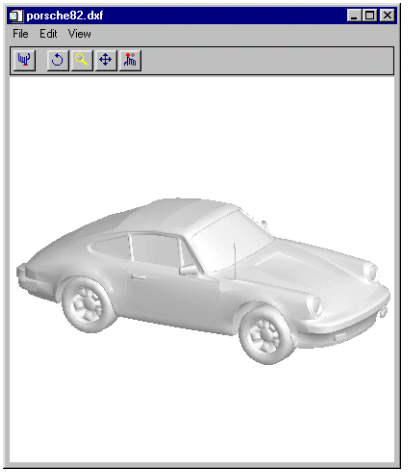

Figure 35: The XDXF Utility

XDXF also displays a dialog that contains block and layer information and allows the user to turn on and off the display of individual layers.

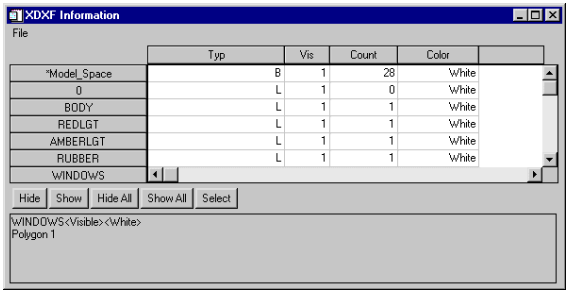

Figure 36: The XDXF Information Dialog

The XDXF Toolbar

The XDXF toolbar contains the following buttons:

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the object and drag to rotate.

Pan: Click the left mouse button on the object and drag to pan.

Zoom: Click the left mouse button on the object and drag to zoom in or out.

Select: Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

The XDXF Information Dialog

The XDXF Information dialog displays information about the blocks and layers contained in the currently displayed object, and allows you to turn on and off the display of each layer.

To show or hide layers in the DXF object, select the layer from the list of layers on the left of the dialog, and click the **Show** or **Hide** button. Alternatively, you can click in the “Vis” field for the desired layer. To show or hide all layers, click the **Show All** or **Hide All** buttons.

If the **View Block Outlines** checkbox is selected, a green box will be displayed around the currently selected block, if any.

Syntax

XDXF [, *Filename*] [, /BLOCK] [, GROUP=*widget_id*] [, SCALE=*value*] [, /TEST] [*keywords to XOBJVIEW*]

Arguments

Filename

A string specifying the name of the DXF file to display. If this argument is not specified, a file selection dialog is opened.

Keywords

XDXF accepts the keywords to XOBJVIEW. (Note, however, that specifying the XOBJVIEW keyword MODAL is interpreted by XDXF as a call to the BLOCK keyword.) In addition, XDXF supports the following keywords:

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XDXF block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XDXF. When this ID is specified, the death of the caller results in the death of XDXF.

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XDXF window, regardless of the object's orientation.

TEST

If this keyword is set, the file `heart.dxf` in the IDL distribution is automatically opened in XDXF.

Examples

Display the file `heart.dxf`, contained in the IDL distribution:

```
XDXF, FILEPATH('heart.dxf', $
   SUBDIR=['examples', 'data'])
```

Version History

Introduced: 5.4

IDLffDXF

XFONT

The XFONT function is a utility that creates a modal widget for selecting and viewing an X Windows font.

Calling XFONT resets the current X Windows font.

Note

This routine is only available on UNIX platforms.

This routine is written in the IDL language. Its source code can be found in the file `xfont.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

Result = XFONT([, GROUP=*widget_id*] [, /PRESERVE_FONT_INFO])

Return Value

The function returns a string containing the name of the last selected font. If no font is selected, or the “Cancel” button is clicked, a null string is returned.

Arguments

None.

Keywords

GROUP

The widget ID of the widget that calls XFONT. When this ID is specified, the death of the caller results in the death of XFONT.

PRESERVE_FONT_INFO

Set this keyword to make XFONT save the server font directory in common blocks so that subsequent calls to XFONT start-up much faster. If this keyword is not set, the common block is cleaned.

EFONT, SHOWFONT

XINTERANIMATE

The XINTERANIMATE procedure is a utility for displaying an animated sequence of images using off-screen pixmaps or memory buffers. The speed and direction of the display can be adjusted using the widget interface.

MPEG animation files can be created either programmatically using keywords to open and save a file, or interactively using the widget interface. Note that the MPEG standard does not allow movies with odd numbers of pixels to be created.

Note

MPEG support in IDL requires a special license. For more information, contact your Research Systems sales representative or technical support.

Note

Only a single copy of XINTERANIMATE can run at a time. If you need to run multiple instances of the animation widget concurrently, use the CW_ANIMATE compound widget.

This routine is written in the IDL language. Its source code can be found in the file `xinteranimate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XINTERANIMATE

Displaying an animated series of images using XINTERANIMATE requires at least three calls to the routine: one to initialize the animation widget, one to load images, and one to display the images. When initialized using the SET keyword, XINTERANIMATE creates an approximately square pixmap or memory buffer, large enough to contain the requested number of frames of the requested size. Images are loaded using the IMAGE and FRAME keywords. Finally, images are displayed by copying them from the pixmap or memory buffer to the visible draw widget.

See CW_ANIMATE for a description of the widget interface controls used by XINTERANIMATE.

Syntax

XINTERANIMATE [, *Rate*]

Keywords for initialization: [, SET=*[sizex, sizey, nframes]*] [, /BLOCK] [, /CYCLE] [, GROUP=*widget_id*] [, /MODAL] [, MPEG_BITRATE=*value*] [, MPEG_IFRAME_GAP=*integer value*] [, MPEG_MOTION_VEC_LENGTH={1 | 2 | 3}] [, /MPEG_OPEN, MPEG_FILENAME=*string*] [MPEG_QUALITY=*value*{0 to 100}] [, /SHOWLOAD] [, /TRACK] [, TITLE=*string*]

Keywords for loading images: [, FRAME=*value*{0 to (*nframes*-1)}[, IMAGE=*value*]] [, /ORDER] [, WINDOW=*[window_num* [, *x0*, *y0*, *sx*, *sy*]*]*]

Keywords for running animations: [, /CLOSE] [, /KEEP_PIXMAPS] [, /MPEG_CLOSE] [, XOFFSET=*pixels*] [, YOFFSET=*pixels*]

Arguments

Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation is with a value of 100 and the slowest is with a value of 0. The default animation rate is 100. The animation must be initialized using the SET keyword before calling XINTERANIMATE with a rate value.

Keywords: Initialization

The following keywords are used to initialize the animation display. The SET keyword *must* be provided. Other keywords described in this section are optional; note that they work only when SET is specified.

SET

Set this keyword to a three-element vector [*Sizex*, *Sizey*, *Nframes*] to initialize XINTERANIMATE. *Sizex* and *Sizey* represent the width and height of the images to be displayed, in pixels. *Nframes* is the number of frames in the animation sequence. Note that *Nframes* must be at least 2 frames.

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active

command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XINTERANIMATE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

CYCLE

Normally, frames are displayed going either forward or backwards. If the CYCLE keyword is set, the animation reverses direction after the last frame in either direction is displayed.

GROUP

Set this keyword to the widget ID of the widget that calls XINTERANIMATE. When GROUP is specified, the death of the calling widget results in the death of XINTERANIMATE.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XINTERANIMATE. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XINTERANIMATE does not block event processing.

MPEG_BITRATE

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 149: BITRATE Value Range

If you do not set this keyword, IDL computes the MPEG_BITRATE value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_BITRATE keyword if changing the MPEG_QUALITY keyword value does not produce the desired results. It is highly recommended to set the MPEG_BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

MPEG_FILENAME

Set this keyword equal to a string specifying the name of the MPEG file. If no file name is specified, the default value (`idl.mpg`) is used.

MPEG_IFRAME_GAP

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the MPEG_IFRAME_GAP value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_IFRAME_GAP keyword if changing the MPEG_QUALITY keyword value does not produce the desired results.

MPEG_MOTION_VEC_LENGTH

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

- 1 = Small motion vectors.
- 2 = Medium motion vectors.
- 3 = Large motion vectors.

If you do not set this keyword, IDL computes the MPEG_MOTION_VEC_LENGTH value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_MOTION_VEC_LENGTH keyword if changing the MPEG_QUALITY value does not produce the desired results.

MPEG_OPEN

Set this keyword to open an MPEG file.

MPEG_QUALITY

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting QUALITY to its highest setting.

SHOWLOAD

Set this keyword to display each frame and update the frame slider as frames are loaded.

TRACK

Set this keyword to cause the frame slider to track the current frame when the animation is in progress. The default is not to track.

TITLE

Use this keyword to specify a string to be used as the title of the animation widget. If TITLE is not specified, the title is set to "XInterAnimate."

Keywords: Loading Images

The following keywords are used to load images into the animation display. They have no effect when initializing or running animations.

FRAME

Use this keyword to specify the frame number when loading frames. FRAME must be set to a number in the range 0 to *Nframes*-1.

IMAGE

Use this keyword to specify a single image to be loaded at the animation position specified by the FRAME keyword. (FRAME *must* also be specified.)

ORDER

Set this keyword to display images from the top down instead of the default bottom up.

WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap or memory buffer. (When using some windowing systems, using this keyword is much faster than reading from the display and then calling XINTERANIMATE with a 2-D array.)

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

Keywords: Running Animations

The following keywords are used when running the animation. They have no effect when initializing the animation or loading images.

CLOSE

Set this keyword to delete the offscreen pixmaps or buffers and the animation widget itself. This also takes place automatically when the user presses the “Done With Animation” button or closes the window with the window manager.

KEEP_PIXMAPS

If this keyword is set, XINTERANIMATE will not destroy the animation pixmaps or buffers when it is killed. Calling XINTERANIMATE again without going through the SET and LOAD steps will play the same animation without the overhead of creating the pixmaps.

MPEG_CLOSE

Set this keyword to close and save the MPEG file. This keyword has no effect if MPEG_OPEN was not used during initialization.

XOFFSET

Use this keyword to specify the horizontal offset, in pixels from the left of the frame, of the image in the destination window.

YOFFSET

Use this keyword to specify the vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

Examples

Enter the following commands to open the file `ABNORM.DAT` (a series of images of a human heart) and animate the images it contains using XINTERANIMATE.

```
OPENR, unit, FILEPATH('abnorm.dat', SUBDIR=['examples','data']), $
   /GET_LUN
H = BYTARR(64, 64, 16)
READU, unit, H
CLOSE, unit

; Read the images into variable H:
H = REBIN(H, 128, 128, 16)

; Initialize XINTERANIMATE:
XINTERANIMATE, SET=[128, 128, 16], /SHOWLOAD

; Load the images into XINTERANIMATE:
FOR I=0,15 DO XINTERANIMATE, FRAME = I, IMAGE = H[*,*,I]

; Play the animation:
XINTERANIMATE, /KEEP_PIXMAPS
```

Note

Since the KEEP_PIXMAPS keyword was supplied, the same animation can be replayed (after the animation widget has been destroyed) with the single command `XINTERANIMATE.`

CW_ANIMATE

XLOADCT

The XLOADCT procedure is a utility that provides a graphical widget interface to the LOADCT procedure. XLOADCT displays the current colortable and shows a list of available predefined color tables. Clicking on the name of a color table causes that color table to be loaded in true color decomposed visual. Many other options, such as Gamma correction, stretching, and transfer functions can also be applied to the colortable.

This routine is written in the IDL language. Its source code can be found in the file `xloadct.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XLOADCT [, /BLOCK] [, BOTTOM=*value*] [, FILE=*string*] [, GROUP=*widget_id*] [, /MODAL] [, NCOLORS=*value*] [, /SILENT]
[, UPDATECALLBACK='*procedure_name*' [, UPDATECBDATA=*value*]]
[, /USE_CURENT]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XLOADCT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

BOTTOM

The first color index to use. XLOADCT will use color indices from BOTTOM to BOTTOM+NCOLORS-1. The default is BOTTOM=0.

FILE

Set this keyword to a string representing the name of the file to be used instead of the file `colors1.tbl` in the IDL directory.

GROUP

The widget ID of the widget that calls XLOADCT. When this ID is specified, a death of the caller results in a death of XLOADCT.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XLOADCT. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XLOADCT does not block event processing.

NCOLORS

The number of colors to use. Use color indices from 0 to the smaller of !D.TABLE_SIZE-1 and NCOLORS-1. The default is all available colors (!D.TABLE_SIZE).

SILENT

Normally, no informational message is printed when a color map is loaded. If this keyword is set to zero, the message is printed.

UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any.

If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

USE_CURRENT

Set this keyword to use the current color tables, regardless of the contents of the COLORS common block.

Version History

Introduced: Pre 4.0

LOADCT, XPALETTE, TVLCT

XMANAGER

The XMANAGER procedure provides the main event loop and management for widgets created using IDL. Calling XMANAGER "registers" a widget program with the XMANAGER event handler. XMANAGER takes control of event processing until all widgets have been destroyed.

Beginning with IDL version 5.0, IDL supports an *active command line* that allows the IDL command input line to continue accepting input while properly configured widget applications are running. See "A Note About Blocking in XMANAGER" on page 2314 for a more detailed explanation of the active command line.

This routine is written in the IDL language. Its source code can be found in the file `xmanager.pro` in the `lib` subdirectory of the IDL distribution.

Warning

Although this routine is written in the IDL language, it may change in the future in its internal implementation. For future upgradability, it is best not to modify or even worry about what this routine does internally.

Syntax

XMANAGER [, *Name*, *ID*] [, /CATCH] [, CLEANUP=*string*]
[, EVENT_HANDLER='*procedure_name*'] [, GROUP_LEADER=*widget_id*]
[, /JUST_REG] [, /NO_BLOCK]

Arguments

Name

A string that contains the name of the routine that creates the widget (i.e., the name of the widget creation routine that is calling XMANAGER).

Note

The *Name* argument is stored in a COMMON block for use by the XREGISTERED routine. The stored name is case-sensitive.

ID

The widget ID of the top-level base that is the root of the widget hierarchy being to be managed.

Keywords

BACKGROUND

This keyword is obsolete and is included in XMANAGER for compatibility with existing code only. Its functionality has been replaced by the TIMER keyword to the WIDGET_CONTROL procedure.

CATCH

Set this keyword to cause XMANAGER to catch any errors, using the CATCH procedure, when dispatching widget events. If the CATCH keyword is set equal to zero, execution halts and IDL provides traceback information when an error is detected. This keyword is set by default (errors are caught and processing continues).

Do not specify either the *Name* or *ID* argument to XMANAGER when specifying the CATCH keyword (they are ignored). CATCH turns error catching on and off for *all* applications managed by XMANAGER. When CATCH is specified, XMANAGER changes its error-catching behavior and returns immediately, without taking any other action.

Note

Beginning with IDL version 5.0, the default behavior of XMANAGER is to catch errors and continue processing events. In versions of IDL prior to version 5.0, XMANAGER halted when an error was detected. This change in default behavior was necessary in order to allow multiple widget applications (all being managed by XMANAGER) to coexist peacefully. When CATCH is set equal to zero, (the old behavior), any error halts XMANAGER, and thus halts event processing for all running widget applications.

Note also that CATCH is only effective if XMANAGER is blocking to dispatch errors. If event dispatching for an active IDL command line is in use, the CATCH keyword has no effect.

The CATCH=0 setting (errors are not caught and processing halts in XMANAGER when an error is detected) is intended as a debugging aid. Finished programs should not set CATCH=0.

CLEANUP

Set this keyword to a string that contains the name of the routine to be called when the widget program dies. If this keyword is not specified, the routine (if any)

specified for the program's top-level base by the KILL_NOTIFY keyword to WIDGET_BASE or WIDGET_CONTROL is used.

The routine specified by CLEANUP becomes the KILL_NOTIFY routine for the widget application, overriding any cleanup routines that have been set previously via the KILL_NOTIFY keyword to WIDGET_BASE or WIDGET_CONTROL.

Note

Specifying a routine for the widget application's top-level base via the KILL_NOTIFY keyword to WIDGET_CONTROL *after* the call to XMANAGER will override the value of the CLEANUP keyword.

The cleanup routine is called with the widget identifier as its only argument.

EVENT_HANDLER

Set this keyword to a string that contains the name of a routine to be called when a widget event occurs in the widget program being registered. If this keyword is not supplied, XMANAGER will construct a default name by adding the "_event" suffix to the *Name* argument. See the example below for a more detailed explanation.

GROUP_LEADER

The widget ID of the group leader for the widget being processed. When the leader dies either by the users actions or some other routine, all widgets that have that leader will also die.

For example, a widget that views a help file for a demo widget would have that demo widget as its leader. When the help widget is registered, it sets the keyword GROUP_LEADER to the widget ID of the demo widget. If the demo widget were destroyed, the help widget led by it would be killed by the XMANAGER.

JUST_REG

Set this keyword to indicate that XMANAGER should just register the widget and return immediately. This keyword is useful if you want to register a group of related top-level widgets before beginning event processing and one or more of the registered widgets requests that XMANAGER block event processing. (Note that in this case a later call to XMANAGER without the JUST_REG keyword is necessary to begin blocking.)

(See "A Note About Blocking in XMANAGER" on page 2314 for further discussion of the active command line.)

Warning

JUST_REG is not the same as NO_BLOCK. See “JUST_REG vs. NO_BLOCK” on page 2314 for additional details.

NO_BLOCK

Set this keyword to tell XMANAGER that the registering client does not require XMANAGER to block if active command line event processing is available. If active command line event processing is available *and* every current XMANAGER client specifies NO_BLOCK, then XMANAGER will not block and the user will have access to the command line while widget applications are running.

Note

NO_BLOCK is ignored by IDL Runtime. If a main procedure uses XMANAGER with the NO_BLOCK keyword set, IDL Runtime defers subsequent processing of the commands following the XMANAGER call until the widget associated with the call to XMANAGER is destroyed.

It is important to understand the result of making nested calls to XMANAGER. XMANAGER can only block event processing for one client at a time. In applications involving multiple calls to XMANAGER (either directly or via calls to other routines that call XMANAGER, such as XLOADCT), blocking occurs only for the outermost call to XMANAGER, unless XMANAGER is told not to block in that call. If an application contains two calls to XMANAGER, the second call cannot block unless the first call sets the NO_BLOCK keyword. If an application contains a call to XMANAGER, followed by a call to XLOADCT, XLOADCT will not block unless the NO_BLOCK keyword was set in the call to XMANAGER (and the BLOCK keyword to XLOADCT is set). Consider the following example:

```
PRO blocking_example_event, event
   ; The following call blocks only if the NO_BLOCK keyword to
   ; XMANAGER is set:
   XLOADCT, /BLOCK
END

PRO blocking_example
   base=WIDGET_BASE(/COLUMN)
   button1=WIDGET_BUTTON(base,VALUE='Run XLOADCT')
   WIDGET_CONTROL,base, /REALIZE
   XMANAGER,'blocking_example', base, /NO_BLOCK
END
```

If the NO_BLOCK keyword to XMANAGER was not set in the above example, XLOADCT would not block, even though the BLOCK keyword was set. Setting the

NO_BLOCK keyword to XMANAGER prevents XMANAGER from blocking, thereby allowing the subsequent call to XMANAGER (via XLOADCT) to block.

Warning

NO_BLOCK is not the same as JUST_REG. See "JUST_REG vs. NO_BLOCK" on page 2314 for additional details.

A Note About Blocking in XMANAGER

By default, IDL widget application blocking is *enabled*. Unless you take the appropriate steps, widget applications will block all other processing from occurring in IDL. Keeping the following issues in mind when writing widget applications will give you the best chance to create applications that coexist with other applications and the IDL command line.

Active Command Line

Beginning with IDL version 5.0, most versions of IDL's command-processing front-end are able to support an *active command line* while running properly constructed widget applications. What this means is that—provided the widget application is properly configured—the IDL command input line is available for input while a widget application is running and widget events are being processed.

There are currently 3 separate IDL command-processing front-end implementations:

- Microsoft Windows IDLDE
- Motif IDLDE (UNIX)
- UNIX plain tty

Note that widget applications must be well-behaved with respect to blocking widget event processing. Since in most cases XMANAGER is used to handle widget event processing, this means that in order for the command line to remain active, all widget applications must be run with the NO_BLOCK keyword to XMANAGER set. (Note that since NO_BLOCK is *not* the default, it is quite likely that some application will block.) If a single application runs in blocking mode, the command line will be inaccessible until the blocking application exits. When a blocking application exits, the IDL command line will once again become active.

JUST_REG vs. NO_BLOCK

Although their names imply a similar function, the JUST_REG and NO_BLOCK keywords perform very different services. It is important to understand what they do and how they differ.

The JUST_REG keyword tells XMANAGER that it should simply register a client and then return immediately. The result is that the client becomes known to XMANAGER, and that future calls to XMANAGER will take this client into account. Therefore, JUST_REG only controls how the registering call to XMANAGER should behave. The client can still be registered as requiring XMANAGER to block by setting NO_BLOCK=0. In this case, *future* calls to XMANAGER will block.

Note

JUST_REG is useful in situations where you suspect blocking might occur—if the active command line is not supported and you wish to keep it active before beginning event processing, if no command line is available (as with IDL Runtime applications), or if blocking will be requested at a later time. If no blocking will occur or if the blocking behavior is useful, it is not necessary to use JUST_REG.

The NO_BLOCK keyword tells XMANAGER that the registered client does not require XMANAGER to block if the command-processing front-end is able to support active command line event processing. XMANAGER remembers this attribute of the client until the client exits, even after the call to XMANAGER that registered the client returns. NO_BLOCK is just a “vote” on how XMANAGER should behave—the final decision is made by XMANAGER by considering the NO_BLOCK attributes of *all* of its current clients as well as the ability of the command-processing front-end in use to support the active command line.

Blocking vs. Non-blocking Applications

The issue of blocking in XMANAGER requires some explanation. IDL widget events are not processed until the WIDGET_EVENT function is called to handle them. Otherwise, they are queued by IDL indefinitely. Knowing how and when to call WIDGET_EVENT is the primary service provided by XMANAGER.

There are two ways blocking is typically handled:

1. The first call to XMANAGER processes events by calling WIDGET_EVENT as necessary until no managed widgets remain on the screen. This is referred to as “blocking” because XMANAGER does not return to the caller until it is done, and the IDL command line is not available.
2. XMANAGER does not block, and instead, the part of IDL that reads command input also watches for widget events and calls WIDGET_EVENT as necessary while also reading command input. This is referred to as “non-blocking” or “active command line” mode.

XMANAGER will block unless the following conditions are met:

- All registered widget applications have the NO_BLOCK keyword to XMANAGER set.
- No modal dialogs are displayed. (Modal dialogs always block until dismissed.)

In general, we suggest that new widget applications be written with XMANAGER blocking disabled (that is, with the NO_BLOCK keyword set), unless the widget application will be run on IDL Runtime.

Note

NO_BLOCK is ignored by IDL Runtime. If a main procedure uses XMANAGER with the NO_BLOCK keyword set, IDL Runtime defers subsequent processing of the commands following the XMANAGER call until the widget associated with the call to XMANAGER is destroyed.

Since a widget application that does block event processing for itself will block event processing for all other widget applications (and the IDL command line) as well, we suggest that older widget applications be upgraded to take advantage of the new, non-blocking behavior by adding the NO_BLOCK keyword to most calls to XMANAGER.

Examples

The following code creates a widget named EXAMPLE that is just a base widget with a “Done” button and registers it with the XMANAGER. Widgets being registered with the XMANAGER must provide at least two routines. The first routine creates the widget and registers it with the manager and the second routine processes the events that occur within that widget. An example widget is supplied below that uses only two routines. A number of other “Simple Widget Examples”, can be viewed by entering WEXMASTER at the IDL prompt. These simple programs demonstrate many aspects of widget programming.

The following lines of code would be saved in a single file, named `example.pro`:

```
; Begin the event handler routine for the EXAMPLE widget:
PRO example_event, ev

; The uservalue is retrieved from a widget when an event occurs:
WIDGET_CONTROL, ev.id, GET_UVALUE = uv

; If the event occurred in the Done button, kill the widget
; example:
if (uv eq 'DONE') THEN WIDGET_CONTROL, ev.top, /DESTROY
```

```
; End of the event handler part:
END

; This is the routine that creates the widget and registers it with
; the XMANAGER:
PRO example

; Create the top-level base for the widget:
base = WIDGET_BASE(TITLE='Example')

; Create the Done button and set its uservalue to "DONE":
done = WIDGET_BUTTON(base, VALUE = 'Done', UVALUE = 'DONE')
; Realize the widget (i.e., display it on screen):
WIDGET_CONTROL, base, /REALIZE

; Register the widget with the XMANAGER, leaving the IDL command
; line active:
XMANAGER, 'example', base, /NO_BLOCK

; End of the widget creation part:
END
```

First the event handler routine is listed. The handler routine has the same name as the main routine with the characters “_event” added. If you would like to use another event handler name, you would need to pass its name to XMANAGER using the EVENT_HANDLER keyword.

Notice that the event routine is listed before the main routine. If you include both the event routine and the main routine in a single `.pro` file with the name of the main routine (a common practice), this is necessary to ensure that the event routine is compiled. If the event routine were placed after the main routine in the file, IDL would compile and execute the main routine — and the compiler would exit — before the event routine was compiled. Alternatively, you can save your event routine in its own file with its own name (which in the above example would be `example_event.pro`), and IDL will compile the routine when it is required.

Notice also the NO_BLOCK keyword to XMANAGER has been included. This allows IDL to continue processing events and accepting input at the command prompt while the `example` widget application is running.

Version History

Introduced: Pre 4.0

XMTOOL, XREGISTERED, Chapter 25, “Creating Widget Applications” in the *Building IDL Applications* manual.

XMNG_TMPL

The XMNG_TMPL procedure is a template for widgets that use the XMANAGER. Use this template instead of writing your widget applications from “scratch”. This template can be found in the file `xmng_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

The documentation header should be altered to reflect the actual implementation of the XMNG_TMPL widget. Use a global search and replace to replace the word `XMNG_TMPL` with the name of the routine you would like to use. All the comments with a “`***`” in front of them should be read, decided upon and removed from the final copy of your new widget routine.

Syntax

XMNG_TMPL [, /BLOCK] [, GROUP=*widget_id*]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XMNG_TMPL block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XMNG_TMPL. When this ID is specified, the death of the caller results in the death of XMNG_TMPL.

Version History

Introduced: Pre 4.0

See Also

CW_TMPL

XMTOOL

The XMTOOL procedure displays a tool for viewing widgets currently being managed by the XMANAGER. Only one instance of the XMTOOL can run at one time.

This routine is written in the IDL language. Its source code can be found in the file `xmtool.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XMTOOL [, /BLOCK] [, GROUP=*widget_id*]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XMTOOL block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XMTOOL. If the calling widget is destroyed, the XMTOOL is also destroyed.

Version History

Introduced: Pre 4.0

XMANAGER

XOBJVIEW

The XOBJVIEW procedure is a utility used to quickly and easily view and manipulate IDL Object Graphics on screen. It displays given objects in an IDL widget with toolbar buttons and menus providing functionality for manipulating, printing, and exporting the resulting graphic. The mouse can be used to rotate, scale, or translate the overall model shown in a view, or to select graphic objects in a view.

This routine is written in the IDL language. Its source code can be found in the file `xobjview.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XOBJVIEW

XOBJVIEW displays a resizeable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

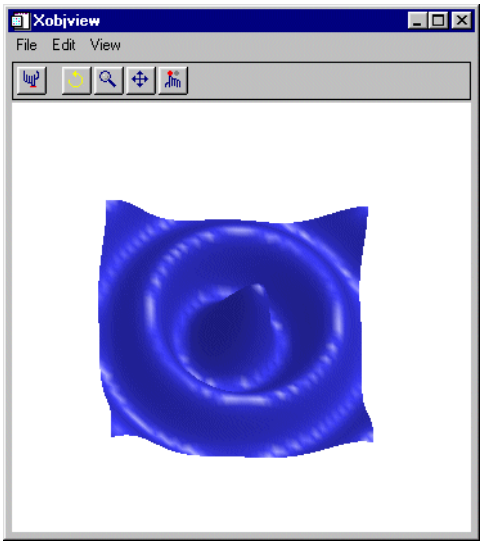

Figure 37: The XOBJVIEW widget

The XOBJVIEW Toolbar

The XOBJVIEW toolbar contains the following buttons:

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the object and drag to rotate.

Pan: Click the left mouse button on the object and drag to pan.

Zoom: Click the left mouse button on the object and drag to zoom in or out.

Select: Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Syntax

XOBJVIEW, *Obj* [, BACKGROUND=*[r, g, b]*] [, /BLOCK] [, /DOUBLE_VIEW] [, GROUP=*widget_id*] [, /JUST_REG] [, /MODAL] [, REFRESH=*widget_id*] [, RENDERER={0 | 1}] [, SCALE=*value*] [, STATIONARY=*objref(s)*] [, /TEST] [, TITLE=*string*] [, TLB=*variable*] [, XOFFSET=*value*] [, XSIZE=*pixels*] [, YOFFSET=*value*] [, YSIZE=*pixels*]

Arguments

Obj

A reference to an atomic graphics object, an IDLgrModel, or an array of such references. If *Obj* is an array, the array can contain a mixture of such references. Also, if *Obj* is an array, all object references in the array must be unique (i.e. no two references in the array can refer to the same object).

Obj is not destroyed when XOBJVIEW is quit or killed.

Keywords

BACKGROUND

Set this keyword to a three-element [r, g, b] color vector specifying the background color of the XOBJVIEW window.

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes

all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XOBJVIEW block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

DOUBLE_VIEW

Set this keyword to cause XOBJVIEW to set the DOUBLE property on the IDLgrView that it uses to display graphical data.

GROUP

The widget ID of the widget that calls XOBJVIEW. When this ID is specified, the death of the caller results in the death of XOBJVIEW.

JUST_REG

Set this keyword to indicate that the XOBJVIEW utility should just be registered and return immediately. This is useful if you want to register XOBJVIEW before beginning event processing and one or more widgets requests that XMANAGER block event processing.

Note

If your application will be distributed for use with an IDL Runtime license, and it allows users to control the contents of an XOBJVIEW window via a separate interface registered with XMANAGER, you must set the JUST_REG keyword. See “JUST_REG vs. NO_BLOCK” on page 2314 for additional details.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XOBJVIEW. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XOBJVIEW fabricates an invisible group leader for you.

Note

To be modal, XOBJVIEW does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures

were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See “Iconizing, Layering, and Destroying Groups of Top-Level Bases” on page 2044 for more information.)

To provide a simple means of invoking XOBJVIEW as a modal widget in applications that contain no other widgets, XOBJVIEW can be invoked as MODAL without specifying a group leader, in which case XOBJVIEW fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XOBJVIEW, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

REFRESH

Set this keyword to the widget ID of the XOBJVIEW instance to be refreshed. To retrieve the widget ID of an instance of XOBJVIEW, first call XOBJVIEW with the TLB keyword. To refresh that instance of XOBJVIEW, call XOBVIEW again and set REFRESH to the value retrieved by the TLB keyword in the earlier call to XOBJVIEW. For example, in the initial call to XOBJVIEW, use the TLB keyword as follows:

```
XOBJVIEW, myobj, TLB=tlb
```

If the properties of `myobj` are changed in your application or at the IDL command line, refresh the view in XOBJVIEW by calling XOBJVIEW again with the REFRESH keyword:

```
XOBJVIEW, REFRESH=tlb
```

For an example application demonstrating the use of the REFRESH keyword, see “Example 3” on page 2330.

Note

Currently, the REFRESH keyword can only be used to refresh the object itself. All other keywords and arguments to XOBJVIEW are ignored when REFRESH is specified, therefore, properties such as the background color and scale are not affected.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects in the XOBJVIEW draw window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of the XOBJVIEW draw window. See "IDLgrWindow" on page 3015 for details.

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XOBJVIEW window, regardless of the object's orientation.

STATIONARY

Set this keyword to a reference to an atomic graphics object, an IDLgrModel, or an array of such references. If this keyword is an array, the array can contain a mixture of such references. Also, if this keyword is an array, all object references in the array must be unique (i.e., no two references in the array can refer to the same object). Objects passed to XOBJVIEW via this keyword will not scale, rotate, or translate in response to mouse events. Default stationary objects are two lights. These two lights are replaced if one or more lights are supplied via this keyword. Objects specified via this keyword are not destroyed by XOBJVIEW when XOBJVIEW is quit or killed.

For example, to change the default lights used by XOBJVIEW, you could specify your own lights using the STATIONARY keyword as follows:

```
mylight1 = OBJ_NEW('IDLgrLight', TYPE=0, $
   COLOR=[255,0,0]) ; Ambient red
mylight2 = OBJ_NEW('IDLgrLight', TYPE=2, $
   COLOR=[255,0,0], LOCATION=[2,2,5]) ; Directional red

mymodel = OBJ_NEW('IDLgrModel')
mymodel -> Add, mylight1
mymodel -> Add, mylight2

XOBJVIEW, /TEST, STATIONARY=mymodel
```

TLB

Set this keyword to a named variable that upon return will contain the widget ID of the top level base.

TEST

If set, the *Obj* argument is not required (and is ignored if provided). A blue sinusoidal surface is displayed. This allows you to test code that uses XOBJVIEW without having to create an object to display.

TITLE

Set this keyword to the string that appears in the XOBJVIEW title bar.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

Set this keyword to the width of the drawable area in pixels. The default is 400.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the upper left corner of the parent widget.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

Set this keyword to the height of the drawable area in pixels. The default is 400.

Examples

Example 1

This example displays a simple IDLgrSurface object using XOBJVIEW:

```
oSurf = OBJ_NEW('IDLgrSURFACE', DIST(20))
XOBJVIEW, oSurf
```

Example 2

This example displays an IDLgrModel object consisting of two separate objects:

```
; Create contour object:
oCont = OBJ_NEW('IDLgrContour', DIST(20), N_LEVELS=10)

; Create surface object:
oSurf = OBJ_NEW('IDLgrSurface', $
   DIST(20),INDGEN(20)+20, INDGEN(20)+20)

; Create model object:
oModel = OBJ_NEW('IDLgrModel')

; Add contour and surface objects to model:
oModel->Add, oCont
oModel->Add, oSurf

; View model:
XOBJVIEW, oModel
```

This code results in the following view in the XOBJVIEW widget:

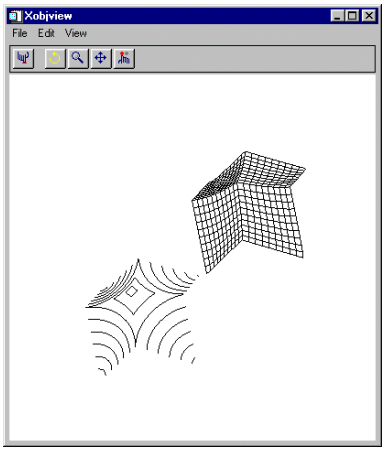

Figure 38: Using XOBJVIEW to view a model consisting of two objects

Note that when you click the Select button, and then click on an object, the class of that object appears next to the Select button. If the selected object has a non-null NAME property associated with it, that string value will be displayed, otherwise the name of the selected object's class will be displayed.

If you want the class of the model to appear when you click over any object in the model, you can set the SELECT_TARGET property of the model as follows:

```
oModel->SetProperty, /SELECT_TARGET
```

Also note that it is not necessary to create a model to view more than one object using XOBJVIEW. We could view the oCont and oSurf objects created in the above example by placing them in an array as follows:

```
XOBJVIEW, [oCont, oSurf]
```

Example 3

This example demonstrates how the REFRESH keyword can be used to refresh the object displayed in an instance of XOBJVIEW.

```
PRO xobjview_refresh_event, event
   WIDGET_CONTROL, event.id, GET_UVALUE=uval
   WIDGET_CONTROL, event.top, GET_UVALUE=state
```

```
   CASE uval OF
      'red': BEGIN
          WIDGET_CONTROL, event.id, GET_VALUE=val
          state.myobj -> GetProperty, COLOR=c
          state.myobj -> SetProperty, COLOR=[val,c[1],c[2]]
          XOBJVIEW, REFRESH=state.tlb
          END
      'green':  BEGIN
          WIDGET_CONTROL, event.id, GET_VALUE=val
          state.myobj -> GetProperty, COLOR=c
          state.myobj -> SetProperty, COLOR=[c[0],val,c[2]]
          XOBJVIEW, REFRESH=state.tlb
          END
      'blue': BEGIN
          WIDGET_CONTROL, event.id, GET_VALUE=val
          state.myobj -> GetProperty, COLOR=c
          state.myobj -> SetProperty, COLOR=[c[0],c[1],val]
          XOBJVIEW, REFRESH=state.tlb
          END
   ENDCASE
END

PRO xobjview_refresh_cleanup, wID
   WIDGET_CONTROL, wID, GET_UVALUE=state
   OBJ_DESTROY, state.myobj
END

PRO xobjview_refresh
   base = WIDGET_BASE(/COLUMN, TITLE='Adjust Object Color', $
      XOFFSET=420, XSIZE=200)

   myobj = OBJ_NEW('IDLgrSurface', $
      BESELJ(SHIFT(DIST(40), 20, 20) / 2,0) * 20, $
      COLOR=[255, 60, 60], STYLE=2, SHADING=1)
   XOBJVIEW, myobj, TLB=tlb, GROUP=base, BACKGROUND=[0,0,0]

   red = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, TITLE='Red', $
      UVALUE='red', VALUE=255)
   green = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
      TITLE='Green', UVALUE='green', VALUE=60)
   blue = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
      TITLE='Blue', UVALUE='blue', VALUE=60)

   WIDGET_CONTROL, base, /REALIZE

   state = {myobj:myobj, tlb:tlb}
   WIDGET_CONTROL, base, SET_UVALUE=state
```

```
    XMANAGER, 'xobjview_refresh', base, /NO_BLOCK, $
      CLEANUP='xobjview_refresh_cleanup'
END
```

XOBJVIEW_ROTATE, XOBJVIEW_WRITE_IMAGE

XOBJVIEW_ROTATE

The XOBJVIEW_ROTATE procedure is used to programmatically rotate the object currently displayed in XOBJVIEW. XOBJVIEW must be called prior to calling XOBJVIEW_ROTATE. This procedure can be used to create animations of object displays.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XOBJVIEW_ROTATE, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A 3-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

Angle

The amount of rotation, measured in degrees.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Examples

The following example creates an animation of the test object (a surface) currently displayed in XOBJVIEW. It does this by rotating the surface through 360 degrees in increments of 10 degrees using XOBJVIEW_ROTATE, and writing the display image to a BMP file for each increment using XOBJVIEW_WRITE_IMAGE.

```
PRO RotateAndWriteObject

XOBJVIEW, /TEST
FOR i = 0, 359 DO BEGIN
   XOBJVIEW_ROTATE, [0, 1, 0], 1, /PREMULTIPLY;
   XOBJVIEW_WRITE_IMAGE, 'img' + $
   STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
ENDFOR

END
```

Version History

Introduced: 5.5

XOBJVIEW, XOBJVIEW_WRITE_IMAGE

XOBJVIEW_WRITE_IMAGE

The XOBJVIEW_WRITE_IMAGE procedure is used to write the object currently displayed in XOBJVIEW to an image file with the specified name and file format. XOBJVIEW must be called prior to calling XOBJVIEW_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XOBJVIEW_WRITE_IMAGE, *Filename*, *Format* [, DIMENSIONS=*[x, y]*]

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. See WRITE_IMAGE for a list of supported formats.

Keywords

DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XOBJVIEW draw widget.

Examples

See XOBJVIEW_ROTATE.

Version History

Introduced: 5.5

See Also

XOBJVIEW, XOBJVIEW_ROTATE

XPALETTE

The XPALETTE procedure is a utility that displays a widget interface that allows interactive creation and modification of colortables using the RGB, CMY, HSV, or HLS color systems. Single colors can be defined or multiple color indices between two endpoints can be interpolated.

This routine is written in the IDL language. Its source code can be found in the file `xpalette.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using the XPALETTE Interface

Calling XPALETTE causes a graphical interface to appear. The elements of this interface are described below.

Plots on Left Side of Interface

Three plots show the current red, green, and blue vectors.

Status Region

The center of the XPALETTE widget is a status region containing:

- The total number of colors.
- The current color index. XPALETTE allows changing one color at a time. This color is known as the “current color” and is indicated in the color spectrum display with a special marker.
- The current mark index. The mark is used to remember a color index. Click the “Set Mark Button” to make the current color index the mark index.
- A sample of the current color. The special marker used in the color spectrum display prevents the user from seeing the color of the current index, but it is visible here.

Control Panel

A panel of 8 buttons control common XPALETTE functions:

- **Done:** Click this button to exit XPALETTE. The new color tables are saved in the COLORS common block and loaded to the display.
- **Predefined:** Click this button to start XLOADCT, allowing selection of one of the predefined color tables. Note that when you change the color map via XLOADCT, XPALETTE is not always able to keep its display accurate. This problem can be overcome by pressing the XPALETTE “Redraw” button after changing the colortable via XLOADCT.

- **Help:** Click this button to display help information.
- **Redraw:** Click this button to redraws the display using the current state of the color map.
- **Set Mark:** Click this button to set the value of the mark index to the current color index.
- **Switch Mark:** Click this button to exchange the mark and the current index.
- **Copy Current:** Click this button to make every color lying between the current index and the mark index (inclusive) the same color as the current color.
- **Interpolate:** Click this button to smoothly interpolate colors between the current index and the mark index.

Color System Control

This section of the interface allows you to select the color system used to modify individual colors. The “Select Color System” pulldown menu lets you select from four different systems—RGB, CMY, HSV, and HLS. Depending upon the current system, 3 sliders below the pulldown menu allow you to alter the current color.

Right Side Color Spectrum Display

A display on the right side of the XPALETTE interface shows the current color map as a series of squares. Color index 0 is at the upper left. The color index increases monotonically by rows going left to right and top to bottom. The current color index is indicated by a special marker symbol. There are 4 ways to change the current color:

- Click on any square in the color map display.
- Use the “By Index” slider to move to the desired color index.
- Use the “Row” Slider to move the marker vertically.
- Use the “Column” Slider to move the marker horizontally.

A Note about the Colors Used in the Interface

XPALETTE uses two colors from the current color table as drawing foreground and background colors. These are used for the RGB plots on the left, and the current index marker on the right. This means that if the user set these two colors to the same value, the XPALETTE display could become unreadable (like writing on black paper with black ink). XPALETTE minimizes this possibility by noting changes to the color map and always using the brightest available color for the foreground color and the darkest for the background. Thus, the only way to make XPALETTE’s display

unreadable is to set the entire color map to a single color, which is highly unlikely. The only side effect of this policy is that you may notice XPALETTE redrawing the entire display after you've modified the current color. This simply means that the change has made XPALETTE pick new drawing colors.

Syntax

XPALETTE [, /BLOCK] [, GROUP=*widget_id*]
[, UPDATECALLBACK='*procedure_name*' [, UPDATECBDATA=*value*]]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XPALETTE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XPALETTE. When this ID is specified, a death of the caller results in a death of XPALETTE.

UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

Version History

Introduced: Pre 4.0

LOADCT, MODIFYCT, XLOADCT, TVLCT

XPCOLOR

The XPCOLOR procedure is a utility that allows you to adjust the value of the current plotting color (foreground) using sliders, and store the desired color in the global system variable, !P.COLOR.

When XPCOLOR is called from the IDL input command line, the **Set Plot Color** dialog box appears. The dialog has two buttons (**Done** and **Help**) a single color swatch window, three sliders, and a pulldown menu with the four color systems: red, green, blue (RGB); cyan, magenta, yellow (CMY); hue, saturation, value (HSV); and hue, lightness, and saturation (HLS).

When you have chosen the color system and adjusted the sliders to your liking, click **Done** to store the color selected in the !P.COLOR system variable. Any plots generated in IDL afterwards use the color selected as the plotting (foreground) color until !P.COLOR is changed again.

Note

For a more flexible color editor, use the XPALETTE User Library routine.

This routine is written in the IDL language. Its source code can be found in the file `xpcolor.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XPCOLOR [, GROUP=*widget_id*]

Arguments

None.

Keywords

GROUP

Set this keyword to the group leader widget ID as passed to XMANAGER.

Version History

Introduced: 4.0

XPLOT3D

The XPLOT3D procedure is a utility for creating and interactively manipulating 3-D plots.

This routine is written in the IDL language. Its source code can be found in the file `xplot3d.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XPLOT3D

XPLOT3D displays a resizeable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

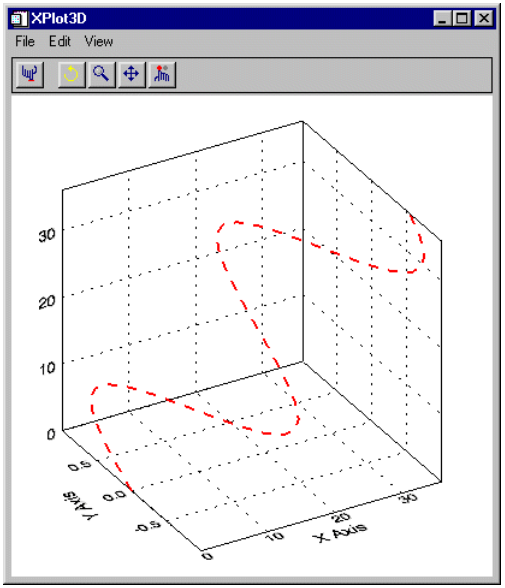

Figure 39: The XPLOT3D Utility

The XPLOT3D Toolbar

The XPLOT3D toolbar contains the following buttons:

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the plot and drag to rotate.

Zoom: Click the left mouse button on the plot and drag to zoom in or out.

Pan: Click the left mouse button on the plot and drag to pan.

Select: Click on a curve to display the curve name (if defined with the NAME keyword) on the XPLOT3D toolbar. If no name was defined for the curve, “IDLGRPOLYLINE” is displayed.

Projecting Data onto Plot “Walls”

To turn on or off the projection of data onto the walls of the box enclosing the 3-D plot, select **All On**, **All Off**, **XY**, **YZ**, or **XZ** from the **View** → **2D Projection** menu.

Changing the Axis Type

The **View** → **Axes** menu allows you to select one of the following types of axes:

- Simple Axes — displays the X, Y, and Z axes as lines.
- Box Axes — displays the X, Y, and Z axes as planes.
- No Axes — turns off the display of axes.

Syntax

XPLOT3D, *X*, *Y*, *Z* [, /BLOCK] [, COLOR=*[r,g,b]*] [, /DOUBLE_VIEW] [, GROUP=*widget_id*] [, LINESTYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}] [, /MODAL] [, NAME=*string*] [, /OVERPLOT] [, SYMBOL=*objref(s)*] [, /TEST] [, THICK=*points*{1.0 to 10.0}] [, TITLE=*string*] [, XRANGE=*[min, max]*] [, YRANGE=*[min, max]*] [, ZRANGE=*[min, max]*] [, XTITLE=*string*] [, YTITLE=*string*] [, ZTITLE=*string*]

Arguments

X

A vector of X data values.

Y

A vector of Y data values.

Z

A vector of Z data values.

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XPLOT3D block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

COLOR

Set this keyword to an [*r*, *g*, *b*] triplet specifying the color of the curve.

DOUBLE_VIEW

Set this keyword to cause XPLOT3D to set the DOUBLE property on the IDLgrView that it uses to display the plot.

GROUP

Set this keyword to the widget ID of the widget that calls XPLOT3D. When this keyword is specified, the death of the caller results in the death of XPLOT3D.

LINESTYLE

Set this keyword to a value indicating the line style that should be used to draw the curve. The value can be either an integer value specifying a pre-defined line style, or a 2-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE keyword to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where repeat indicates the number of times consecutive runs of 1s or 0s in the bitmask should be repeated. (That is, if three consecutive 0s appear in the bitmask and the value of repeat is 2, then the line that is drawn will have six consecutive bits turned off.) The value of repeat must be in the range 1 ≤ repeat ≤ 255.

The bitmask indicates which pixels are drawn and which are not along the length of the line. The bitmask is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

MODAL

Set this keyword to block processing of events from other widgets until the user quits XPLOT3D. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XPLOT3D fabricates an invisible group leader for you.

Note

To be modal, XPLOT3D does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See “Iconizing, Layering, and Destroying Groups of Top-Level Bases” on page 2044 for more information.)

To provide a simple means of invoking XPLOT3D as a modal widget in applications that contain no other widgets, XPLOT3D can be invoked as MODAL without specifying a group leader, in which case XPLOT3D fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XPLOT3D, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

NAME

Set this keyword to a string specifying the name for the data curve being plotted. The name is displayed on the XPLOT3D toolbar when the curve is selected with the

mouse. (To select the curve with the mouse, XPLOT3D must be in select mode. You can put XPLOT3D in select mode by clicking on the rightmost button on the XPLOT3D toolbar.)

OVERPLOT

Set this keyword to draw the curve in the most recently created view. The TITLE, [XYZ]TITLE, [XYZ]RANGE, and MODAL keywords are ignored if this keyword is set.

SYMBOL

Set this keyword to a vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

TEST

If set, the *X*, *Y*, and *Z* arguments are not required (and are ignored if provided). A sinusoidal curve is displayed instead. This allows you to test code that uses XPLOT3D without having to specify plot data.

THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

TITLE

Set this keyword to a string to appear in the XPLOT3D title bar.

XRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the X-axis range.

YRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Y-axis range.

ZRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Z-axis range.

XTITLE

Set this keyword to a string specifying the title for the X axis of the plot.

YTITLE

Set this keyword to a string specifying the title for the Y axis of the plot.

ZTITLE

Set this keyword to a string specifying the title for the Z axis of the plot.

Examples

The following example displays two curves in XPLOT3D, using a custom plotting symbol for one of the curves:

```
;Define plot data:
X = INDGEN(20)
Y1 = SIN(X/3.)
Y2 = COS(X/3.)
Z = X

;Display curve 1 in XPLOT3D:
XPLOT3D, X, Y1, Z, NAME='Curve1', THICK=2

;Define custom plotting symbols:
oOrb = OBJ_NEW('orb', COLOR=[0, 0, 255])
oOrb->Scale, .75, .1, .5
oSymbol = OBJ_NEW('IDLgrSymbol', oOrb)

;Overplot curve 2 in XPLOT3D:
XPLOT3D, X, Y2, Z, COLOR=[0,255,0], NAME='Curve2', $
   SYMBOL=oSymbol, THICK=2, /OVERPLOT
```

This code results in the following:

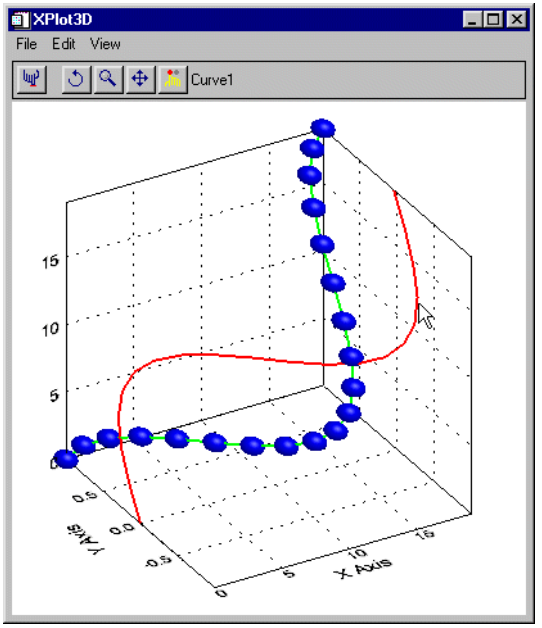

Figure 40: Two curves displayed in XPLOT3D

Version History

Introduced: 5.4

XREGISTERED

The XREGISTERED function returns the number of instances of the widget named as its argument that are currently registered with the XMANAGER. The registered widget is brought to the front of the desktop unless the NOSHOW keyword is set.

If the specified widget is not currently registered with XMANAGER, XREGISTERED returns zero.

This routine is written in the IDL language. Its source code can be found in the file `xregistered.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = XREGISTERED(*Name* [, /NOSHOW])

Arguments

Name

A string containing the name of the widget in question.

Note

XREGISTERED checks for *Name* in a COMMON block created by XMANAGER. The stored name is case-sensitive.

Keywords

NOSHOW

If the widget in question is registered, it is brought to the front of all the other windows by default. Set this keyword to keep the widget from being brought to the front.

Examples

Suppose that you have a widget program that registers itself with the XMANAGER with the command:

```
XMANAGER, 'mywidget', base
```

You could limit this widget to one instantiation by adding the following line as the first line (after the procedure definition statement) of the widget creation routine:

```
IF ( XREGISTERED('mywidget') NE 0 ) THEN RETURN
```

Version History

Introduced: Pre 4.0

See Also

XMANAGER

XROI

The XROI procedure is a utility for interactively defining regions of interest (ROIs), and obtaining geometry and statistical data about these ROIs.

This routine is written in the IDL language. Its source code can be found in the file `xroi.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Note

See "Using XROI" on page 2357, for detailed information describing importing images, modifying image and ROI colors, retrieving ROI information and growing regions.

Syntax

XROI [, *ImageData*] [, *R*] [, *G*] [, *B*] [, /BLOCK]
[[, /FLOATING] , GROUP=*widget_ID*] [, /MODAL] [, REGIONS_IN=*value*]
[, REGIONS_OUT=*value*] [, REJECTED=*variable*] [, RENDERER={0 | 1}]
[, ROI_COLOR=*[r, g, b] or variable*] [, ROI_GEOMETRY=*variable*]
[, ROI_SELECT_COLOR=*[r, g, b] or variable*] [, STATISTICS=*variable*]
[, TITLE=*string*] [, TOOLS=*string/string array* {valid values are 'Translate-Scale', 'Rectangle', 'Ellipse', 'Freehand Draw', 'Polygon Draw', and 'Selection'}]
[, X_SCROLL_SIZE=*value*] [, Y_SCROLL_SIZE=*value*]

Arguments

ImageData

ImageData is both an input and output argument. It is an array representing an 8-bit or 24-bit image to be displayed. *ImageData* can be any of the following:

- [*m*, *n*] — 8-bit image
- [3, *m*, *n*] — 24-bit image
- [*m*, 3, *n*] — 24-bit image
- [*m*, *n*, 3] — 24-bit image

If *ImageData* is not supplied, the user will be prompted for a file via DIALOG_PICKFILE. On output, *ImageData* will be set to the current image data. (The current image data can be different than the input image data if the user imported an image via the **File** → **Import Image** menu item.)

R, G, B

R, *G*, and *B* are arrays of bytes representing red, green, or blue color table values, respectively. *R*, *G*, and *B* are both input and output arguments. On input, these values are applied to the image if the image is 8-bit. To get the red, green, or blue color table values for the image on output from XROI, specify a named variable for the appropriate argument. (If the image is 24-bit, this argument will output a 256-element byte array containing the values given at input, or BINDGEN(256) if the argument was undefined on input.)

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XROI block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

FLOATING

Set this keyword, along with the GROUP keyword, to create a floating top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

Note

Floating widgets must have a group leader. Setting this keyword without also setting the GROUP keyword causes an error.

GROUP

Set this keyword to the widget ID of the widget that calls XROI. When this keyword is specified, the death of the caller results in the death of XROI.

MODAL

Set this keyword to block other IDL widgets from receiving events while XROI is active.

REGIONS_IN

Set this keyword to an array of IDLgrROI references. This allows you to open XROI with previously defined regions of interest (see Example 3). This is also useful when using a loop to open multiple images in XROI. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see Example 2). This keyword also accepts –1, or OBJ_NEW() (Null object) to indicate that there are no ROIs to read in. This allows you to assign the result of a previous REGIONS_OUT to REGIONS_IN without worrying about the case where the previous REGIONS_OUT is undefined.

REGIONS_OUT

Set this keyword to a named variable that will contain an array of IDLgrROI references. This keyword is assigned the null object reference if there are no ROIs defined. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see Example 2).

Note

This keyword must be used in conjunction with the BLOCK keyword.

REJECTED

Set this keyword to a named variable that will contain those REGIONS_IN that are not in REGIONS_OUT. The objects defined in the variable specified for REJECTED can be destroyed with a call to OBJ_DESTROY, allowing you to perform cleanup on objects that are not required (see Example 2). This keyword is assigned the null object reference if no REGIONS_IN are rejected by the user.

Note

This keyword must be used in conjunction with the BLOCK keyword.

RENDERER

Set this keyword to an integer value to indicate which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation (the default)

ROI_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, [*r*, *g*, *b*], indicating the color of ROI outlines when they are not selected. This color will be used by XROI unless and until the color is changed by the user via the "Unselected Outline Color" portion of the "ROI Outline Colors" dialog (which is accessed by selecting **Edit → ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current [*r*, *g*, *b*] value at the time that XROI returns.

ROI_GEOMETRY

Set this keyword to a named variable that will contain an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
area	The area of the region of interest, in square pixels.
centroid	The coordinates (*x*, *y*, *z*) of the centroid of the region of interest, in pixels.
perimeter	The perimeter of the region of interest, in pixels.

Table 150: Fields of the structure returned by ROI_GEOMETRY

If there are no valid regions of interest when this routine returns, ROI_GEOMETRY will be undefined.

Note

If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for ROI_GEOMETRY to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and ROI_GEOMETRY will therefore be undefined.

Note

This keyword must be used in conjunction with the BLOCK keyword.

ROI_SELECT_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, [*r*, *g*, *b*], indicating the color of ROI outlines when they are selected. This color will be used by XROI unless and until the color is changed by the user via the “Selected Outline Color” portion of the “ROI Outline Colors” dialog (which is accessed by selecting **Edit → ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current [*r*, *g*, *b*] value at the time that XROI returns.

STATISTICS

Set this keyword to a named variable to receive an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
count	Number of pixels in region.
minimum	Minimum pixel value.
maximum	Maximum pixel value.
mean	Mean pixel value.
stddev	Standard deviation of pixel values.

Table 151: Fields of the structure returned by STATISTICS

If *ImageData* is 24-bit, or if there are no valid regions of interest when the routine exits, STATISTICS will be undefined.

Note

If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for STATISTICS to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and STATISTICS will therefore be undefined.

TITLE

Set this keyword to a string to appear in the XROI title bar.

TOOLS

Set this keyword a string or vector of strings from the following list to indicate which ROI manipulation tools should be supported when XROI is run:

- 'Translate-Scale' — Translation and scaling of ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
- 'Rectangle' — Rectangular ROI drawing. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
- 'Ellipse' — Elliptical ROI drawing. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
- 'Freehand Draw' — Freehand ROI drawing. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
- 'Polygon Draw' — Polygon ROI drawing. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
- 'Selection' — ROI selection. Mouse down/up selects the nearest region. The nearest vertex in that region is identified with a crosshair symbol.

If more than one string is specified, a series of bitmap buttons will appear at the top of the XROI widget in the order specified (to the right of the fixed set of bitmap buttons used for saving regions, displaying region information, copying to clipboard, and flipping the image). If only one string is specified, no additional bitmap buttons will appear, and the manipulation mode is implied by the given string. If this keyword is not specified, bitmap buttons for all three manipulation tools are included on the XROI toolbar.

X_SCROLL_SIZE

Set this keyword to the width of the scroll window. If this keyword is larger than the image width then it will be set to the image width. The default is to use the image width or the screen width, whichever is smaller.

Y_SCROLL_SIZE

Set this keyword to the height of the scroll window. If this keyword is larger than the image height then it will be set to the image height. The default is to use the image height or the screen height, whichever is smaller.

Using XROI

XROI displays a top-level base with a menu, toolbar and draw widget. After defining an ROI, the **ROI Information** window appears, as shown in the following figure:

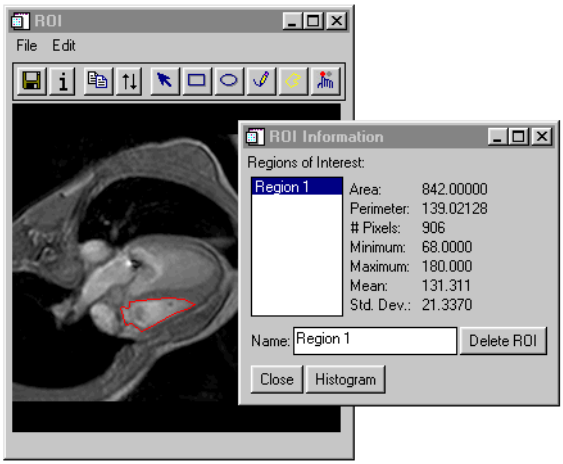

Figure 41: The XROI Utility

As you move the mouse over an image, the x and y pixel locations are shown in the status line on the bottom of the XROI window. For 8-bit images, the data value (z) is also shown. If an ROI is defined, the status line also indicates the mouse position relative to the ROI using the text “Inside”, “Outside”, “On Edge,” or “On Vertex.”

The XROI Toolbar

The XROI toolbar contains the following buttons:

Save: Opens a file selection dialog for saving the currently defined ROIs to a save file.

Info: Opens the **ROI Information** window.

Copy: Copies the contents of the display area to the clipboard.

Flip: Flips image vertically. Note that only the image is flipped; any ROIs that have been defined do not move.

Depending on the value of the TOOLS keyword, the XROI toolbar may also contain the following buttons:

Translate/ Scale: Click this button to translate or scale ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.

Draw Rectangle: Click this button to draw rectangular ROIs. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.

Draw Ellipse: Click this button to draw elliptical ROIs. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.

Draw Freehand: Click this button to draw freehand ROIs. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.

Draw Polygon: Click this button to draw polygon ROIs. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.

Select: Click this button to select an ROI region. Clicking the image causes a cross hairs symbol to be drawn at the nearest vertex of the selected ROI.

Importing an Image into XROI

To import an image into XROI, select **File** → **Import Image**. This opens a DIALOG_READ_IMAGE dialog, which can be used to preview and select an image.

Changing the Image Color Table

To change the color table properties for the current image, select **Edit** → **Image Color Table**. This opens the CW_PALETTE_EDITOR dialog, which is a compound widget used to edit color palettes. See CW_PALETTE_EDITOR for more information. This menu item is grayed out if the image does not have a color palette.

Changing the ROI Outline Colors

To change the outline colors for selected and unselected ROIs, select **Edit** → **ROI Outline Colors**. This opens the **ROI Outline Colors** dialog, which consists of two CW_RGBSLIDER widgets for interactively adjusting the ROI outline colors. The left widget is used to define the color for the selected ROI, and the right widget is used to define the color of unselected ROIs. You can select the RGB, CMY, HSV, or HLS color system from the **Color System** drop-down list.

Viewing ROI Information

To view geometry and statistical data about the currently selected ROI, click the **Info** button or select **Edit** → **ROI Information**. This opens the **ROI Information** dialog, which displays area, perimeter, number of pixels, minimum and maximum pixel values, mean, and standard deviation. Values for statistical information (minimum, maximum, mean, and standard deviation) appear as “N/A” for 24-bit images.

Viewing a Histogram Plot for an ROI

To view a histogram for an ROI, use either the shortcut menu or the ROI Information dialog.

To view an ROI’s histogram plot using the shortcut menu:

1. Position the cursor on the line defining the boundary of an ROI in the drawing window and click the right mouse button. This selects the region and brings up its shortcut menu.
2. Select the **Plot Histogram** menu option from the shortcut menu.

To view an ROI’s histogram plot using the ROI Information dialog:

1. Open the ROI Information dialog by clicking the **Info** button or selecting **Edit** → **ROI Information**.

2. Select a region from the list and click the **Histogram** button on the ROI Information dialog.

Either of the previous methods opens a LIVE_PLOT dialog showing the ROI's histogram that can be used to interactively control the plot properties.

Note

XROI's histogram plot feature now supports RGB images.

Growing an ROI

Once a region has been created, it may be used as a source ROI for region growing. Region growing is a process of generating one or more new ROIs based upon the image pixel values that fall within the source ROI and the values of the neighboring pixels. New pixels are added to the new grown region if those image pixel values fall within a specified threshold.

Note

This option is an interactive implementation of the REGION_GROW function.

To create a new, grown region, do the following:

1. Within the draw area, click the right mouse button on the ROI that is to be grown. This will select the region and bring up its shortcut menu.
2. Select **Grow Region** → **By threshold** or select **Grow Region** → **By std. dev. multiple** from the shortcut menu to control how the region is grown.

   The **By threshold** option grows the region to include all neighboring pixels that fall within a specified threshold range. By default, the range is defined by the minimum and maximum pixel values occurring within the original region. To specify a different threshold range, see Using the Region Grow Properties Dialog in the following section.

   The **By std. dev. multiple** option grows a region to include all neighboring pixels that fall within the range of:

   ```
   Mean +/- StdDevMultiplier * StdDev
   ```

   where `Mean` is the mean value of the pixel values within the source ROI, `StdDevMultiplier` is a multiplier that is set using the Region Grow Properties dialog (described below), and `StdDev` is the sample standard deviation of the pixel values within the original region.

Using the Region Grow Properties Dialog

The Region Grow Properties dialog allows you to view and edit the properties associated with a region growing process. To bring up the Region Grow Properties dialog, do one of the following:

- Click the right mouse button on an ROI in the drawing window and select **Grow Region** → **Properties...** shortcut menu option.
- Select **Edit** → **Region Grow Properties**... from the XROI menu bar.

This brings up the Region Grow Properties dialog, shown in the following figure.

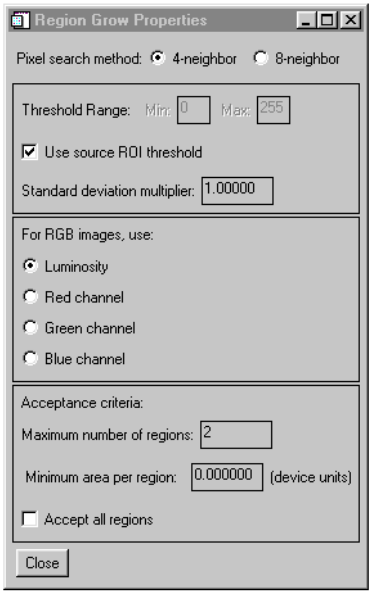

Figure 42: XROI's Region Grow Properties Dialog

The Region Grow Properties dialog offers the following options:

Option	Description
Pixel search method:	Describes which pixels are searched when growing the original ROI. The option are: • **4-neighbor** — Searches only the four neighboring pixels that share a common edge with the current pixel. This is the default. • **8-neighbor** — Searches all eight neighboring pixels, including those that are located diagonally relative to the original pixel and share a common corner.
Threshold range:	Represents the minimum and maximum image pixel values that are to be included in the grown region when using the **Grow Region → By threshold** option (described in "Growing an ROI" on page 2360). By default, the range of pixel values used are those occurring in the ROI to be grown. To change the threshold values, uncheck **Use source ROI threshold** and enter the minimum and maximum threshold values in the **Min:** and **Max:** fields provided.
Standard deviation multiplier:	Represents the factor by which the sample standard deviation of the original ROI's pixel values is multiplied. This factor only applies when the **Grow Region → By std. dev. multiple** option (described in "Growing an ROI" on page 2360) is used. Change the multiplier value by typing the value into the **Standard deviation multiplier** field provided.

Table 152: Options of the Region Grow Properties Dialog

Option	Description
For RGB image, use:	Determines the basis of region growing for an RGB (rather than indexed) image. The image data values used when growing a RGB region can be one of the following: • **Luminosity** — Uses the luminosity values associated with an RGB image. This is the default method. Luminosity is computed as: Luminosity = (0.3 * Red) + (0.59 * Green) + (0.11 * Blue) • **Red Channel**, **Green Channel** or **Blue Channel** — Uses the ROI's red, green or blue channel as a basis for region growing. Click the channel's associated button to specify the channel to be used. **Note -** For indexed images, the image data itself is always used for region growing.
Acceptance criteria:	Determines which contours of the grown region are accepted as new regions, (which will also be displayed in the draw area and in the ROI Information dialog list of regions). The region growing process can result in a large number of contours, some of which may be considered insignificant. By default, no more than two regions (those with the greatest geometrical area) are accepted. Modify the acceptance criteria by altering the following values: • **Maximum number of regions:** — Specifies the upper limit of the number of regions to create when growing an ROI. • **Minimum area per region:** — Specifies that only contours having a geometric area (computed in device coordinates) of at least the value stated are accepted and displayed. • **Accept all regions:** — Select this option to accept all generated contours, regardless of count or area.

Table 152: Options of the Region Grow Properties Dialog (Continued)

Deleting an ROI

An ROI can be deleted using either the shortcut menu or using the ROI Information dialog.

To delete an ROI using the shortcut menu:

1. Click the right mouse button on the line defining the boundary of the ROI in the drawing area that you wish to delete. This selects the region and bring up the shortcut menu.
2. Select the **Delete** menu option from the shortcut menu.

To delete an ROI using the ROI Information dialog:

1. Click the **Info** button or select **Edit** → **ROI Information**. This opens the **ROI Information** dialog.
2. In the **ROI Information** dialog, select the ROI you wish to delete from the list of ROIs. You can also select an ROI by clicking the **Select** button on the XROI toolbar, then clicking on an ROI on the image.
3. Click the **Delete ROI** button.

Examples

Example 1

This example opens a single image in XROI:

```
image = READ_PNG(FILEPATH('mineral.png', $
   SUBDIR=['examples', 'data']))
XROI, image
```

Example 2

This example reads 3 images from the file `mr_abdomen.dcm`, and calls XROI for each image. A single list of regions is maintained, saving the user from having to redefine regions on each image:

```
;Read 3 images from mr_abdomen.dcm and open each one in XROI:
FOR i=0,2 DO BEGIN
   image = READ_DICOM(FILEPATH('mr_abdomen.dcm',$
      SUBDIR=['examples', 'data']), IMAGE_INDEX=i)
   XROI, image, r, g, b, REGIONS_IN = regions, $
      REGIONS_OUT = regions, $
      ROI_SELECT_COLOR = roi_select_color, $
      ROI_COLOR = roi_color, REJECTED = rejected, /BLOCK
```

```
    OBJ_DESTROY, rejected
ENDFOR

OBJ_DESTROY, regions
```

Perform the following steps:

1. Draw an ROI on the first image, then close that XROI window. Note that the next image contains the ROI defined in the first image. This is accomplished by setting REGIONS_IN and REGIONS_OUT to the same named variable in the FOR loop of the above code.
2. Draw another ROI on the second image.
3. Click the **Select** button and select the first ROI. Then click the **Info** button to open the **ROI Information** window, and click the **Delete ROI** button.
4. Close the second XROI window. Note that the third image contains the ROI defined in the second image, but not the ROI deleted on the second image. This example sets the REJECTED keyword to a named variable, and calls OBJ_DESTROY on that variable. Use of the REJECTED keyword is not necessary to prevent deleted ROIs from appearing on subsequent images, but allows you perform cleanup on objects that are no longer required.

Example 3

XROI's **File** → **Save ROIs** option allows you to save selected regions of interest. This example shows how to restore such a save file. Suppose you have a file named `mineralRoi.sav` that contains regions of interest selected in the `mineral.png` image file. You would need to complete the following steps to restore the file:

1. First, restore the file, `mineralRoi.sav`. Provide a value for the RESTORE procedure's RESTORED_OBJECTS keyword. Using the scenario stated above, you could enter the following:

```
RESTORE, 'mineralRoi.sav', RESTORED_OBJECTS = myRoi
```

2. Pass the restored object data containing your regions of interest into XROI by specifying `myRoi` as the value for REGIONS_IN as follows:

```
XROI, READ_PNG(FILEPATH('mineral.png', SUBDIRECTORY = $
    ['examples', 'data'])), REGIONS_IN = myRoi
```

   This opens the previously selected regions of interest in the XROI utility.

Version History

Introduced: 5.4

X_SCROLL_SIZE and Y_SCROLL_SIZE keywords added: 5.6

XSQ_TEST

The XSQ_TEST function computes the Chi-square goodness-of-fit test between observed frequencies and the expected frequencies of a theoretical distribution.

Expected frequencies of magnitude less than 5 are combined with adjacent elements resulting in a reduction of cells used to formulate the chi-squared test statistic. If the observed frequencies differ significantly from the expected frequencies, the Chi-square test statistic will be large and the fit is poor. This situation requires the rejection of the hypothesis that the given observed frequencies are an accurate approximation to the expected frequency distribution.

This routine is written in the IDL language. Its source code can be found in the file `xsq_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = XSQ_TEST(*Obfreq*, *Exfreq* [, EXCELL=*variable*] [, OBCELL=*variable*] [, RESIDUAL=*variable*])

Return Value

The result is a two-element vector containing the Chi-square test statistic X2 and the one-tailed probability of obtaining a value of X2 or greater.

Arguments

Obfreq

An *n*-element integer, single-, or double-precision floating-point vector containing observed frequencies.

Exfreq

An *n*-element integer, single-, or double-precision floating-point vector containing expected frequencies.

Keywords

EXCELL

Set this keyword to a named variable that will contain a vector of expected frequencies used to formulate the Chi-square test statistic. If each of the expected frequencies contained in *Exfreq*, has a magnitude of 5 or greater, then this vector is identical to *Exfreq*. If *Exfreq* contains elements of magnitude less than 5, adjacent expected frequencies are combined. The identical combinations are performed on the corresponding elements of *Obfreq*.

OBCELL

Set this keyword to a named variable that will contain a vector of observed frequencies used to formulate the Chi-square test statistic. The elements of this vector are often referred to as the “cells” of the observed frequencies. The length of this vector is determined by the length of EXCELL described below.

RESIDUAL

Set this keyword to a named variable that will contain a vector of signed differences between corresponding cells of observed frequencies and expected frequencies.

```
RESIDUAL[i] = OBCELL[i] - EXCELL[i].
```

The length of this vector is determined by the length of EXCELL described above.

Examples

```
; Define the vectors of observed and expected frequencies:
obfreq = [2, 1, 4, 15, 10, 5, 3]
exfreq = [0.5, 2.1, 5.9, 10.3, 10.7, 7.0, 3.5]

; Test the hypothesis that the given observed frequencies are an
; accurate approximation to the expected frequency distribution:
result = XSQ_TEST(obfreq, exfreq)
PRINT, result
```

IDL Output

```
3.05040       0.383920
```

Since the vector of expected frequencies contains elements of magnitude less than 5, adjacent expected frequencies are combined resulting in fewer cells. The identical combinations are performed on the corresponding elements of observed frequencies.

The computed value of 0.383920 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level.

Version History

Introduced: 4.0

CTI_TEST

XSURFACE

The XSURFACE procedure is a utility that provides a graphical interface to the SURFACE and SHADE_SURF commands. Different controls are provided to change the viewing angle and other plot parameters. The command used to generate the resulting surface plot is shown in a text window. Note that this procedure does not accept SURFACE or SHADE_SURF keywords.

This routine is written in the IDL language. Its source code can be found in the file `xsurface.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XSURFACE, *Data* [, /BLOCK] [, GROUP=*widget_id*]

Arguments

Data

The two-dimensional array to display as a wire-mesh or shaded surface.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XSURFACE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

Set this keyword to the widget ID of the widget that calls XSURFACE. When GROUP is specified, the death of the calling widget results in the death of XSURFACE.

Examples

```
; Make a 2-D array:
z = DIST(30)

; Call XSURFACE. The XSURFACE widget appears:
XSURFACE, z
```

Version History

Introduced: Pre 4.0

SHADE_SURF, SURFACE

XVAREDIT

The XVAREDIT procedure is a utility that provides a widget-based editor for any IDL variable. Use the input fields to change desired values of the variable or array. Click “Accept” to write the new values into the variable. Click “Cancel” to exit XVAREDIT without saving changes.

This routine is written in the IDL language. Its source code can be found in the file `xvaredit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XVAREDIT, *Var* [, NAME='*variable_name*'{ignored if variable is a structure}] [, GROUP=*widget_id*] [, X_SCROLL_SIZE=*columns*] [, Y_SCROLL_SIZE=*rows*]

Arguments

Var

The variable to be edited. On output, this variable contains the edited value if the user selects the “Accept” button, or the original value if the user selects the “Cancel” button.

Keywords

NAME

The NAME of the variable. This keyword is overwritten with the structure name if the variable is a structure.

GROUP

The widget ID of the widget that calls XVAREDIT. When this ID is specified, a death of the caller results in a death of XVAREDIT.

X_SCROLL_SIZE

Set this keyword to the column width of the scrolling viewport. The default is 4.

Y_SCROLL_SIZE

Set this keyword to the row width of the scrolling viewport. The default is 4.

Version History

Introduced: Pre 4.0

XVOLUME

The XVOLUME procedure is a utility for viewing and interactively manipulating volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Tip

The XVOLUME_ROTATE and XVOLUME_WRITE_IMAGE procedures, which can be called only after a call to XVOLUME, can be used to easily create animations of volumes and isosurfaces displayed in XVOLUME. See XVOLUME_ROTATE for an example.

Using XVOLUME

XVOLUME displays a resizeable top-level base with a toolbar, a menu, a graphical interface for controlling volume and isosurface properties, and a draw widget for displaying and manipulating the volume, as shown in the following figure:

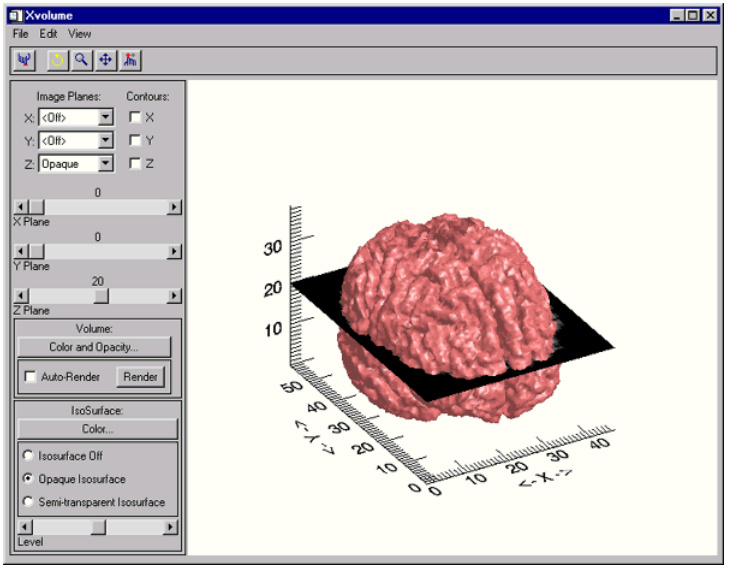

Figure 43: The XVOLUME Utility

The XVOLUME Toolbar

The XVOLUME toolbar contains the following buttons.

Note

If you have the **Auto-Render** option selected, the Rotate, Zoom, and Pan features may be more difficult to use. For the best performance while manipulating the orientation of a volume using these features, uncheck the **Auto-Render** option.

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the volume and drag to rotate.

Zoom: Click the left mouse button on the volume and drag to zoom in or out.

Pan: Click the left mouse button on the volume and drag to pan.

Select: Click in the draw widget to identify the selected item. A name identifying the selected item is displayed next to the Select button.

The XVOLUME Interface

The XVOLUME interface provides the following elements for controlling the display of image planes and contours, volumes, and isosurfaces:

Image Planes and Contours

Image planes and contours allow you to visualize the values associated with the volume or isosurface at a specified X, Y, or Z plane.

- **Image Planes** — Select one of the following options from the drop-down list for each dimension to control the display of image planes:
  - **Off**: Turns off the image plane display.
  - **Opaque**: Displays an opaque image plane at the location specified by the corresponding plane slider.
  - **Transparent**: Displays a transparent image plane at the location specified by the corresponding plane slider. The transparency value of the plane is taken from the volume at the current location of the image plane.

- **Contours** — Check this option to display contours on the specified plane at the location specified by corresponding the plane slider.
- **Plane Sliders** — Move these sliders to change the position of the plane in each dimension.

Volume

- **Color and Opacity**: Click this button to change the color and/or opacity of the current volume. This opens a CW_PALETTE_EDITOR dialog, which is a compound widget used to edit color palettes. See CW_PALETTE_EDITOR for more information.
- **Auto-Render**: Select this option to have rendering executed automatically after each change you make to the volume. If **Auto-Render** is unchecked, you must manually click the **Render** button to see changes you have made to the volume. If **Auto-Render** is checked, the **Render** button will be grayed out.
- **Render**: Click on this button to execute rendering computations and display the current volume. If **Auto-Render** is checked, this button will be grayed out.

Isosurface

An isosurface is a 3-D surface on which the data values are constant along the entire surface. Use the following elements to control the appearance of the isosurface:

- **Color**: Click this button to change the color system and/or values for the current isosurface. This opens a CW_RGBSLIDER dialog, which is a compound widget that provides a drop-down list for selecting the RGB, CMY, HSV, or HLS color system, and three sliders for adjusting the values associated with each color system.
- **Isosurface Off**: Select this option to turn off the isosurface display.
- **Opaque Isosurface**: Select this option to display an opaque isosurface.
- **Semi-transparent Isosurface**: Select this option to display a semi-transparent isosurface.
- **Level**: Use this slider to adjust the threshold value of the isosurface.

Syntax

XVOLUME, *Vol*, [, /BLOCK] [, GROUP=*widget_id*] [, /INTERPOLATE] [, /MODAL] [, RENDERER={0 | 1}] [, /REPLACE] [, SCALE=*value*] [, /TEST] [, XSIZE=*pixels*] [, YSIZE=*pixels*]

Arguments

Vol

A 3-dimensional array of the form [*x*, *y*, *z*] that specifies a data volume.

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XVOLUME block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

Set this keyword to the widget ID of the widget that calls XVOLUME. When this keyword is specified, the death of the caller results in the death of XVOLUME.

INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used when rendering the volume and the image planes. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XVOLUME. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XVOLUME fabricates an invisible group leader for you.

Note

To be modal, XVOLUME does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2044 for more information.)

To provide a simple means of invoking XVOLUME as a modal widget in applications that contain no other widgets, XVOLUME can be invoked as MODAL without specifying a group leader, in which case XVOLUME fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XVOLUME, /MODAL. As with other IDL widget procedures with names prefixed with "X", specify the group leader via the GROUP keyword.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL (the default)
- 1 = IDL's software implementation

REPLACE

If this keyword is set, and there is a current instance of XVOLUME running, the volume displayed in XVOLUME is replaced with the volume specified by *Vol*. For example, display volume1 using the command

```
XVOLUME, volume1
```

To replace volume1 with volume2, you would use the command

```
XVOLUME, volume2, /REPLACE
```

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the volume, while ensuring that no portion of the volume will be clipped by the XVOLUME window, regardless of the volume's orientation.

When using the SCALE keyword for XVOLUME, you can scale with a 3-element array of values [x, y, z].

TEST

If set, the *Vol* argument is not required (and is ignored if provided). A volume of random numbers is displayed instead. This allows you to test code that uses XVOLUME without having to specify volume data.

XSIZE

The width of the drawable area in pixels.

YSIZE

The height of the drawable area in pixels.

Examples

Create a volume and display using XVOLUME:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

Version History

Introduced: 5.4

See Also

XVOLUME_ROTATE, XVOLUME_WRITE_IMAGE, IDLgrVolume, INTERPOLATE, ISOSURFACE, SHADE_VOLUME, SLICER3, “Volume Objects” in Chapter 32 of the *Using IDL* manual.

XVOLUME_ROTATE

The XVOLUME_ROTATE procedure is used to programmatically rotate the volume currently displayed in XVOLUME. XVOLUME must be called prior to calling XVOLUME_ROTATE. This procedure can be used to create animations of volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XVOLUME_ROTATE, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A 3-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

Angle

The amount of rotation, measured in degrees.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Examples

The following example creates an animation of the volume currently displayed in XVOLUME. It does this by rotating the volume through 360 degrees in increments of 10 degrees using XVOLUME_ROTATE, and writing the volume to a BMP file for each increment using XVOLUME_WRITE_IMAGE. It then loops through the images and uses TV to display each image.

First, display a volume as follows:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

Now, use the XVOLUME interface to modify the orientation and appearance of the volume or isosurface as desired. Once you have the volume or isosurface displayed the way you want it, run the following program:

```
PRO spin_volume

   inc = 10. ; degrees.
   ; Create images
   FOR i=0,(360./inc)-2 DO BEGIN
      XVOLUME_WRITE_IMAGE, $
         'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
      XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY
   ENDFOR
   XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY

   ; Read images
   img = READ_BMP('spin0.bmp')
   siz = SIZE(img, /DIM)
   arr = BYTARR(3, siz[1], siz[2], 360./inc-1)
   FOR i=0,360./inc-2 DO BEGIN
      img = READ_BMP( $
         'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', /RGB)
      arr[0,0,0, i] = img
      PRINT, i
   ENDFOR

   ; Display animation
   FOR i=0,2 DO BEGIN ; num rotations
      FOR j=0,(360./inc)-2 DO BEGIN
         TV, arr[*,*,*,j], /TRUE
      ENDFOR
   ENDFOR

   TV, arr[*,*,*,0], /TRUE

END
```

Version History

Introduced: 5.4

XVOLUME, XVOLUME_WRITE_IMAGE

XVOLUME_WRITE_IMAGE

The XVOLUME_WRITE_IMAGE procedure is used to write the volume currently displayed in XVOLUME to an image file with the specified name and file format. XVOLUME must be called prior to calling XVOLUME_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XVOLUME_WRITE_IMAGE, *Filename*, *Format* [, DIMENSIONS=*[x, y]*]

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. See QUERY_IMAGE for a list of supported formats.

Keywords

DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XVOLUME draw widget.

Examples

See XVOLUME_ROTATE.

Version History

Introduced: 5.4

XVOLUME, XVOLUME_ROTATE

XYOUTS

The XYOUTS procedure draws text on the currently-selected graphics device starting at the designated coordinate.

Arguments *X*, *Y*, and *String* can be any combination of scalars or arrays. If the arguments are arrays, multiple strings are output.

If the optional *X* and *Y* arguments are omitted, the text is positioned at the end of the most recently output text string.

Important keywords that control the appearance and positioning of the text include: ALIGNMENT, the justification of the text; CHARSIZE, the size of the text; FONT, chooses between vector drawn and hardware fonts; COLOR, the color of the text; and ORIENTATION, the angle between the baseline of the text and the horizontal. With hardware fonts, most of the text attributes, (e.g., size and orientation), are predetermined and not changeable.

Note

Specify the Z coordinate with the Z keyword when positioning text in three dimensions.

Syntax

XYOUTS, [*X*, *Y*,] *String* [, ALIGNMENT=*value*{0.0 to 1.0}] [, CHARSIZE=*value*] [, CHARTHICK=*value*] [, TEXT_AXES={0 | 1 | 2 | 3 | 4 | 5}] [, WIDTH=*variable*]

Graphics Keywords:[, CLIP=*[X_0, Y_0, X_1, Y_1]*] [, COLOR=*value*][, /DATA | , /DEVICE | , /NORMAL] [, FONT=*integer*]
[, ORIENTATION=*ccw_degrees_from_horiz*] [, /NOCLIP] [, /T3D] [, Z=*value*]

Arguments

X, Y

The horizontal and vertical coordinates used to position the string(s). *X* and *Y* are normally interpreted in data coordinates. The DEVICE and NORMAL keywords can be used to specify the coordinate units.

X and *Y* can be arrays of positions if *String* is an array.

String

The string(s) to be output. This argument can be a scalar string or an array of strings. If this argument is not a string, it is converted prior to use using the default formatting rules. If *String* is an array, *X*, *Y*, and the COLOR keyword can also be arrays so that each string can have a separate location and color.

Keywords

ALIGNMENT

Specifies the alignment of the text baseline. An alignment of 0.0 (the default) aligns the left edge of the text baseline with the given (*x*, *y*) coordinate. An alignment of 1.0 right-justifies the text, while 0.5 results in text centered over the point (*x*, *y*).

CHARSIZE

The overall character size for the annotation. A CHARSIZE of 1.0 is normal. Setting CHARSIZE = -1 suppresses output of the text string. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see "Scaled Hardware Fonts" on page 2387.

CHARTHICK

The line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see "Scaled Hardware Fonts" on page 2387. The default value is 1.0.

TEXT_AXES

This keyword specifies the plane of vector drawn text when three-dimensional plotting is enabled. By default, text is drawn in the plane of the XY axes. The horizontal text direction is in the X plane, and the vertical text direction is in the Y plane. Values for this keyword can range from 0 to 5, with the following effects: 0 for XY, 1 for XZ, 2 for YZ, 3 for YX, 4 for ZX, and 5 for ZY. The notation ZY means that the horizontal direction of the text lies in the Z plane, and the vertical direction of the text is drawn in the Y plane.

WIDTH

Set this keyword to a named variable in which to return the width of the text string, in normalized coordinate units.

Graphics Keywords Accepted

See Appendix H, “Graphics Keywords” for the description of graphics and plotting keywords not listed above. CLIP, COLOR, DATA, DEVICE, FONT, NOCLIP, NORMAL, ORIENTATION, T3D, Z.

Examples

Print the string “This is text” at device coordinate position (100,100):

```
XYOUTS, 100, 100, 'This is text', /DEVICE
```

Print an array of strings with each element of the array printed at a different location. Use larger text than in the previous example:

```
XYOUTS, [0, 200, 250], [200, 50, 100], $
   ['This', 'is', 'text'], CHARSIZE = 3, /DEVICE
```

Determine the text size for a window device before opening an on-screen window:

```
WINDOW, /FREE, /PIXMAP, XSIZE=myWinXSize, YSIZE=myWinYSize
XYOUTS, 'Check this out', WIDTH=w
WDELETE
```

myWinXSize and *myWinYSize* are chosen to match your onscreen window. Since we can not know the characteristics of a given device (such as character size) until a window has been opened, the PIXMAP keyword to WINDOW allows you to compute appropriate dimensions for text with an invisible window before displaying a window on your screen.

Scaled Hardware Fonts

One example of hardware fonts which can be scaled are PostScript fonts. If you are using PostScript fonts, the keywords CHARTHICK and CHARSIZE will have an effect on a call to XYOUTS. Of the devices we provide that support hardware fonts, only the PostScript device uses scalable PostScript fonts for its “hardware” font system. All other devices use a bitmapped font technology.

Scaling is related to whether or not a device supports Hershey formatting commands when hardware fonts are used. Formatting requires the ability to scale the text on a per-character basis (i.e. for subscripting). To see if a given device supports Hershey formatting when hardware fonts are used, look at bit 12 of !D.FLAGS. You can also use this indicator to determine whether or not the hardware fonts will be scaled.

ANNOTATE, PRINT/PRINTF

ZOOM

The ZOOM procedure displays part of an image from the current window enlarged in a new (“zoom”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

Note

ZOOM only works with color systems.

This routine is written in the IDL language. Its source code can be found in the file `zoom.pro` in the `lib` subdirectory of the IDL distribution.

Using ZOOM

After calling ZOOM, place the mouse cursor over an image in an IDL graphics window. Click the left mouse button to display a magnified version of the image in a new window. The zoomed image is centered around the pixel selected in the original window. Click the middle mouse button to display a menu of zoom factors. Click the right mouse button to exit the procedure.

Using ZOOM with Draw Widgets

Note that the ZOOM procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

Syntax

ZOOM [, /CONTINUOUS] [, FACT=*integer*] [, /INTERP] [, /KEEP]
[, /NEW_WINDOW] [, XSIZE=*value*] [, YSIZE=*value*]
[, ZOOM_WINDOW=*variable*]

Arguments

None.

Keywords

CONTINUOUS

Set this keyword to make the zoom window track the mouse without requiring the user to press the left mouse button. This feature only works well on fast computers.

FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

INTERP

Set this keyword to use bilinear interpolation. The default is to use pixel replication.

KEEP

Set this keyword to keep the zoom window after exiting the procedure.

NEW_WINDOW

Normally, if ZOOM is called with KEEP and then called again, it will use the same window to display the new zoomed image. Set the NEW_WINDOW keyword to force ZOOM to create a new window for this purpose.

XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

ZOOM_WINDOW

Set this keyword to a named variable that will contain the index of the zoom window. KEEP must also be set. If KEEP is not set, ZOOM_WINDOW will contain the integer -1.

Version History

Introduced: Original

See Also

CW_ZOOM, ZOOM_24

ZOOM_24

The ZOOM_24 procedure displays part of a 24-bit color image from the current window expanded in a new (“zoom”) window, and provides information about cursor location and color values in an auxiliary (“data”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

Note

ZOOM only works on 24-bit color systems.

This routine is written in the IDL language. Its source code can be found in the file `zoom_24.pro` in the `lib` subdirectory of the IDL distribution.

Using ZOOM_24

After calling ZOOM_24, windows titled “Zoomed Image” (the zoom window) and “Pixel Values” (the data window) appear on the screen. Place the mouse cursor over a 24-bit color image in an IDL graphics window and click the left mouse button to display a magnified version of the image in the zoom window. The zoomed image is centered around the pixel selected in the original window. Move the mouse cursor in the zoom window to determine the coordinates (in the original image) and color values of individual pixels.

With the cursor located in the zoom window, click the right mouse button to return to selection mode, which allows you to either choose a new zoom center, change the zoom factor, or exit the procedure. Move the cursor to the original image and click the middle mouse button to display a menu of zoom factors, or click the right mouse button to exit the procedure.

Using ZOOM_24 with Draw Widgets

Note that the ZOOM_24 procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

Syntax

ZOOM_24 [, FACT=*integer*] [, /RIGHT] [, XSIZE=*value*] [, YSIZE=*value*]

Arguments

None.

Keywords

FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

RIGHT

Set this keyword to position the zoom and data windows to the right of the original window.

XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

Version History

Introduced: Pre 4.0

Appendix A:

IDL Object Class & Method Reference

This appendix describes IDL’s built-in graphics class library.

Using this Appendix

The elements of IDL's graphics class library are documented alphabetically in this appendix. The page or pages describing each class include references to sub- and super-classes, and to the methods associated with the class. Class methods are documented alphabetically following the description of the class itself.

A description of each method follows its name. Beneath the general description of the method are a number of sections that describe the Syntax for the method, its arguments (if any), its keywords (if any). These sections are described below.

Syntax

The Syntax section shows the proper syntax for calling the method.

Procedure Methods

IDL procedure methods have the syntax:

Obj -> Procedure_Name, *Argument* [, *Optional_Arguments*]

where *Obj* is a valid object reference, *Procedure_Name* is the name of the procedure method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter to the procedure method. Note that the square brackets around optional arguments are not used in the actual call to the procedure, they are simply used to denote the optional nature of the arguments within this document.

Function Methods

IDL function methods have the syntax:

Result = *Obj -> Function_Name*(*Argument* [, *Optional_Arguments*])

where *Obj* is a valid object reference, *Result* is the returned value of the function method, *Function_Name* is the name of the function method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter. Note that the square brackets around optional arguments are not used in the actual call to the function, they are simply used to denote the optional nature of the arguments within this document. Note also that all arguments and keyword arguments to functions should be supplied *within* the parentheses that follow the function's name.

Arguments

The “Arguments” section describes each valid argument to the method. Note that these arguments are positional parameters that must be supplied in the order indicated by the method’s syntax.

Named Variables

Often, arguments that contain values upon return from the function or procedure method (“output arguments”) are described as accepting “named variables”. A named variable is simply a valid IDL variable name. This variable *does not* need to be defined before being used as an output argument. Note, however that when an argument calls for a named variable, only a named variable can be used—sending an expression causes an error.

Keywords

The “Keywords” section describes each valid keyword argument to the method. Note that keyword arguments are formal parameters that can be supplied in any order.

Keyword arguments are supplied to IDL methods by including the keyword name followed by an equal sign (“=”) and the value to which the keyword should be set. Note that keywords can be abbreviated to their shortest unique length. For example, the XSTYLE keyword can be abbreviated to XST.

Setting Keywords

When the documentation for a keyword says something similar to, “Set this keyword to enable logarithmic plotting,” the keyword is simply a switch that turns an option on and off. Usually, setting such keywords equal to 1 causes the option to be turned on. Explicitly setting the keyword to zero (or not including the keyword) turns the option off.

There is a “shortcut” that can be used to set a keyword equal to 1 without the usual syntax (i.e., `KEYWORD=1`). To “set” a keyword, simply preface it with a slash character (“/”). For example, to create a surface object with a skirt around it, set the SKIRT keyword to the SURFACE routine as follows:

```
mySurface = OBJ_NEW('IDLgrSurface', DIST(10), /SKIRT)
```

Creating Objects from the Graphics Class Library

To create an object from the IDL Graphics Class Library, use the OBJ_NEW function. See “OBJ_NEW” on page 1328. The Init method for each class describes the arguments and keywords available when you are creating a new graphics object.

For example, to create a new graphics object from the IDLgrAxis class, use the following call to OBJ_NEW along with the arguments and keywords accepted by the IDLgrAxis::Init method:

```
myAxis = OBJ_NEW(IDLgrAxis, DIRECTION=1, RANGE=[0.0,40.0])
```

IDL_Container

An IDL_Container object holds other objects. Destroying an IDL_Container object destroys any objects that have been added to the container via the Add method.

Superclasses

This class has no superclasses.

Subclasses

The following classes are subclassed from this class:

- IDLanROIGroup
- IDLgrModel
- IDLgrScene
- IDLgrView
- IDLgrViewgroup

Creation

See “IDL_Container::Init” on page 2404.

Methods

Intrinsic Methods

This class has the following methods:

- IDL_Container::Add
- IDL_Container::Cleanup
- IDL_Container::Count
- IDL_Container::Get
- IDL_Container::Init
- IDL_Container::IsContained
- IDL_Container::Move
- IDL_Container::Remove

Version History

Introduced: 5.0

IDL_Container::Add

The IDL_Container::Add procedure method adds one or more child objects to the container.

Syntax

Obj -> [IDL_Container::]Add, *Objects* [POSITION=*index*]

Arguments

Objects

An object instance or array of object instances to be added to the container object.

Keywords

POSITION

Set this keyword equal to a scalar or array of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within the container at which a new object should be placed. The default is to add new objects at the end of the list of contained items.

Examples

If the container has three objects, a new object will be placed at the fourth position. Since positions begin at zero, this would be equivalent to setting POSITION=3.

Version History

Introduced: 5.0

IDL_Container::Cleanup

The IDL_Container::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDL_Container::]Cleanup(*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::Count

The IDL_Container::Count function method returns the number of objects contained by the container object.

Syntax

Result = *Obj* -> [IDL_Container::]Count()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::Get

The IDL_Container::Get function method returns an array of object references to objects in a container. Unless the ALL or POSITION keywords are specified, the first object in the container is returned. If no objects are found in the container, the Get function returns -1.

Syntax

Result = *Obj* -> [IDL_Container::]Get ([, /ALL [, ISA=*class_name(s)*] | , POSITION=*index*] [COUNT=*variable*])

Arguments

None.

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function. If the ALL keyword is also specified, specifying this keyword is the same as calling the IDL_Container::Count method.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

Version History

Introduced: 5.0

IDL_Container::Init

The IDL_Container::Init function method initializes the container object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDL_Container')

or

Result = *Obj* -> [IDL_Container::]Init( ) (*Only in a subclass' Init method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::IsContained

The IDL_Container::IsContained function method returns true (1) if the specified object is in the container, or false (0) otherwise.

Syntax

Result = *Obj* -> [IDL_Container::]IsContained(*Object* [, POSITION=*variable*])

Arguments

Object

The object reference or vector of object references of the object(s) to search for in the container.

Keywords

POSITION

Set this keyword to a named variable that upon return will contain the position(s) at which (each of) the argument(s) is located within the container, or -1 if it is not contained.

Version History

Introduced: 5.0

IDL_Container::Move

The IDL_Container::Move procedure method moves an object from one position in a container to a new position. The order of the other objects in the container remains unchanged.

Positioning within a container controls the rendering order of the contained objects. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later. Objects located “behind” other objects in three-dimensional space must be rendered before objects in front of them, even if the “front” objects are translucent.

Syntax

Obj -> [IDL_Container::]Move, *Source*, *Destination*

Arguments

Source

The zero-based index of the current location of the object to be moved.

Destination

The zero-based index of the location in the container where the object will reside after being moved.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::Remove

The IDL_Container::Remove procedure method removes an object from the container.

Syntax

Obj -> [IDL_Container::]Remove [, *Child_object* | , POSITION=*index* | , /ALL]

Arguments

Child_object

The object reference of the object to be removed from the container. If *Child_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the container will be removed.

Keywords

ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Child_object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child_object* argument is supplied, this keyword is ignored.

Version History

Introduced: 5.0

IDLanROI

The IDLanROI object class represents a region of interest.

Note

The IDLan* naming convention is used for objects in the analysis domain.

Regions of interest are described as a set of vertices that may be connected to generate a path or a polygon, or may be treated as separate points. This object may be used as a source for analytical computations on regions. (For additional information about display of ROIs in Object Graphics, refer to the IDLgrROI object class.)

Superclasses

None.

Subclasses

This class is a superclass of IDLgrROI.

Creation

See IDLanROI::Init.

Methods

Intrinsic Methods

The IDLanROI class has the following methods.

- IDLanROI::AppendData
- IDLanROI::Cleanup
- IDLanROI::ComputeGeometry
- IDLanROI::ComputeMask
- IDLanROI::ContainsPoints
- IDLanROI::GetProperty
- IDLanROI::Init
- IDLanROI::RemoveData

- IDLanROI::ReplaceData
- IDLanROI::Rotate
- IDLanROI::Scale
- IDLanROI::SetProperty
- IDLanROI::Translate

Version History

Introduced: 5.3

IDLanROI::AppendData

The IDLanROI::AppendData procedure method appends vertices to the region.

Syntax

Obj -> [IDLanROI::]AppendData, *X* [, *Y*] [, *Z*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

X

A vector providing the X components of the vertices to be appended. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2,*] or [3,*]), in which case, X[0,*] represents the X values, X[1,*] represents the Y values, and X[2,*] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Y

A vector providing the Y components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Z

A vector providing the Z components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Keywords

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], representing the *X* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::Cleanup

The IDLanROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLanROI::]Cleanup (In a subclass' Cleanup method only)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLanROI::ComputeGeometry

The IDLanROI::ComputeGeometry function method computes the geometrical values for area, perimeter, and/or centroid of the region.

Syntax

Result = *Obj* -> [IDLanROI::]ComputeGeometry([, AREA=*variable*] [, CENTROID=*variable*] [, PERIMETER=*variable*] [, SPATIAL_OFFSET=*vector*] [, SPATIAL_SCALE=*vector*])

Return Value

Result

This function method returns a 1 for success, or a 0 for failure. Each computed value is returned in the *variable* name assigned to each keyword.

Arguments

None.

Keywords

AREA

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the area of the region. Interior regions (holes) return a negative area.

CENTROID

Set this keyword to a named variable that upon return contains a double-precision floating-point vector [*x*,*y*,*z*] representing the centroid for the region. If the TYPE of the region is 0 (points), the centroid is computed as the average of each of the vertices in the region. If the TYPE of the region is 1 (path), the centroid is computed as the weighted average of each of the midpoints of the lines in the region. Weights are proportional to the length of the lines. If the TYPE of the region is 2 (polygon), the centroid is computed as a weighted average of the centroids of the polygons making up the ROI (interior centroids use negative weights). Weights are proportional to the polygon area.

PERIMETER

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the perimeter of the region.

SPATIAL_OFFSET

Set this keyword to a two or three-element vector, [*tx*, *ty*] or [*tx*, *ty*, *tz*], representing the spatial calibration offset factors to be applied for the geometry calculations. The value of SPATIAL_SCALE is applied before the spatial offset values are applied. The default is [0.0, 0.0, 0.0]. IDL converts and maintains this value in double-precision floating-point.

SPATIAL_SCALE

Set this keyword to a two or three-element vector, [*sx*, *sy*] or [*sx*, *sy*, *sz*], representing the spatial calibration scaling factors to be applied for the geometry calculations. The spatial calibration scale is applied first, then the value of SPATIAL_OFFSET is applied. The default is [1.0, 1.0, 1.0]. IDL converts and maintains this value in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::ComputeMask

The IDLanROI::ComputeMask function method prepares a two-dimensional mask for the region.

Syntax

Result = *Obj* -> [IDLanROI::]ComputeMask([, INITIALIZE={ –1 | 0 | 1 }] [, DIMENSIONS=*[xdim, ydim]*] | [, MASK_IN=*array*] [, LOCATION=*[x, y* [, *z]]*] [, MASK_RULE={ 0 | 1 | 2 }] [, PLANE_NORMAL=*[x, y, z]*] [, PLANE_XAXIS=*[x,y,z]*] [, /RUN_LENGTH])

Return Value

Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \mathrm{MAX}(\mathrm{MIN}(\ 255,\ (M_{\mathrm{roi}} * Ext) + M_{\mathrm{in}}),\ 0)$$

where M_{roi} is 255 and *Ext* is 1 for points within an exterior region and –1 for points within an interior region.

If the TYPE of the region is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the region is 1 (path), one-pixel-wide line segments are set within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a region, and the pixel falls within the region (according to the MASK_RULE).

Arguments

None.

Keywords

DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword is ignored and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- –1 = The mask is not initialized. This option is useful when updating an already existing mask. This is the default if the MASK_IN keyword is set.
- 0 = The mask is initialized so that each pixel is set to 0. This is the default if the MASK_IN keyword is not set.
- 1 = The mask is initialized so that each pixel is set to 255.

LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0]. IDL converts and maintains this value in double-precision floating-point.

MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary only. All pixels falling on a region's boundary are set.
- 1 = Interior only. All pixels falling within the region's boundary, but not on the boundary, are set.
- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set.

PLANE_NORMAL

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the normal vector for the plane on which the mask is to be computed. The default is [0, 0, 1].

PLANE_XAXIS

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is [1, 0, 0].

RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

Version History

Introduced: 5.3

RUN_LENGTH keyword: 5.6

IDLanROI::ContainsPoints

The IDLanROI::ContainsPoints function method determines whether the given data coordinates are contained within the closed polygon region.

Syntax

Result = *Obj* -> [IDLanROI::]ContainsPoints(*X* [, *Y* [, *Z*]])

Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly out of bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On edge. The point lies on an edge of the ROI boundary.
- 3 = On vertex. The point matches a vertex of the ROI.

A point is considered to be exterior if:

- the point falls within the boundary of an interior region (hole).
- the point does not lie in the plane of the region.
- the region TYPE property is set to 0 (points) or 1 (path).

Arguments

X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

Y

A vector providing the *Y* components of the points to be tested.

Z

A scalar or vector providing the *Z* component(s) of the points to be tested. If not provided, the *Z* components default to 0.0.

Keywords

None.

Version History

Introduced: 5.3

IDLanROI::GetProperty

The IDLanROI::GetProperty procedure method retrieves the value of a property or group of properties for the region.

Syntax

Obj -> [IDLanROI::]GetProperty [, ALL=*variable*] [, N_VERTS=*variable*] [, ROI_XRANGE=*variable*] [, ROI_YRANGE=*variable*] [, ROI_ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLanROI::Init followed by the word *(Get)* can be retrieved using IDLanROI::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the state of this object. State information about the object includes things like block size, type, etc., but not vertex data.

Note

The fields in this structure may change in subsequent releases of IDL.

N_VERTS

Set this keyword to a named variable that will contain the number of vertices currently being used by the region.

ROI_XRANGE

Set this keyword to a named variable. Upon return, ROI_XRANGE contains a two-element double-precision floating-point vector of the form [*xmin, xmax*] that specifies the range of X data coordinates covered by the region.

ROI_YRANGE

Set this keyword to a named variable. Upon return, ROI_YRANGE contains a two-element double-precision floating-point vector of the form [*ymin, ymax*] that specifies the range of Y data coordinates covered by the region.

ROI_ZRANGE

Set this keyword to a named variable. Upon return, ROI_ZRANGE contains a two-element double-precision floating-point vector of the form [*zmin, zmax*] that specifies the range of Z data coordinates covered by the region.

Version History

Introduced: 5.3

IDLanROI::Init

The IDLanROI::Init function method initializes a region of interest object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLanROI' [, *X* [, *Y* [, *Z*]]] [, BLOCKSIZE{Get, Set}=*vertices*] [, DATA{Get, Set}=*array*] [, /DOUBLE{Get, Set}] [, /INTERIOR{Get, Set}] [, TYPE{Get}={ 0 | 1 | 2 }])

or

Result = *Obj* -> [IDLanROI::]Init([*X* [, *Y* [, *Z*]]]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector providing the *X* components of the vertices for the region. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Y

A vector providing the *Y* components of the vertices. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Z

A scalar or vector providing the *Z* component(s) of the vertices. If not provided, *Z* values default to 0.0. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Keywords

BLOCK_SIZE *(Get, Set)*

Set this keyword to the number of vertices to allocate per block as needed for the region. When additional vertices are required, an additional block is allocated. The default is 100.

DATA *(Get, Set)*

Set this keyword to a *2 x n* or a *3 x n* array which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is stored as single precision floating point.

DOUBLE *(Get, Set)*

Set this keyword to a non-zero value to indicate that data should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default. The DOUBLE property controls the precision used for storing the data in the AppendData, Init, and ReplaceData methods via the X, Y, and Z arguments and in SetProperty method via the DATA keyword. IDL converts any data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

INTERIOR *(Get, Set)*

Set this keyword to mark this region as an interior region (i.e., a region treated as a hole). By default, the region is treated as an exterior region.

TYPE *(Get)*

Set this keyword to indicate the type of the region. The TYPE keyword determines how computational operations, such as mask generation, are performed. Valid values include:

- 0 = points
- 1 = path
- 2 = closed polygon (the default)

Version History

Introduced: 5.3

IDLanROI::RemoveData

The IDLanROI::RemoveData procedure method removes vertices from the region.

Syntax

Obj -> [IDLanROI::]RemoveData[, COUNT=*vertices*] [, START=*index*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

COUNT

Set this keyword to the number of vertices to remove. The default is one vertex.

START

Set this keyword to an index (into the region's current vertex list) where the removal is to begin. By default, the final vertex is removed.

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], that represents the *X* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], that represents the *Y* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin*, *zmax*], that represents the *Z* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::ReplaceData

The IDLanROI::ReplaceData procedure method replaces vertices in the region with alternate values. The number of replacement values need not match the number of values being replaced.

Syntax

Obj -> [IDLanROI::]ReplaceData, *X*[, *Y*[, *Z*]] [, START=*index*] [, FINISH=*index*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

X

A vector providing the X components of the new replacement vertices. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Y

A vector providing the Y components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Z

A vector providing the Z components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Keywords

FINISH

Set this keyword to the index of the region's current subregion vertex list where the replacement ends. If the START keyword value is ≥ 0, the default FINISH is given by

FINISH = ((START + N_NEW – 1) MOD N_OLD)

where N_NEW is the number of replacement vertices provided via the [*X, Y, Z*] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the START keyword is not set or is negative, the default FINISH is given by

FINISH = N_OLD – 1

FINISH may be less than START in which case the vertices, including and following START and the vertices preceding and including FINISH, are replaced with the new values.

START

Set this keyword to an index of the region's current subregion vertex list where the replacement begins. If the FINISH keyword value is ≥ 0, the default START is given by

START = ((FINISH – N_NEW + 1) MOD N_OLD)

where N_NEW is the number of replacement vertices provided via the [*X, Y, Z*] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the FINISH keyword is not set (or negative), the default START is clamped to 0 and is given by

N_OLD – N_NEW

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], representing the *X* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::Rotate

The IDLanROI::Rotate procedure method modifies the vertices for the region by applying a rotation.

Syntax

Obj -> [IDLanROI::]Rotate, *Axis*, *Angle* [, CENTER=*[x, y*[, *z*]*]*]

Arguments

Axis

A three-element vector of the form [*x, y, z*] describing the axis about which the region is to be rotated.

Angle

The angle, measured in degrees, by which the rotation is to occur.

Keywords

CENTER

Set this keyword to a two or three-element vector of the form [*x, y*], or [*x, y, z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::Scale

The IDLanROI::Scale procedure method modifies the vertices for the region by applying a scale.

Syntax

Obj -> [IDLanROI::]Scale, *Sx*[, *Sy*[, *Sz*]]

Arguments

Sx

The *X* scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in *X*, *Sx*[1] represents the scale in *Y*, *Sx*[2] represents the scale in *Z*. IDL converts and applies this data in double-precision floating-point.

Sy

The *Y* scale factor. IDL converts and applies this data in double-precision floating-point.

Sz

The *Z* scale factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLanROI::SetProperty

The IDLanROI::SetProperty procedure method sets the value of a property or group of properties for the region.

Syntax

Obj -> [IDLanROI::]SetProperty

Arguments

None.

Keywords

Any keywords to IDLanROI::Init followed by the word (*Set*) can be set using IDLanROI::SetProperty.

Version History

Introduced: 5.3

IDLanROI::Translate

The IDLanROI::Translate procedure method modifies the vertices for the region by applying a translation.

Syntax

Obj -> [IDLanROI::]Translate, *Tx*[, *Ty*[, *Tz*]]

Arguments

Tx

The X translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

Tz

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup

The IDLanROIGroup object class is an analytical representation of a group of regions of interest.

Superclasses

This class is a subclass of IDL_Container.

Subclasses

This class is a superclass of IDLgrROIGroup.

Creation

See IDLanROIGroup::Init.

Methods

Intrinsic Methods

The IDLanROIGroup class has the following methods:

- IDLanROIGroup::Add
- IDLanROIGroup::Cleanup
- IDLanROIGroup::ComputeMask
- IDLanROIGroup::ComputeMesh
- IDLanROIGroup::ContainsPoints
- IDLanROIGroup::GetProperty
- IDLanROIGroup::Init
- IDLanROIGroup::Rotate
- IDLanROIGroup::Scale
- IDLanROIGroup::Translate

Inherited Methods

This class inherits the following methods:

- IDL_Container::Count
- IDL_Container::Get
- IDL_Container::IsContained
- IDL_Container::Move
- IDL_Container::Remove

Version History

Introduced: 5.3

IDLanROIGroup::Add

The IDLanROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLanROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj -> [IDLanROIGroup::]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLanROI object class representing the region of interest to be added to the group.

Keywords

Accepts all keywords accepted by the IDL_Container::Add method.

Version History

Introduced: 5.3

IDLanROIGroup::Cleanup

The IDLanROIGroup::Cleanup procedure method performs all cleanup for a region of interest group object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLanROIGroup::]Cleanup (In a subclass' Cleanup method only.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::ComputeMask

The IDLanROIGroup::ComputeMask function method prepares a two-dimensional mask for this group of regions.

Syntax

Result = *Obj* -> [IDLanROIGroup::]ComputeMask([, INITIALIZE={ -1 | 0 | 1 }] [, DIMENSIONS=*[xdim, ydim]*] | [, MASK_IN=*array*] [, LOCATION=*[x, y* [, *z]]*] [, MASK_RULE={ 0 | 1 | 2 }] [, /RUN_LENGTH])

Return Value

Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = MAX(MIN(0, (M_{roi}*Ext) + M_{in}), 255)$$

where M_{roi} is 255 and *Ext* is 1 for points within an exterior region and –1 for points within an interior region.

If the TYPE of the contained regions is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the contained regions is 1 (path), each pixel along the paths of the regions is set if it falls within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a contained region, and the pixel falls within that region (according to the MASK_RULE).

Arguments

None.

Keywords

DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword

is ignored, and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- –1 = The mask is not initialized; the default if the MASK_IN keyword is set. This option is useful when updating an already existing mask.
- 0 = The mask is initialized with each pixel set to 0; the default if the MASK_IN keyword is not set.
- 1 = The mask is initialized with each pixel set to 255.

LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0].

MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary Only. All pixels falling on a region's boundary are set.
- 1 = Interior Only. All pixels falling within the region's boundary, but not on the boundary, are set.
- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set.

PLANE_NORMAL

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the normal vector for the plane on which the mask is to be computed. The default is [0, 0, 1].

PLANE_XAXIS

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is [1, 0, 0].

RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

Version History

Introduced: 5.3

RUN_LENGTH keyword: 5.6

IDLanROIGroup::ComputeMesh

The IDLanROIGroup::ComputeMesh function method triangulates a surface mesh with optional capping from the stack of regions contained within this group.

Note

The contained regions may be concave. However, this method will fail under the following conditions:

- The region group contains fewer than two regions.
- The TYPE property of the contained regions is 0 (points) or 1 (path).
- Any of the contained regions are not simple (i.e., a region is self-intersecting).
- The region group contains interior regions (holes).
- More than one region lies on the same plane (i.e., the region group contains branches).

Each region pair is normalized by perimeter and the triangulation is computed by walking the contours in parallel, keeping the normalized progress along each contour in sync. The returned triangulation minimizes the mesh surface area. Each vertex may appear only once in the output, and the resulting polygon mesh is solid with outward facing normals computed via the right-hand rule. If capping is requested, it is computed using the IDLgrTessellator on the top and bottom regions, and/or the regions on either side of an inter-slice gap.

Syntax

Result = *Obj*->[IDLanROIGroup::]ComputeMesh(*Vertices*, *Conn* [, CAPPED={ 0 | 1 | 2}] [, SURFACE_AREA=*variable*])

Return Value

Result

The return value of this function method is the number of triangles generated if the surface mesh triangulation is successful, or zero if unsuccessful.

Arguments

Vertices

An output [3, n] array of vertices. If all regions in the group are defined with single precision vertices (DOUBLE property is zero), then IDL returns a single precision floating point array. Otherwise, if any of the regions in the group are defined with double precision vertices (DOUBLE property is non-zero), then IDL returns a double precision floating point array.

Conn

An output polygon mesh connectivity array.

Keywords

CAPPED

Set this keyword to a value to indicate whether flat caps are to be computed at the top-most or bottom-most regions (as selected by a counter-clockwise rule), or at the regions on either side of an inter-slice gap. The value of this keyword is a bit-wise OR of the values shown below. For example, to cap the top-most and bottom-most regions only, set the CAPPED keyword to 3. The default is 0 (no caps).

- 0 = no caps
- 1 = cap the top-most region
- 2 = cap the bottom-most region

SURFACE_AREA

Set this keyword to a named variable that upon return contains the overall surface area of the computed triangulation. This value was minimized in the computation of the triangulation. IDL returns this value in a double-precision floating-point variable.

Version History

Introduced: 5.3

IDLanROIGroup::ContainsPoints

The IDLanROIGroup::ContainsPoints function method determines whether the given points (in data coordinates) are contained within this region group.

The regions within this group must have a TYPE of 2 (closed polygon) and must fall on parallel planes for successful containment testing to occur.

For each point to be tested:

- If the point lies directly on one of the region planes, it is tested for containment within each of the regions that fall on that plane.
- If the point lies between two of the region planes, it is projected onto the nearest region plane, and tested for containment within each of the regions on that plane.
- If the point lies above or below the stack of parallel region planes, the point will be considered to be exterior to the region group.

On a given plane, a point will be considered to be exterior if either of the following conditions are true:

- The point does not fall within any of the regions on that plane.
- The point falls within as many or more holes than non-hole regions on that plane.

Syntax

Result = *Obj* **->** [IDLanROIGroup::]ContainsPoints(*X*[, *Y*[, *Z*]])

Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly outside the bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On Edge. The point lies on an edge of the ROI boundary.
- 3 = On Vertex. The point matches a vertex of the ROI.

Arguments

X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

Y

A vector providing the *Y* components of the points to be tested.

Z

A scalar or vector providing the *Z* components of the points to be tested. If not provided, the *Z* components default to 0.0.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::GetProperty

The IDLanROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj -> [IDLanROIGroup::]GetProperty[, ALL=*variable*]
[, ROIGROUP_XRANGE=*variable*] [, ROIGROUP_YRANGE=*variable*]
[, ROIGROUP_ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLanROIGroup::Init followed by the word (*Get*) can be retrieved using IDLanROIGroup::GetProperty.To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable. Upon return, ALL contains an anonymous structure with the values of all of the properties associated with the state of this object.

Note

The fields in this structure may change in subsequent releases of IDL.

ROIGROUP_XRANGE

Set this keyword to a named variable. Upon return, ROIGROUP_XRANGE contains a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of X data coordinates covered by the region.

ROIGROUP_YRANGE

Set this keyword to a named variable. Upon return, ROIGROUP_YRANGE contains a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of Y data coordinates covered by the region.

ROIGROUP_ZRANGE

Set this keyword to a named variable. Upon return, ROIGROUP_ZRANGE contains a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of Z data coordinates covered by the region.

Version History

Introduced: 5.3

IDLanROIGroup::Init

The IDLanROIGroup::Init function method initializes a region of interest group object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLanROIGroup')

or

Result = *Obj* -> [IDLanROIGroup::]Init( ) (*Only in a subclass' Init method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::Rotate

The IDLanROIGroup::Rotate procedure method modifies the vertices for all regions within the group by applying a rotation.

Syntax

Obj -> [IDLanROIGroup::]Rotate, *Axis*, *Angle*[, CENTER=*[x*, *y*[, *z*]*]*]

Arguments

Axis

A three-element vector of the form [*x, y, z*] describing the axis about which the region group is to be rotated.

Angle

The angle, measured in degrees, by which to rotate the ROI group.

Keywords

CENTER

Set this keyword to a two or three-element vector of the form [*x, y*], or [*x, y, z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROIGroup::Scale

The IDLanROIGroup::Scale procedure method modifies the vertices for the region by applying a scale.

Syntax

Obj -> [IDLanROIGroup::]Scale, *Sx*[, *Sy*[, *Sz*]]

Arguments

Sx

The *X* scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in *X*, *Sx*[1] represents the scale in *Y*, *Sx*[2] represents the scale in *Z*. IDL converts and applies this data in double-precision floating-point.

Sy

The *Y* scale factor. IDL converts and applies this data in double-precision floating-point.

Sz

The *Z* scale factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::Translate

The IDLanROIGroup::Translate procedure method modifies the vertices of all regions within the group by applying a translation.

Syntax

Obj -> [IDLanROIGroup::]Translate, *Tx*[, *Ty*[, *Tz*]]

Arguments

Tx

The *X* translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

Tz

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLcomActiveX

The IDLcomActiveX object class creates an IDL object that encapsulates an ActiveX control. IDL provides data type and other translation services, allowing IDL programs to access the ActiveX control's methods and properties using standard IDL syntax.

For detailed information on using the IDLcomActiveX object, see "Using ActiveX Controls in IDL" in Chapter 5 of the *External Development Guide* manual.

Superclasses

This class is a subclass of IDLcomIDispatch.

Subclasses

When an ActiveX control is instantiated, IDL creates a dynamic subclass of the IDLcomActiveX class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See "ActiveX Control Naming Scheme" in Chapter 5 of the *External Development Guide* manual for details.

Creation

IDLcomActiveX objects are always created automatically by IDL, as a result of a call to the WIDGET_ACTIVEX function. They should never be created manually.

Methods

The IDLcomActiveX object class is a direct subclass of the IDLcomIDispatch class, and relies entirely on the superclass methods, providing none of its own.

Version History

Introduced: 5.5

IDLcomIDispatch

The IDLcomIDispatch object class creates an IDL object that encapsulates a COM object. IDL provides data type and other translation services, allowing IDL programs to access the COM object's methods and properties using standard IDL syntax.

Note

COM objects encapsulated by IDLcomIDispatch objects must implement an IDispatch interface.

For detailed information on using the IDLcomIDispatch object, see Chapter 4, "Using COM Objects in IDL" in the *External Development Guide* manual.

Superclasses

This class has no superclasses.

Subclasses

When a COM object is instantiated, IDL creates a dynamic subclass of the IDLcomIDispatch class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See "IDLcomIDispatch Object Naming Scheme" in Chapter 4 of the *External Development Guide* manual for details.

ActiveX controls are instantiated within IDL as a special subclass of the IDLcomIDispatch class named IDLcomActiveX.

Creation

See IDLcomIDispatch::Init

Methods

- IDLcomIDispatch::Init
- IDLcomIDispatch::GetProperty
- IDLcomIDispatch::SetProperty

In addition to these methods, you can call the underlying COM object's methods directly. See "Method Calls on IDLcomIDispatch Objects" in Chapter 4 of the *External Development Guide* manual for details.

Note

The IDL object system uses method names to identify and call object lifecycle methods (Init and Cleanup). If the COM object underlying an IDLcomIDispatch object implements Init or Cleanup methods, they will be overridden by IDL's lifecycle methods — the COM object's methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for the IDLcomIDispatch object, so any methods of the underlying COM object that use these names will be inaccessible from IDL.

Version History

Introduced: 5.5

IDLcomIDispatch::Init

The IDLcomIDispatch::Init function method is used to initialize a given COM object and establish a link between the resulting IDL object and the IDispatch interface of the underlying COM object.

Syntax

Obj = OBJ_NEW('IDLcomIDispatch$*ID_type*$*ID*')

or

Result = *Obj* -> [IDLcomIDispatch$*ID_type*$*ID*::]Init( ) (*Only in a subclass' Init method*)

where *ID_type* is one of the following:

- `CLSID` if the object is identified by its COM class ID, or
- `PROGID` if the object is identified by its COM program ID,

and *ID* is the COM object's actual class or program identifier string. If the COM object's class identifier string is used to create the IDLcomIDispatch object, the braces ({ }) must be removed and the hyphens replaced by underscores. For details on constructing the class name, see "IDLcomIDispatch Object Naming Scheme" in Chapter 4 of the *External Development Guide* manual for details.

Note

While COM objects incorporated into IDL are instances of the dynamic subclass created when the COM object is instantiated, they still expose the functionality of the class IDLcomIDispatch, which is the direct superclass of the dynamic subclass. All IDLcomIDispatch methods are available to the dynamic subclass.

Arguments

None.

Keywords

None.

Version History

Introduced: 5.5

IDLcomIDispatch::GetProperty

The IDLcomIDispatch::GetProperty function method is used to get properties from the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See "Managing COM Object Properties" in Chapter 4 of the *External Development Guide* manual.

Syntax

Obj -> [IDLcomIDispatch::]GetProperty, *KEYWORD=Variable*, [*arg0*, *arg1*, …]

Arguments

Because some of the underlying COM object's property methods may require arguments, the GetProperty method will accept optional arguments. The values of the arguments themselves will depend on the COM object that underlies the IDLcomIDispatch object.

Note

If arguments are required, you can only specify one property to retrieve in a given call to the GetProperty method.

Keywords

KEYWORD is the name of one of the underlying COM object's properties, and *Variable* is the name of an IDL variable that will contain the retrieved property value. You can get multiple property values in a single statement by supplying multiple *KEYWORD=Variable* pairs.

Note

KEYWORD must map exactly to the full name of the underlying COM object's property method. The partial keyword name functionality provided by IDL is not valid with IDLcomIDispatch objects.

Version History

Introduced: 5.5

IDLcomIDispatch::SetProperty

The IDLcomIDispatch::SetProperty function method is used to set properties for the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See "Managing COM Object Properties" in Chapter 4 of the *External Development Guide* manual for details.

Syntax

Obj -> [IDLcomIDispatch::]SetProperty, *KEYWORD=Expression*

Arguments

None.

Keywords

KEYWORD is the name of one of the underlying COM object's properties, and *Expression* is an IDL expression representing the property value to be set. You can set multiple property values in a single statement by supplying multiple *KEYWORD=Expression* pairs.

Note

KEYWORD must map exactly to the full name of the underlying COM object's property method. The partial keyword name functionality provided by IDL is not valid with IDLcomIDispatch objects.

Version History

Introduced: 5.5

IDLffDICOM

An IDLffDICOM object contains the data for one or more images embedded in a DICOM Part 10 file. The API to the IDLffDICOM object provides accessor methods to the basic data elements of a DICOM file, namely the group/element tag, value representation, length, and data values. Additional methods deal with the file header preamble, data dictionary description for individual elements, and embedded sequences of elements. Most methods take a DICOM group/element tag as a parameter. An alternative parameter to the DICOM tag in some methods is the reference. A reference value is a LONG integer that is unique to each element in the DICOM object. This value can be used to directly access a specific element and to differentiate between elements in the DICOM file that have the same group/element tag. Valid reference values are always positive.

See "IDL DICOM v3.0 Conformance Summary" on page 2459 for information regarding IDL DICOM file reading support.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See IDLffDICOM::Init.

Methods

- IDLffDICOM::Cleanup
- IDLffDICOM::DumpElements
- IDLffDICOM::GetChildren
- IDLffDICOM::GetDescription
- IDLffDICOM::GetElement
- IDLffDICOM::GetGroup
- IDLffDICOM::GetLength

- IDLffDICOM::GetParent
- IDLffDICOM::GetPreamble
- IDLffDICOM::GetReference
- IDLffDICOM::GetValue
- IDLffDICOM::GetVR
- IDLffDICOM::Init
- IDLffDICOM::Read
- IDLffDICOM::Reset

Version History

Introduced: 5.2

IDL DICOM v3.0 Conformance Summary

Introduction

This section is an abbreviated DICOM conformance statement for IDL, and specifies the compliance of Research Systems IDL DICOM file reading support to the DICOM v3.0 standard. As described in the DICOM Standard PS 3.2 (Conformance), the purpose of this document is to outline the level of conformance to the DICOM standard and to enumerate the supported DICOM Service Classes, Information Objects, and Communications Protocols supported by this implementation.

IDL does not contain or support any of the DICOM services such as Storage, Query/Retrieve, Print, Verification, etc., so there will be no conformance claims relating to these services and no mention of any Application Entities for these services. Communications Protocol profiles will also be absent from this document for the same reasons. The remainder of this document will describe how IDL handles the various Information Objects it is capable of reading.

Reading of DICOM Part 10 files

IDL supports reading files that conform to the DICOM Standard PS 3.10 DICOM File Format. This format provides a means to encapsulate in a file the Data Set representing a SOP (Service Object Pair) Instance related to a DICOM IOD (Information Object Definition). Files written to disk in this DICOM File Format will be referred to as DICOM Part 10 files for the remainder of this document. Note that IDL does NOT support the writing of files in this DICOM File Format, only reading.

Encapsulated Transfer Syntaxes Supported

IDL supports reading DICOM Part 10 files whose contents have been written using the following Transfer Syntaxes. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2	Implicit VR Little Endian: Default Transfer Syntax for DICOM
1.2.840.10008.1.2.1	Explicit VR Little Endian
1.2.840.10008.1.2.2	Explicit VR Big Endian

Table A-1: Encapsulated Transfer Syntaxes Supported

Encapsulated Transfer Syntaxes NOT Supported

IDL does NOT support reading DICOM Part 10 files whose contents have compressed data that has been written using the following Transfer Syntaxes. IDL will NOT be able to access the data element (DICOM Tag field (7FE0,0010)) of files with these types of compressed data. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2.4.50	JPEG Baseline (Process 1): Default Transfer Syntax for Lossy JPEG 8 Bit Image Compression
1.2.840.10008.1.2.4.51	JPEG Extended (Process 2 & 4): Default Transfer Syntax for Lossy JPEG 12 Bit Image Compression (Process 4 only)
1.2.840.10008.1.2.4.52	JPEG Extended (Process 3 & 5)
1.2.840.10008.1.2.4.53	JPEG Spectral Selection, Non-Hierarchical (Process 6 & 8)
1.2.840.10008.1.2.4.54	JPEG Spectral Selection, Non-Hierarchical (Process 7 & 9)
1.2.840.10008.1.2.4.55	JPEG Full Progression, Non-Hierarchical (Process 10 & 12)
1.2.840.10008.1.2.4.56	JPEG Full Progression, Non-Hierarchical (Process 11 & 13)
1.2.840.10008.1.2.4.57	JPEG Lossless, Non-Hierarchical (Process 14)
1.2.840.10008.1.2.4.58	JPEG Lossless, Non-Hierarchical (Process 15)
1.2.840.10008.1.2.4.59	JPEG Extended, Hierarchical (Process 16 & 18)
1.2.840.10008.1.2.4.60	JPEG Extended, Hierarchical (Process 17 & 19)
1.2.840.10008.1.2.4.61	JPEG Spectral Selection, Hierarchical (Process 20 & 22)
1.2.840.10008.1.2.4.62	JPEG Spectral Selection, Hierarchical (Process 21 & 23)
1.2.840.10008.1.2.4.63	JPEG Full Progression, Hierarchical (Process 24 & 26)
1.2.840.10008.1.2.4.64	JPEG Full Progression, Hierarchical (Process 25 & 27)
1.2.840.10008.1.2.4.65	JPEG Lossless, Hierarchical (Process 28)

Table A-2: Encapsulated Transfer Syntaxes NOT Supported

UID Value	UID Name
1.2.840.10008.1.2.4.66	JPEG Lossless, Hierarchical (Process 29)
1.2.840.10008.1.2.4.70	JPEG Lossless, Non-Hierarchical, First-Order Prediction (Process 14 [Selection Value 1]): Default Transfer Syntax for Lossless JPEG Image Compression
1.2.840.10008.1.2.5	RLE Lossless

Table A-2: Encapsulated Transfer Syntaxes NOT Supported (Continued)

Encapsulated SOP Classes Supported

IDL supports reading DICOM Part 10 files whose contents encapsulate the data of the following SOP Classes. The SOP Class UID is in the file's DICOM Tag field (0008,0016).

UID Value	UID Name
1.2.840.10008.5.1.4.1.1.1	CR Image Storage
1.2.840.10008.5.1.4.1.1.2	CT Image Storage
1.2.840.10008.5.1.4.1.1.4	MR Image Storage
1.2.840.10008.5.1.4.1.1.6.1	Ultrasound Image Storage
1.2.840.10008.5.1.4.1.1.7	Secondary Capture Image Storage
1.2.840.10008.5.1.4.1.1.12.1	X-Ray Angiographic Image Storage
1.2.840.10008.5.1.4.1.1.12.2	X-Ray Radiofluoroscopic Image Storage
1.2.840.10008.5.1.4.1.1.20	Nuclear Medicine Image Storage
1.2.840.10008.5.1.4.1.1.128	Positron Emission Tomography Image Storage

Table A-3: Encapsulated SOP Classes Supported

Handling of odd length data elements

The DICOM Standard PS 3.5 (Data Structures and Encoding) specifies that the data element values which make up a DICOM data stream must be padded to an even length. The toolkit upon which IDL's DICOM reading functionality is built strictly enforces this specification. If IDL encounters an incorrectly formed odd length data field while reading a DICOM Part 10 file it will report an error and stop the reading process.

Handling of undefined VRs

The VR (Value Representation) of a data element describes the data type and format of that data element's values. If IDL encounters an undefined VR while reading a DICOM Part 10 file, it will set that data element's VR to be UN (unknown).

Handling of retired and private data elements

Certain data elements are no longer supported under the v3.0 of the DICOM standard and are denoted as retired. Also, some DICOM implementations may require the communication of information that cannot be contained in standard data elements, and thus create private data elements to contain such information. Retired and private data elements should pose no problem to IDL's DICOM Part 10 file reading capability. When IDL encounters a retired or private data element tag during reading a DICOM Part 10 file, it will treat it just like any standard data element: read the data value and allow it to be accessed via the IDLffDICOM::GetValue method.

IDLffDICOM::Cleanup

This method destroys the IDLffDICOM object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj `->` [IDLffDICOM::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER="*"))
obj->DumpElements
OBJ_DESTROY, obj

; Executing this statement should produce an invalid object
; reference error since obj no longer exists:
obj->DumpElements
```

Version History

Introduced: 5.2

IDLffDICOM::DumpElements

This method dumps a description of the DICOM data elements of the IDLffDICOM object to the screen or to a file.

Syntax

Obj -> [IDLffDICOM::]DumpElements [, *Filename*]

Arguments

Filename

A scalar string that contains the full path and filename of the file to which to dump the elements. The file is written as ASCII text.

Keywords

None.

Examples

The columns output by DumpElements are the element reference, the (group, element) tuple, the value representation, the description, the value length, and some of the data values.

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements

; Dump the contents of the current DICOM object to a file under
; Windows:
obj->DumpElements, 'c:\rsi\elements.dmp'

; Dump the contents of the current DICOM object to a file under
; UNIX:
obj->DumpElements, '/rsi/elements.dmp'

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetChildren

This method is used to find the member element references of a DICOM sequence. It takes as an argument a scalar reference to a DICOM element representing the parent of the sequence, and returns an array of references to the elements of the object that are members of that sequence. The scalar parent reference is possibly obtained by a previous call to GetReference or any method that generates a reference list. Any member of a sequence may also itself be the parent of another sequence. If the scalar reference argument is not the parent of a sequence, the method returns -1.

Syntax

array = *Obj* `->` [IDLffDICOM::]GetChildren(*Reference*)

Arguments

Reference

This argument is a scalar reference to a DICOM element that is known to be the parent of a DICOM sequence.

Keywords

None.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get a list of references to all elements that are sequences:
refs = obj->GetReference(VR='SQ')

; Cycle through the returned list and print out the immediate
; children references and descriptions of each sequence:
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   IF (refs[i] NE -1) THEN $
      BEGIN
         children = obj->GetChildren(refs[i])
         FOR j = 0, N_ELEMENTS(children)-1 DO $
            BEGIN
               PRINT,children[j]
                 PRINT,obj->GetDescription(REFERENCE=children[j])
         ENDFOR
```

```
   ENDIF
ENDFOR
OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetDescription

This accessor method takes optional DICOM group and element arguments and returns an array of STRING descriptions. The description is a string describing the field's contents as per the data dictionary in the DICOM specification PS 3.6. If no arguments or keywords are specified, the returned array contains the descriptions for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no DICOM elements can be found matching the search criteria, -1 will be returned.

Syntax

array = *Obj* -> [IDLffDICOM::]GetDescription([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

Arguments

Group

Set this optional argument to the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this argument to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element reference values from which to return description values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the description of the patient name element:
arr = obj->GetDescription('0010'x,'0010'x)
PRINT, arr

; Get array of all of the descriptions from the patient info group:
arr = obj->GetDescription('0010'x)
FOR i = 0, N_ELEMENTS(arr)-1 DO BEGIN
   PRINT, arr[i]
ENDFOR

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetElement

This accessor method takes optional DICOM group and/or element arguments and returns an array of DICOM Element numbers for those parameters. If no arguments or keywords are specified, the returned array contains Element numbers for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Syntax

array = *Obj* `->` [IDLffDICOM::]GetElement([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

Arguments

Group

Set this optional argument to the value for the DICOM group to search for, i.e. ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this argument to the value for the DICOM element to search for, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element reference values from which to return element number values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')
```

```
; Get the element numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   num = obj->GetElement(REFERENCE=refs[i])
   PRINT,num
ENDFOR

; Get the element numbers from the Patient Info group, 0010:
elements = obj->GetElement('0010'x)
PRINT, elements

OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetGroup

This accessor method takes optional DICOM group and/or element arguments and returns an array of DICOM Group numbers for those parameters. If no arguments or keywords are specified, the returned array contains Group numbers for all groups in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Syntax

array = *Obj* -> [IDLffDICOM::]GetGroup([*Group*[, *Element*]] [, REFERENCE=*list of element references*])

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return group number values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')
```

```
; Get the group numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   num = obj->GetGroup(REFERENCE=refs[i])
   PRINT, num
ENDFOR

; Get the group numbers from the Patient Info group, 0010:
grp = obj->GetGroup('0010'x)
PRINT, grp

OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetLength

This accessor method takes optional DICOM group and/or element arguments and returns an array of LONGs. The length is the field length that explicitly exists in the DICOM file, and represents the length of the element value in bytes. If no arguments or keywords are specified, the returned array contains the lengths for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Syntax

array = *Obj* -> [IDLffDICOM::]GetLength([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, all DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return length values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the length of the patient name element:
arr = obj->GetLength('0010'x,'0010'x)
PRINT, arr
```

```
; Get an array of all of the lengths from the patient info group:
arr = obj->GetLength('0010'x)
PRINT, arr
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetParent

This method is used to find the parent references of a set of elements in a DICOM sequence. It takes as an argument an array of references that represent DICOM elements. If no members of the ReferenceList are members of a sequence, a -1 is returned, and for each member of the ReferenceList which is not a member of a sequence, a -1 is returned.

Syntax

array = *Obj* ->[IDLffDICOM::]GetParent(*ReferenceList*)

Arguments

ReferenceList

An array of references to DICOM elements that are known to be members of a DICOM sequence.

Keywords

None.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the reference to the Referenced Study Sequence
; element, if it exists:
ref = obj->GetReference('0008'x,'1110'x)
PRINT, ref
PRINT, obj->GetDescription(REFERENCE=ref)

; Get and print the parent sequence, if it exists.
; This should result in a -1 since this element is not
; a member of a sequence:
parent = obj->GetParent(ref)
PRINT, parent
PRINT, obj->GetDescription(REFERENCE=parent)

; Get the children of the  Referenced Study Sequence
; element, if it exists:
refs = obj->GetChildren(ref[0])
```

```
PRINT, refs
PRINT, obj->GetDescription(REFERENCE=refs)
OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetPreamble

This method returns the preamble of a DICOM v3.0 Part 10 file. The preamble is a fixed 128 byte field available for implementation specified usage. If it is not used by the implementor of the file, it will be set to all zeroes. The return value is a 128-element BYTE array.

Syntax

array = *Obj* `->` [IDLffDICOM::]GetPreamble( )

Arguments

None.

Keywords

None.

Examples

```
; Create a DICOM object, read a DICOM file:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get an array of the byte contents of the DICOM file preamble:
arr = obj->GetPreamble( )
PRINT, arr

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetReference

This method takes optional DICOM group and/or element arguments and returns an array of references to matching elements in the object. References are opaque, meaning that they have no specific significance other than a correspondence to the element they refer to. If no arguments or keywords are specified, the returned array contains references to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Syntax

array = Obj -> [IDLffDICOM::]GetReference([*Group* [, *Element*]] [, DESCRIPTION=*string*] [, VR=*DICOM VR string*])

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element to search for, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

DESCRIPTION

Set this keyword to a string containing text to be searched for in each element’s DICOM description. An element will be returned only if the text in this string can be found in the description. The text comparison is case-insensitive.

VR

Set this keyword to a DICOM VR string. An element will be returned only if its value representation matches this string.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the reference to the patient name element:
ref = obj->GetReference('0010'x,'0010'x)
PRINT, ref

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   PRINT, refs[i]
   PRINT, obj->GetDescription(REFERENCE=refs[i])
ENDFOR

; Get references to all elements with a VR of DA (date):
refs = obj->GetReference(vr='DA')
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   PRINT, refs[i]
   PRINT, obj->GetDescription(REFERENCE=refs[i])
ENDFOR

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetValue

This method takes optional DICOM group and/or element arguments and returns an array of POINTERs to the values of the elements matching those parameters. If no arguments or keywords are specified, the returned array contains pointers to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Syntax

ptrArray = *Obj* -> [IDLffDICOM::]GetValue([*Group* [, *Element*]] [, REFERENCE=*list of element references*] [, /NO_COPY])

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return pointer values.

NO_COPY

If this keyword is set, the pointers returned point to the actual data in the object for the specified DICOM fields. If not set (the default), the pointers point to copies of the data instead, and need to be freed by using PTR_FREE.

Examples

Example 1

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the image data
array = obj->GetValue('7fe0'x, '0010'x)
OBJ_DESTROY, obj

TVScl, *array[0]
PTR_FREE, array
```

Example 2

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get all of the image data element(s), 7fe0,0010, from the file:
array = obj->GetValue('7fe0'x,'0010'x,/NO_COPY)

; Get the row & column size of the image(s):
rows = obj->GetValue('0028'x,'0010'x,/NO_COPY)
cols = obj->GetValue('0028'x,'0011'x,/NO_COPY)

; If the image has a samples per pixel value greater than 1
; it is most likely a color image, get the samples per pixel:
isColor = 0
samples = obj->GetValue('0028'x,'0002'x,/NO_COPY)
IF (SIZE(samples,/N_DIMENSIONS) NE 0) THEN BEGIN
   IF (*samples[0] GT 1) THEN isColor = 1
ENDIF

; Next, we need to differentiate between files with color data
; that is either color-by-plane or color-by-pixel, get the planar
; configuration:
IF (isColor EQ 1) THEN BEGIN
   isPlanar = 0
   planar = obj->GetValue('0028'x,'0006'x, /NO_COPY)
   IF (SIZE(planar, /N_DIMENSIONS) NE 0) THEN BEGIN
      IF (*planar[0] EQ 1) THEN isPlanar = 1
   ENDIF
ENDIF

; Display the first NumWin images from the file:
IF N_ELEMENTS(array) GT 10 THEN NumWin = 10 $
ELSE NumWin = N_ELEMENTS(array)
```

```
offset = 0
FOR index = 0, NumWin-1 DO BEGIN
   ; Create window for each image that is the size of the image:
   WINDOW,index,XSize=*cols[0],YSize=*rows[0],XPos=offset,YPos=0
   WSET,index
   ; Display the image data
   IF (isColor EQ 1) THEN $
       IF (isPlanar EQ 1) THEN $
          ; color-by-plane
          TVScl,TRANSPOSE(*array[index],[2,0,1]),/TRUE $
       ELSE $
          ; color-by-pixel
          TVScl,*array[index],/TRUE $
   ELSE $
      ; monochrome
      TVScl,*array[index]
      offset = offset+10
ENDFOR

; Clean up
OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetVR

This accessor method takes optional DICOM group and/or element arguments and returns an array of VR (Value Representation) STRINGs for those parameters. A VR is a string that represents a DICOM value representation as described in the DICOM specification PS 3.5. If no arguments or keywords are specified, the returned array contains VRs for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Syntax

array = *Obj* `->` [IDLffDICOM::]GetVR([*Group* [, *Element*]] [, REFERENCE=*list of references*])

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Use the specified list of references from which to return VR STRING values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the VR of the patient name element:
arr = obj->GetVR('0010'x,'0010'x)
```

```
PRINT, arr

; Get an array of all of the VRs from the patient info group:
arr = obj->GetVR('0010'x)
PRINT, arr

OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::Init

This method creates a new IDLffDICOM object and optionally reads the specified file as defined in the IDLffDICOM::Read method.

Syntax

Result = OBJ_NEW('IDLffDICOM' [, *Filename*] [, /VERBOSE])

or

Result = *Obj* -> [IDLffDICOM::]Init([*Filename*] [, /VERBOSE]) (*Only in a subclass' Init method*.)

Arguments

Filename

This optional argument is a scalar string that contains the full path and filename of a DICOM v3.0 Part 10 file to open, read into memory, then close, when the object is created. It is the same as calling: result->Read(Filename).

Keywords

VERBOSE

Set this keyword to print informational messages to the Output Log during the operational life of the object.

Examples

```
; Create a DICOM object:
obj = OBJ_NEW( 'IDLffDICOM' )

; Create a DICOM object and read in a DICOM file named ct_head.dcm
; under Microsoft Windows:
obj = OBJ_NEW( 'IDLffDICOM', $
   'c:\rsi\idl52\examples\data\mr_brain.dcm' )

; Create a DICOM object and allow the user to choose a DICOM file
; to be read:
obj = OBJ_NEW( 'IDLffDICOM', DIALOG_PICKFILE(FILTER='*'))
```

Version History

Introduced: 5.2

IDLffDICOM::Read

This method opens and reads from the specified disk file, places the information into the DICOM object, then closes the file. The return value is 1 on success and 0 on failure.

Syntax

result = *Obj* -> [IDLffDICOM::]Read(*Filename* [, ENDIAN={1 | 2 | 3 | 4}])

Arguments

Filename

This argument is a scalar string that contains the full path and filename of a DICOM Part 10 file to open and read into memory.

Keywords

ENDIAN

Set this keyword to configure the endian format when reading a DICOM file.

- 1 = Implicit VR Little Endian
- 2 = Explicit VR Little Endian
- 3 = Implicit VR Big Endian
- 4 = Explicit VR Big Endian

Examples

```
; Create a DICOM object and read a DICOM file:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::Reset

This method removes all of the elements from the IDLffDICOM object, leaving the object otherwise intact.

Syntax

Obj -> [IDLffDICOM::]Reset

Arguments

None.

Keywords

None.

Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements
obj->Reset

; DumpElements should produce no output here:
obj->DumpElements
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDXF

An IDLffDXF object contains geometry, connectivity and attributes for graphics primitives.

Note

IDL supports version 2.003 of the DXF Library.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See “IDLffDXF::Init” on page 2509

Methods

Intrinsic Methods

This class has the following methods:

- IDLffDXF::Cleanup
- IDLffDXF::GetContents
- IDLffDXF::GetEntity
- IDLffDXF::GetPalette
- IDLffDXF::Init
- IDLffDXF::PutEntity
- IDLffDXF::Read
- IDLffDXF::RemoveEntity
- IDLffDXF::Reset
- IDLffDXF::SetPalette

- IDLffDXF::Write

This object treats a DXF file as a list of entities. Note, these are not directly mapped to DXF entity types, rather they are an abstraction of the DXF types. The Read method is used to read the contents of a DXF file into the current entity list. The user may then query this list using the GetContents method to determine the types and number of entities in the file. The user may retrieve arrays of entities from the list using the GetEntity method and add additional entities using the PutEntity method. Entities can also be removed from the list (RemoveEntity) or the entire list destroyed (Reset). The current list of entities can also be written to disk as a DXF file. Note, this object converts DXF entities to IDL entities and back. This conversion is not reversible; thus, if a DXF file is read and then written, the data in the file is not changed, but the internal DXF entity types may be changed by IDL. As an example, DXF face3d entities may be written as DXF polyline entities.

The object has one attribute which can be modified using the Get/SetPalette methods. This palette is used to convert color index values. The palette is not actually written to the DXF file. So, if the user wanted to specify entity colors from a 256 entry table, that table would be set using SetPalette, but the actual colors written to the file are the closest colors matched to the fixed AutoCAD color palette. There are two special color values: (0) = color by block color, (256) = color by layer color.

In this object, blocks and layers are treated as named entities with attributes, but are special in that all other entities have a block and layer entity reference in them. This allows the user to use these entity names as filters for many operations. There is a default block and a default layer. The default block has the name “” (the null string), and the default layer is '0'. The user may change the (non-name) attributes for these implicit blocks using PutEntity.

Version History

Introduced: 5.2

IDLffDXF::Cleanup

The IDLffDXF::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLffDXF::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.2

IDLffDXF::GetContents

The IDLffDXF::GetContents method returns a description of the content of the DXF file. The returned value is an array of the DXF entity type codes and the number of occurrences of each entity type contained in the object.

See the Examples following the GetEntity method description for an illustration of the difference between the GetContents and the GetEntity methods.

The Read or PutEntity methods must have been called previously for the results of this method to be valid.

Valid DXF ENTITY Types	DXF_TYPE (0=default)
ARC	1
CIRCLE	2
ELLIPSE	3
LINE	4
LINE3D	5
TRACE	6
POLYLINE	7
LWPOLYLINE	8
POLYGON	9
FACE3D	10
SOLID	11
RAY	12
XLINE	13
TEXT	14
MTEXT	15
POINT	16
SPLINE	17

Table A-4: DXF Entity Types

Valid DXF ENTITY Types	DXF_TYPE (0=default)
BLOCK	18
INSERT	19
LAYER	20

Table A-4: DXF Entity Types (Continued)

This object uses a small number of IDL named structures to return the data associated which each entity. This means that several of these DXF types are returned in the same structures, using different values of the DXF_TYPE field. The mapping of DXF entities to IDL named structures is as follows (each of these structures is documented in the GetEntity method):

IDL Structure	DXF Entity
IDL_DXF_ELLIPSE	arc, circle, ellipse
IDL_DXF_POLYLINE	line, line3d, trace, polyline, lwpolyline
IDL_DXF_POLYGON	face3d, solid, polyline (3-d mesh)
IDL_DXF_POINT	point
IDL_DXF_XLINE	ray, xline
IDL_DXF_SPLINE	spline
IDL_DXF_TEXT	text, multitext
IDL_DXF_BLOCK	block
IDL_DXF_INSERT	insert
IDL_DXF_LAYER	layer

Table A-5: DXF mapping to IDL structures

Syntax

Result = *Obj*-> [IDLffDXF::]GetContents([*Filter*] [BLOCK=*string*] [, COUNT=*variable*] [LAYER=*string*])

Arguments

Filter

An integer array of the DXF entity types to which the return types are restricted. If set, Result can contain only types given in this argument and count will also reflect that restriction.

Keywords

BLOCK

Set this keyword to a string value containing the block name to obtain the entities from. The default is all blocks.

COUNT

A long array containing the number of each entity type contained within the DXF object. If the Filter argument was provided, the numbers reflect the reduced set of entities caused by the Filter argument.

LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

Version History

Introduced: 5.2

IDLffDXF::GetEntity

The IDLffDXF::GetEntity method returns an array of data for the requested entity type.

Syntax

Result = *Obj*->[IDLffDXF::]GetEntity(*Type* [, BLOCK=*string*] [, INDEX=*value*] [, LAYER=*string*])

Note

Result has one of the named structure formats described in "Structure Formats" on page 2497.

Arguments

Type

The integer DXF entity type from which to obtain the geometry information.

Keywords

BLOCK

Set this keyword to a block name specifying the graphic block from which to obtain the entity geometry information. The default is all blocks. Setting this keyword to the null string " " will cause this method to only return entities from the default DXF entity block.

INDEX

Set this keyword to a scalar index or a long array of indices of entities of the given type to return. If not set, this method returns all entities for the given type.

LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

Fields Common to All Structures

BLOCK

The name of the block this entity is in (these may be in the default block “”).

COLOR

A color index value into the current object palette with 0=use block color and 256=use layer color.

EXTRUSION

The DXF extrusion vector (if any).

LAYER

The name of the layer this entity is in (the default layer is '0').

LINESTYLE

Defined the same as the user linestyle for IDLgrPolyline::Init.

Note

IDL will always return a solid line regardless of the linestyle in DXF

THICKNESS

In AutoCAD units.

DXF_TYPE

Set to one of the values listed in IDLffDXF::GetContents.

Note

It is the user’s responsibility to free all the pointers returned in these structures when the entity is no longer needed.

Structure Formats

Structure IDL_DXF_ELLIPSE

Field	Data Type
PT0	Double [3]
PT1_OFFSET	Double [3]
MIN_TO_MAJ_RATIO	Double
START_ANGLE	Double
END_ANGLE	Double
EXTRUSION	Double [3]
LINESTYLE	Integer [2]
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-6: Fields of the IDL_DXF_ELLIPSE Structure

This object is centered at PT0 and has a radius defined by the vector PT1_OFFSET. This vector determines the length and orientation of the major axis of an ellipse as well.

The MIN_TO_MAJ_RATIO value specifies the length of the minor axis as a fraction of the major axis length. For a circle, this value is 1.0.

The START_ANGLE and END_ANGLE values select the portion of the curve to be drawn. If they are equal, the entire circle or ellipse is drawn.

Structure IDL_DXF_POLYGON

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
COLOR	Integer
EXTRUSION	Double [3]
FIT_TYPE	Integer
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-7: Fields of the IDL_DXF_POLYGON Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polygons (see the POLYGONS keyword for IDLgrPolygon::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polygon assumes.

Structure IDL_DXF_POLYLINE

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
COLOR	Integer
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
FIT_TYPE	String
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-8: Fields of the IDL_DXF_POLYLINE Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polylines (see the POLYLINES keyword for IDLgrPolyline::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polyline assumes.

Structure IDL_DXF_POINT

Field	Data Type
PT0	Double [3]
UCSX_ANGLE	Double
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-9: Fields of the IDL_DXF_POINT Structure

PT0 is the location of the point in space.

UCSX_ANGLE is an internal DXF orientation parameter used for symbol plotting.

Structure IDL_DXF_SPLINE

Field	Data Type
CTR_PTS	Pointer
FIT_PTS	Pointer
KNOTS	Pointer
WEIGHTS	Pointer
COLOR	Integer
DEGREE	Integer
PERIODIC	Integer
RATIONAL	Integer
PLANAR	Integer
LINEAR	Integer
KNOT_TOLERANCE	Double
CTL_TOLERANCE	Double
FIT_TOLERANCE	Double
START_TANGENT	Double [3]
END_TANGENT	Double [3]
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-10: Fields of the IDL_DXF_SPLINE Structure

This structure is returned verbatim from the DXF spline structure without interpretation. It is up to the user to interpret these values.

Structure IDL_DXF_TXT

Field	Data Type
PT0	Double [3]
TEXT_STR	String
COLOR	Integer
HEIGHT	Double
WIDTH_FACTOR	Double
BOX_WIDTH	Double
DIRECTION	Double [3]
ROT_ANGLE	Double
JUSTIFICATION	Integer (0=left, 1=center, 2=right, 3=aligned, 4=middle, 5=fit)
VERTICAL_ALIGN	Integer (0=baseline, 1=bottom, 2=middle, 3=top)
SHAPE_FILE	String
THICKNESS	Double
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-11: Fields of the IDL_DXF_TXT Structure

PT0 is the location of the text string.

TEXT_STR is the actual string.

HEIGHT specifies the overall scaling of the glyphs while WIDTH_FACTOR is a correction in the baseline direction (anisotropic scaling). For multi-line text, BOX_WIDTH determines where the line breaks should be placed (0.0 for single line text).

The text baseline is specified by DIRECTION and its rotation about the *z*-axis is specified by ROT_ANGLE. Justification is specified by JUSTIFICATION and VERTICAL_ALIGN. SHAPE_FILE is the name of the glyph file used to image this string. The shape file is NOT read by IDL.

Structure IDL_DXF_XLINE

Field	Data Type
PT0	Double [3]
UNIT_VEC	Double [3]
COLOR	Integer
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table A-12: Fields of the IDL_DXF_XLINE Structure

PT0 is the start of a ray or a point on a infinite line in space in the case of an XLINE entity.

UNIT_VEC determines the direction of the line in space.

Structure IDL_DXF_INSERT

Field	Data Type
SCALE	Double [3]
PT0	Double [3]
ROTATION	Double
INSTANCE_BLOCK	String
NUM_ROW_COL	Integer [2]
DISTANCE_BETWEEN	Double [2]
DXF_TYPE	Integer
BLOCK	String
COLOR	Integer
LAYER	String

Table A-13: Fields of the IDL_DXF_INSERT Structure

The insert entity allows for the “instancing” of a block in a grid fashion.

INSTANCE_BLOCK is the name of a block to repeat.

The block is scaled by SCALE and rotated about the Z axis by ROTATION. The grid begins at PT0 and contains the number of rows and columns specified by NUM_ROW_COL (Note: 0 rows or columns will always give a single instance of the block).

The spacing of the grid is specified by DISTANCE_BETWEEN.

Structure IDL_DXF_BLOCK

Field	Data Type
PT0	Double [3]
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table A-14: Fields of the IDL_DXF_BLOCK Structure

This entity specifies a BLOCK. Blocks have a location in space (PT0) [objects in the block are interpreted relative to this point], a name, and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Structure IDL_DXF_LAYER

Field	Data Type
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table A-15: Fields of the IDL_DXF_LAYER Structure

This entity specifies a LAYER. Layer is a NAME and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Examples

This example illustrates the difference between the GetEntity and GetContents methods within the IDLffDXF object method. The GetContents method gives a description of the content of the file read, listing the entity types and the number of occurrences. GetEntity accesses the values returned by GetContents and determines how the entities can be logically combined into common structures for drawing efficiency.

```
PRO view_heart
; Determine path to data file.
heartFile = FILEPATH('heart.dxf', $
   SUBDIRECTORY = ['examples', 'data'])
; Initialize DXF data access object.
oHeart = OBJ_NEW('IDLffDXF')
; Read data within DXF file into access object.
status = oHeart -> Read(heartFile)
; Determine what type of entities (and how many of
; each entity) exist in the file.
heartTypes = oHeart -> GetContents(COUNT = heartCounts)
PRINT, 'Entity Types:   ', heartTypes
PRINT, 'Count of Types: ', heartCounts
; Initialize a model for displaying polygon and polyline
; objects.
oModel = OBJ_NEW('IDLgrModel')
; Obtain the tissue data.  The tissue is accessed into
; IDL as a single polygon.
tissue = oHeart -> GetEntity(heartTypes[1])
HELP, tissue
HELP, tissue, /STRUCTURE
; Initialize color parameter.
tissueColor = [255, 0, 0]
; Initialize polygon data.
vertices = tissue.vertices
connectivity = tissue.connectivity
; Initialize the polygon object.
oTissue = OBJ_NEW('IDLgrPolygon', $
   *vertices, POLYGONS = *connectivity, $
   COLOR = tissueColor)
; Add the polygon to the model.
oModel -> Add, oTissue
; Clean-up all the related pointers.
PTR_FREE, tissue.vertices, tissue.connectivity, $
   tissue.vertex_colors
PTR_FREE, vertices, connectivity
; Display the polylines and the polygon in the XOBJVIEW
; utility.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75
; Clean-up the object references.
OBJ_DESTROY, [oHeart, oModel]
END
```

An Xobjview window with the mesh heart object appears when this program is compiled and run. The following lines are found in the IDLDE Output Log window.

```
IDL> view_heart
% Compiled module: VIEW_HEART.
% Compiled module: FILEPATH.
```

```
% Loaded DLM: DXF.
Entity Types:              7          10          18          20
Count of Types:           13        1624           1           2
```

The Entity Types (7, 10, 18, and 20) are the GetContents method return values corresponding to the occurrence of DXF ENTITY types found in the object: POLYLINES, FACE3D, BLOCK, and LAYER, respectively. Note there are a total of 1624 FACE3D entity types, but for efficiency and speed IDL logically combines all of the similar entities into a single structure that can be used in an IDLgrPolygon object. This is illustrated by the output resulting from the first Help command in the program as shown below.

```
TISSUE          STRUCT    = -> IDL_DXF_POLYGON Array[1]
** Structure IDL_DXF_POLYGON, 13 tags, length=72:
   EXTRUSION       DOUBLE    Array[3]
   VERTICES        POINTER   <PtrHeapVar3>
   CONNECTIVITY    POINTER   <PtrHeapVar4>
   VERTEX_COLORS   POINTER   <PtrHeapVar5>
   MESH_DIMS       INT       Array[2]
   CLOSED          INT       Array[2]
   COLOR           INT            256
   FIT_TYPE        INT             -1
   CURVE_FIT       INT              0
   SPLINE_FIT      INT              0
   DXF_TYPE        INT             10
   BLOCK           STRING    ''
   LAYER           STRING    '0----'
% Compiled module: XOBJVIEW.
% Compiled module: UNIQ.
% Compiled module: IDENTITY.
% Compiled module: XMANAGER.
```

Note that the tissue is represented as an array of polygons having 1 element. This is evident by the mesh representation of the heart object showing the 1624 individual polygons as a single object.

Version History

Introduced: 5.2

IDLffDXF::GetPalette

The IDLffDXF::GetPalette method returns the current color table in the object.

Syntax

Obj->[IDLffDXF::]GetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Returns an array of the red components to the current color table.

Green

Returns an array of the green components to the current color table.

Blue

Returns an array of the blue components to the current color table.

Keywords

None.

Version History

Introduced: 5.2

IDLffDXF::Init

The IDLffDXF::Init function method initializes the DXF object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = OBJ_NEW('IDLffDXF' [, *Filename*])

or

Result = *Obj* -> [IDLffDXF::]Init([*Filename*]) (*Only in a subclass' Init method.*)

Arguments

Filename

Set this optional argument to a scalar string containing the full path and filename of a DXF file to be read as the object is created.

Keywords

None.

Version History

Introduced: 5.2

IDLffDXF::PutEntity

The IDLffDXF::PutEntity procedure method inserts an entity into the DXF object. The type of the entity is determined from the DXF_TYPE field of the entity structure. If DXF_TYPE is set to 0, the type is implied by the entity structure.

Note

Line3D entity types will be written as Line entities due to the obsolete status of Line3D. Polyline entities will be automatically converted to Lightweight Polylines where applicable.

Syntax

Obj -> [IDLffDXF::]PutEntity, *Data*

Arguments

Data

An array of Entity structures as defined by the GetEntity method.

Note

If the entity references a non-existent block or layer, one will automatically be created. Blocks and layers can also be created by passing IDL_DXF_BLOCK or IDL_DXF_LAYER structures to this routine.

Keywords

None.

Version History

Introduced: 5.2

IDLffDXF::Read

The IDLffDXF::Read method reads a file, parsing the DXF object information contained in the file, and inserts it into itself. This method returns an indication of success in reading the file.

Syntax

Result = *Obj*->[IDLffDXF::]Read(*Filename*)

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be read.

Keywords

None.

Examples

```
; Read all the lines from the electrical layer:
oDXF = OBJ_NEW('IDLffDXF')
IF (oDXF->Read('myDXF.dxf')) THEN BEGIN
   contents = oDXF->GetContents(4,COUNT=numLines, $
      LAYER='Electrical')
   IF (numLines ne 0) THEN BEGIN
      lines = oDXF->GetEntity(4,LAYER='Electrical')
   ENDIF
ENDIF
```

Version History

Introduced: 5.2

IDLffDXF::RemoveEntity

The IDLffDXF::RemoveEntity method removes the specified entity or entities from the DXF object.

Syntax

Obj -> [IDLffDXF::]RemoveEntity[, *Type*] [, INDEX=*value*]

Arguments

Type

An optional scalar string containing the DXF type to be removed from the DXF object.

Note

Specifying a block or layer entity will cause all the entities in that layer or block to be removed.

Keywords

INDEX

Set this keyword to a scalar long or a long array of indices to remove from the DXF object. If not set, or set negative, all entities of the given type are removed.

Version History

Introduced: 5.2

IDLffDXF::Reset

The IDLffDXF::Reset method removes all the entities from the DXF object.

Syntax

Obj->[IDLffDXF::]Reset

Arguments

None.

Keywords

None.

Version History

Introduced: 5.2

IDLffDXF::SetPalette

The IDLffDXF::SetPalette method sets the current color table in the object.

Syntax

Obj->[IDLffDXF::]SetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Sets the red components of the current color table to this array.

Green

Sets the green components of the current color table to this array.

Blue

Sets the blue components of the current color table to this array.

Keywords

None.

Version History

Introduced: 5.2

IDLffDXF::Write

The IDLffDXF::Write method writes a file for the DXF entity information this object contains. This method returns an indication of success in writing the file.

Syntax

Result = *Obj*->[IDLffDXF::]Write(*Filename*)

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be written.

Keywords

None.

Examples

```
; Write a square to a new DXF file using lines:
oDXF = OBJ_NEW('IDLffDXF')
lines = {IDL_DXF_POLYLINE}
lines.dxf_type = 4
lines.layer='myLayer'
lines.thickness = 1.0

; Create clockwise square:
lines = REPLICATE(lines, 4)
lines[0].vertices = PTR_NEW([[0.0,0.0,0.0], $
     [0.0,1.0,0.0]])
lines[0].connectivity = PTR_NEW([0,1])
lines[1].vertices = PTR_NEW([[0.0,1.0,0.0], $
    [1.0,1.0,0.0]])
lines[1].connectivity = PTR_NEW([0,1])
lines[2].vertices = PTR_NEW([[1.0,1.0,0.0], $
    [1.0,0.0,0.0]])
lines[2].connectivity = PTR_NEW([0,1])
lines[3].vertices = PTR_NEW([[1.0,0.0,0.0], $
    [0.0,0.0,0.0]])
lines[3].connectivity = PTR_NEW([0,1])
oDXF->PutEntity, lines
IF (not oDXF->Write('mySquare.dxf')) THEN $
   PRINT, 'Write Failed.'
```

```
   ; Clean up the memory in the structs:
   OBJ_DESTROY, oDXF
   FOR i=0,3 DO BEGIN
      PTR_FREE, lines[i].vertices, lines[i].connectivity
ENDFOR
```

Version History

Introduced: 5.2

IDLffLanguageCat

The IDLffLanguageCat object provides an interface to IDL language catalog files.

Note

This object is not savable. Restored IDLffLanguageCat objects may contain invalid data.

Note

This object is not intended to be created with OBJ_NEW. The MSG_CAT_OPEN function is used to return the correct object reference.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See MSG_CAT_OPEN.

Methods

- IDLffLanguageCat::IsValid
- IDLffLanguageCat::Query
- IDLffLanguageCat::SetCatalog

Version History

Introduced: 5.2.1

See Also

MSG_CAT_CLOSE, MSG_CAT_COMPILE, MSG_CAT_OPEN

IDLffLanguageCat::IsValid

The IDLffLanguageCat::IsValid function method is used to determine whether the object has a valid catalog.

Syntax

Result = *Obj* ->[IDLffLanguageCat::]IsValid( )

Arguments

None.

Keywords

None.

Version History

Introduced: 5.2.1

IDLffLanguageCat::Query

The IDLffLanguageCat::Query function method is used to return the language string associated with the given key. If the key is not found in the given catalog, the default string is returned.

Syntax

Result = *Obj* ->[IDLffLanguageCat::]Query(*key* [, DEFAULT_STRING=*string*])

Arguments

key

The scalar, or array of (string) keys associated with the desired language string. If key is an array, *Result* will be a string array of the associated language strings.

Keywords

DEFAULT_STRING

Set this keyword to the desired value of the return string if the key cannot be found in the catalog file. The default value is the empty string.

Version History

Introduced: 5.2.1

IDLffLanguageCat::SetCatalog

The IDLffLanguageCat::SetCatalog function method is used to set the appropriate catalog file. This function returns 1 upon success, and 0 on failure.

Syntax

Result = *Obj* ->[IDLffLanguageCat::]SetCatalog(*application* [, FILENAME=*string*] [, LOCALE=*string*] [, PATH=*string*])

Arguments

application

A scalar string representing the name of the desired application's catalog file.

Keywords

FILENAME

Set this keyword to a scalar string containing the full path and filename of the catalog file to open. If this keyword is set, *application*, PATH, and LOCALE are ignored.

LOCALE

Set this keyword to the desired locale for the catalog file. If not set, the current locale is used.

PATH

Set this keyword to a scalar string containing the path to search for language catalog files. The default is the current directory.

Version History

Introduced: 5.2.1

IDLffMrSID

An IDLffMrSID object class is used to query information about and load image data from a MrSID (`.sid`) image file.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See IDLffMrSID::Init

Methods

This class has the following methods:

- IDLffMrSID::Cleanup
- IDLffMrSID::GetDimsAtLevel
- IDLffMrSID::GetImageData
- IDLffMrSID::GetProperty
- IDLffMrSID::Init

Version History

Introduced: 5.5

IDLffMrSID::Cleanup

The IDLffMrSID::Cleanup procedure method deletes all MrSID objects, closing the MrSID file in the process. It also deletes the IDL objects used to communicate with the MrSID library.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLffMrSID::]Cleanup (*Only in subclass' Cleanup metho*d.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.5

IDLffMrSID::GetDimsAtLevel

The IDLffMrSID::GetDimsAtLevel function method is used to retrieve the dimensions of the image at a given level. This can be used, for example, to determine what level is required to fit the image into a certain area.

Syntax

Dims = *Obj* -> [IDLffMrSID::]GetDimsAtLevel (*Level*)

Arguments

Level

Set this argument to a scalar integer that specifies the level at which the dimensions are to be determined. This level must be in the range returned by the LEVELS keyword of IDLffMrSID::GetProperty.

Keywords

None.

Examples

```
PRO MrSID_GetDimsAtLevel

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile -> GetProperty, LEVELS = lvls
PRINT, lvls
; IDL prints, -9, 4

; Print the image dimensions at the lowest image resolution
; where image level = 4.
imgLevelA = MAX(lvls)
dimsAtA = oFile-> GetDimsAtLevel(imgLevelA)
PRINT, 'Dimensions of lowest resolution image is', dimsAtA
;IDL prints, 32, 32
```

```
; Print the image dimensions at full resolution
; where image level = 0
dimsAtFull = oFile -> GetDimsAtLevel(0)
PRINT, 'Dimensions of full resolution image is', dimsAtFull
;IDL prints, 512, 512

;Print the image dimensions at the highest resolution
; where image level = -9
highestLvl = MIN(lvls)
dimsAtHighest = oFile -> GetDimsAtLevel(highestLvl)
PRINT, 'Dimensions of highest resolution image is', dimsAtHighest
;IDL prints, 262144, 262144

; Clean up object references.
OBJ_DESTROY, [oFile]

END
```

Version History

Introduced: 5.5

IDLffMrSID::GetImageData

The IDLffMrSID::GetImageData function method extracts and returns the image data from the MrSID file at the specified level and location.

Syntax

ImageData = *Obj*->[IDLffMrSID::]GetImageData ([, LEVEL = *lvl*] [, SUB_RECT = *rect*])

Return Value

ImageData returns an *n*-by-*w*-by-*h* array containing the image data where *n* is 1 for grayscale or 3 for RGB images, *w* is the width and *h* is the height.

Note

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left corner of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left corner of the image.

Arguments

None.

Keywords

LEVEL

Set this keyword to an integer that specifies the level at which to read the image.

If this keyword is not set, the maximum level is used which returns the minimum resolution (see the LEVELS keyword to IDLffMrSID::GetProperty).

SUB_RECT

Set this keyword to a four-element vector [x, y, xdim, ydim] specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying portions of a high-resolution image.

If this keyword is not set, the whole image will be returned. This may require significant memory if a high-resolution image level is selected.

If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

Note

The elements of SUB_RECT are measured in pixels at the current level. This means the point x = 10, y = 10 at level 1 will be located at x = 20, y = 20 at level 0 and x = 5, y = 5 at level 2.

Examples

```
PRO MrSID_GetImageData

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile -> GetProperty, LEVELS = lvls
PRINT, lvls
; IDL prints, -9, 4

; Get the image data at level 0.
imgDataA = oFile -> GetImageData(LEVEL = 0)
HELP, 'image array data at full resolution', imgDataA
;IDL prints, Array[1, 512, 512] indicating a grayscale 512 x 512
array.

; Display the full resolution image.
oImgA = OBJ_NEW('IDLgrImage', imgDataA)
oModelA = OBJ_NEW('IDLgrModel')
oModelA -> Add, oImgA
XOBJVIEW, oModelA, BACKGROUND = [0,0,0], $
   TITLE = 'Full Resolution Image', /BLOCK

; Get the image data of a higher resolution image,
imgDataB = oFile -> GetImageData(LEVEL = -2)
HELP, imgDataB
; IDL returns [1,2048,2048] indicating a grayscale 2048 x 2048
array.
```

```
; To save processing time, display only a 1024 x 1024 portion of
; the high resolution, using 512,512 as the origin..
imgDataSelect = oFile -> GetImageData(LEVEL = -2,$
   SUB_RECT = [512, 512, 1024, 1024])
oImgSelect = OBJ_NEW('IDLgrImage', imgDataSelect)
oModel = OBJ_NEW('IDLgrModel')
oModel -> Add, oImgSelect

XOBJVIEW, oModel, BACKGROUND = [0,0,0], $
   TITLE = 'Detail of High Resolution Image', /BLOCK

; Clean up object references.
OBJ_DESTROY, [oFile, oImgA, oModelA, oImgSelect, oModel]

END
```

Version History

Introduced: 5.5

IDLffMrSID::GetProperty

The IDLffMrSID::GetProperty function method is used to query properties associated with the MrSID image.

Syntax

Obj->[IDLffMrSID::]GetProperty [, CHANNELS=*nChannels*] [, DIMENSIONS=*Dims*] [, LEVELS=*Levels*] [, PIXEL_TYPE=*pixelType*] [, TYPE=*strType*] [, GEO_VALID=*geoValid*] [, GEO_PROJTYPE=*geoProjType*] [, GEO_ORIGIN=*geoOrigin*] [, GEO_RESOLUTION=*geoRes*]

Arguments

None.

Keywords

CHANNELS

Set this keyword to a named variable that will contain the number of image bands. For RGB images this is 3, for grayscale it is 1.

DIMENSIONS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*width*, *height*] that specifies the dimensions of the MrSID image at level 0 (full resolution).

LEVELS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*minlvl*, *maxlvl*] that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

PIXEL_TYPE

Set this keyword to a named variable that will contain the IDL basic type code for a pixel sample. For a list of the data types indicated by each type code, see the “IDL Type Codes” section of the SIZE function.

TYPE

Set this keyword to a named variable that will contain a string identifying the file format. This should always be MrSID.

GEO_VALID

Set this keyword to a named variable that will contain a long integer that is set to:

- 1 - If the MrSID image contains valid georeferencing data.
- 0 - If the MrSID image does not contain georeferencing data or the data is in an unsupported format.

Note

Always verify that this keyword returns 1 before using the data returned by any other GEO_* keyword.

GEO_PROJTYPE

Set this keyword to a named variable that will contain an unsigned integer that specifies the geoTIFF projected coordinate system type code. For example, type code 32613 corresponds to PCS_WGS84_UTM_zone_13N.

For more information on the geoTIFF file type and available type codes see:

`http://www.remotesensing.org/geotiff/geotiff.html`

GEO_ORIGIN

Set this keyword to a named variable that will contain a two-element double precision array of the form [*x*, *y*] that specifies the location of the center of the upper-left pixel.

GEO_RESOLUTION

Set this keyword to a named variable that will contain a two-element double precision array of the form [*xres*, *yres*] that specifies the pixel resolution.

Examples

```
PRO MrSID_GetProperty

; Initialize the MrSID object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))

; Get the property information of the MrSID file
oFile -> GetProperty, CHANNELS = chan, LEVELS = $
   lvls, Pixel_Type = pType, TYPE = fileType, GEO_VALID = geoQuery

; Print MrSID file information.
PRINT, 'Number of image channels = ', chan
; IDL returns 1 indicating one image band.

PRINT, 'Range of image levels = ', lvls
; IDL returns -9, 4, the minimum and maximum level values.

PRINT, 'Type code of image pixels = ', pType
; IDL returns 1 indicating byte data type.

PRINT, 'Image file type = ', FileType
; IDL returns "MrSID"

PRINT, 'Result of georeferencing data query = ', geoQuery
; IDL returns 0 indicating that the image does not contain
; georeferencing  data.

; Destroy object references.
OBJ_DESTROY, [oFile]

END
```

Version History

Introduced: 5.5

IDLffMrSID::Init

The IDLffMrSID::Init function method initializes an IDLffMrSID object containing the image data from a MrSID image file.

Syntax

Result = OBJ_NEW('IDLffMrSID', *Filename* [, /QUIET])

or

Result = *Obj* -> [IDLffMrSID::]Init(*Filename*) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Filename

Set this argument to a scalar string containing the full path and filename of a MrSID file to be accessed through this IDLffMrSID object.

Note

This is a required argument; it is not possible to create an IDLffMrSID object without specifying a valid MrSID file.

Keywords

QUIET

Set to suppress error messages while constructing the IDLffMrSID object.

Examples

```
oMrSID = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))
```

Version History

Introduced: 5.5

IDLffShape

An IDLffShape object contains geometry, connectivity and attributes for graphics primitives accessed from ESRI Shapefiles.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See IDLffShape::Init

Methods

Intrinsic Methods

This class has the following methods:

- IDLffShape::AddAttribute
- IDLffShape::Cleanup
- IDLffShape::Close
- IDLffShape::DestroyEntity
- IDLffShape::GetAttributes
- IDLffShape::GetEntity
- IDLffShape::GetProperty
- IDLffShape::Init
- IDLffShape::Open
- IDLffShape::PutEntity
- IDLffShape::SetAttributes

Version History

Introduced: 5.4

Overview

An ESRI Shapefile stores nontopological geometry and attribute information for the spatial features in a data set.

A Shapefile consists of a main file (`.shp`), an index file (`.shx`), and a dBASE table (`.dbf`). For example, the Shapefile “states” would have the following files:

- states.shp
- states.shx
- states.dbf

Naming Conventions for a Shapefile

All the files that comprise an ESRI Shapefile must adhere to the 8.3 filename convention and must be lower case. The main file, index file, and dBASE file must all have the same prefix. The prefix must start with an alphanumeric character and can contain any alphanumeric, underscore (_), or hyphen (-). The main file suffix must use the `.shp` extension, the index file the `.shx` extension, and the dBASE table the `.dbf` extension.

Major Elements of a Shapefile

A Shapefile consists of the following elements that you can access through the IDLffShape class:

- Entities
- Attributes

Entities

The geometry for a feature is stored as a shape comprising a set of vector coordinates (referred to as ‘entities’). The entities in a Shapefile must all be of the same type. The following are the possible types for entities in a Shapefile:

Shape Type	Type Code
Point	1
PolyLine	3
Polygon	5
MultiPoint	8
PointZ	11
PolyLineZ	13
PolygonZ	15
MultiPointZ	18
PointM	21
PolyLineM	23
PolygonM	25
MultiPointM	28
MultiPatch	31

Table A-16: Entity Types

When retrieving entities using the IDLffShape::GetEntity method, an IDL structure is returned. This structure has the following fields:

Field	Data Type
SHAPE_TYPE	IDL_LONG
ISHAPE	IDL_LONG
BOUNDS	Double[8]

Table A-17: Entity Structure Field Data Types

Field	Data Type
N_VERTICES	IDL_LONG
VERTICES	Pointer (to Vertices array)
MEASURE	Pointer (to Measure array)
N_PARTS	IDL_LONG
PARTS	Pointer (to Parts array).
PART_TYPES	Pointer (to part types)
ATTRIBUTES	Pointer to attribute array.

Table A-17: Entity Structure Field Data Types (Continued)

The following table describes each field in the structure:

Field	Description
SHAPE_TYPE	The entity type.
ISHAPE	The identifier of the specific entity in the shape object.

Table A-18: Entity Structure Field Descriptions

Field	Description
BOUNDS	A bounding box that specifies the range limits of the entity. This eight element array contains the following information: • Index 0 — X minimum value • Index 1 — Y minimum value • Index 2 — Z minimum value (if Z is supported by type) • Index 3 — Measure minimum value (if measure is supported by entity type) • Index4 — X maximum value • Index5 — Y maximum value • Index6 — Z maximum value (if Z is supported by the entity type) • Index7 — Measure maximum value (if measure is supported by entity type) **Note -** If the entity is a point type, the values contained in the bounds array are also the values of the entity.
N_VERTICES	The number of vertices in the entity. If this value is one and the entity is a POINT type (POINT, POINTM, POINTZ), the vertices pointer will be set to NULL and the entity value will be maintained in the BOUNDS field.
VERTICES	An IDL pointer that contains the vertices of the entity. This pointer contains a double array that has one of the following formats: • [2, *N*] - If Z data is not present • [3, *N*] - If Z data is present where *N* is the number of vertices. These array formats can be passed to the polygon and polyline objects of IDL Object Graphics. **Note -** This pointer will be null if the entity is a point type, with the values maintained in the BOUNDS array.

Table A-18: Entity Structure Field Descriptions (Continued)

Field	Description
MEASURE	If the entity has a measure value (this is dependent on the entity type), this IDL pointer will contain a vector array of measure values. The length of this vector is N_VERTICES. **Note -** This pointer will be null if the entity is of type POINTM, with the values contained in the BOUNDS array.
N_PARTS	If the values of the entity are separated into parts, the break points are enumerated in the parts array. This field lists the number of parts in this entity. If this value is 0, the entity is one part and the PARTS pointer will be NULL.
PARTS	An IDL pointer that contains an array of indices into the vertex/measure arrays. These values represent the start of each part of the entity. The index range of each entity part is defined by the following: • Start = Parts[I] • End = Parts[I+1]-1 or the end of the array
PART_TYPES	This IDL pointer is only valid for entities of type MultiPatch and defines the type of the particular part. If the entity type is not MultiPatch, part types are assumed to be type RING (SHPP_RING). **Note -** This pointer is NULL if the entity is not type MultiPatch.
ATTRIBUTES	If the attributes for an entity were requested, this field contains an IDL pointer that contains a structure of attributes for the entity. For more information on this structure, see “Attributes” on page 2538.

Table A-18: Entity Structure Field Descriptions (Continued)

Attributes

A Shapefile provides the ability to associate information describing each entity (a geometric element) contained in the file. This descriptive information, called attributes, consists of a set of named data elements for each geometric entity contained in the file. The set of available attributes is the same for every entity contained in a Shapefile, with each entity having it's own set of attribute values.

An attribute consist of two components:

- A name
- A data value

The name consists of an 11 character string that is used to identify the data value. The data value is not limited to any specific format.

The two components that form an attribute are accessed differently using the shape object. To get the name of attributes for the specific file, the ATTRIBUTE_NAMES keyword to the IDLffShape::GetProperty method is used. This returns a string array that contains the names for the attributes defined for the file.

To get the attribute values for an entity, the IDLffShape::GetAttributes method is called or the ATTRIBUTES keyword of the IDLffShape::GetEntity method is set. In each case, the attribute values for the specified entity is returned as an anonymous IDL structure. The numeric order of the fields in the returned structure map to the numeric order of the attributes defined for the file. The actual format of the returned structure is:

```
ATTRIBUTE_0 : VALUE,
ATTRIBUTE_1 : VALUE,
ATTRIBUTE_2 : VALUE,
...
ATTRIBUTE_<N-1> : VALUE
```

To access the values in the returned structure, you can either hardcode the structure field names or use the structure indexing feature of IDL.

Accessing Shapefiles

The following example shows how to access data in a Shapefile. This example sets up a map to display parts of a Shapefile, opens a Shapefile, reads the entities from the Shapefile, and then plots only the state of Colorado:

```
PRO ex_shapefile

DEVICE, RETAIN=2, DECOMPOSED=0
!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0             ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255       ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0           ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0         ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,45, -120,  /ISOTROPIC, $
/HORIZON, E_HORIZON={FILL:1, COLOR:blue}, $
/GRID, COLOR=black, /NOBORDER

; Fill the continent boundaries:
MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=green

; Overplot coastline data:
MAP_CONTINENTS, /COASTS, COLOR=black

; Show national borders:
MAP_CONTINENTS, /COUNTRIES, COLOR=black

;Open the states Shapefile in the examples directory
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

;Get the number of entities so we can parse through them
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent

;Parsing through the entities and only plotting the state of
;Colorado
FOR x=1, (num_ent-1) DO BEGIN
   ;Get the Attributes for entity x
   attr = myshape -> IDLffShape::GetAttributes(x)
```

```
   ;See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
   ;entity x
   IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN
      ;Get entity
      ent = myshape -> IDLffShape::GetEntity(x)
      ;Plot entity
      POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*],
COLOR=yellow
      ;Clean-up of pointers
      myshape -> IDLffShape::DestroyEntity, ent
   ENDIF
ENDFOR

;Close the Shapefile
OBJ_DESTROY, myshape

END
```

This results in the following:

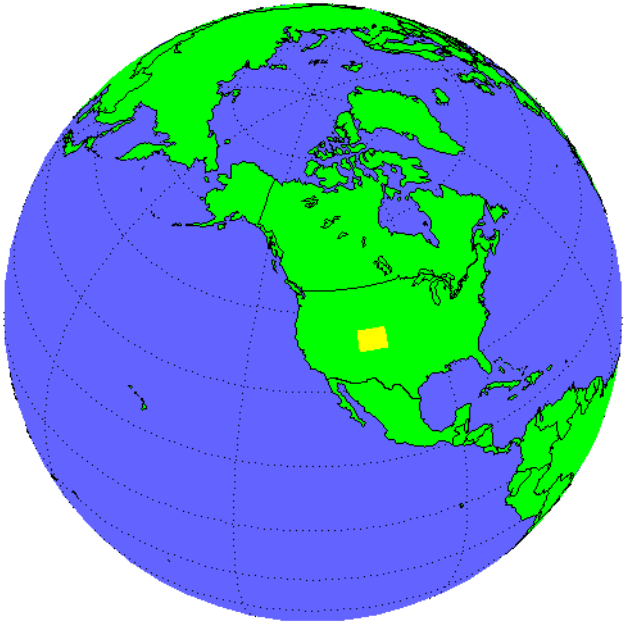

Figure A-1: Example Use of Shapefiles

Creating New Shapefiles

To create a Shapefile, you need to create a new Shapefile object, define the entity and attributes definitions, and then add your data to the file. For example, the following program creates a new Shapefile (`cities.shp`), defines the entity type to be "Point", defines 2 attributes (CITY_NAME and STATE_NAME), and then adds an entity to the new file:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
   PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
   PRECISION=0

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = mynewshape ->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape -> IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
mynewshape -> IDLffShape::SetAttributes, 0, attrNew
```

```
;Close the shapefile
OBJ_DESTROY, mynewshape

END
```

Updating Existing Shapefiles

You can modify existing Shapefiles with the following:

- Adding new entities
- Adding new attributes (only to Shapefiles without any existing values in any attributes)
- Modifying existing attributes

Note

You cannot modify existing entities.

For example, the following program adds an entity and attributes for the city of Boulder to the `cities.shp` file we created in the previous example:

```
PRO ex_shapefile_modify

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE)

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1380
entNew.BOUNDS[0] = -105.25100
entNew.BOUNDS[1] = 40.026878
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -105.25100
entNew.BOUNDS[5] = 40.026878
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = myshape ->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)
```

```
;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Boulder'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
myshape -> IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
myshape -> IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, myshape

END
```

IDLffShape::AddAttribute

The IDLffShape::AddAttribute method adds an attribute definition to a Shapefile. Adding a the attribute definition is required before adding the actual attribute data to a file. For more information on attributes, see “Attributes” on page 2538.

Note

You can only define new attributes to Shapefiles that do not have any existing values in any attributes.

Syntax

Obj->[IDLffShape::]AddAttribute, *Name*, *Type*, *Width* [, PRECISION=*integer*]

Arguments

Name

Set to a string that contains the attribute name. Name values are limited to 11 characters. Arguments longer than 11 characters will be truncated.

Type

Set to the IDL type code that corresponds to the data type that will be stored in the attribute. The valid types are:

Code	Description
3	Longword Integer
5	Double-precision floating-point
7	String

Table A-19: Type Code Descriptions

Width

Set to the width of the field for the data value of the attribute. The following table describes the possible values depending on the defined Type:

Field Type	Valid Values
Longword Integer	Maximum size of the field.
Double-precision floating-point	Maximum size of the field.
String	Maximum length of the string.

Table A-20: Width Values

Keywords

PRECISION

Set this keyword to the number of positions to be included after the decimal point. The default is 8. This keyword is only valid for fields defined as double-precision floating-point.

Examples

In the following example, we add the attribute “ELEVATION” to an existing Shapefile. Note that if the file already contains data in an attribute for any of the entities defined in the file, this operation will fail.

```
PRO ex_addattr_shapefile

;Open a shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE)

;Define a new attribute for the Shapefile
myshape->IDLffShape::AddAttribute, 'ELEVATION', 3, 4, $
   PRECISION=0

;Close the shapefile
OBJ_DESTROY, myshape

END
```

Version History

Introduced: 5.4

IDLffShape::Cleanup

The IDLffShape::Cleanup method performs all cleanup on a Shapefile object. If the Shapefile being accessed by the object is open and the file has been modified, the new information is written to the file if one of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

Note

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLffShape::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.4

IDLffShape::Close

The IDLffShape::Close method closes a Shapefile. If the file has been modified, it is also written to the disk if neither of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

If the file has been modified and one of the previous conditions is not met, the file is closed and the changes are not written to disk.

Syntax

Obj->[IDLffShape::]Close

Arguments

None.

Keywords

None.

Version History

Introduced: 5.4

IDLffShape::DestroyEntity

The IDLffShape::DestroyEntity method frees memory associated with the entity structure. For more information on the entity structure, see “Entities” on page 2534.

Syntax

Obj->[IDLffShape::]DestroyEntity, *Entity*

Arguments

Entity

This argument specifies a scalar or array of entities to destroy.

Keywords

None.

Examples

In the following example, all of the entities from the `states.shp` Shapefile are read and then the DestroyEntity method is called to clean up all pointers:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
   ;Read the entity x
   ent = myshape -> IDLffShape::GetEntity(x)
   ;Clean-up of pointers
   myshape -> IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

Version History

Introduced: 5.4

IDLffShape::GetAttributes

The IDLffShape::GetAttributes method retrieves the attributes for the entities you specify from a Shapefile.

Syntax

Result = *Obj*->[IDLffShape::]GetAttributes([*Index*] [, /ALL] [, /ATTRIBUTE_STRUCTURE])

Return Value

This method returns an anonymous structure array. For more information on the structure, see “Attributes” on page 2538.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve the attributes, with 0 being the first entity in the Shapefile.

Note

If you do not specify *Index* and the ALL keyword is not set, the attributes for the first entity (0) are returned.

Keywords

ALL

Set this keyword to retrieve the attributes for all entities in a Shapefile. If you set this keyword, the *Index* argument is not required.

ATTRIBUTE_STUCTURE

Set this keyword to return an empty attribute structure that can then be used with the IDLffShape::SetAttributes method to add attributes to a Shapefile.

Examples

In the first example, we retrieve the attributes associated with entity at location 0 (the first entity in the file):

```
attr = myShape->getAttributes( 0)
```

In the next example, we retrieve the attributes associated with entities 10 through 20:

```
attr = myShape->getAttributes( 10+indgen(11) )
```

In the next example, we retrieve the attributes for entities 1,4, 9 and 70:

```
attr = myShape->getAttributes( [1, 4, 9, 70] )
```

In the next example, we retrieve all the attributes for a Shapefile:

```
attr = myShape->getAttributes( /ALL )
```

Version History

Introduced: 5.4

IDLffShape::GetEntity

The IDLffShape::GetEntity method returns the entities you specify from a Shapefile.

Syntax

Result = *Obj*->[IDLffShape::]GetEntity([*Index*] [, /ALL] [, /ATTRIBUTES])

Return Value

This method returns a type {IDL_SHAPE_ENTITY} structure array. For more information on the structure, see “Entities” on page 2534.

Note

Since an entity structure contains IDL pointers, you must free all the pointers returned in these structures when the entity is no longer needed using the IDLffShape::DestroyEntity method.

Note

Since entities cannot be modified in a Shapefile, an entity is read directly from the Shapefile each time you use the IDLffShape::GetEntity method even if you have already read that entity. If you modify the structure array returned by this method for a given entity and then use IDLffShape::GetEntity on that same entity, the modified data will NOT be returned, the data that is actually written in the file is returned.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve with 0 being the first entity in the Shapefile. If the ALL keyword is set, this argument is not required. If you do not specify any entities and the ALL keyword is not set, the first entity (0) is returned.

Keywords

ALL

Set this keyword to retrieve all entities from the Shapefile. If this keyword is set, the Index argument is not required.

ATTRIBUTES

Set this keyword to return the attributes in the entity structure. If not set, the ATTRIBUTES tag in the entity structure will be a null IDL pointer.

Examples

In the following example, all of the entities from the `states.shp` Shapefile are read:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
   ;Read the entity x
   ent = myshape -> IDLffShape::GetEntity(x)
   ;Clean-up of pointers
   myshape -> IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

Version History

Introduced: 5.4

IDLffShape::GetProperty

The IDLffShape::GetProperty method returns the values of properties associated with a Shapefile object. These properties are:

- Number of entities
- The type of the entities
- The number of attributes associated with each entity
- The names of the attributes
- The name, type, width, and precision of the attributes
- The status of a Shapefile
- The filename of the Shapefile object

Syntax

Obj->[IDLffShape::]GetProperty [, N_ENTITIES=*variable*]
[, ENTITY_TYPE=*variable*] [, N_ATTRIBUTES=*variable*]
[, ATTRIBUTE_NAMES=*variable*] [, ATTRIBUTE_INFO=*variable*]
[, N_RECORDS=*variable*] [, IS_OPEN=*variable*] [, FILENAME=*variable*]

Arguments

None.

Keywords

N_ENTITIES

Set this keyword to a named variable to return the number of entities contained in Shapefile object. If the value is unknown, this method returns 0.

ENTITY_TYPE

Set this keyword to a named variable to return the integer type code for the entities contained in the Shapefile object. If the value is unknown, this method returns -1. For more information on entity type codes, see “Entities” on page 2534.

N_ATTRIBUTES

Set this keyword to a named variable to return the number of attributes associated with a Shapefile object. If the value is unknown, this method returns 0.

ATTRIBUTE_NAMES

Set this keyword to a named variable to return the names of each attribute in the Shapefile object. These names are returned as a string array.

ATTRIBUTE_INFO

Set this keyword to a named variable to return the attribute information for each attribute. This consists of an array of attribute information structures that have the following fields:

Field	Description
NAME	A string that contains the name of the attribute.
TYPE	The IDL type code of the attribute.
WIDTH	The width of the attribute.
PRECISION	The precision of the attribute.

Table A-21: ATTRIBUTE_INFO Fields

The file must be open to obtain this information.

N_RECORDS

Return the number of records in the dBASE table (`.dbf`) component of the shapefile. In a normal operating mode, this is accomplished by getting the number of entities. However, in DBF_ONLY mode, no entity file exits.

IS_OPEN

Set this keyword to a named variable to return information about the status of a Shapefile. The following values can be returned:

Value	Description
0	File is not open.
1	File is open in read-only mode.
3	File is open in update mode.

Table A-22: IS_OPEN Values

FILENAME

Set this keyword to a named variable to return the fully qualified path name of the Shapefile in the current Shapefile object.

Examples

In the following example, the number of entities and the entity type is returned:

```
PRO entity_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities and the entity type.
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent, $
   ENTITY_TYPE=ent_type

; Print the number of entities and the type.
PRINT, 'Number of Entities: ', num_ent
PRINT, 'Entity Type: ', ent_type

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

This results in the following:

```
Number of Entities:       51
Entity Type:               5
```

In the next example, the definitions for attribute 1 are returned:

```
PRO attribute_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the info for all attribute.
myshape -> IDLffShape::GetProperty, ATTRIBUTE_INFO=attr_info

; Print Attribute Info.
PRINT, 'Attribute Number: ', '1'
PRINT, 'Attribute Name: ', attr_info[1].name
PRINT, 'Attribute Type: ', attr_info[1].type
PRINT, 'Attribute Width: ', attr_info[1].width
PRINT, 'Attribute Precision: ', attr_info[1].precision

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

This results in the following:

```
Attribute Number:           1
Attribute Name:    STATE_NAME
Attribute Type:             7
Attribute Width:           25
Attribute Precision:        0
```

Version History

Introduced: 5.4

N_RECORDS keyword: 5.6

IDLffShape::Init

The IDLffShape::Init function method initializes or constructs a Shapefile object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = OBJ_NEW('IDLffShape' [, *Filename*] [, /DBF_ONLY] [, /UPDATE] [, ENTITY_TYPE='*Value*'])

or

Result = *Obj* `->` [IDLffShape::]Init([, *Filename*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Return Value

This method returns a Shapefile object.

Arguments

Filename

Set this argument to a scalar string containing the full path and filename of a Shapefile (`.shp`) to open. If this file exists, it is opened. If the file does not exist, a new Shapefile object is constructed. You do not need to use IDLffShape::Open to open an existing file when specifying this keyword.

Note

The `.shp`, `.shx`, and `.dbx` files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

Keywords

DBF_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (`.dbf`) component of the shapefile is opened. All entity related files are left closed. Two values to this keyword are accepted: 1 - Open an existing `.dbf` file, > 1 - Create a new `.dbf` file

Note

The UPDATE keyword is required to open the `.dbf` file for updating.

UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

ENTITY_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when creating a new Shapefile. For more information on entity types, see “Entities” on page 2534.

Examples

In the following example, we create a new Shapefile object and open the `examples/data/states.shp` file:

```
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))
```

Version History

Introduced: 5.4

DBF_ONLY keyword: 5.6

IDLffShape::Open

The IDLffShape::Open method opens a specified Shapefile.

Syntax

Result = *Obj*->[IDLffShape::]Open(*'Filename'* [, /DBF_ONLY] [, /UPDATE] [, ENTITY_TYPE=*'value'*])

Return Value

This method returns 1 if the file can be read successfully. If not able to open the file, it returns 0.

Arguments

Filename

Set this argument to a scalar string containing the full path and filename of a Shapefile (`.shp`) to open. Note that the `.shp`, `.shx`, and `.dbx` files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

Keywords

DBF_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (`.dbf`) component of the shapefile is opened. All entity related files are left closed. Two values to this keyword are accepted: 1 - Open an existing `.dbf` file, > 1 - Create a new `.dbf` file

The UPDATE keyword is required to open the `.dbf` file for updating.

UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

ENTITY_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when creating a new Shapefile. For more information on entity types, see "Entities" on page 2534.

Examples

In the following example, the file `examples/data/states.shp` is opened for reading and writing:

```
status = myShape->Open(FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']), /UPDATE)
```

Version History

Introduced: 5.4

DBF_ONLY keyword: 5.6

IDLffShape::PutEntity

The IDLffShape::PutEntity method inserts an entity into the Shapefile object. The entity must be in the proper structure. For more information on the structure, see “Entities” on page 2534.

Note

The shape type of the new entity must be the same as the shape type defined for the Shapefile. If the shape type has not been defined for the Shapefile using the ENTITY_TYPE keyword for the IDLffShape::Open or IDLffShape::Init methods, the first entity that is inserted into the Shapefile defines the type.

Note

Only new entities can be inserted into a Shapefile. Existing entities cannot be updated.

Syntax

Obj->[IDLffShape::]PutEntity, *Data*

Arguments

Data

Set this argument to a scalar or an array of entity structures.

Keywords

None.

Examples

In the following example, we create a new shapefile, define a new entity, and then use the PutEntity method to insert it into the new file:

```
PRO ex_shapefile_newfile

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)
```

```
; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity.
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Add the new entity to new shapefile.
mynewshape -> IDLffShape::PutEntity, entNew

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

Version History

Introduced: 5.4

IDLffShape::SetAttributes

The IDLffShape::SetAttributes method sets the attributes for a specified entity in a Shapefile object.

Syntax

Obj->[IDLffShape::]SetAttributes, *Index*, *Attribute_Num*, *Value*

or

Obj->[IDLffShape::]SetAttributes, *Index*, *Attributes*

Arguments

Index

A scalar specifying the entity in which you want to set the attributes. The first entity in the Shapefile object is 0.

Attribute_Num

The field number for the attribute whose value is being set. This value is 0-based.

Value

The value that the attribute is being set to. If the value is not of the correct type, type conversion is attempted.

If *Value* is an array and *Index* is a scalar, the value of record is treated as a starting point. Using this feature, all the attribute values of a specific field can be set for a Shapefile.

Attributes

An Attribute structure whose fields match the fields in the attribute table. If *Attributes* is an array, the entities specified in *Index*, up to the size of the Attributes array, are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

The type of this Attribute structure must match the type that is generated internally for Attribute table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE_STRUCTURE keyword of the IDLffShape::GetProperty method.

Keywords

None.

Examples

In the following example, we create a new shapefile, define the attributes for the new file, define a new entity, define some attributes, insert the new entity, and then use the SetAttributes method to insert the attributes into the new file:

```
PRO ex_shapefile_newfile

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

; Set the attribute definitions for the new Shapefile.
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
   PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
   PRECISION=0

; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Create structure for new attributes.
attrNew = mynewshape ->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

; Define the values for the new attributes.
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

; Add the new entity to new shapefile.
mynewshape -> IDLffShape::PutEntity, entNew
```

```
; Add the Colorado attributes to new shapefile.
mynewshape -> IDLffShape::SetAttributes, 0, attrNew

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

Version History

Introduced: 5.4

IDLffXMLSAX

An IDLffXMLSAX object uses an XML SAX level 2 parser. The XML parser allows you to read an XML file and store arbitrary data from the file in IDL variables. The parser object's methods are *callbacks*. These methods are called automatically when the parser encounters different types of XML elements or attributes.

Note

To use the XML parser, you *must* write a subclass of this object class, overriding the object methods as necessary to process the data in a specific XML file or files. See Chapter 22, "Using the XML Parser Object Class" in the *Building IDL Applications* manual for further information and examples.

The IDLffXMLSAX object encapsulates the Xerces validating XML parser; see `http://xml.apache.org` for details.

Superclasses

This class has no superclass.

Subclasses

You *must* write a subclass of this object, overriding object methods as necessary to retrieve information from the XML file.

Creation

See "IDLffXMLSAX::Init" on page 2590

Methods

Intrinsic Methods

This class has the following methods:

- IDLffXMLSAX::AttributeDecl
- IDLffXMLSAX::Characters
- IDLffXMLSAX::Cleanup
- IDLffXMLSAX::Comment

- IDLffXMLSAX::ElementDecl
- IDLffXMLSAX::EndCDATA
- IDLffXMLSAX::EndDocument
- IDLffXMLSAX::EndDTD
- IDLffXMLSAX::EndElement
- IDLffXMLSAX::EndEntity
- IDLffXMLSAX::EndPrefixMapping
- IDLffXMLSAX::Error
- IDLffXMLSAX::ExternalEntityDecl
- IDLffXMLSAX::FatalError
- IDLffXMLSAX::GetProperty
- IDLffXMLSAX::IgnorableWhitespace
- IDLffXMLSAX::Init
- IDLffXMLSAX::InternalEntityDecl
- IDLffXMLSAX::NotationDecl
- IDLffXMLSAX::ParseFile
- IDLffXMLSAX::ProcessingInstruction
- IDLffXMLSAX::SetProperty
- IDLffXMLSAX::SkippedEntity
- IDLffXMLSAX::StartCDATA
- IDLffXMLSAX::StartDocument
- IDLffXMLSAX::StartDTD
- IDLffXMLSAX::StartElement
- IDLffXMLSAX::StartEntity
- IDLffXMLSAX::StartPrefixmapping
- IDLffXMLSAX::StopParsing
- IDLffXMLSAX::UnparsedEntityDecl
- IDLffXMLSAX::Warning

Version History

Introduced: 5.6

IDLffXMLSAX::AttributeDecl

The IDLffXMLSAX::AttributeDecl procedure method is called when the parser detects an `<!ATTLIST ...>` declaration in a DTD. This method is called once for each attribute declared by the tag.

Syntax

Obj `->` [IDLffXMLSAX::]AttributeDecl, *eName*, *aName*, *Type*, *Mode*, *Value*

Arguments

eName

A named variable that will contain the name of the element for which the attribute is being declared.

aName

A named variable that will contain the name of the attribute being declared.

Type

A named variable that will contain a string that specifies the type of attribute being defined. Possible values are:

- 'CDATA'
- 'ID'
- 'IDREF'
- 'IDREFS'
- 'NMTOKEN'
- 'NMTOKENS'
- 'ENTITY'
- 'ENTITIES'

or two types of enumerated values. Enumerated values are encoded with parenthesized strings such as `(a|b|c)` to indicate that strings `a`, `b`, or `c` are permissible. If the string is an enumeration of notation names, the string `"NOTATION "` (note the space after the second “N”) precedes the parenthesized string.

Mode

A named variable that will contain a string that specifies restrictions on the value of the attribute. Possible values are:

- '#IMPLIED' - the application determines the value
- '#REQUIRED' - the value must be given; defaulting is not permitted
- '#FIXED' - only one value is permitted
- '' - a null string (the value specified by the *Value* argument is used as the default)

Value

A named variable that will contain the default value for the attribute. If *Value* contains a null string, no default value was specified.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::Characters

The IDLffXMLSAX::Characters procedure method is called when the parser detects text in the parsed document.

Syntax

Obj -> [IDLffXMLSAX::]Characters, *Chars*

Arguments

Chars

A named variable that will contain the text detected by the parser.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::Cleanup

The IDLffXMLSAX::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLffXMLSAX::]Cleanup(*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::Comment

The IDLffXMLSAX::Comment procedure method is called when the parser detects a comment section of the form <!-- ... -->.

Syntax

Obj -> [IDLffXMLSAX::]Comment, *Comment*

Arguments

Comment

A named variable that will contain the text within the detected comment section, without the delimiting characters ("<!--" and "-->").

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::ElementDecl

The IDLffXMLSAX::ElementDecl procedure method is called when the parser detects an `<!ELEMENT ...>` declaration in the DTD.

Syntax

Obj `->` [IDLffXMLSAX::]ElementDecl, *Name*, *Model*

Arguments

Name

A named variable that will contain the name of the element.

Model

A named variable that will contain the *content model* (sometimes called the *content specification*) for the element, with all whitespace removed.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::EndCDATA

The IDLffXMLSAX::EndCDATA procedure method is called when the parser detects the end of a `<[CDATA[...]]>` text section.

Syntax

Obj `->` [IDLffXMLSAX::]EndCDATA

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::EndDocument

The IDLffXMLSAX::EndDocument procedure method is called when the parser detects the end of the XML document.

Syntax

Obj -> [IDLffXMLSAX::]EndDocument

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::EndDTD

The IDLffXMLSAX::EndDTD procedure method is called when the parser detects the end of a Document Type Definition (DTD).

Syntax

Obj -> [IDLffXMLSAX::]EndDTD

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::EndElement

The IDLffXMLSAX::EndElement procedure method is called when the parser detects the end of an element.

Syntax

Obj -> [IDLffXMLSAX::]EndElement, *URI*, *Local*, *qName*

Arguments

URI

A named variable that will contain the namespace URI with which the element is associated, if any.

Note

A URI (or Uniform Resource Identifier) refers to the generic set of all names and addresses which are short strings which refer to objects.

Local

A named variable that will contain the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A named variable that will contain the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::EndEntity

The IDLffXMLSAX::EndEntity procedure method is called when the parser detects the end of an internal or external entity expansion.

Syntax

Obj -> [IDLffXMLSAX::]EndEntity, *Name*

Arguments

Name

A named variable that will contain the name of the entity.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::EndPrefixMapping

The IDLffXMLSAX::EndPrefixMapping procedure method is called when a previously declared prefix mapping goes out of scope.

Syntax

Obj -> [IDLffXMLSAX::]EndPrefixMapping, *Prefix*

Arguments

Prefix

A named variable that will contain the namespace prefix that is going out of scope.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::Error

The IDLffXMLSAX::Error procedure method is called when the parser detects an error that is not expected to be fatal. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

For example, a violation of XML validity constraints is generally a non-fatal error.

Note

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj -> [IDLffXMLSAX::]Error, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A named variable that will contain the URI of the associated text.

LineNumber

A named variable that will contain the line number that contains the error.

ColumnNumber

A named variable that will contain the column number that contains the error.

Message

A named variable that will contain the error message sent to the IDL output log.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::ExternalEntityDecl

The IDLffXMLSAX::ExternalEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declarations in the DTD for a parsed external entity.

Syntax

Obj `->` [IDLffXMLSAX::]ExternalEntityDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A named variable that will contain the entity name.

PublicID

A named variable that will contain the Public ID for the entity.

Note

If this value is not specified in the entity declaration, this variable will contain an empty string.

SystemID

A named variable that will contain the System ID for the entity, provided as an absolute URI.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::FatalError

The IDLffXMLSAX::FatalError procedure method is called when the parser detects a fatal error. When called, parsing will normally stop, but may sometimes continue long enough to report further errors. This method prints an IDL error string to the IDL output log.

Syntax

Obj -> [IDLffXMLSAX::]FatalError, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A named variable that will contain the URI of the associated text.

LineNumber

A named variable that will contain the line number that contains the error.

ColumnNumber

A named variable that will contain the column number that contains the error.

Message

A named variable that will contain the error message sent to the IDL output log.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::GetProperty

The IDLffXMLSAX::GetProperty procedure method is used to get the values of various properties of the parser.

Syntax

Obj -> [IDLffXMLSAX::]GetProperty [, FILENAME=*variable*]
[, PARSER_LOCATION=*variable*] [, PARSER_PUBLICID=*variable*]
[, PARSER_URI=*variable*]

Arguments

None.

Keywords

Any keyword to the IDLffXMLSAX::Init followed by Get can be retrieved using IDLffXMLSAX::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

Note

These properties are only available during a parse operation.

FILENAME

Set this keyword equal to a named variable that will contain the filename of the XML file being parsed.

PARSER_LOCATION

Set this keyword equal to a named variable that will contain the approximate location of the parser within the entity being parsed. The value is returned as a two-element array, with the first element set to the line number and the second element set the column number.

PARSER_PUBLICID

Set this keyword equal to a named variable that will contain the Public ID for the entity being parsed, if it is available. If the Public ID is not available, an empty string is returned.

PARSER_URI

Set this keyword equal to a named variable that will contain the base URI (System ID) for the entity being parsed, if it is available. If the value is available, it is always an absolute URI. If the System ID is not available, an empty string is returned.

Note

Use this value to identify the document or external entity in diagnostics, or to resolve relative URIs.

Version History

Introduced: 5.6

IDLffXMLSAX::IgnorableWhitespace

The IDLffXMLSAX::IgnorableWhitespace procedure method is called when the parser detects whitespace that separates elements in an element content model.

Syntax

Obj -> [IDLffXMLSAX::]IgnorableWhitespace, *Chars*

Arguments

Chars

A named variable that will contain the whitespace detected by the parser. Whitespace can consist of spaces, tabs, or newline characters in any combination.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::Init

The IDLffXMLSAX::Init function method initializes an XML parser object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. In most cases, you cannot call the Init method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLffXMLSAX' [, /NAMESPACE_PREFIXES]
[, SCHEMA_CHECKING=[0,1,2] [, VALIDATION_MODE=[0,1,2]])

or

Result = *Obj* -> [IDLffXMLSAX::]Init( )(*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Return Value

Returns the object reference to this newly-created IDLffXMLSAX object.

Arguments

None.

Keywords

Properties you can retrieve via the IDLffXMLSAX::GetProperty are indicated by the word Get following the keyword. Properties you can set via the IDLffXMLSAX::SetProperty are indicated by the word Set following the keyword.

NAMESPACE_PREFIXES *(Get, Set)*

Set this keyword to indicate that namespace prefixes are enabled. By default, namespace prefixes are disabled.

SCHEMA_CHECKING *(Get, Set)*

XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. Set this keyword to an integer value to indicate the type of validation the parser should perform. By default, the parser will validate the parsed XML file against the specified schema, if one is provided; if no schema is provided, no validation will occur. Possible values are:

Value	Description
0	No validation.
1	Validate only if a schema is provided (the default).
2	Perform full schema constraint checking, if a schema is provided. This feature checks the schema grammar itself for additional errors. It does not affect the level of checking performed on document instances that use schema grammars.

Table A-23: SCHEMA_CHECKING Values

VALIDATION_MODE *(Get, Set)*

XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. Set this keyword to indicate the type of XML validation that the parser should perform. By default, the parser will validate the parsed XML file against the specified DTD, if one is provided; if no DTD is provided, no validation will occur. Possible values are:

Value	Description
0	No validation.
1	Validate only if a DTD is provided (the default).
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Table A-24: VALIDATION_MODE Values

Version History

Introduced: 5.6

IDLffXMLSAX::InternalEntityDecl

The IDLffXMLSAX::InternalEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declaration in a DTD for (parsed) internal entities. The entity can be either a general entity or a parameter entity.

Syntax

Obj `->` [IDLffXMLSAX::]InternalEntityDecl, *Name*, *Value*

Arguments

Name

A named variable that will contain the entity name. Names that start with the "%" character are parameter entities; all others are general entities.

Value

A named variable that will contain the entity value. The entity value can contain arbitrary XML content, which will be reparsed when the entity is expanded.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::NotationDecl

The IDLffXMLSAX::NotationDecl procedure method is called when the parser detects a `<!NOTATION ...>` declaration in a DTD.

Syntax

Obj `->` [IDLffXMLSAX::]NotationDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A named variable that will contain the notation name.

PublicID

A named variable that will contain the Public ID for the notation.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

SystemID

A named variable that will contain the System ID for the notation, provided as an absolute URI.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::ParseFile

The IDLffXMLSAX::ParseFile procedure method parses the specified XML file. During the parsing operation, different object methods are called as different items within the XML file are detected. When this method returns, the parse operation is complete.

Syntax

Obj -> [IDLffXMLSAX::]ParseFile, *Filename*

Arguments

Filename

A string containing the full path name of the XML file to parse.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::ProcessingInstruction

The IDLffXMLSAX::ProcessingInstruction procedure method is called when the parser detects a processing instruction.

Syntax

Obj -> [IDLffXMLSAX::]ProcessingInstruction, *Target*, *Data*

Arguments

Target

A named variable that will contain a string specifying the target, which is the application that should process the instruction.

Data

A named variable that will contain a string specifying the data to be passed to the application specified by *Target*.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::SetProperty

The IDLffXMLSAX::SetProperty procedure method is used to set the values of various properties of the parser.

Syntax

Obj -> [IDLffXMLSAX::]SetProperty [, /NAMESPACE_PREFIXES] [, SCHEMA_CHECKING=[0,1,2] [, VALIDATION_MODE=[0,1,2]]

Arguments

None.

Keywords

Any keyword to the IDLffXMLSAX::Init followed by `Set` can be set using IDLffXMLSAX::SetProperty.

Version History

Introduced: 5.6

IDLffXMLSAX::SkippedEntity

The IDLffXMLSAX::SkippedEntity procedure method is called when the parser skips an entity and validation is not being performed. This method is rarely called by SAX parsers.

Syntax

Obj -> [IDLffXMLSAX::]SkippedEntity, *Name*

Arguments

Name

A named variable that will contain the name of the entity that was skipped.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StartCDATA

The IDLffXMLSAX::StartCDATA procedure method is called when the parser detects the beginning of a `<[CDATA[...]]>` text section.

Syntax

Obj `->` [IDLffXMLSAX::]StartCDATA

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StartDocument

The IDLffXMLSAX::StartDocument procedure method is called when the parser begins processing a document, and before any data is processed.

Syntax

Obj -> [IDLffXMLSAX::]StartDocument

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StartDTD

The IDLffXMLSAX::StartDTD procedure method is called when the parser detects the beginning of a Document Type Definition (DTD).

Syntax

Obj -> [IDLffXMLSAX::]StartDTD, *Name*, *PublicID*, *SystemID*

Arguments

Name

A named variable that will contain the declared name of the root element for the document.

PublicID

A named variable that will contain the *normalized* version of the Public ID (a URI) declared for the external subset, or an empty string if no external subset was declared. *Normalization* involves removal of unnecessary "." and ".." segments from the URI.

SystemID

A named variable that will contain the System ID (a URI) of the external subset, or an empty string if no external subset was declared.

Note

This URI has not been resolved into an absolute URI.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StartElement

The IDLffXMLSAX::StartElement procedure method is called when the parser detects the beginning of an element.

Syntax

Obj -> [IDLffXMLSAX::]StartElement, *URI*, *Local*, *qName* [, *attName*, *attValue*]

Arguments

URI

A named variable that will contain the namespace URI with which the element is associated, if any.

Local

A named variable that will contain the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A named variable that will contain the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

attrName

A named variable that will contain a string array, which is the names of the attributes associated with the element, if any.

attrValue

A named variable that will contain a string array, which is the values of each attribute associated with the element, if any. The returned array will have the same number of elements as the array returned in the *attrName* keyword variable.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StartEntity

The IDLffXMLSAX::StartEntity procedure method is called when the parser detects the start of an internal or external entity expansion.

Syntax

Obj -> [IDLffXMLSAX::]StartEntity, *Name*

Arguments

Name

A named variable that will contain the name of the entity.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StartPrefixmapping

The IDLffXMLSAX::StartPrefixMapping procedure method is called when the parser detects the beginning of a namespace declaration.

Syntax

Obj -> [IDLffXMLSAX::]StartPrefixmapping, *Prefix*, *URI*

Arguments

Prefix

A named variable that will contain the prefix, which is being mapped. If the variable specified by *Prefix* contains an empty string, the mapping is for the default element namespace.

URI

A named variable that will contain the URI of the prefix namespace.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::StopParsing

Call the IDLffXMLSAX::StopParsing procedure method during a parse operation to halt the operation and cause the ParseFile method to return. This may be useful when parsing large XML files and the desired information is known to have been returned.

Syntax

Obj -> [IDLffXMLSAX::]StopParsing

Arguments

None.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::UnparsedEntityDecl

The IDLffXMLSAX::UnparsedEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declaration that includes the NDATA keyword, indicating that the entity is not meant to be parsed. The value of the NDATA keyword generally specifies the name of a *notation*, which in turn specifies the type of data.

Syntax

Obj `->` [IDLffXMLSAX::]UnparsedEntityDecl, *Name*, *PublicID*, *SystemID*, *Notation*

Arguments

Name

A named variable that will contain the name of the unparsed entity.

PublicID

A named variable that will contain the Public ID of the notation specified by the entity's NDATA keyword, or an empty string if no Public ID was declared.

SystemID

A named variable that will contain the System ID of the notation specified by the entity's NDATA keyword. This value is normally an absolute URI.

Notation

A named variable containing the name of the notation specified by the entity's NDATA keyword.

Keywords

None.

Version History

Introduced: 5.6

IDLffXMLSAX::Warning

The IDLffXMLSAX::Warning procedure method is called when the parser detects a problem during processing. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

Note

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj -> [IDLffXMLSAX::]Warning, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A named variable that will contain the URI of the text that generated the error.

LineNumber

A named variable that contains the line number that contains the error.

ColumnNumber

A named variable that contains the column number that contains the error.

Message

A named variable that contains the error message.

Keywords

None.

Version History

Introduced: 5.6

IDLgrAxis

An axis object represents a single vector that may include a set of tick marks, tick labels, and a title.

An IDLgrAxis object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrAxis::Init" on page 2616.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrAxis::Cleanup
- IDLgrAxis::GetCTM
- IDLgrAxis::GetProperty
- IDLgrAxis::Init
- IDLgrAxis::SetProperty

Version History

Introduced: 5.0

IDLgrAxis::Cleanup

The IDLgrAxis::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrAxis::]Cleanup(*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrAxis::GetCTM

The IDLgrAxis::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrAxis::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the axis object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrAxis::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrAxis::GetProperty

The IDLgrAxis::GetProperty procedure method retrieves the value of a property or group of properties for the axis.

Syntax

Obj -> [IDLgrAxis::]GetProperty [, ALL=*variable*] [, CRANGE=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrAxis::Init followed by "Get" can be retrieved using IDLgrAxis::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

CRANGE

Set this keyword to a named variable that will contain the actual full range of the axis as a double-precision floating-point vector of the form [minval, maxval]. This range may not exactly match the requested range provided via the RANGE keyword in the Init and SetProperty methods. Adjustments may have been made to round to the nearest even tick interval or to accommodate the EXTEND keyword.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

YRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Version History

Introduced: 5.0

IDLgrAxis::Init

The IDLgrAxis::Init function method initializes an axis object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrAxis' [, *Direction*] [, AM_PM{Get, Set}=*array*] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB_vector*] [, DAYS_OF_WEEK{Get, Set}=*array*] [, DIRECTION{Get, Set}=*integer*] [, /EXACT{Get, Set}] [, /EXTEND{Get, Set}] [, GRIDSTYLE{Get, Set}=*integer*{0 to 6}or *[repeat*{1 to 255}, *bitmask]*] [, /HIDE{Get, Set}] [, LOCATION{Get, Set}=*[x, y]* or *[x, y, z]*] [, /LOG{Get, Set}] [, MAJOR{Get, Set}=*integer*] [, MINOR{Get, Set}=*integer*] [, MONTHS{Get, Set}=*array*] [, NAME{Get, Set}=*string*] [, /NOTEXT{Get, Set}] [, PALETTE{Get, Set}=*objref*] [, RANGE{Get, Set}=*[min, max]*] [, SUBTICKLEN{Get, Set}=*value*] [, TEXTALIGNMENTS{Get, Set}=*[horiz*{0.0 to 1.0}, *vert*{0.0 to 1.0}*]*] [, TEXTBASELINE{Get, Set}=*vector*] [, TEXTPOS{Get, Set}={0 | 1}] [, TEXTUPDIR{Get, Set}=*vector*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, TICKDIR{Get, Set}={0 | 1}] [, TICKFORMAT{Get, Set}=*string or array of strings*] [, TICKFRMTDATA{Get, Set}=*value*] [, TICKINTERVAL{Get, Set}=*value*] [, TICKLAYOUT{Get, Set}=*scalar*] [, TICKLEN{Get, Set}=*value*] [, TICKTEXT{Get, Set}=*objref or vector*] [, TICKUNITS{Get, Set}=*string*] [, TICKVALUES{Get, Set}=*vector*] [, TITLE{Get, Set}=*objref*] [, /USE_TEXT_COLOR{Get, Set}] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrAxis::]Init([*Direction*]) (*Only in a subclass' Init method.*)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Direction

An integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis.

Keywords

Properties retrievable via IDLgrAxis::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrAxis::SetProperty are indicated by the word “Set” following the keyword.

AM_PM *(Get, Set)*

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the TICKFORMAT keyword.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to the color to be used as the foreground color for this axis. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

DAYS_OF_WEEK *(Get, Set)*

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the TICKFORMAT keyword.

DIRECTION *(Get, Set)*

Set this keyword to an integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis. Specifying this keyword is the same as specifying the optional *Direction* argument.

EXACT *(Get, Set)*

Set this keyword to force the axis range to be exactly as specified. If this keyword is not set, the range may be lengthened or shortened slightly to allow for evenly spaced tick marks.

EXTEND *(Get, Set)*

Set this keyword to a nonzero value to extend the axis slightly beyond the specified range. This can be useful when you specify the axis range based on the minimum and maximum data values, but do not want the graphic to extend all the way to the end of the axis.

GRIDSTYLE *(Get, Set)*

Set this keyword to indicate the line style that should be used to draw the axis' tick marks. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the GRIDSTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `GRIDSTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

LOCATION *(Get, Set)*

Set this keyword to a two- or three-element vector of the form [*x*, *y*] or [*x*, *y*, *z*] to specify the coordinate through which the axis should pass. The default is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

LOG *(Get, Set)*

Set this keyword to indicate that the axis is logarithmic.

MAJOR *(Get, Set)*

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

MINOR *(Get, Set)*

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

MONTHS *(Get, Set)*

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the TICKFORMAT keyword.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

NOTEXT *(Get, Set)*

Set this keyword to prevent the tick labels and the axis title from being drawn.

PALETTE

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

RANGE *(Get, Set)*

Set this keyword to a two-element vector containing the minimum and maximum data values covered by the axis. The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

SUBTICKLEN *(Get, Set)*

Set this keyword to a scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

TEXTALIGNMENTS *(Get, Set)*

Set this keyword to a two-element floating-point vector, [horizontal, vertical], specifying the horizontal and vertical alignments for the tick text. Each alignment value should be a value between 0.0 and 1.0. For horizontal alignment, 0.0 left-justifies the text; 1.0 right-justifies the text.

For vertical alignment, 0.0 bottom-justifies the text, 1.0 top-justifies the text. The defaults are as follows:

- *X*-Axis: [0.5, 1.0] (centered horizontally, top-justified vertically)
- Y-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)
- Z-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)

TEXTBASELINE *(Get, Set)*

Set this keyword to a two- or three-element vector describing the direction in which the baseline of the tick text is to be oriented. Use this keyword in conjunction with the TEXTUPDIR keyword to specify the plane on which the tick text lies. The default is [1,0,0].

TEXTPOS *(Get, Set)*

Set this keyword to either a zero or one to indicate on which side of the axis the tick text labels are to be drawn. The table below describes the placement of the tick text with each setting.

Axis	TEXTPOS=0	TEXTPOS=1
X	Tick text will be drawn *below* the X axis, where *below* is defined as being toward the direction of the negative Y axis (this is the default).	Tick text will be drawn *above* the X axis, where *above* is described as being toward the direction of the positive Y axis.
Y	Tick text will be drawn to the *left* of the Y Axis, where *left* is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the *right* of the Y axis, where *right* is defined as being toward the direction of the positive X axis.
Z	Tick text will be drawn to the *left* of the Z axis, where *left* is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the *right* of the Z axis, where *right* is defined as being toward the direction of the positive X axis.

Table A-25: Values for the TEXTPOS Keyword

TEXTUPDIR *(Get, Set)*

Set this keyword to a two- or three-element vector describing the direction in which the up-vector of the tick text is to be oriented. Use this keyword in conjunction with the TEXTBASELINE keyword to specify the plane on which the tick text lies. TEXTUPDIR should be orthogonal to TEXTBASELINE. The default is as follows:

- *X*-Axis: [0, 1, 0]
- *Y*-Axis: [0, 1, 0]
- *Z*-Axis: [0, 0, 1]

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness used to draw the axis, in points. The default is 1.0 points.

TICKDIR *(Get, Set)*

Set this keyword to either zero or one to indicate the tick mark direction. For an X axis, setting TICKDIR=0 means the tick marks will be drawn above the X axis, in the direction of the positive Y axis (this is the default); setting TICKDIR=1 means the tick marks will be drawn below the X axis. For a Y axis, setting TICKDIR=0 means the tick marks will be drawn to the right of the Y axis, in the direction of the positive X axis (this is the default); setting TICKDIR=1 means the tick marks will be drawn to the left of the Y axis. For a Z axis, setting TICKDIR=0 means the tick marks will be drawn to the right the Z axis, in the direction of the positive X axis (this is the default); setting TICKDIR=1 means the tick marks will be drawn to the left of the Z axis.

TICKFORMAT *(Get, Set)*

Set this keyword to a string (or an array of strings), where each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. (The TICKUNITS keyword determines the number of levels for an axis.) If the number of strings stored in this property is one, GetProperty returns a scalar string, otherwise GetProperty returns an array of strings.

If the string begins with an open parenthesis, it is treated as a standard format string. (See “Format Codes” in Chapter 10 of the *Building IDL Applications* manual.)

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels.

If TICKUNITS are not specified:

- The callback function is called with three parameters: Axis, Index, and Value, where:
- Axis is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- Index is the tick mark index (indices start at 0)
- Value is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: Axis, Index, Value, and Level, where:

- Axis, Index, and Value are the same as described above.
- Level is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Used with the LABEL_DATE function, this keyword can easily create axes with date/time labels.

TICKFRMTDATA *(Get, Set)*

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT keyword, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function.)

Note

TICKFRMTDATA will not be included in the structure returned via the ALL keyword to the IDLgrAxis::GetProperty method.

TICKINTERVAL (Get, Set)

Set this keyword to a scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis RANGE and the number of major tick marks (MAJOR). This keyword takes precedence over MAJOR.

For example, if TICKUNITS=['S','H','D'], and TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

TICKLAYOUT *(Get, Set)*

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

TICKLEN *(Get, Set)*

Set this keyword to the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

TICKTEXT *(Get, Set)*

Set this keyword to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (one per major tick) to specify the annotations to be assigned to the tickmarks. By default, with TICKTEXT set equal to a null object, IDL computes the tick labels based on major tick values. The positions of the provided text objects may be overwritten; position is determined according to tick mark location. The tickmark text will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object or objects, unless the USE_TEXT_COLOR keyword is specified.

Note

If IDL computes the tick labels, the text object it creates will be destroyed automatically when the axis object is destroyed, even if you have altered the

properties of the text object. If you create your own text object containing tickmark text, however, it will *not* be destroyed automatically.

TICKUNITS *(Get, Set)*

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If the number of levels in the axis is one, GetProperty returns a scalar string, otherwise GetProperty returns an array of strings.

If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- ""- Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

TICKVALUES *(Get, Set)*

Set this keyword to a vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

TITLE *(Get, Set)*

Set this keyword to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location. The title will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object, unless the USE_TEXT_COLOR keyword is specified.

USE_TEXT_COLOR *(Get, Set)*

Set this keyword to indicate that, for the tick text and/or title of the axis, the color property values set for the given IDLgrText objects are to be used to draw those text items. By default, this value is zero, indicating that the color properties of the IDLgrText objects will be ignored, and that the COLOR property for the axis object will be used for these text items instead.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, [s_0, s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrAxis::SetProperty

The IDLgrAxis::SetProperty procedure method sets the value of a property or group of properties for the axis.

Syntax

Obj -> [IDLgrAxis::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrAxis::Init followed by the word “Set” can be set using IDLgrAxis::SetProperty.

Version History

Introduced: 5.0

IDLgrBuffer

An IDLgrBuffer object is an in-memory, off-screen destination object. Object trees can be drawn to instances of the IDLgrBuffer object and the resulting image can be retrieved from the buffer using the Read() method. The off-screen representation avoids dithering artifacts by providing a full-resolution buffer for objects using either the RGB or Color Index color models.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See “IDLgrBuffer::Init” on page 2643.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrBuffer::Cleanup
- IDLgrBuffer::Draw
- IDLgrBuffer::Erase
- IDLgrBuffer::GetContiguousPixels
- IDLgrBuffer::GetDeviceInfo
- IDLgrBuffer::GetFontnames
- IDLgrBuffer::GetProperty
- IDLgrBuffer::GetTextDimensions

- IDLgrBuffer::Init
- IDLgrBuffer::PickData
- IDLgrBuffer::Read
- IDLgrBuffer::Select
- IDLgrBuffer::SetProperty

Version History

Introduced: 5.0

IDLgrBuffer::Cleanup

The IDLgrBuffer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrBuffer::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrBuffer::Draw

The IDLgrBuffer::Draw procedure method draws the given picture to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj -> [IDLgrBuffer::]Draw [, *Picture*] [, CREATE_INSTANCE={1 | 2}] [, /DRAW_INSTANCE]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object) or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that this scene, viewgroup, or view is the changing part of the drawing. It is overlaid on the result of the most recent CREATE_INSTANCE draw.

Version History

Introduced: 5.0

IDLgrBuffer::Erase

The IDLgrBuffer::Erase procedure method erases this graphics destination.

Syntax

Obj -> [IDLgrBuffer::]Erase [, COLOR=*index or RGB vector*]

Arguments

None.

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as an RGB vector.

Version History

Introduced: 5.0

IDLgrBuffer::GetContiguousPixels

The IDLgrBuffer::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Return = *Obj* `->` [IDLgrBuffer::]GetContiguousPixels()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrBuffer::GetDeviceInfo

The IDLgrBuffer::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj -> [IDLgrBuffer::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None.

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two-element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two-element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

Introduced: 5.0

MAX_NUM_CLIP_PLANES keyword: 5.6

IDLgrBuffer::GetFontnames

The IDLgrBuffer::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned. See Appendix N, “Fonts” for more information.

Syntax

Return = *Obj* -> [IDLgrBuffer::]GetFontnames(*FamilyName*[, IDL_FONTS={0 | 1 | 2 }] [, STYLES=*string*])

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.0

IDLgrBuffer::GetProperty

The IDLgrBuffer::GetProperty procedure method retrieves the value of a property or group of properties for the buffer.

Syntax

Obj -> [IDLgrBuffer::]GetProperty [, ALL=*variable*] [, IMAGE_DATA=*variable*] [, SCREEN_DIMENSIONS=*variable*] [, ZBUFFER_DATA=*variable*]

Keywords

Any keyword to IDLgrBuffer::Init followed by the word “Get” can be retrieved using IDLgrBuffer::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object (except IMAGE_DATA and ZBUFFER_DATA).

IMAGE_DATA

Set this keyword to a named variable that will contain a byte array representing the image that is currently rendered within the buffer. If the buffer uses an RGB color model, the returned array will have dimensions (3, *xdim*, *ydim*). If the window object uses an indexed color model, the returned array will have dimensions (*xdim*, *ydim*).

SCREEN_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector of the form [*width*, *height*] specifying the maximum allowed dimensions (measured in device units) for the buffer object.

Note

The maximum buffer dimension size is always 2048 by 2048.

ZBUFFER_DATA

Set this keyword to a named variable that will contain a float array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Version History

Introduced: 5.0

IDLgrBuffer::GetTextDimensions

The IDLgrBuffer::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

Result = *Obj* ->[IDLgrBuffer::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Arguments

TextObj

The object reference to a text or axis object for which text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrBuffer::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.0

IDLgrBuffer::Init

The IDLgrBuffer::Init function method initializes the buffer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrBuffer' [, COLOR_MODEL{Get}={0 | 1}]
[, DIMENSIONS{Get, Set}=*[width, height]*]
[, GRAPHICS_TREE{Get, Set}=*objref*] [, N_COLORS{Get}=*integer*{2 to 256}]
[, PALETTE{Get, Set}=*objref*] [, QUALITY{Get, Set}={0 | 1 | 2}]
[, RESOLUTION{Get, Set}=*[xres, yres]*] [, UNITS{Get, Set}={0 | 1 | 2 | 3}]
[, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrBuffer::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrBuffer::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrBuffer::SetProperty are indicated by the word "Set" following the keyword.

COLOR_MODEL *(Get)*

Set this keyword to the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

DIMENSIONS *(Get, Set)*

Set this keyword to a two-element vector of the form [*width*, *height*] to specify the dimensions of the buffer in units specified by the UNITS property. The default is [640,480].

GRAPHICS_TREE *(Get, Set)*

Set this keyword to an object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

N_COLORS *(Get)*

Set this keyword to the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

PALETTE *(Get, Set)*

Set this keyword to the object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the buffer's color lookup table.

QUALITY *(Get, Set)*

Set this keyword to an integer indicating the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

RESOLUTION *(Get, Set)*

Set this keyword to a two-element vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

UNITS *(Get, Set)*

Set this keyword to indicate the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to 1600 x 1200

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

IDLgrBuffer::PickData

The IDLgrBuffer::PickData function method maps a point in the two-dimensional device space of the buffer to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Syntax

Result = *Obj* -> [IDLgrBuffer::]PickData(*View*, *Object*, *Location*, *XYZLocation* [, DIMENSIONS=*[width,height]*][, PATH=*objref(s)*] [, PICK_STATUS=*variable*])

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Location

A two-element vector [*x*, *y*] specifying the location in the buffer's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the LOCATION or DIMENSIONS properties (this is only possible with IDLgrAxis, IDLgrImage, and IDLgrText objects), these transformations will *not* be included in the data coordinates returned by the PickData function. This means that you may need to re-apply the transformation accomplished by specifying LOCATION or DIMENSIONS once you have retrieved the data coordinates with PickData. This

situation does not occur if you transform the axis, text, or image object using the [XYZ]COORD_CONV properties.

Keywords

DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates [*x*, *y*] specified in the *Location* argument, and will occupy the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))
```

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions [*3*, *w*, *h*].

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 0-1: PICK_STATUS Keyword Values

Version History

Introduced: 5.0

PICK_STATUS keyword: 5.6

IDLgrBuffer::Read

The IDLgrWindow::Read function method reads an image from a buffer. The returned value is an instance of the IDLgrImage object class.

Syntax

Result = *Obj* -> [IDLgrBuffer::]Read()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrBuffer::Select

The IDLgrBuffer::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

Result = *Obj* -> [IDLgrBuffer::]Select(*Picture, XY* [, DIMENSIONS=*[width, height]*] [, UNITS={0 | 1 | 2 | 3}])

Arguments

Picture

The view, viewgroup, or scene (an instance of the IDLgrView, IDLgrViewgroup, or IDLgrScene class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the last object drawn will appear at a lower index in the list.

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

Keywords

DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify that the selection box will have a width *w* and a height *h*, and will be centered about the coordinates [*x*, *y*] specified in the *XY* argument. The box occupies the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/1), y+(h/2))
```

Any object which intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination.

Version History

Introduced: 5.0

IDLgrBuffer::SetProperty

The IDLgrBuffer::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj -> [IDLgrBuffer::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrBuffer::Init followed by the word “Set” can be retrieved using IDLgrBuffer::SetProperty.

Version History

Introduced: 5.0

IDLgrClipboard

An IDLgrClipboard object will send Object Graphics output to the operating system native clipboard in bitmap format. The format of bitmaps sent to the clipboard is operating system dependent: output is stored as a device-independent bitmap under Windows and as an Encapsulated PostScript (EPS) image under UNIX.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrClipboard::Init" on page 2668.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrClipboard::Cleanup
- IDLgrClipboard::Draw
- IDLgrClipboard::GetContiguousPixels
- IDLgrClipboard::GetDeviceInfo
- IDLgrClipboard::GetFontnames
- IDLgrClipboard::GetProperty
- IDLgrClipboard::GetTextDimensions
- IDLgrClipboard::Init
- IDLgrClipboard::SetProperty

Version History

Introduced: 5.1

IDLgrClipboard::Cleanup

The IDLgrClipboard::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj-> [IDLgrClipboard::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrClipboard::Draw

The IDLgrClipboard::Draw procedure method draws the given picture to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj -> [IDLgrClipboard::]Draw [, *Picture*] [, FILENAME=*string*] [, POSTSCRIPT=*value*] [, VECTOR={ 0 | 1 }]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object) or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

FILENAME

Set this keyword to a string representing the name of a file to which the output should be written. By default, this keyword is the null string, indicating that the output is written to the clipboard.

POSTSCRIPT

Set this keyword to a nonzero value to indicate that the generated output should be in PostScript format. By default, the generated output is in Windows Enhanced Metafile Format on Windows platforms and PostScript on UNIX platforms.

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values include:

- 0 = Bitmap (default)
- 1 = Vector

If VECTOR = 0 (Bitmap), the Draw method renders the scene to a buffer and then copies the buffer to the printer in bitmap format. The bitmap retains the quality of the original image, but the user cannot scale the bitmap effectively on all devices.

If VECTOR = 1 (Vector), the Draw method renders the scene using simple vector operations that result in a representation of the Scene that is scalable to the printer. The vector representation does not retain all the attributes of the original image, however, a user can effectively scale it on other devices. On Windows, the representation is the Windows Enhanced Metafile (EMF). On UNIX platforms, the representation is PostScript.

Examples

This example demonstrates the process of copying the contents of an IDL graphics display object (a buffer or a window) to the system clipboard, where it becomes available for pasting into another application. The example also uses the IDLgrClipboard::Draw method to create an encapsulated PostScript file in the current directory.

```

Version History

Introduced: 5.1

IDLgrClipboard::GetContiguousPixels

The IDLgrClipboard::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Return = *Obj* ->[IDLgrClipboard::]GetContiguousPixels()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrClipboard::GetDeviceInfo

The IDLgrClipboard::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj -> [IDLgrClipboard::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None.

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

Introduced: 5.1

MAX_NUM_CLIP_PLANES keyword: 5.6

IDLgrClipboard::GetFontnames

The IDLgrClipboard::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix N, "Fonts" for more information.

Syntax

Return = *Obj* -> [IDLgrClipboard::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.1

IDLgrClipboard::GetProperty

The IDLgrClipboard::GetProperty procedure method retrieves the value of a property or group of properties for the clipboard buffer.

Syntax

Obj -> [IDLgrClipboard::]GetProperty [, ALL=*variable*]
[, SCREEN_DIMENSIONS=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrClipboard::Init followed by the word “Get” can be retrieved using IDLgrClipboard::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

SCREEN_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector of the form [*width*, *height*] specifying the maximum allowed dimensions (measured in device units) for the clipboard object.

Version History

Introduced: 5.1

IDLgrClipboard::GetTextDimensions

The IDLgrClipboard::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in the clipboard buffer. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

Result = *Obj* ->[IDLgrClipboard::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrClipboard::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.1

IDLgrClipboard::Init

The IDLgrClipboard::Init function method initializes the clipboard object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrClipboard' [, COLOR_MODEL{Get}={0 | 1}] [, DIMENSIONS{Get, Set}=*[width, height]*] [, GRAPHICS_TREE{Get, Set}=*objref*] [, N_COLORS{Get}=*integer*{2 to 256}] [, PALETTE{Get, Set}=*objref*] [, QUALITY{Get, Set}={0 | 1 | 2}] [, RESOLUTION{Get, Set}=*[xres, yres]*] [, UNITS{Get, Set}={0 | 1 | 2 | 3}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrClipboard::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrClipboard::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrClipboard::SetProperty are indicated by the word "Set" following the keyword.

COLOR_MODEL *(Get)*

Set this keyword to the color model to be used for the clipboard buffer:

- 0 = RGB (default)
- 1 = Color Index

DIMENSIONS *(Get, Set)*

Set this keyword to a two-element vector of the form [*width*, *height*] to specify the dimensions of the clipboard buffer in units specified by the UNITS property. The default is [640,480].

GRAPHICS_TREE *(Get, Set)*

Set this keyword to an object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

N_COLORS *(Get)*

Set this keyword to the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

PALETTE *(Get, Set)*

Set this keyword to the object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the clipboard buffer's color lookup table.

QUALITY *(Get, Set)*

Set this keyword to an integer indicating the rendering quality at which graphics are to be drawn to the clipboard buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

RESOLUTION *(Get, Set)*

Set this keyword to a two-element vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

Note

To match screen rendering on an IDLgrClipboard object, the following properties should be matched between the devices: DIMENSIONS, UNITS, RESOLUTION, COLOR_MODEL and N_COLORS.

UNITS *(Get, Set)*

Set this keyword to indicate the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.1

IDLgrClipboard::SetProperty

The IDLgrClipboard::SetProperty procedure method sets the value of a property or group of properties for the clipboard buffer.

Syntax

Obj -> [IDLgrClipboard::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrClipboard::Init followed by the word “Set” can be retrieved using IDLgrClipboard::SetProperty.

Version History

Introduced: 5.1

IDLgrColorbar

The IDLgrColorbar object consists of a color-ramp with an optional framing box and annotation axis. The object can be horizontal or vertical.

An IDLgrColorbar object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrcolorbar__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

This class is a subclass of IDLgrModel.

Subclasses

This class has no subclasses.

Creation

See “IDLgrColorbar::Init” on page 2678.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrColorbar::Cleanup
- IDLgrColorbar::ComputeDimensions
- IDLgrColorbar::GetProperty
- IDLgrColorbar::Init
- IDLgrColorbar::SetProperty

Inherited Methods

This class inherits the following methods:

- IDLgrModel::GetCTM

Version History

Introduced: 5.1

IDLgrColorbar::Cleanup

The IDLgrColorbar::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY,*Obj*

or

Obj -> [IDLgrColorbar::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrColorbar::ComputeDimensions

The IDLgrColorbar::ComputeDimensions function method retrieves the dimensions of a colorbar object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim, yDim, zDim*] representing the dimensions of the colorbar object measured in data units.

Syntax

Result = *Obj* ->[IDLgrColorbar::]ComputeDimensions(*DestinationObj* [, PATH=*objref(s)*])

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the colorbar are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrColorbar::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.1

IDLgrColorbar::GetProperty

The IDLgrColorbar::GetProperty procedure method retrieves the value of a property or group of properties for the colorbar.

Syntax

Obj -> [IDLgrColorbar::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrColorbar::Init followed by the word “Get” can be retrieved using IDLgrColorbar::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

PARENT

Set this keyword to a named variable that will contain an object reference to the object that contains this colorbar.

XRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *x* data coordinates covered by the colorbar.

YRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] specifying the range of the *Y* data coordinates covered by the colorbar.

ZRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of the *Z* data coordinates covered by the colorbar.

Note

Until the colorbar is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the colorbar object to get the data dimensions of the colorbar prior to a draw operation.

Version History

Introduced: 5.1

IDLgrColorbar::Init

The IDLgrColorbar::Init function method initializes the colorbar object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrColorbar' [, *aRed*, *aGreen*, *aBlue*] [, BLUE_VALUES{Get, Set}=*vector*] [, COLOR{Get, Set}=*index or RGB vector*] [, DIMENSIONS{Get, Set}=*[dx, dy]*] [, GREEN_VALUES{Get, Set}=*vector*] [, /HIDE{Get, Set}] [, MAJOR{Get, Set}=*integer*] [, MINOR{Get, Set}=*integer*] [NAME{Get, Set}=*string*] [, PALETTE{Get, Set}=*objref*] [, RED_VALUES{Get, Set}=*vector*] [, SHOW_AXIS{Get, Set}={0 | 1 | 2}] [, /SHOW_OUTLINE{Get, Set}] [, SUBTICKLEN{Get, Set}=*minor_tick_length/major_tick_length*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, /THREED{Get}] [, TICKFORMAT{Get, Set}=*string*] [, TICKFRMTDATA{Get, Set}=*value*] [, TICKLEN{Get, Set}=*value*] [, TICKTEXT{Get, Set}=*objref(s)*] [, TICKVALUES{Get, Set}=*vector*] [, TITLE{Get, Set}=*objref*] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrColorbar::]Init([*aRed*, *aGreen*, *aBlue*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

aRed

A vector containing the red values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aBlue* vector must not exceed 256.

If *aRed*, *aGreen*, and *aBlue* are not provided, the color palette will default to a 256 entry greyscale ramp.

Keywords

Properties retrievable via IDLgrColorbar::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrColorbar::SetProperty are indicated by the word "Set" following the keyword.

BLUE_VALUES *(Get, Set)*

A vector containing the blue values for the color palette. Setting this value is the same as specifying the aBlue argument to the IDLgrColorbar::Init method.

COLOR *(Get, Set)*

Set this keyword to the color to be used as the foreground color for the axis and outline box. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

DIMENSIONS *(Get, Set)*

Set this keyword to a two element vector [*dx*, *dy*] that specifies the size of the ramp display (not the axis) in pixels. If *dx* > *dy*, the colorbar is drawn horizontally with the

axis placed below or above the ramp box depending on the value of the SHOW_AXIS property. If *dx* < *dy*, the colorbar is drawn vertically with the axis placed to the right or left of the ramp box depending on the value of the SHOW_AXIS property. The default value is [16,256].

GREEN_VALUES *(Get, Set)*

A vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrColorbar::Init method.

HIDE *(Get, Set)*

Set this keyword to a boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

MAJOR *(Get, Set)*

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

MINOR *(Get, Set)*

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

NAME *(Get, Set)*

Set this keyword to a string representing the name to be associated with this object. The default is the null string, ''.

PALETTE *(Get, Set)*

Set this keyword to an instance of the IDLgrPalette object class. If this keyword is a valid object reference, the colors within the IDLgrPalette are used to specify the colors for the colorbar.

RED_VALUES *(Get, Set)*

A vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrColorbar::Init method.

SHOW_AXIS *(Get, Set)*

Set this keyword to an integer value indicating whether the axis should be drawn:

- 0 = Do not display axis (the default)
- 1 = Display axis on left side or below the color ramp
- 2 = Display axis on right side or above the color ramp

SHOW_OUTLINE *(Get, Set)*

Set this keyword to a boolean value indicating whether the colorbar bounds should be outlined:

- 0 = Do not display outline (the default)
- 1 = Display outline

SUBTICKLEN *(Get, Set)*

Set this keyword to a scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness used to draw the axis and box outline, in points. The default is 1.0 points.

THREED *(Get)*

Set this keyword on initialization to create the colorbar as a graphic object that can be fully transformed in three dimensions. By default, the colorbar always faces the viewer and is drawn at z=0.

TICKFORMAT *(Get, Set)*

Set this keyword to either a standard IDL format string (see *"Format Codes"* in Chapter 10 of the *Building IDL Applications* manual for details on format codes) or a string containing the name of a user-supplied function that returns a string to be used to format the axis tick mark labels. The function should accept integer arguments for the direction of the axis, the index of the tick mark, and the value of the tick mark, and should return a string to be used as the tick mark's label. The function may optionally accept a keyword called DATA, which will be automatically set to the TICKFRMTDATA value. The default TICKFORMAT is '', the null string, which indicates that IDL will determine the appropriate format for each value.

TICKFRMTDATA *(Get, Set)*

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT keyword, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function). Note that TICKFRMTDATA will not be included in the structure returned via the ALL keyword to the IDLgrColorbar::GetProperty method.

TICKLEN *(Get, Set)*

Set this keyword to the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

TICKTEXT *(Get, Set)*

Set this keyword to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (each with a single string) to specify the annotations to be assigned to the tick marks. By default, TICKTEXT is set to the NULL object, which indicates that IDL will compute tick annotations based upon the major tick values. The positions and orientation of the provided text object(s) may be overwritten by the colorbar.

TICKVALUES *(Get, Set)*

Set this keyword to a vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

TITLE *(Get, Set)*

Set this keyword to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You may use this value to contain any information you wish.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.1

IDLgrColorbar::SetProperty

The IDLgrColorbar::SetProperty procedure method sets the value of a property or group of properties for the colorbar.

Syntax

Obj -> [IDLgrColorbar::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrColorbar::Init followed by the word “Set” can be retrieved using IDLgrColorbar::SetProperty.

Version History

Introduced: 5.1

IDLgrContour

The IDLgrContour object draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created.

An IDLgrContour object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

The object stores the following argument or property in double-precision if the DOUBLE_DATA keyword parameter is specified, and in single-precision otherwise.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrContour::Init" on page 2695.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrContour::AdjustLabelOffsets
- IDLgrContour::Cleanup
- IDLgrContour::GetCTM
- IDLgrContour::GetLabelInfo
- IDLgrContour::GetProperty
- IDLgrContour::Init
- IDLgrContour::SetProperty

Version History

Introduced: 5.1

IDLgrContour::AdjustLabelOffsets

The IDLgrContour::AdjustLabelOffsets procedure method adjusts the offsets at which contour labels are positioned.

Syntax

Obj->[IDLgrContour::]AdjustLabelOffsets, *LevelIndex*, *LabelOffsets*

Arguments

LevelIndex

The index of the contour level for which the label offsets are being adjusted. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS keyword in the IDLgrContour::Init method).

LabelOffsets

A scalar or vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each contour line at which each label is to be positioned. The number of elements in this vector must exactly match the number of elements returned in the LABEL_OFFSETS vector retrieved via the IDLgrContour::GetLabelInfo method for the same level.

Keywords

None.

Version History

Introduced: 5.1

IDLgrContour::Cleanup

The IDLgrContour::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrContour::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrContour::GetCTM

The IDLgrContour::GetCTM method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrContour::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrContour::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.1

IDLgrContour::GetLabelInfo

The IDLgrContour::GetLabelInfo procedure method retrieves information about the labels for a contour. The returned information is only valid until the next time the C_LABEL_INTERVAL or C_LABEL_OBJECTS property is modified using the IDLgrContour::SetProperty method, or the offsets are adjusted using the IDLgrContour::AdjustLabelOffsets method.

Syntax

Obj->[IDLgrContour::]GetLabelInfo, *Destination*, *LevelIndex*
[, LABEL_OFFSETS=*variable*] [, LABEL_POLYS=*variable*]
[, LABEL_OBJECTS=*variable*]

Arguments

Destination

A reference to a destination object (such as an IDLgrWindow or IDLgrBuffer object). The contour label information will be computed so that the requested font size is satisfied for this destination device.

LevelIndex

The index of the contour level for which the label information is being requested. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS keyword in the IDLgrContour::Init method).

Keywords

LABEL_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each contour line at which the contour labels are positioned.

LABEL_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of contour polyline indices, [P_0, P_1, …], that indicate which contour lines are labeled. P_i corresponds to the ith contour line.

Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

LABEL_OBJECTS

Set this keyword to a named variable that upon return will contain a vector of objects that represent the labels for each contour label.

Version History

Introduced: 5.1

IDLgrContour::GetProperty

The IDLgrContour::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj -> [IDLgrContour::]GetProperty [, ALL=*variable*] [, GEOM=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrContour::Init followed by the word “Get” can be retrieved using IDLgrContour::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

GEOM

Set this keyword to a named variable that will contain the geometry associated with the contour. IDL returns this data in single-precision floating-point by default or in double-precision floating-point if the DOUBLE_GEOM keyword is set in the IDLgrContour::Init method.

PARENT

Set this keyword to a named variable that will contain an object reference to the object that contains this contour.

XRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *X* data coordinates covered by the contour.

YRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] specifying the range of the *Y* data coordinates covered by the contour.

ZRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of the *Z* data coordinates covered by the contour.

Version History

Introduced: 5.1

IDLgrContour::Init

The IDLgrContour::Init function method initializes the contour object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrContour' [, *Values*] [, AM_PM{Get, Set}=*vector of two strings*] [, ANISOTROPY{Get, Set}=*[x, y, z]*] [, C_COLOR{Get, Set}=*vector*] [, C_FILL_PATTERN{Get, Set}=*array of IDLgrPattern objects*] [, C_LABEL_INTERVAL{Get, Set} =*vector*] [, C_LABEL_NOGAPS{Get, Set}=*vector*] [, C_LABEL_OBJECTS{Get, Set}=*array of object references*] [, C_LABEL_SHOW{Get, Set}=*vector of integers*] [, C_LINESTYLE{Get, Set}=*array of linestyles*] [, C_THICK{Get, Set}=*float array*{each element 1.0 to 10.0}] [, C_USE_LABEL_COLOR{Get, Set}=*vector of values*] [, C_USE_LABEL_ORIENTATION{Get, Set}=*vector of values*] [, C_VALUE{Get, Set}=*scalar or vector*] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB vector*] [, DATA_VALUES{Get, Set}=*vector or 2-D array*] [, DAYS_OF_WEEK{Get, Set}=*vector of seven strings*] [, DEPTH_OFFSET{Get, Set}=*value*] [, /DOUBLE_DATA{Get, Set}] [, /DOUBLE_GEOM{Get, Set}] [, /DOWNHILL{Get, Set}] [, /FILL{Get, Set}] [, GEOMX{Set}=*vector or 2-D array*] [, GEOMY{Set}=*vector or 2-D array*] [, GEOMZ{Set}=*scalar, vector, or 2-D array*] [, /HIDE{Get, Set}] [, LABEL_FONT{Get, Set}=*objref*] [, LABEL_FORMAT{Get, Set}=*string*] [, LABEL_FRMTDATA=*value*] [, LABEL_UNITS{Get, Set}=*string*] [, MAX_VALUE{Get, Set}=*value*] [, MIN_VALUE{Get, Set}=*value*] [, MONTHS{Get, Set}=*vector of 12 values*] [, NAME{Get, Set}=*string*] [, N_LEVELS{Get, Set}=*value*] [, PALETTE{Get, Set}=*objref*] [, /PLANAR{Get, Set}] [, POLYGONS{Get, Set}=*array of polygon descriptions*] [, SHADE_RANGE{Get, Set}=*[min, max]*] [, SHADING{Get, Set}={0 |1}] [, TICKINTERVAL{Get, Set}=*value*] [, TICKLEN{Get, Set}=*value*] [, USE_TEXT_ALIGNMENTS{Get, Set}=*value*] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrContour::]Init([*Values*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Values

A vector or two-dimensional array of values to be contoured. If no values are provided, the values will be derived from the GEOMZ keyword value (if set and the PLANAR keyword is not set). In this case, the values to be contoured will match the Z coordinates of the provided geometry. IDL converts and maintains this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Keywords

Properties retrievable via IDLgrContour::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrContour::SetProperty are indicated by the word "Set" following the keyword.

AM_PM *(Get, Set)*

Set this keyword to a vector of 2 strings indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL_FORMAT keyword.

ANISOTROPY *(Get, Set)*

Set this keyword equal to a three-element vector [*x*, *y*, *z*] that represents the multipliers to be applied to the internally computed correction factors along each axis that account for anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range [*xmin*, *ymin*, *zmin*] to [*xmax*, *ymax*, *zmax*], then the default correction factors are computed as follows:

```
dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
   xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
   ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
   zcorrection = maxRange / dz
```

This internally computed correction is then multiplied by the corresponding [*x, y, z*] values of the ANISOTROPY keyword. The default value for this keyword is [1,1,1]. IDL converts, maintains, and returns this data as double-precision floating-point.

C_COLOR *(Get, Set)*

Set this keyword to a vector of colors representing the colors to be applied at each contour level. If there are more contour levels than elements in this vector, the colors will be cyclically repeated. If C_COLOR is set to 0, all contour levels will be drawn in the color specified by the COLOR keyword (this is the default).

C_FILL_PATTERN *(Get, Set)*

Set this keyword to an array of IDLgrPattern objects representing the patterns to be applied at each contour level if the FILL keyword is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this keyword is set to 0, all contour levels are filled with a solid color (this is the default).

C_LABEL_INTERVAL *(Get, Set)*

Set this keyword to a vector of values indicating the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C_LABEL_INTERVAL values will be repeated cyclically. The default is 0.4.

C_LABEL_NOGAPS *(Get, Set)*

Set this keyword to a vector of values indicating whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_NOGAPS values will be repeated cyclically. By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

C_LABEL_OBJECTS *(Get, Set)*

Set this keyword to an array of object references to provide examples of labels to be drawn for each contour level. The objects specified via this keyword must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C_LABEL_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values. Note that the objects specified via this keyword are used as descriptors only. The actual objects drawn as labels are generated by IDL, and may be accessed via the IDLgrContour::GetLabelInfo method. The contour labels will have the same color as the corresponding contour level (see C_COLOR) unless the C_USE_LABEL_COLOR keyword is specified. The orientation of the label will be automatically computed unless the C_USE_LABEL_ORIENTATION keyword is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS keyword is specified.

Note

The object(s) set via this keyword will not be destroyed automatically when the contour is destroyed.

C_LABEL_SHOW *(Get, Set)*

Set this keyword to a vector of integers. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements

in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

C_LINESTYLE *(Get, Set)*

Set this keyword to an array of linestyles representing the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this keyword is set to 0, all levels are drawn as solid lines (this is the default).

To use a pre-defined line style, set the C_LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

C_THICK *(Get, Set)*

Set this keyword to an array of line thicknesses representing the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this keyword is set to 0, all contour levels are drawn with a line thickness of 1.0 points (this is the default).

C_USE_LABEL_COLOR *(Get, Set)*

Set this keyword to a vector of values to indicate whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C_COLOR property for the contour object will be used instead.

C_USE_LABEL_ORIENTATION *(Get, Set)*

Set this keyword to a vector of values to indicate whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_ORIENTATION values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

C_VALUE *(Get, Set)*

Set this keyword to a scalar value or a vector of values for which contour values are to be drawn. If this keyword is set to 0, contour levels will be evenly sampled across the range of the DATA_VALUES, using the value of the N_LEVELS keyword to determine the number of samples. IDL converts, maintains, and returns this data as double-precision floating-point.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to the color to be used to draw the contours. The color may be specified as a color lookup table index or as an RGB vector. The default is [0,0,0]. This value will be ignored if the C_COLOR keyword is set to a vector.

DATA_VALUES *(Get, Set)*

Set this keyword to a vector or two-dimensional array specifying the values to be contoured. The keyword is the same as the *Values* argument described in the Arguments section above. IDL converts and stores this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

DAYS_OF_WEEK *(Get, Set)*

Set this keyword to a vector of 7 strings indicate the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the LABEL_FORMAT keyword.

DEPTH_OFFSET *(Get, Set)*

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

Research Systems suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on

another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFSET has no effect unless the FILL keyword is set.

DOUBLE_DATA *(Get, Set)*

Set this keyword to indicate that the object is to store data provided by either the *Values* argument or the DATA_VALUES keyword parameter in double-precision floating-point. Otherwise, the data is stored in single-precision floating-point. IDL converts any value data already stored in the object to the requested precision, if necessary.

DOUBLE_GEOM *(Get, Set)*

Set this keyword to indicate that the object is to store data provided by any of the GEOMX, GEOMY, or GEOMZ keyword parameters in double-precision floating-point. Otherwise, the data is stored in single-precision floating-point. IDL converts any geometry data already stored in the object to the requested precision, if necessary.

DOWNHILL *(Get, Set)*

Set this keyword to indicate that downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

FILL *(Get, Set)*

Set this keyword to indicate that the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contour may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

GEOMX *(Set)*

Set this keyword to a vector or two-dimensional array specifying the X coordinates of the geometry with which the contour values correspond. If X is a vector, it must match the number of elements in the *Values* argument or DATA_VALUES keyword value, or it must match the first of the two dimensions of the *Values* argument or DATA_VALUES keyword value (in which case, the X coordinates will be repeated for each row of data values). IDL converts and maintains this data as double-precision floating-point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single-

precision. IDL returns the data as double-precision if it was stored in double-precision.

GEOMY *(Set)*

Set this keyword to a vector or two-dimensional array specifying the Y coordinates of the geometry with which the contour values correspond. If Y is a vector, it must match the number of elements in the *Values* argument or DATA_VALUES keyword value, or it must match the second of the two dimensions of the *Values* argument or DATA_VALUES keyword value (in which case, the Y coordinates will be repeated for each column of data values). IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

GEOMZ *(Set)*

Set this keyword to a scalar, a vector, or a two-dimensional array specifying the Z coordinates of the geometry with which the contour values correspond.

- If GEOMZ is a scalar, and the PLANAR keyword is set, the resulting contour geometry will be projected onto the plane Z=GEOMZ. If GEOMZ is a scalar, and the PLANAR keyword is not set, any geometry associated with the contour will be freed.
- If GEOMZ is a vector of Z coordinates, the number of elements in the vector should be the same as the number of elements in DATA_VALUES.
- If GEOMZ is an array and the leading dimension is 3, then the data is treated as a list or array of 3-D vertices. The product of the array dimensions following the 3 should equal the number of DATA_VALUES.
- If GEOMZ is an array and the leading dimension is not 3, then the data is treated as a list or array of single Z coordinates. If the number of dimensions is 2, then the data is treated as a 2-D array of Z values. Otherwise, it is treated as a vector of Z values. In either case, the total number of elements in the array should be the same as the number of DATA_VALUES.
- If GEOMZ is not set, the geometry will be derived from the DATA_VALUES property (if it is set to a two-dimensional array). In this case, the connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero.

Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

HIDE *(Get, Set)*

Set this keyword to a boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

LABEL_FONT *(Get, Set)*

Set this keyword to an instance of an IDLgrFont object to describe the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if C_LABEL_SHOW is set but the corresponding C_LABEL_OBJECTS text object is not provided), or for any text label objects provided via C_LABEL_OBJECTS that do not already have the font property set. The default value for this keyword is a NULL object reference, indicating that 12 pt. Helvetica will be used.

LABEL_FORMAT *(Get, Set)*

Set this keyword to a string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: Axis, Index, and Value, where:

- Axis is simply the value 2 to indicate that values along the Z axis are being formatted. (This allows a single callback routine to be used for both axis labeling and contour labeling.)
- Index is the contour level index (indices start at 0).
- Value is the data value of the current contour level.

LABEL_FRMTDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied formatting function specified via the LABEL_FORMAT keyword, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

Note

LABEL_FRMTDATA will not be included in the structure returned via the ALL keyword to the IDLgrContour::GetProperty method.

LABEL_UNITS *(Get, Set)*

Set this keyword to a string indicating the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

Note

The singular form of each of the time unit strings is also acceptable (for example, LEVEL_UNITS='Day' is equivalent to LEVEL_UNITS='Days').

MAX_VALUE *(Get, Set)*

Set this keyword to the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

MONTHS *(Get, Set)*

Set this keyword to a vector of 12 strings indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C_LABEL_FORMAT keyword.

MIN_VALUE *(Get, Set)*

Set this keyword to the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME *(Get, Set)*

Set this keyword to a string representing the name to be associated with this object. The default is the null string, ''.

N_LEVELS *(Get, Set)*

Set this keyword to the number of contour levels to generate. This keyword is ignored if the C_VALUE keyword is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this keyword to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

PALETTE

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

PLANAR *(Get, Set)*

Set this keyword to indicate that the contoured data is to be projected onto a plane. This keyword is ignored if GEOMZ is not a scalar. The default is non-planar (i.e., to display the contoured data at the Z locations provided by the GEOMZ keyword.

POLYGONS *(Get, Set)*

Set this keyword to an array of polygon descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument or the DATA_VALUES keyword). A polygon description is an integer or longword array of

the form: [*n*, i0, i1, ..., i*n*-1], where *n* is the number of vertices that define the polygon, and i0..i*n*-1 are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

SHADE_RANGE *(Get, Set)*

Set this keyword to a two-element array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

SHADING *(Get, Set)*

Set this keyword to an integer representing the type of shading to use:

- 0 = Flat (default): The color has a constant intensity for each face of the contour, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

TICKINTERVAL *(Get, Set)*

Set this keyword equal to a number indicating the distance between downhill tickmarks, in data units. If TICKINTERVAL is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

TICKLEN *(Get, Set)*

Set this keyword equal to a number indicating the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

USE_TEXT_ALIGNMENTS *(Get, Set)*

Set this keyword to indicate that, for any IDLgrText labels (as specified via the C_LABEL_OBJECTS keyword), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the label IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

UVALUE *(Get, Set)*

Set this keyword to a value of any type. Use this value to contain any information you wish.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.1

AM_PM, C_LABEL_INTERVAL, CLIP_PLANES, C_LABEL_OBJECTS, C_LABEL_NOGAPS, C_LABEL_SHOW, C_USE_LABEL_COLOR, C_USE_LABEL_ORIENTATION, DAYS_OF_WEEK, LABEL_FONT, LABEL_FORMAT, LABEL_FRMATDATA, LABEL_UNITS, MONTHS, USE_TEXT_ALIGNMENTS keywords: 5.6

IDLgrContour::SetProperty

The IDLgrContour::SetProperty procedure method sets the value of a property or group of properties for the contour.

Syntax

Obj -> [IDLgrContour::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrContour::Init followed by the word “Set” can be retrieved using IDLgrContour::SetProperty.

Version History

Introduced: 5.1

IDLgrFont

A font object represents a typeface, style, weight, and point size that may be associated with text objects.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See “IDLgrFont::Init” on page 2714.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrFont::Cleanup
- IDLgrFont::GetProperty
- IDLgrFont::Init
- IDLgrFont::SetProperty

Version History

Introduced: 5.0

IDLgrFont::Cleanup

The IDLgrFont::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrFont::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrFont::GetProperty

The IDLgrFont::GetProperty procedure method retrieves the value of a property or group of properties for the font.

Syntax

Obj -> [IDLgrFont:]GetProperty [, ALL=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrFont::Init followed by the word “Get” can be retrieved using IDLgrFont::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Version History

Introduced: 5.0

IDLgrFont::Init

The IDLgrFont::Init function method initializes the font object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrFont' [, *Fontname*] [, NAME{Get, Set}=*string*] [, SIZE{Get, Set}=*points*] [, SUBSTITUTE{Get, Set}={ 'Helvetica' | 'Courier' | 'Times' | 'Symbol' | 'Hershey'}] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrFont::]Init([*Fontname*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Fontname

A string representing the name of the font to be used. This string should take the form 'fontname*modifier1*modifier2*...*modifierN'. All destination objects support the following fontnames: Helvetica, Courier, Times, Symbol, and Monospace Symbol. (These fonts are included with IDL; you may have other fonts installed on your system as well.) Valid modifiers for each of these fonts (except Symbol and Monospace Symbol) are:

- *Font weight:* Bold
- *Font angle:* Italic

For example, 'Helvetica*Bold*Italic'.

To select a Hershey font, use a fontname of the form: 'Hershey*fontnum'. See Appendix N, “Fonts” for further information and a list of fonts supported by IDL.

Note

Beginning with IDL version 5.1, only TrueType and Hershey fonts are supported in the Object Graphics system.

Keywords

Properties retrievable via IDLgrFont::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrFont::SetProperty are indicated by the word “Set” following the keyword.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name of the font to use. Setting the NAME keyword is the same as supplying the *Fontname* argument described above.

SIZE *(Get, Set)*

Set this keyword equal to a floating-point value representing the point size of the font. The default is 12.0 points.

SUBSTITUTE *(Get, Set)*

Set this keyword to a string that indicates the font to use as a substitute if the specified *Fontname* is not available on the graphics destination. Valid values are only those fonts that are available on all destination objects (the fonts included with IDL). These are: 'Helvetica' (the default), 'Courier', 'Times', 'Symbol', or 'Hershey'.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, indicating the line thickness (measured in points) to use for the Hershey vector fonts. The default is 1.0 points.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

IDLgrFont::SetProperty

The IDLgrFont::SetProperty procedure method sets the value of a property or group of properties for the font.

Syntax

Obj -> [IDLgrFont:]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrFont::Init followed by the word “Set” can be set using IDLgrFont::SetProperty.

Version History

Introduced: 5.0

IDLgrImage

An image object represents a mapping from a two-dimensional array of data values to a two dimensional array of pixel colors, resulting in a flat 2-D-scaled version of the image, drawn at Z = 0.

The image object is drawn at Z =0 and is positioned and sized with respect to two points:

```
p1 = [LOCATION(0), LOCATION(1), 0]
p2 = [LOCATION(0) + DIMENSION(0), LOCATION(1) + DIMENSION(1), 0].
```

where LOCATION and DIMENSION are properties of the image object. These points are transformed in three dimensions, resulting in screen space points designated as p1' and p2'. The image data is drawn on the display as a 2-D image within the 2-D rectangle defined by (p1'[0], p1'[1] - p2'[0], p2'[1]). The 2-D image data is scaled in 2-D (not rotated) to fit into this projected rectangle and then drawn with Z buffering disabled

Note

Image objects do not take into account the Z locations of other objects that may be included in the view object. This means that objects that are drawn to the destination object (window or printer) *after the image is drawn* will appear to be in front of the image, even if they are located at a negative Z value (behind the image object). Objects are drawn to a destination device in the order that they are added (via the Add method) to the model, view, or scene that contains them. To rotate or position image objects in three-dimensional space, use the IDLgrPolygon object with texture mapping enabled.

An IDLgrImage object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See “IDLgrImage::Init” on page 2725.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrImage::Cleanup
- IDLgrImage::GetCTM
- IDLgrImage::GetProperty
- IDLgrImage::Init
- IDLgrImage::SetProperty

Version History

Introduced: 5.0

IDLgrImage::Cleanup

The IDLgrImage::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrImage::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrImage::GetCTM

The IDLgrImage::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrImage::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the image object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrImage::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrImage::GetProperty

The IDLgrImage::GetProperty procedure method retrieves the value of the property or group of properties for the image.

Syntax

Obj -> [IDLgrImage::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrImage::Init followed by the word "Get" can be retrieved using IDLgrImage::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

YRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Version History

Introduced: 5.0

IDLgrImage::Init

The IDLgrImage::Init function method initializes the image object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrImage' [, *ImageData*] [, BLEND_FUNCTION{Get, Set}=*vector*] [, CHANNEL{Get, Set}=*hexadecimal bitmask*] [, CLIP_PLANES{Get, Set}=*array*] [, DATA{Get, Set}=*nxm, 2xnxm, 3xnxm,* or *4xnxm array of image data*] [, DIMENSIONS{Get, Set}=*[width, height]*] [, /GREYSCALE{Get, Set}] [, /HIDE{Get, Set}] [, INTERLEAVE{Get, Set}={0 | 1 | 2}] [, /INTERPOLATE{Get, Set}] [LOCATION{Get, Set}=*[x, y] or [x, y, z]*] [, NAME{Get, Set}=*string*] [, /NO_COPY{Get, Set}] [, /ORDER{Get, Set}] [, PALETTE{Get, Set}=*objref*] [, /RESET_DATA{Set}] [, SHARE_DATA{Set}=*objref*] [, SUB_RECT{Get, Set}=*[x, y, xdim, ydim]*] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrImage::]Init([*ImageData*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

ImageData

An array of data values to be displayed as an image. If this argument is not already of byte type, it is converted to byte type when the image object is created. Since IDL maintains the image data using the byte type, the input data values should range from

0 through 255. Image objects can have a single channel (one value per pixel—greyscale or color indexed), two channels (greyscale and alpha), three channels (red, green, and blue), or four channels (red, green, blue, and alpha). The alpha channel, if present, determines the transparency of the pixel. The BLEND_FUNCTION property controls the interpretation of the alpha channel values. With channels, the data value of 0 specifies minimum intensity and the data value of 255 specifies maximum intensity. The alpha channel values are also specified in the image data in the range 0 through 255, with an image data value of 0 corresponding to an alpha blend factor of 0 and an image data value of 255 corresponding to an alpha blend factor of 1.0. *ImageData* can be any of the following, where *n* is the width of the image, and *m* is the height:

- An *n* x *m* array of color lookup table indices.
- An *n* x *m* greyscale image, or a 2 x *n* x *m*, *n* x 2 x *m*, or *n* x *m* x 2 greyscale image with an alpha channel. (The alpha channel is ignored if the destination device uses indexed color mode.)
- A 3 x *n* x *m*, *n* x 3 x *m*, or *n* x *m* x 3 RGB image, or a 4 x *n* x *m*, *n* x 4 x *m*, or *n* x *m* x 4 RGB image with an alpha channel.

If the array has more than one channel, the interleave is specified by the INTERLEAVE property.

Keywords

Properties retrievable via IDLgrImage::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrImage::SetProperty are indicated by the word “Set” following the keyword.

BLEND_FUNCTION *(Get, Set)*

If the image data contains an alpha channel, use this keyword to control how the alpha channel values will be interpreted. Set this keyword equal to a two-element vector [*src*, *dst*] specifying one of the functions listed below for each of the source and destination objects. These are only valid for RGB model destinations. If an alpha channel is not specified in an image, the image’s alpha blend factor is assumed to be 1.0. The values of the blending function (V_{src} and V_{dst}) are used in the following equation

$$C_d' = (V_{src} \cdot C_i) + (V_{dst} \cdot C_d)$$

where C_d is the initial color of a pixel on the destination device (the background color), C_i is the color of the pixel in the image, and C_d' is the resulting color of the pixel.

Setting *src* and *dst* in the BLEND_FUNCTION vector to the following values determine how each term in the equation is calculated:

src or dst	V_{src} or V_{dst}	What the function does
0	n/a	Alpha blending is disabled. $C_d' = C_i$.
1	0	The value of V_{src} or V_{dst} in the equation is zero, thus the value of the term is zero.
2	1	The value of V_{src} or V_{dst} in the equation is one, thus the value of the term is the same as the color value.
3	$Image_a$	The value of V_{src} or V_{dst} in the equation is the blend factor of the image's alpha channel.
4	1-$Image_a$	The value of V_{src} or V_{dst} in the equation is one minus the blend factor of the image's alpha channel.

Table A-26: Values for src and dst in BLEND_FUNCTION

For example, setting BLEND_FUNCTION = [3, 4] creates an image in which you can see through the foreground image to the background to the extent defined by the alpha channel values of the foreground image.

Since the alpha blending operation is dependent on the values of pixels already drawn to the destination for some blending functions, the final result may depend more on the order of drawing the images, and not necessarily on their relative location along the Z axis. IDL draws images in the order that they are stored in the IDLgrModel object that contains them.

CHANNEL *(Get, Set)*

Set this keyword to a hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, 'ff0000'X represents a Red channel write. The default is to draw all channels, and is represented by the hexadecimal value 'ffffff'X.

Note

This keyword is ignored for CI destination objects.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

DATA *(Get, Set)*

Set this keyword to a *n* x *m*, *2 x n x m*, *3 x n* x *m*, or *4 x n* x *m* array of image data for the object. The *n* and *m* values may be in any position as specified by the INTERLEAVE keyword. This keyword is equivalent to the optional argument, *ImageData*.

DIMENSIONS *(Get, Set)*

Set this keyword equal to a two-element vector of the form [*width*, *height*] specifying the dimensions of the rectangle in which the image is to be drawn on the device. The image will be resampled as necessary to fit within this rectangle. The default is derived from the dimensions of the given image data and is measured in pixels. IDL converts, maintains, and returns this data as double-precision floating-point.

GREYSCALE *(Get, Set)*

Set this keyword to specify that the image not be drawn through a palette.

If this keyword is not set, for an RGB color model destination, if a palette is present in the image object, it is used. If there is no current destination palette, a greyscale

palette is used. For a Color Index color model destination, the current destination palette is used.

Note

Only single band images (i.e. *1 x n x m*) are affected by this keyword. By default, GREYSCALE is disabled.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

INTERLEAVE *(Get, Set)*

Set this keyword to indicate the dimension over which color is interleaved for images with more than one channel:

- 0 = Pixel interleaved: Images with dimensions (3, *m*, *n*)
- 1 = Line interleaved (row interleaved): Images with dimensions (*m*, 3, *n*)
- 2 = Planar or image interleaved: Images with dimensions (*m*, *n*, 3).

Note

If an alpha channel is present, the 3s should be replaced by 4s. In a greyscale image with an alpha channel, the 3s should be replaced by 2s.

INTERPOLATE *(Get, Set)*

Set this keyword to one to display the IDLgrImage object using bilinear interpolation. The default is to use nearest neighbor interpolation.

LOCATION *(Get, Set)*

A two- or three-element vector [*x*, *y*] or [*x*, *y*, *z*] specifying the position of the lower lefthand corner of the image, measured in data units. If the vector is of the form [*x*, *y*], then the *z* value is set equal to zero. The default is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

NO_COPY *(Get, Set)*

Set this keyword to relocate the image data from the input variable to the image object, leaving the input variable *ImageData* undefined. Only the *ImageData* argument is affected. If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

ORDER *(Get, Set)*

Set this keyword to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

PALETTE *(Get, Set)*

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

RESET_DATA *(Set)*

Set this keyword to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this keyword if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This keyword has no effect if no new data is provided via the DATA property.

SHARE_DATA *(Set)*

Set this keyword equal to the object reference of an object with which data is to be shared by this image. An image may only share data with another image. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

SUB_RECT *(Get, Set)*

Set this keyword to a four-element vector, [*x*, *y*, *xdim*, *ydim*], specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle to display.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrImage::SetProperty

The IDLgrImage::SetProperty procedure method sets the value of the property or group of properties for the image.

Syntax

Obj -> [IDLgrImage::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrImage::Init followed by the word “Set” can be set using IDLgrImage::SetProperty.

Version History

Introduced: 5.0

IDLgrLegend

The IDLgrLegend object provides a simple interface for displaying a legend. The legend itself consists of a (filled and/or framed) box around one or more legend items (arranged in a single column) and an optional title string. Each legend item consists of a glyph patch positioned to the left of a text string. The glyph patch is drawn in a square which is a fraction of the legend label font height. The glyph itself can be in one of two types (see the TYPE keyword). In line type, the glyph is a line segment with linestyle, thickness and color attributes and an optional symbol object drawn over it. In fill type, the glyph is a square patch drawn with color and optional pattern object attributes.

An IDLgrLegend object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrlegend__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

This class is a subclass of IDLgrModel.

Subclasses

This class has no subclasses.

Creation

See “IDLgrLegend::Init” on page 2740.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrLegend::Cleanup
- IDLgrLegend::ComputeDimensions
- IDLgrLegend::GetProperty

- IDLgrLegend::Init
- IDLgrLegend::SetProperty

Inherited Methods

This class inherits the following methods:

- IDLgrModel::GetCTM

Version History

Introduced: 5.1

IDLgrLegend::Cleanup

The IDLgrLegend::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrLegend::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrLegend::ComputeDimensions

The IDLgrLegend::ComputeDimensions function method retrieves the dimensions of a legend object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim, yDim, zDim*] representing the dimensions of the legend object measured in data units.

Syntax

Result = *Obj* ->[IDLgrLegend::]ComputeDimensions(*DestinationObject* [, PATH=*objref(s)*])

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the legend are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLegend::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.1

IDLgrLegend::GetProperty

The IDLgrLegend::GetProperty procedure method retrieves the value of a property or group of properties for the legend.

Syntax

Obj -> [IDLgrLegend::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrLegend::Init followed by the word “Get” can be retrieved using IDLgrLegend::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

PARENT

Set this keyword to a named variable that will contain an object reference to the object that contains this legend.

XRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *X* data coordinates covered by the legend.

YRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] specifying the range of the *Y* data coordinates covered by the legend.

ZRANGE

Set this keyword to a named variable that will contain a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of the *Z* data coordinates covered by the legend.

Note

Until the legend is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the legend object to get the data dimensions of the legend prior to a draw operation.

Version History

Introduced: 5.1

IDLgrLegend::Init

The IDLgrLegend::Init function method initializes the legend object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrLegend' [, *aItemNames*] [, BORDER_GAP{Get, Set}=*value*] [, COLUMNS{Get, Set}=*integer*] [, FILL_COLOR{Get, Set}=*index or RGB vector*] [, FONT{Get, Set}=*objref*] [, GAP{Get, Set}=*value*] [, GLYPH_WIDTH{Get, Set}=*value*] [, /HIDE{Get, Set}] [, ITEM_COLOR{Get, Set}=*array of colors*] [, ITEM_LINESTYLE{Get, Set}=*int array*] [, ITEM_NAME{Get, Set}=*string array*] [, ITEM_OBJECT{Get, Set}=*array of objrefs of type IDLgrSymbol or IDLgrPattern*] [, ITEM_THICK{Get, Set}=*float array*{each element 1.0 to 10.0}] [, ITEM_TYPE{Get, Set}=*int array*{each element 0 or 1}] [, NAME{Get, Set}=*string*] [, OUTLINE_COLOR{Get, Set}=*index or RGB vector*] [, OUTLINE_THICK{Get, Set}=*points*{1.0 to 10.0}] [, /SHOW_FILL{Get, Set}] [, /SHOW_OUTLINE{Get, Set}] [, TEXT_COLOR{Get, Set}=*index or RGB vector*] [, TITLE{Get, Set}=*objref*] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrLegend::]Init([*aItemNames*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

aItemNames

An array of strings to be used as the displayed item label. The length of this array is used to determine the number of items to be displayed. Each item is defined by taking one element from the ITEM_NAME, ITEM_TYPE, ITEM_LINESTYLE, ITEM_THICK, ITEM_COLOR, and ITEM_OBJECT vectors. If the number of items (as defined by the ITEM_NAME array) exceeds any of the attribute vectors, the attribute defaults will be used for any additional items.

Keywords

Properties retrievable via IDLgrLegend::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrLegend::SetProperty are indicated by the word “Set” following the keyword.

BORDER_GAP *(Get, Set)*

Set this keyword to a floating-point value to indicate the amount of blank space to be placed around the outside of the glyphs and text items. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height).

COLUMNS *(Get, Set)*

Set this keyword to an integer value to indicate the number of columns the legend items should be displayed in. The default is one column.

FILL_COLOR *(Get, Set)*

Set this keyword to the color to be used to fill the legend background box. The color may be specified as a color lookup table index or as an RGB vector. The default is [255,255,255].

FONT *(Get, Set)*

Set this keyword to an instance of an IDLgrFont object class to describe the font to use to draw the legend labels. The default is 12 point Helvetica.

Note

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a font object that will be destroyed when this legend object is destroyed, leaving a dangling object reference.

GAP *(Get, Set)*

Set this keyword to a floating-point value to indicate the amount of blank space to be placed vertically between each legend item. The units for this keyword are fractions of the legend label font height. The default is 0.1 (10% of the label font height). The same gap is placed horizontally between the legend glyph and the legend text string.

GLYPH_WIDTH *(Get, Set)*

Set this keyword to a floating-point value to indicate the width of the glyphs, measured as a fraction of the font height. The default is 0.8 (80% of the font height).

HIDE *(Get, Set)*

Set this keyword to a boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

ITEM_COLOR *(Get, Set)*

Set this keyword to an array of colors defining the color of each item. The array defines *M* different colors, and should be either of the form [3,*M*] or [*M*]. In the first case, the three values are used as an RGB triplet, in the second case, the single value is used as a color index value. The default color is [0,0,0].

ITEM_LINESTYLE *(Get, Set)*

Set this keyword to an array of integers defining the style of the line to be drawn if the TYPE property is set to zero. The array can be of the form [*M*] or [2,*M*]. The first form selects the linestyle for each legend item from the predefined defaults:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot

- 5 = long dash
- 6 = no line drawn

The second form specifies the stippling pattern explicitly for each legend item (see the LINESTYLE keyword to IDLgrPolyline::Init for details).

ITEM_NAME *(Get, Set)*

Set this keyword to an array of strings. Specifying this keyword is the same as providing the *aName* argument for the IDLgrLegend::Init method.

ITEM_OBJECT *(Get, Set)*

Set this keyword to an array of object references of type IDLgrSymbol or IDLgrPattern. A symbol object is drawn only if the TYPE property is set to zero. A pattern object is used when drawing the color patch if the TYPE property is set to one. The default object is the NULL object.

Note

If one or more IDlgrSymbol object references are provided, the SIZE property of those objects may be modified by this legend to suit its layout needs.

ITEM_THICK *(Get, Set)*

Set this keyword to an array of floats that define the thickness of each item line, in points, where each element is a value between 1.0 and 10.0. This property is only used if the TYPE property is set to zero. The default is 1.0 points.

ITEM_TYPE *(Get, Set)*

Set this keyword to an array of integers which define the type of glyph to be displayed for each item:

- 0 = line type (the default)
- 1 = filled box type

NAME *(Get, Set)*

Set this keyword to a string representing the name to be associated with this object. The default is the null string, ''.

OUTLINE_COLOR *(Get, Set)*

Set this keyword to the color to be used to draw the legend outline box. The color may be specified as a color lookup table index or as an RGB vector. The default is [0,0,0].

OUTLINE_THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0 that defines the thickness of the outline frame, in points. The default is 1.0 points.

SHOW_FILL *(Get, Set)*

Set this keyword to a boolean value indicating whether the background should be filled with a color:

- 0 = Do not fill background (the default)
- 1 = Fill background

SHOW_OUTLINE *(Get, Set)*

Set this keyword to a boolean value indicating whether the outline box should be displayed:

- 0 = Do not display outline (the default)
- 1 = Display outline

TEXT_COLOR *(Get, Set)*

Set this keyword to the color to be used to draw the legend item text. The color may be specified as a color lookup table index or as an RGB vector. The default is [0,0,0].

TITLE *(Get, Set)*

Set this keyword to an instance of the IDLgrText object class to specify the title for the legend. The default is the null object, specifying that no title is drawn. The title will be centered at the top of the legend, even if the text object itself has an associated location.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. Use this value to contain any information you wish.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.1

IDLgrLegend::SetProperty

The IDLgrLegend::SetProperty procedure method sets the value of a property or group of properties for the legend.

Syntax

Obj-> [IDLgrLegend::]SetProperty [, RECOMPUTE={0 | 1}{0 prevents recompute, 1 is the default}]

Arguments

None.

Keywords

Any keyword to IDLgrLegend::Init followed by the word “Set” can be retrieved using IDLgrLegend::SetProperty. In addition, the following keywords are available:

RECOMPUTE

Set this keyword to 1 to force IDL to recompute the legend dimensions when the legend is redrawn. Set this keyword to 0 to prevent IDL from recomputing legend dimensions.

Version History

Introduced: 5.1

IDLgrLight

A light object represents a source of illumination for three-dimensional graphic objects. Lights may be either ambient, positional, directional, or spotlights. A maximum of 8 lights per view are allowed. Lights are not required for objects displayed in two dimensions.

An IDLgrLight object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrLight::Init" on page 2752.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrLight::Cleanup
- IDLgrLight::GetCTM
- IDLgrLight::GetProperty
- IDLgrLight::Init
- IDLgrLight::SetProperty

Version History

Introduced: 5.0

IDLgrLight::Cleanup

The IDLgrLight::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrLight::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrLight::GetCTM

The IDLgrLight::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrLight::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the light object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLight::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrLight::GetProperty

The IDLgrLight::GetProperty procedure method retrieves the value of a property or group of properties for the light.

Syntax

Obj -> [IDLgrLight::]GetProperty [, ALL=*variable*] [, PARENT=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrLight::Init followed by the word “Get” can be retrieved using IDLgrLight::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

Version History

Introduced: 5.0

IDLgrLight::Init

The IDLgrLight::Init function method initializes the light object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrLight' [, ATTENUATION{Get, Set}=*[constant, linear, quadratic]*] [, COLOR{Get, Set}=*[R, G, B]*] [, CONEANGLE{Get, Set}=*degrees*] [, DIRECTION{Get, Set}=*3-element vector*] [, FOCUS{Get, Set}=*value*] [, /HIDE{Get, Set}] [, INTENSITY{Get, Set}=*value*{0.0 to 1.0}] [, LOCATION{Get, Set}=*[x, y, z]*] [, NAME{Get, Set}=*string*] [, TYPE{Get, Set}={0 | 1 | 2 | 3}] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrLight::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrLight::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrLight::SetProperty are indicated by the word "Set" following the keyword.

ATTENUATION *(Get, Set)*

Set this keyword to a 3-element floating-point vector of the form [constant, linear, quadratic] that describes the factor by which light intensity is to fall with respect to distance from the light source. ATTENTUATION applies only to Positional and Spot lights, as specified by the TYPE keyword. The overall attenuation factor is computed as follows:

```
attenuation = 1/(constant + linear*distance +
quadratic*distance^2)
```

By default, the values are [1, 0, 0].

COLOR *(Get, Set)*

Set this keyword to a three-element vector specifying the RGB color of the light. The default is [255, 255, 255], which is a white light. The color of a light is ignored when graphics are sent to graphics destinations using the Indexed color model, in which case light intensities are scaled into the range of colors available on the graphics destination.

CONEANGLE *(Get, Set)*

Set this keyword to the angle (measured in degrees) of coverage for a spotlight. The default is 60.

DIRECTION *(Get, Set)*

Set this keyword to the three-element vector representing the direction in which a spotlight is to be pointed. The default is [0,0,-1].

Note

For directional lights, the light's parallel rays follow a vector beginning at the position specified by LOCATION and ending at [0, 0, 0].

FOCUS *(Get, Set)*

Set this keyword to a floating-point value that describes the attenuation of intensity for spotlights as the distance from the center of the cone of coverage increases. This factor is used as an exponent to the cosine of the angle between the direction of the spotlight and the direction from the light to the vertex being lighted. The default is 0.0.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this light should be enabled:

- 0 = Enable light (the default)
- 1 = Disable light

Note

If no lights are present in the view (or if all lights in the view are hidden), an ambient light will be provided by default.

INTENSITY *(Get, Set)*

Set this keyword to a floating-point value between 0.0 (darkest) and 1.0 (brightest) indicating the intensity of the light. The default is 1.0.

LOCATION *(Get, Set)*

Set this keyword to a vector of the form [*x*, *y*, *z*] describing the position of the light. By default, the position is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

TYPE *(Get, Set)*

Set this keyword to one of the following values, indicating the type of light. Valid values are:

- 0 = Ambient light. An ambient light is a universal light source, which has no direction or position. An ambient light illuminates every surface in the scene equally, which means that no edges are made visible by contrast. Ambient lights control the overall brightness and color of the entire scene. If no value is specified for the TYPE property, an ambient light is created.
- 1 = Positional light. A positional light supplies divergent light rays, and will make the edges of surfaces visible by contrast if properly positioned. A positional light source can be located anywhere in the scene.
- 2 = Directional light. A directional light supplies parallel light rays. The effect is that of a positional light source located at an infinite distance from scene.

- 3 = Spot light. A spot light illuminates only a specific area defined by the light's position, direction, and the cone angle, or angle which the spotlight covers.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this "user value" to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.0

IDLgrLight::SetProperty

The IDLgrLight::SetProperty procedure method sets the value of a property or group of properties for the light.

Syntax

Obj -> [IDLgrLight::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrLight::Init followed by the word “Set” can be set using IDLgrLight::SetProperty.

Version History

Introduced: 5.0

IDLgrModel

A model object represents a graphical item or group of items that can be transformed (rotated, scaled, and/or translated). It serves as a container of other IDLgrModel objects or atomic graphic objects. IDLgrModel applies a transform to the current view tree.

Superclasses

This class is a subclass of IDL_Container.

Subclasses

The following classes are subclassed from this class:

- IDLgrColorbar
- IDLgrLegend

Creation

See “IDLgrModel::Init” on page 2767.

Methods

Intrinsic Methods

This class has this following methods:

- IDLgrModel::Add
- IDLgrModel::Cleanup
- IDLgrModel::Draw
- IDLgrModel::GetByName
- IDLgrModel::GetCTM
- IDLgrModel::GetProperty
- IDLgrModel::Init
- IDLgrModel::Reset
- IDLgrModel::Rotate

- IDLgrModel::Scale
- IDLgrModel::SetProperty
- IDLgrModel::Translate

Inherited Methods

This class inherits the following methods:

- IDL_Container::Count
- IDL_Container::Get
- IDL_Container::IsContained
- IDL_Container::Move

Version History

Introduced: 5.0

IDLgrModel::Add

The IDLgrModel::Add procedure method adds a child to this Model.

Syntax

Obj -> [IDLgrModel::]Add, *Object* [, /ALIAS] [, POSITION=*index*]

Arguments

Object

An instance of an atomic graphic object or another model object to be added to the model object.

Keywords

ALIAS

Set this keyword to a nonzero value to indicate that an alias—rather than the object itself—is to be added to the model. With this keyword you can add the same object to multiple models without duplicating that object and its children. If this keyword is set, the PARENT keyword on the object being added will not change. Furthermore, if this keyword is set, the object being added will not be destroyed when the model is destroyed.

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced: 5.0

IDLgrModel::Cleanup

The IDLgrModel::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrModel::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrModel::Draw

The IDLgrModel::Draw procedure method draws the specified picture to the specified graphics destination. *This method is provided for purposes of sub-classing only, and is intended to be called only from the Draw method of a subclass of IDLgrModel.*

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj -> [IDLgrModel::]Draw, *Destination*, *Picture*

Arguments

Destination

The destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) to which the specified view object will be drawn.

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

None.

Version History

Introduced: 5.0

IDLgrModel::GetByName

The IDLgrModel::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj* `->` [IDLgrModel::]GetByName(*Name*)

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX file system. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None.

Version History

Introduced: 5.0

IDLgrModel::GetCTM

The IDLgrModel::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrModel::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the model object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrModel::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrModel::GetProperty

The IDLgrModel::GetProperty procedure method retrieves the value of a property or group of properties for the model.

Syntax

Obj -> [IDLgrModel::]GetProperty [, ALL=*variable*] [, PARENT=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrModel::Init followed by the word “Get” can be retrieved using IDLgrModel::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with this object.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

Version History

Introduced: 5.0

IDLgrModel::Init

The IDLgrModel::Init procedure method initializes the model object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrModel' [, CLIP_PLANES{Get, Set}=*array*] [, /HIDE{Get, Set}] [, LIGHTING{Get, Set}={0 | 1 | 2}] [, NAME{Get, Set}=*string*] [, /SELECT_TARGET{Get, Set}] [, TRANSFORM{Get, Set}=*4x4 transformation matrix*] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrModel::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrModel::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrModel::SetProperty are indicated by the word "Set" following the keyword.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0.

Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Note - Clipping planes are applied in the data space of the objects this model contains (prior to the application of this model's transform).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw model and children (the default)
- 1 = Do not draw model or children

Note

HIDE only controls the display attributes of IDLgrModel children since the IDLgrModel object itself lacks geometry.

LIGHTING *(Get, Set)*

Set this keyword to one of the following values to indicate whether lighting is to be enabled or disabled for all atomic graphic objects that have this model as a parent. IDLgrModel objects that have this model as a parent will not be effected, as they have their own value for this property. If this value is set to 0, any lights added as children of this model will be used to illuminate any other models in the view hierarchy that have lighting enabled.

- 0 = Disable lighting
- 1 = Enable single-sided lighting
- 2 = Enable double-sided lighting (the default)

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

SELECT_TARGET *(Get, Set)*

Set this keyword to tag the model object as the target object to be returned when any object contained by the model is selected via the IDLgrWindow::Select method. By default, an IDLgrModel object cannot be returned as the target of a SELECT operation since it contains no geometry.

TRANSFORM *(Get, Set)*

Set this keyword to a 4x4 transformation matrix to be applied to the object. This matrix will be multiplied by its parent's transformation matrix (if the parent has one). The default is the identity matrix. IDL converts, maintains, and returns this data as double-precision floating-point.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this "user value" to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrModel::Reset

The IDLgrModel::Reset procedure method sets the current transform matrix for the model object to the identity matrix.

Note

Using this method is functionally identical to the following statement:

```
Obj ->[IDLgrModel::]SetProperty, TRANSFORM=IDENTITY(4)
```

Syntax

Obj -> [IDLgrModel::]Reset

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrModel::Rotate

The IDLgrModel::Rotate procedure method rotates the model about the specified axis by the specified angle. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj -> [IDLgrModel::]Rotate, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

Angle

The angle (measured in degrees) by which the rotation is to occur.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Version History

Introduced: 5.0

IDLgrModel::Scale

The IDLgrModel::Scale procedure method scales the model by the specified scaling factors. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj -> [IDLgrModel::]Scale, *Sx*, *Sy*, *Sz* [, /PREMULTIPLY]

Arguments

Sx, Sy, Sz

The scaling factors in the *x*, *y*, and *z* dimensions by which the model is to be scaled.

Keywords

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx, Sy, Sz* to be pre-multiplied to the model's transformation matrix. By default, the scaling matrix is post-multiplied.

Version History

Introduced: 5.0

IDLgrModel::SetProperty

The IDLgrModel::SetProperty procedure method sets the value of a property or group of properties for the model.

Syntax

Obj -> [IDLgrModel::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrModel::Init followed by the word “Set” can be set using IDLgrModel::SetProperty.

Version History

Introduced: 5.0

IDLgrModel::Translate

The IDLgrModel::Translate procedure method translates the model about the specified axis by the specified translation offsets. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj -> [IDLgrModel::]Translate, *Tx, Ty, Tz* [, /PREMULTIPLY]

Arguments

Tx, Ty, Tz

The offsets in *X*, *Y*, and *Z*, respectively, by which the model is to be translated.

Keywords

PREMULTIPLY

Set this keyword to cause the translation matrix specified by *Tx, Ty, Tz* to be pre-multiplied to the model's transformation matrix. By default, the translation matrix is post-multiplied.

Version History

Introduced: 5.0

IDLgrMPEG

An IDLgrMPEG object creates an MPEG movie file from an array of image frames.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

Note

MPEG support in IDL requires a special license. For more information, contact your Research Systems sales representative or technical support.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrMPEG::Init" on page 2779.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrMPEG::Cleanup
- IDLgrMPEG::GetProperty
- IDLgrMPEG::Init
- IDLgrMPEG::Put
- IDLgrMPEG::Save
- IDLgrMPEG::SetProperty

Version History

Introduced: 5.1

IDLgrMPEG::Cleanup

The IDLgrMPEG::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrMPEG::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrMPEG::GetProperty

The IDLgrMPEG::GetProperty procedure method retrieves the value of a property or group of properties for the MPEG object.

Syntax

Obj -> [IDLgrMPEG::]GetProperty [, ALL=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrMPEG::Init followed by the word “Get” can be retrieved using IDLgrMPEG::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

Version History

Introduced: 5.1

IDLgrMPEG::Init

The IDLgrMPEG::Init function method initializes the MPEG object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Note

MPEG support in IDL requires a special license. For more information, contact your Research Systems sales representative or technical support.

Syntax

Obj = OBJ_NEW('IDLgrMPEG' [, BITRATE{Get, Set}=*value*] [, DIMENSIONS{Get, Set}=*2-element array*] [, FILENAME{Get, Set}=*string*] [, FORMAT{Get, Set}={0 | 1}] [, FRAME_RATE{Get, Set} ={1 | 2 | 3 | 4 | 5 | 6 | 7 | 8}] [, IFRAME_GAP{Get, Set}=*integer value*] [, /INTERLACED{Get, Set}] [, MOTION_VEC_LENGTH{Get, Set}={1 | 2 | 3}] [QUALITY{Get, Set}=*value*{0 to 100}] [, SCALE{Get, Set}=*[xscale, yscale]*] [, /STATISTICS{Get, Set}] [, TEMP_DIRECTORY=*string*])

or

Result = *Obj* -> [IDLgrMPEG::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrMPEG::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrMPEG::SetProperty are indicated by the word “Set” following the keyword.

BITRATE *(Get, Set)*

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table A-27: BITRATE Value Range

Set this keyword to 0.0 (the default setting) to indicate that IDL should compute the BITRATE value based upon the value you have specified for the QUALITY keyword. The value of BITRATE returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the BITRATE keyword if changing the QUALITY keyword value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

DIMENSIONS *(Get, Set)*

Set this keyword to a 2-element array specifying the dimensions (in pixels) of each of the images to be used as frames for the movie. If this property is not specified, the dimensions of the first image loaded will be used. Once IDLgrMPEG::Put has been called, this keyword can no longer be set.

Note

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer

size, and memory bandwidth. For example, the Windows Media Player supports a limited set of sampling and bitrate parameters. In this case, it is best to use 352 x 240 x 30 fps or 352 x 288 x 25 fps when determining the dimensions and frame rate for your MPEG file. When opening a file in Windows Media Player that does not use these dimensions, you will receive a “Bad Movie File” error message. The file is not “bad”, this decoder just doesn’t support the dimensions of the MPEG.

FILENAME *(Get, Set)*

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is `'idl.mpg'`.

FORMAT *(Get, Set)*

Set this keyword to one of the following values to specify the type of MPEG encoding to use:

- 0 = MPEG1 (the default)
- 1 = MPEG2

FRAME_RATE *(Get, Set)*

Set this keyword to one of the following integer values to specify the frame rate used in creating the MPEG file:

Value	Descriptions
1	23.976 frames/sec: NTSC encapsulated film rate
2	24 frames/sec: Standard international film rate
3	25 frames/sec: PAL video frame rate
4	29.97 frames/sec: NTSC video frame rate
5	30 frames/sec: NTSC drop frame video frame rate (the default)
6	50 frames/sec: Double frame rate/progressive PAL
7	59.94 frames/sec: Double frame rate NTSC
8	60 frames/sec: Double frame rate NTSC drop frame video

Table A-28: FRAME_RATE Values

IFRAME_GAP *(Get, Set)*

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

Set this keyword to 0 (the default setting) to indicate that IDL should compute the IFRAME_GAP value based upon the value you have specified for the QUALITY keyword. The value of IFRAME_GAP returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the IFRAME_GAP keyword if changing the QUALITY keyword value does not produce the desired results.

INTERLACED *(Get, Set)*

Set this keyword to indicate that frames in the encoded MPEG file should be interlaced. The default is non-interlaced.

MOTION_VEC_LENGTH *(Get, Set)*

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. The following table describes the valid values:

Value	Description
1	Small motion vectors.
2	Medium motion vectors.
3	Large motion vectors.

Table A-29: MOTION_VEC_LENGTH Values

Set this keyword to 0 (the default setting) to indicate that IDL should compute the MOTION_VEC_LENGTH value based upon the value you have specified for the QUALITY keyword. The value of MOTION_VEC_LENGTH returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero value stored in this property.

Note

Only use the MOTION_VEC_LENGTH keyword if changing the QUALITY value does not produce the desired results.

QUALITY *(Get, Set)*

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting QUALITY to its' highest setting.

SCALE *(Get, Set)*

Set this keyword to a two-element vector, [*xscale*, *yscale*], indicating the scale factors to be stored with the MPEG file as hints for playback. The default is [1.0, 1.0], indicating that the movie should be played back at the dimensions of the stored image frames.

STATISTICS *(Get, Set)*

Set this keyword to save statistical information about MPEG encoding for the supplied image frames in a file when the IDLgrMPEG::Save method is called. The information will be saved in a file with a name that matches that specified by the FILENAME keyword, with the extension "`.stat`". By default, statistics are not saved.

TEMP_DIRECTORY

Set the keyword to a string value which specifies a directory in which to place temporary files while creating the MPEG movie file. The default value is platform specific.

Version History

Introduced: 5.1

IDLgrMPEG::Put

The IDLgrMPEG::Put procedure method puts a given image into the MPEG sequence at the specified frame. Note that all images in a given MPEG movie must have matching dimensions. If no dimensions were explicitly specified when the MPEG object was initialized, the dimensions will be set according to the dimensions of the first image.

Syntax

Obj -> [IDLgrMPEG::]Put, *Image*[, *Frame*]

Arguments

Image

An instance of an IDLgrImage object or a *m* x *n* or 3 x *m* x *n* array representing the image to be loaded at the given frame.

Frame

An integer specifying the index of the frame at which the image is to be added. Frame indices start at zero. If *Frame* is not supplied, the frame number used will be one more than the last frame that was put. Frame number need not be consecutive; in case of a gap in frame numbers, the frame before the gap is repeated to fill the space.

Keywords

None.

Version History

Introduced: 5.1

IDLgrMPEG::Save

The IDLgrMPEG::Save procedure method encodes and saves the MPEG sequence to the specified filename.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

Syntax

Obj `->` [IDLgrMPEG::]Save [, FILENAME=*string*]

Arguments

None.

Keywords

FILENAME

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is `idl.mpg`.

Obsolete Keywords

The following keywords are obsolete:

- CREATOR_TYPE

For information on obsolete keywords, See Appendix O, “Obsolete Features”.

Version History

Introduced: 5.1

IDLgrMPEG::SetProperty

The IDLgrMPEG::SetProperty procedure method sets the value of a property or group of properties for the MPEG object.

Syntax

Obj -> [IDLgrMPEG::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrMPEG::Init followed by the word “Set” can be retrieved using IDLgrMPEG::SetProperty.

Version History

Introduced: 5.1

IDLgrPalette

A palette object represents a color lookup table that maps indices to red, green, and blue values.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See “IDLgrPalette::Init” on page 2791.

Methods

Intrinsic Methods

This class has this following methods:

- IDLgrPalette::Cleanup
- IDLgrPalette::GetRGB
- IDLgrPalette::GetProperty
- IDLgrPalette::Init
- IDLgrPalette::LoadCT
- IDLgrPalette::NearestColor
- IDLgrPalette::SetRGB
- IDLgrPalette::SetProperty

Version History

Introduced: 5.0

IDLgrPalette::Cleanup

The IDLgrPalette::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrPalette::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPalette::GetRGB

The IDLgrPalette::GetRGB function method returns the RGB values contained in the palette at the given index. The returned value is a three-element vector of the form [red, green, blue].

Syntax

Result = *Obj* -> [IDLgrPalette::]GetRGB(*Index*)

Arguments

Index

The index whose RGB values are desired. This value should be in the range of $0 \leq Index < N_COLORS$, where N_COLORS is the number of elements in the color palette, as returned by the N_COLORS keyword to the IDLgrPalette:GetProperty method.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPalette::GetProperty

The IDLgrPalette::GetProperty procedure method retrieves the value of a property or group of properties for the palette.

Syntax

Obj -> [IDLgrPalette::]GetProperty [, ALL=*variable*] [, N_COLORS=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrPalette::Init followed by the word “Get” can be retrieved using IDLgrPalette::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

N_COLORS

Set this keyword to a named variable that upon return will contain the number of elements in the color palette.

Version History

Introduced: 5.0

IDLgrPalette::Init

The IDLgrPalette::Init function method initializes a palette object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj=OBJ_NEW('IDLgrPalette', *aRed*, *aGreen*, *aBlue* [, BLUE_VALUES{Get, Set}=*vector*] [, BOTTOM_STRETCH{Get, Set}=*value*{0 to 100}] [, GAMMA{Get, Set}=*value*{0.1 to 10.0}] [, GREEN_VALUES{Get, Set}=*vector*] [, NAME{Get, Set}=*string*] [, RED_VALUES{Get, Set}=*vector*] [, TOP_STRETCH{Get, Set}=*value*{0 to 100}] [, UVALUE{Get, Set}=*value*])

or

Result=*Obj*->[IDLgrPalette::]Init([*aRed*, *aGreen*, *aBlue*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

aRed

A vector containing the red values for the color palette. These values should be within the range of 0 ≤ Value ≤ 255. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of 0 ≤ Value ≤ 255. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of 0 ≤ Value ≤ 255. The number of elements comprising the *aBlue* vector must not exceed 256.

Keywords

Properties retrievable via IDLgrPalette::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrPalette::SetProperty are indicated by the word “Set” following the keyword.

BLUE_VALUES *(Get, Set)*

A vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the IDLgrPalette::Init method.

BOTTOM_STRETCH *(Get, Set)*

Set this keyword equal to a value in the range of 0 ≤ *Value* ≤ 100 to indicate what percentage of the palette entries at the bottom of the palette should be filled with the value of the first palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at this entry and ending at the entry specified by the value of the TOP_STRETCH keyword. The default is 0 (zero).

GAMMA *(Get, Set)*

Set this keyword to the gamma value to be applied to the color palette. This value should be in the range of 0.1 ≤ *Gamma* ≤ 10.0. The default is 1.0.

GREEN_VALUES *(Get, Set)*

A vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrPalette::Init method.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ''.

RED_VALUES *(Get, Set)*

A vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrPalette::Init method.

TOP_STRETCH *(Get, Set)*

Set this keyword equal to a value in the range of $0 \leq Value \leq 100$ to indicate what percentage of the palette entries at the top of the palette should be filled with the value of the last palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at the entry specified by the value of the BOTTOM_STRETCH keyword and ending at this entry. The default is 0 (zero).

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object to which the user value applies.

Version History

Introduced: 5.0

IDLgrPalette::LoadCT

The IDLgrPalette::LoadCT procedure method loads one of the IDL predefined color tables into an IDLgrPalette object.

Syntax

Obj `->` [IDLgrPalette::]LoadCT, *TableNum* [, FILENAME=*colortable filename*]

Arguments

TableNum

The number of the pre-defined IDL color table to load, from 0 to 40.

Keywords

FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl` in the IDL distribution. The MODIFYCT procedure can be used to create and modify colortable files.

Version History

Introduced: 5.0

IDLgrPalette::NearestColor

The IDLgrPalette::NearestColor function method returns the index of the color in the palette that best matches the given RGB values.

Syntax

Result = *Obj*->[IDLgrPalette::]NearestColor(*Red*, *Green*, *Blue*)

Arguments

Red

The red value of the color that should be matched. This value should be within the range of 0 ≤ Value ≤ 255.

Green

The green value of the color that should be matched. This value should be within the range of 0 ≤ Value ≤ 255.

Blue

The blue value of the color that should be matched. This value should be within the range of 0 ≤ Value ≤ 255.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPalette::SetRGB

The IDLgrPalette::SetRGB procedure method sets the color values at a specified index in the palette to the specified Red, Green and Blue values.

Syntax

Obj -> [IDLgrPalette::]SetRGB, *Index*, *Red*, *Green*, *Blue*

Arguments

Index

The index within the Palette object to be set. This value should be in the range of $0 \leq Value < N_COLORS$.

Red

The red value to set in the color palette.

Green

The green value to set in the color palette.

Blue

The blue value to set in the color palette.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPalette::SetProperty

The IDLgrPalette::SetProperty procedure method sets the value of a property or group of properties for the palette.

Syntax

Obj -> [IDLgrPalette::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrPalette::Init followed by the word “Set” can be set using IDLgrPalette::SetProperty.

Version History

Introduced: 5.0

IDLgrPattern

A pattern object describes which pixels are filled and which are left blank when an area is filled. Pattern objects are used by setting the FILL_PATTERN property of a polygon object equal to the object reference of the pattern object.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See IDLgrPattern::Init.

Methods

Intrinsic Methods

This class has this following methods:

- IDLgrPattern::Cleanup
- IDLgrPattern::GetProperty
- IDLgrPattern::Init
- IDLgrPattern:SetProperty

Version History

Introduced: 5.0

IDLgrPattern::Cleanup

The IDLgrPattern::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrPattern::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPattern::GetProperty

The IDLgrPattern::GetProperty procedure method retrieves the value of a property or group of properties for the pattern.

Syntax

Obj -> [IDLgrPattern::]GetProperty [, ALL=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrPattern::Init followed by the word “Get” can be retrieved using IDLgrPattern::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Version History

Introduced: 5.0

IDLgrPattern::Init

The IDLgrPattern::Init function method initializes the pattern object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPattern' [, *Style*] [, ORIENTATION{Get, Set}=*ccw degrees from horiz*] [, NAME{Get, Set}=*string*] [, PATTERN{Get, Set}=*32 x 32 bit array*] [, SPACING{Get, Set}=*pixels*] [, STYLE*{Get, Set}*={0 | 1 | 2}] [, THICK=*pixels*{1.0 to 10.0}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrPattern::]Init([*Style*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Style

A integer value representing the type of pattern. Valid values are:

- 0 = Solid color (default)
- 1 = Line Fill
- 2 = Pattern

Keywords

Properties retrievable via IDLgrPattern::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrPattern:SetProperty are indicated by the word “Set” following the keyword.

ORIENTATION *(Get, Set)*

Set this keyword to a scalar representing the angle (measured in degrees counterclockwise from the horizontal) of the lines used in a Line Fill. This keyword is ignored unless the *Style* argument (or STYLE property) is set to one.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

PATTERN *(Get, Set)*

Set this keyword to a 32 x 32 bit array (bitmap) describing the pattern that will be tiled over a polygon when a pattern fill is used. The bitmap must be configured as a 4 x 32 “bitmap byte array” as created by the CVTTOBM function. Each bit that is a 1 is drawn, each bit that is 0 is not drawn. Each bit in this array represents a 1 point by 1 point square area of pixels on the destination device. This keyword is ignored unless the *Style* argument (or STYLE keyword) is set to 2.

SPACING *(Get, Set)*

Set this keyword equal to a floating-point value representing the distance (measured in points) between the lines used for a Line Fill. This keyword is ignored unless the *Style* argument (or STYLE property) is set to 1. The default is 2.0 points.

STYLE *(Get, Set)*

Set this keyword to one of the following values specifying the type of pattern:

- 0 = Solid (default)
- 1 = Line Fill
- 2 = Pattern

This keyword is the same as the *Style* argument described above.

THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the pattern lines for a Line Fill, in points. The default is 1.0 points. This keyword is ignored unless the *Style* argument or STYLE keyword is set to 1.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object to which the user value applies.

Version History

Introduced: 5.0

IDLgrPattern:SetProperty

The IDLgrPattern::SetProperty procedure method sets the value of a property or group of properties for the pattern.

Syntax

Obj -> [IDLgrPattern::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrPattern::Init followed by the word “Set” can be set using IDLgrPattern::SetProperty.

Version History

Introduced: 5.0

IDLgrPlot

A plot object creates a set of polylines connecting data points in two-dimensional space.

An IDLgrPlot object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrPlot::Init" on page 2811.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrPlot::Cleanup
- IDLgrPlot::GetCTM
- IDLgrPlot::GetProperty
- IDLgrPlot::Init
- IDLgrPlot::SetProperty

Version History

Introduced: 5.0

IDLgrPlot::Cleanup

The IDLgrPlot::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj* or *Obj* -> [IDLgrPlot::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPlot::GetCTM

The IDLgrPlot::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrPlot::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the plot object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPlot::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrPlot::GetProperty

The IDLgrPlot::GetProperty procedure method retrieves the value of the property or group of properties for the plot.

Syntax

Obj -> [IDLgrPlot::]GetProperty [, ALL=*variable*] [, DATA=*variable*] [, PARENT=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrPlot::Init followed by the word "Get" can be retrieved using IDLgrPlot::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

DATA

Set this keyword to a named variable that will contain the plot data in a 3 x *n* array, [*DataX*, *DataY*, *DataZ*].

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

ZRANGE

Set this keyword to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] specifying the range of *z* data values covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Note

The XRANGE and YRANGE properties can also be retrieved via the GetProperty method; ZRANGE, however, can only be retrieved, not initialized (Init method) or set (SetProperty method).

Version History

Introduced: 5.0

IDLgrPlot::Init

The IDLgrPlot::Init function method initializes the plot object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPlot' [, [*X*,] *Y*] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB vector* | , VERT_COLORS{Get, Set}=*vector*] [, DATAX {Set}=*vector*] [, DATAY{Set}=*vector*] [, /DOUBLE{Get, Set}] [, /HIDE{Get, Set}] [, /HISTOGRAM{Get, Set}] [, LINESTYLE{Get, Set}=*integer or two-element vector*] [, MAX_VALUE{Get, Set}=*value*] [, MIN_VALUE{Get, Set}=*value*] [, NAME{Get, Set}=*string*] [, NSUM{Get, Set}=*value*] [, PALETTE{Get, Set}=*objref*] [, /POLAR{Get, Set}] [, /RESET_DATA{Set}] [, SHARE_DATA{Set}=*objref*] [, SYMBOL{Get, Set}=*objref(s)*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, /USE_ZVALUE] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, XRANGE{Get, Set}=*[xmin, xmax]*] [, YCOORD_CONV{Get, Set}=*vector*] [, YRANGE{Get, Set}=*[ymin, ymax]*] [, ZCOORD_CONV{Get, Set}=*vector*] [, ZVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrPlot::]Init([[*X*,] *Y*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector representing the abscissa values to be plotted. If *X* is provided, *Y* is plotted as a function of *X*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Y

Either a vector of two-element arrays [*x, y*] representing the points to be plotted, or a vector representing the ordinate values to be plotted. If *Y* is a vector of ordinate values and *X* is not specified, *Y* is plotted as a function of the vector index of *Y*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Keywords

Properties retrievable via IDLgrPlot::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrPlot::SetProperty are indicated by the word “Set” following the keyword.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to the color to be used as the foreground color for this plot. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

DATAX *(Set)*

Set this keyword to a vector specifying the X values to be plotted. This keyword is the same as the X argument.

DATAY *(Set)*

Set this keyword to a vector specifying the Y values to be plotted. This keyword is the same as the Y argument.

DOUBLE *(Get, Set)*

Set this keyword to indicate that data provided by any of the X or Y arguments or DATAX or DATAY keywords will be stored in this object as double-precision floating-point. If you set this keyword equal to 0, the data provided will be stored in this object as single-precision floating-point. If you do not specify this keyword, the data is stored as double-precision floating-point if the original data was of type DOUBLE or as single-precision floating-point if the original data was not of type DOUBLE.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

HISTOGRAM *(Get, Set)*

Set this keyword to force only horizontal and vertical lines to be used to connect the plotted points. By default, the points are connected using a single straight line.

LINESTYLE *(Get, Set)*

Set this keyword to indicate the line style that should be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

MAX_VALUE *(Get, Set)*

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

MIN_VALUE *(Get, Set)*

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

NSUM *(Get, Set)*

Set this keyword to the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

PALETTE *(Get, Set)*

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

POLAR *(Get, Set)*

Set this keyword to create a polar plot. The *X* and *Y* arguments must both be present. The *X* argument represents the radius, and the *Y* argument represents the angle expressed in radians.

RESET_DATA *(Set)*

Set this keyword to treat the data provided via one of the DATA[XY] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this keyword if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This keyword has no effect if no new data is provided via a DATA property.

SHARE_DATA *(Set)*

Set this keyword to an object with which data is to be shared by this plot. A plot may only share data with another plot. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

SYMBOL *(Get, Set)*

Set this keyword to a vector containing instances of the IDLgrSymbol object class. Each symbol in the vector will be drawn at the corresponding plotted point. If there are more points than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a plot, set the SYMBOL property equal to a null object reference.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. The default is 1.0 points.

USE_ZVALUE

Set this keyword to use the current ZVALUE. The plot is considered three-dimensional if this keyword is set.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

VERT_COLORS *(Get, Set)*

Set this keyword to a vector of colors to be used to draw at each vertex. Color is interpolated between vertices. If there are more plot points than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the plot is all drawn in the single color provided by the COLOR keyword. If the VERT_COLORS is provided, the COLOR keyword is ignored.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

XRANGE *(Get, Set)*

Set this keyword equal to a two-element vector of the form [*xmin*, *xmax*] specifying the range of *x* data coordinates covered by the graphic object. If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YRANGE *(Get, Set)*

Set this keyword equal to a two-element vector of the form [*ymin*, *ymax*] specifying the range of *y* data values covered by the graphic object. If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZVALUE *(Get, Set)*

Set this keyword to a scalar value to be used as the Z coordinate for the entire plot. By default, 0.0 is used as the Z coordinate.

Note

The USE_ZVALUE keyword needs to be set in order for ZVALUE to take effect.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrPlot::SetProperty

The IDLgrPlot::SetProperty procedure method sets the value of the property or group of properties for the plot.

Syntax

Obj -> [IDLgrPlot::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrPlot::Init followed by the word “Set” can be set using IDLgrPlot::SetProperty.

Version History

Introduced: 5.0

IDLgrPolygon

A polygon object represents one or more polygons that share a given set of vertices and rendering attributes. All polygons must be convex—that is, a line connecting any pair of vertices on the polygon cannot fall outside the polygon. Concave polygons can be converted to a set of convex polygons using the IDLgrTessellator object.

An IDLgrPolygon object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See “IDLgrPolygon::Init” on page 2826.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrPolygon::Cleanup
- IDLgrPolygon::GetCTM
- IDLgrPolygon::GetProperty
- IDLgrPolygon::Init
- IDLgrPolygon::SetProperty

Version History

Introduced: 5.0

IDLgrPolygon::Cleanup

The IDLgrPolygon::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrPolygon::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPolygon::GetCTM

The IDLgrPolygon::GetCTM The IDLgrPolygon::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrPolygon::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polygon object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolygonl::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrPolygon::GetProperty

The IDLgrPolygon::GetProperty procedure method retrieves the value of the property or group of properties for the polygons.

Syntax

Obj -> [IDLgrPolygon::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

There are no arguments for this methods.

Keywords

Any keyword to IDLgrPolygon::Init followed by the word “Get” can be retrieved using IDLgrPolygon::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

YRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Version History

Introduced: 5.0

IDLgrPolygon::Init

The IDLgrPolygon::Init function method initializes the polygons object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPolygon' [, *X* [, *Y*[, *Z*]]] [, BOTTOM{Get, Set}=*index or RGB vector*] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB vector* | , VERT_COLORS{Get, Set}=*vector*] [, DATA{Get, Set}=*array*] [, DEPTH_OFFSET{Get, Set}=*value*] [, /DOUBLE{Get, Set}] [, FILL_PATTERN{Get, Set}=*objref to IDLgrPattern object*] [, /HIDDEN_LINES] [, /HIDE{Get, Set}] [, LINESTYLE{Get, Set}=*value*] [, NAME{Get, Set}=*string*] [, NORMALS{Get, Set}=*array*] [, PALETTE=*objref*] [, POLYGONS{Get, Set}=*array of polygon descriptions*] [, REJECT{Get, Set}={0 | 1 | 2}] [, /RESET_DATA{Set}] [, SHADE_RANGE{Get, Set}=*array*] [, SHADING{Get, Set}={0 | 1}] [, SHARE_DATA{Set}=*objref*] [, STYLE{Get, Set}={0 | 1 | 2}] [, TEXTURE_COORD{Get, Set}=*array*] [, /TEXTURE_INTERP{Get, Set}] [, TEXTURE_MAP*{Get, Set}=objref to IDLgrImage object*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*] [, ZERO_OPACITY_SKIP{Get, Set}={0 | 1}])

or

Result = *Obj* -> [IDLgrPolygon::]Init([*X*, [*Y*, [*Z*]]]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector argument providing the X coordinates of the vertices. The vector must contain at least three elements. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values.

This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Y

A vector argument providing the Y coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Z

A vector argument providing the Z coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Keywords

Properties retrievable via IDLgrPolygon::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrPolygon::SetProperty are indicated by the word “Set” following the keyword.

BOTTOM *(Get, Set)*

Set this keyword to an RGB or Indexed color for drawing the backs of the polygons. (The *back* of a polygon is the side opposite the normal direction). Setting a bottom color is only supported when the destination device uses RGB color mode.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to an RGB or Indexed color for drawing polygons. The default color is [0, 0, 0] (black). If the TEXTURE_MAP property is used, the final color is modulated by the texture map pixel values. This keyword is ignored if the VERT_COLORS keyword is provided.

DATA *(Get, Set)*

Set this keyword to a *2* x *n* or a *3* x *n* array which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the property variable is of type DOUBLE or if the DOUBLE keyword parameter is also specified, otherwise it is converted to single precision floating point.

DEPTH_OFFSET *(Get, Set)*

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFEST has no effect unless the value of the STYLE keyword is 2 (Filled).

DOUBLE *(Get, Set)*

Set this keyword to a non-zero value to indicate that data provided by any of the X, Y, or Z arguments or DATA keyword should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point. IDL converts any value data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

FILL_PATTERN *(Get, Set)*

Set this keyword equal to an object reference to an IDLgrPattern object (or an array of IDLgrPattern objects) to specify the fill pattern to use for filling the polygons. By default, FILL_PATTERN is set to a null object reference, specifying a solid fill.

HIDDEN_LINES

Set this keyword to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

LINESTYLE *(Get, Set)*

Set this keyword to indicate the line style that should be used to draw the polygon. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

NORMALS *(Get, Set)*

Set this keyword to a *3* x *n* array of unit polygon normals at each vertex. If this keyword is not set, vertex normals are computed by averaging shared polygon normals at each vertex. Normals are computed using the Right Hand Rule; that is, if the polygon is facing the viewer, vertices are taken in counterclockwise order. To remove previously specified normals, set NORMALS to a scalar.

Note

Computing normals is a computationally expensive operation. Rendering speed increases significantly if you supply the surface normals explicitly. You can compute the array of polygon normals used by this keyword automatically. See "COMPUTE_MESH_NORMALS" on page 262 for details.

Once you use the NORMALS keyword in a call to IDLgrPolygon::Init or IDLgrPolygon::SetProperty, you are responsible for that IDLgrPolygon's normals from then on. IDL will not calculate that IDLgrPolygon's normals for you automatically, even if you draw the IDLgrPolygon after vertices or connectivity have been changed.

If you do not use the NORMALS keyword, IDL calculates normals the first time it draws the IDLgrPolygon. IDL reuses those normals for subsequent draws unless it determines that a fresh recalculation of normals is required, such as if the vertices of the IDLgrPolygon are changed, or you supply new normals via the NORMALS keyword.

PALETTE

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

POLYGONS *(Get, Set)*

Set this keyword to an array of polygon descriptions. A polygon description is an integer or longword array of the form: [*n*, i_0, i_1, ..., i_{n-1}], where *n* is the number of vertices that define the polygon, and i_0..i_{n-1} are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

REJECT *(Get, Set)*

Set this keyword to an integer value to reject polygons as being hidden depending on the orientation of their normals. Select from one of the following values:

- 0 = No polygons are hidden
- 1 = Polygons whose normals point away from the viewer are hidden
- 2 = Polygons whose normals point toward the viewer are hidden

Set this keyword to zero to draw all polygons regardless of the direction of their normals.

RESET_DATA *(Set)*

Set this keyword to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this keyword if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This keyword has no effect if no new data is provided via the DATA property.

SHADE_RANGE *(Get, Set)*

Set this keyword to a two-element array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. The default is [0, 255].

This keyword is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

SHADING *(Get, Set)*

Set this keyword to an integer representing the type of shading to use:

- 0 = Flat (default): The color of the first vertex in each polygon is used to define the color for the entire polygon. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

SHARE_DATA *(Set)*

Set this keyword to an object with which data is to be shared by this polygon(s). Polygons may only share data with another polygons object or a polyline. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

STYLE *(Get, Set)*

Set this keyword to specify how the polygon should be drawn:

- 0 = Points: Only vertices are drawn, using either COLOR or VERT_COLORS.
- 1 = Lines: Each polygon is outlined by connecting vertices.
- 2 = Filled (default): The polygon faces are shaded.

TEXTURE_COORD *(Get, Set)*

A 2 x *n* array containing the texture map coordinates for each of the *n* polygon vertices. Use this keyword in conjunction with the TEXTURE_MAP keyword to wrap images over 2-D and 3-D polygons. Default coordinates are not provided.

Texture coordinates are normalized. This means that the *m* x *n* image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

TEXTURE_INTERP *(Get, Set)*

Set this keyword to indicate that bilinear sampling is to be used for texture mapping an image onto the polygon(s). The default is nearest neighbor sampling.

TEXTURE_MAP *(Get, Set)*

Set this keyword to the object reference of an IDLgrImage object to be texture mapped onto the polygons. The tiling or mapping of the texture is defined expressly by TEXTURE_COORD. If this keyword is omitted, polygons are filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) To remove a texture map, set TEXTURE_MAP equal to a null object reference.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrPolygon object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function src=alpha and dst=1 – alpha, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If the width and/or height of the provided image is not an exact power of two, then the texture map will consist of the given image pixel values resampled to the nearest larger dimensions that are exact powers of two.

Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note

Texture mapping is applied to all styles that are set by the STYLE property.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the size of the points or the thickness of the lines to be drawn when STYLE is set to either 0 (Points) or 1 (Lines), in points. The default is 1.0 points.

Note

The value of this keyword is ignored if STYLE is set to 2 (Filled).

VERT_COLORS *(Get, Set)*

Set this keyword to a vector of colors to be used to draw at each vertex. Color is interpolated between vertices if SHADING is set to 1 (Gouraud). If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the polygons are all drawn in the single color provided by the COLOR keyword. To remove vertex colors, set VERT_COLORS to a scalar.

Note

If the polygon object is being rendered on a destination device that uses the Indexed color model, and the view that contains the polygon also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZERO_OPACITY_SKIP *(Get, Set)*

Set this keyword to gain finer control over the rendering of textured polygon pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this keyword is set to 1, any texels are “skipped” and not rendered at all. If this keyword is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the polygon can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this keyword is 1.

Note

This keyword has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrPolygon::SetProperty

The IDLgrPolygon::SetProperty procedure method sets the value of the property or group of properties for the polygons.

Syntax

Obj -> [IDLgrPolygon::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrPolygon::Init followed by the word “Set” can be set using IDLgrPolygon::SetProperty.

Version History

Introduced: 5.0

IDLgrPolyline

A polyline object represents one or more polylines that share a set of vertices and rendering attributes.

An IDLgrPolyline object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrPolyline::Init" on page 2844.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrPolyline::Cleanup
- IDLgrPolyline::GetCTM
- IDLgrPolyline::GetProperty
- IDLgrPolyline::Init
- IDLgrPolyline::SetProperty

Version History

Introduced: 5.0

IDLgrPolyline::Cleanup

The IDLgrPolyline::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrPolyline::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPolyline::GetCTM

The IDLgrPolyline::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrPolyline::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polyline object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolyline::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrPolyline::GetProperty

The IDLgrPolyline::GetProperty procedure method retrieves the value of a property or group of properties for the polylines.

Syntax

Obj -> [IDLgrPolyline::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrPolyline::Init followed by the word “Get” can be retrieved using IDLgrPolyline::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

YRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Version History

Introduced: 5.0

IDLgrPolyline::Init

The IDLgrPolyline::Init function method initializes the polylines object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPolyline' [, *X* [, *Y*[, *Z*]]] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB vector* | , VERT_COLORS{Get, Set}=*vector*] [, DATA{Get, Set}=*array*] [, /DOUBLE{Get, Set}] [, /HIDE{Get, Set}] [, LABEL_NOGAPS{Get, Set}=*vector*] [, LABEL_OBJECTS{Get, Set}=*objref*] [, LABEL_OFFSETS{Get, Set}=*scalar or vector of offsets*}] [, LABEL_POLYLINES{Get, Set}=*scalar or vector of polyline indices*] [, LABEL_USE_VERTEX_COLOR{Get, Set}=*value*] [, LINESTYLE{Get, Set}=*value*] [, NAME{Get, Set}=*string*] [, PALETTE{Get, Set}=*objref*] [, POLYLINES{Get, Set}=*array of polyline descriptions*] [, /RESET_DATA{Set}] [, SHADING{Get, Set}={0 | 1}] [, SHARE_DATA{Set}=*objref*] [, SYMBOL{Get, Set}=*objref(s)*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, USE_LABEL_COLOR{Get, Set}=*vector*] [, USE_LABEL_ORIENTATION{Get, Set}=*vector*] [, /USE_TEXT_ALIGNMENTS{Get, Set}] [, UVALUE{Get, Set}=*value*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = *Obj* -> [IDLgrPolyline::]Init([*X*, [*Y*, [*Z*]]]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector providing the X components of the points to be connected. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Y

A vector providing the Y coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Z

A vector providing the Z coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Keywords

Properties retrievable via IDLgrPolyline::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrPolyline::SetProperty are indicated by the word “Set” following the keyword.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to an RGB or Indexed color for drawing polylines. The default color is [0, 0, 0] (black). This keyword is ignored if the VERT_COLORS keyword is provided.

DATA *(Get, Set)*

Set this keyword to a 2 x *n* or a 3 x *n* array which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, *X*, *Y*, and *Z*. This property is converted to double-precision floating-point values if the DOUBLE keyword is set. Otherwise, it is converted to single-precision floating-point.

DOUBLE *(Get, Set)*

Set this keyword to indicate that data provided by any of the *X*, *Y*, or *Z* arguments or the DATA keyword will be stored in this object as double-precision floating-point. If you set this keyword equal to 0, the data provided will be stored in this object as single-precision floating-point. If you do not specify this keyword, the data is stored as double-precision floating-point if the original data was of type DOUBLE or as single-precision floating-point if the original data was not of type DOUBLE.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

LABEL_NOGAPS *(Get, Set)*

Set this keyword to a vector of values indicating whether gaps should be computed for the corresponding label. A zero value indicates that a gap will be computed for the labels; a non-zero value indicates that no gap will be computed for the label. If the

number of labels exceeds the number of elements in this vector, the LABEL_NOGAPS values will be repeated cyclically. By default, gaps are computed for all labels (so that the polyline does not pass through the label).

LABEL_POLYLINES *(Get, Set)*

Set this keyword to a scalar or a vector of polyline indices, [P0, P1, …], that indicate which polylines are to be labeled. Pi corresponds to the ith polyline specified via the POLYLINES keyword. This keyword is intended to be used in conjunction with the LABEL_OBJECTS keyword. If a scalar is provided, all labels will be drawn along the single indicated polyline. If a vector is provided, the number of polyline indices must match the number of labels provided via LABEL_OBJECTS.

By default, this keyword is set to the scalar, 0, indicating that only the first polyline will be labeled.

Note

If a given polyline has more than one label, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

LABEL_OFFSETS *(Get, Set)*

Set this keyword to a scalar or vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each polyline (specified via the LABEL_POLYLINES keyword) at which each label (as specified via the LABEL_OBJECTS keyword) would be positioned. If LABEL_OFFSETS is set to a scalar less than zero, then the offsets will be automatically computed to be evenly distributed along the length of the polyline. If a scalar value greater than or equal to zero is provided, it is used for all labels. If a vector is provided, the number of offsets must match the number of labels provided via LABEL_OBJECTS. By default, this keyword is set to the scalar, -1, indicating that the label offsets will be automatically computed.

LABEL_OBJECTS *(Get, Set)*

Set this keyword to an object reference (or vector of object references) to specify the labels to be drawn along the polyline path(s). The objects specified via this keyword must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a label. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a label.

If one or more IDLgrText objects are provided, the LOCATION property of the provided text object(s) may be overwritten; position is determined according to the values provided via the LABEL_OFFSETS keyword. The labels will have the same color as the corresponding polyline (see the COLOR keyword) unless the USE_LABEL_COLOR keyword is specified. The orientation of the label objects USE_LABEL_ORIENTATION keyword is specified. The horizontal and vertical alignment for any text labels will each default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS keyword is specified.

Note

The objects provided via this keyword will not be destroyed automatically when this IDLgrPolyline is destroyed.

LABEL_USE_VERTEX_COLOR *(Get, Set)*

Set this keyword to a non-zero value to indicate that labels should be colored according to the vertex coloring (if the VERT_COLORS keyword is set). By default, this value is zero, indicating that the label will be drawn using the color specified via the COLOR property of the polyline object (unless the USE_LABEL_COLOR keyword is set).

LINESTYLE *(Get, Set)*

Set this keyword to indicate the line style that should be used to draw the polyline. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ''.

PALETTE *(Get, Set)*

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

POLYLINES *(Get, Set)*

Set this keyword to an array of polyline descriptions. A polyline description is an integer or longword array of the form: [*n*, i_0, i_1, ..., i_{n-1}], where *n* is the number of vertices that define the polyline, and $i_0..i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the vertices of the polyline(s). To ignore an entry in the POLYLINES array, set the vertex count, *n*, and all associated indices to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single connected polyline will be generated from the *X*, *Y*, and *Z* arguments.

Note

The connectivity array described by POLYLINES allows an individual object to contain more than one polyline. Vertex, normal and color information can be shared by the multiple polylines. Consequently, the polyline object can represent an entire mesh and compute reasonable normal estimates in most cases.

RESET_DATA *(Set)*

Set this keyword to treat the data provided via one of the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this keyword if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This keyword has no effect if no new data is provided via the DATA property.

SHADING *(Get, Set)*

Set this keyword to an integer representing the type of shading to use:

- 0 = Flat (default): The color of the second vertex in a line segment is used to define the color for the entire line segment. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

SHARE_DATA *(Set)*

Set this keyword to an object whose data is to be shared by this polyline. A polyline may only share data with a polygon object or another polyline. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

SYMBOL *(Get, Set)*

Set this keyword to a vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

USE_LABEL_COLOR *(Get, Set)*

Set this keyword to a vector of values to indicate whether the COLOR property value for the corresponding label object is to be used to draw that label. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR property of each label object will be ignored, and the COLOR property for the polyline object will be used instead.

USE_LABEL_ORIENTATION *(Get, Set)*

Set this keyword to a vector of values to indicate whether the orientation of the corresponding label object is to be used to draw that label. For IDLgrText objects, this refers to the BASELINE and UPDIR property values. For IDLgrSymbol objects, this refers to the default (un-rotated) orientation of the symbol. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_ORIENTATION values will be repeated cyclically. By default, USE_LABEL_ORIENTATION is zero, indicating that the orientation will be automatically computed so that the baseline is parallel to the polyline, and the updir is perpendicular to the polyline.

USE_TEXT_ALIGNMENTS *(Get, Set)*

Set this keyword to indicate that, for any IDLgrText labels (as specified via the LABEL_OBJECTS keyword), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw those labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the IDLgrText object(s) will be overwritten with default values (0.5 for each, indicating centered labels).

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

VERT_COLORS *(Get, Set)*

Set this keyword to a vector of colors to be used to draw at each vertex. Color is interpolated between vertices if SHADING is set to 1 (Gouraud). If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the polyline is drawn in the single color provided by the COLOR keyword. To remove vertex colors, set VERT_COLORS to a scalar.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.0

CLIP_PLANES, LABEL_NOGAPS, LABEL_POLYLINES, LABEL_OFFSETS, LABEL_OBJECTS, LABEL_USE_VERTEX_COLOR, USE_LABEL_COLOR, USE_LABEL_ORIENTATION, USE_TEXT_ALIGNMENTS keywords: 5.6

IDLgrPolyline::SetProperty

The IDLgrPolylines::SetProperty procedure method sets the value of a property or group of properties for the polylines.

Syntax

Obj -> [IDLgrPolyline::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrPolyline::Init followed by the word “Set” can be set using IDLgrPolyline::SetProperty.

Version History

Introduced: 5.0

IDLgrPrinter

A printer object represents a hardcopy graphics destination. When a printer object is created, the printer device to which it refers is the default system printer. To change the printer, utilize the printer dialogs (see "DIALOG_PRINTJOB" on page 491 and "DIALOG_PRINTERSETUP" on page 489.)

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See "IDLgrPrinter::Init" on page 2867.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrPrinter::Cleanup
- IDLgrPrinter::Draw
- IDLgrPrinter::GetContiguousPixels
- IDLgrPrinter::GetFontnames
- IDLgrPrinter::GetProperty
- IDLgrPrinter::GetTextDimensions
- IDLgrPrinter::Init
- IDLgrPrinter::NewDocument
- IDLgrPrinter::NewPage

- IDLgrPrinter::SetProperty

Version History

Introduced: 5.0

IDLgrPrinter::Cleanup

The IDLgrPrinter::Cleanup procedure method performs all cleanup on the object. If a document is open (that is, if graphics have been draw to the printer), the document is closed and the pending graphics are sent to the current printer.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrPrinter::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPrinter::Draw

The IDLgrPrinter::Draw procedure method draws the given picture to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj -> [IDLgrPrinter::]Draw [, *Picture*] [, VECTOR={ 0 | 1 }]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values include:

- 0 = Bitmap (default)
- 1 = Vector

If VECTOR = 0 (Bitmap), the Draw method renders the scene to a buffer and then copies the buffer to the printer in bitmap format. The bitmap retains the quality of the original image.

If VECTOR = 1 (Vector), the Draw method renders the scene using simple vector operations that result in a representation of the Scene that is scalable to the printer. The vector representation does not retain all the attributes of the original image. The vector representation is sent to the printer.

Examples

This example demonstrates the process of printing the contents of an IDL graphics display object (a buffer or a window) to an IDLgrPrinter object. The resolution of the printed page is based on the resolution of the screen. The model object in the printer object must be scaled to maintain the same size as displayed on the screen. The location of the view must also be changed to center the display on the page.

```
PRO PrintingAnImage

; Determine the path to the "convec.dat" file.
convecFile = FILEPATH('convec.dat', $
   SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the image with the file.
convecSize = [248, 248]
convecImage = BYTARR(convecSize[0], convecSize[1])

; Open the file, read in the image, and then close the
; file.
OPENR, unit, convecFile, /GET_LUN
READU, unit, convecImage
FREE_LUN, unit

; Initialize the display objects.
windowSize = convecSize
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
   DIMENSIONS = windowSize, $
   TITLE = 'Earth Mantle Convection')
oView = OBJ_NEW('IDLgrView', $
   VIEWPLANE_RECT = [0., 0., windowSize])
oModel = OBJ_NEW('IDLgrModel')

; Initialize the image object with its palette.
oPalette = OBJ_NEW('IDLgrPalette')
oPalette -> LOADCT, 27
oImage = OBJ_NEW('IDLgrImage', convecImage, $
   PALETTE = oPalette)

; Add image to model, which is added to the view, and
; then the view is displayed in the window.
oModel -> Add, oImage
oView -> Add, oModel
oWindow -> Draw, oView

; Determine the centimeter measurements of the image
; on the screen.
oWindow -> GetProperty, RESOLUTION = screenResolution
```

```
windowSizeCM = windowSize*screenResolution

; Initialize printer destination object.
oPrinter = OBJ_NEW('IDLgrPrinter', PRINT_QUALITY = 2, $
   QUALITY = 2)

; Obtain page parameters to determine the page
; size in centimeters.
oPrinter -> GetProperty, DIMENSIONS = pageSize, $
   RESOLUTION = pageResolution
pageSizeCM = pageSize*pageResolution

; Calculate a ratio between screen size and page size.
pageScale = windowSizeCM/pageSizeCM

; Use ratio to scale the model within the printer to the
; same size as the model on the screen.
oModel -> Scale, pageScale[0], pageScale[1], 1.

; Determine the center of the page and the image in
; pixels.
centering = ((pageSizeCM - windowSizeCM)/2.) $
   /pageResolution

; Move the view to center the image.
oView -> SetProperty, LOCATION = centering

; Display the view within the printer destination.
oPrinter -> Draw, oView
oPrinter -> NewDocument

; Cleanup object references.
OBJ_DESTROY, [oPrinter, oView, oPalette]

END
```

Version History

Introduced: 5.0

IDLgrPrinter::GetContiguousPixels

The IDLgrPrinter::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Return = *Obj* `->` [IDLgrPrinter::]GetContiguousPixels()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPrinter::GetFontnames

The IDLgrPrinter::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix N, "Fonts" for more information.

Syntax

Return = *Obj* -> [IDLgrPrinter::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.0

IDLgrPrinter::GetProperty

The IDLgrPrinter::GetProperty procedure method retrieves the value of a property or group of properties for the printer.

Syntax

Obj -> [IDLgrPrinter::]GetProperty [, ALL=*variable*] [, DIMENSIONS=*variable*] [, NAME=*string*] [, RESOLUTION=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrPrinter::Init followed by the word “Get” can be retrieved using IDLgrPrinter::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector of the form [*width*, *height*] specifying the overall ‘drawable’ area that may be printed on a page. By default, the dimensions are measured in device units (refer to the UNITS (Get, Set) keyword).

NAME

A string containing the operating system-specific name of the print stream. e.g. '\\BORG\HpJet'.

RESOLUTION

Set this keyword to a named variable that will contain a vector of the form [*xres*, *yres*] defining the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Version History

Introduced: 5.0

IDLgrPrinter::GetTextDimensions

The IDLgrPrinter::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

Result = *Obj* ->[IDLgrPrinter::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPrinter::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.0

IDLgrPrinter::Init

The IDLgrPrinter::Init function method initializes the printer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPrinter' [, COLOR_MODEL{Get}={0 | 1}] [, GRAPHICS_TREE{Get, Set}=*objref of type IDLgrScene, IDLgrViewgroup, or IDLgrView*] [, /LANDSCAPE{Get, Set}] [, N_COLORS{Get}=*integer*{2 to 256}] [, N_COPIES{Get, Set}=*integer*] [, PALETTE{Get, Set}=*objref*] [, PRINT_QUALITY{Get, Set}={0 | 1 | 2}] [, QUALITY{Get, Set}={0 | 1 | 2}] [, UNITS{Get, Set}={0 | 1 | 2 | 3}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrPrinter::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrPrinter::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrPrinter::SetProperty are indicated by the word "Set" following the keyword.

COLOR_MODEL *(Get)*

Set this keyword to the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

GRAPHICS_TREE *(Get, Set)*

Set this keyword to an object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

LANDSCAPE *(Get, Set)*

Set this keyword to produce hardcopy output in landscape mode. The default value of zero indicates Portrait mode.

Note

The printer driver may not support the LANDSCAPE option; in general, it is best to use the printer dialogs to set orientation.

N_COLORS *(Get)*

Set this keyword to the number of colors (between 2 and 256) to be used if the COLOR_MODEL is set to Indexed (1). This keyword is ignored if the COLOR_MODEL is set to RGB (0).

N_COPIES *(Get, Set)*

Set this keyword equal to an integer that determines the number of copies of print data to be generated. The default is 1 copy.

Note

Your specific printer driver may not support the N_COPIES option. You can also use the printer dialogs to set the number of copies.

PALETTE *(Get, Set)*

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table if the Indexed color model is used.

PRINT_QUALITY *(Get, Set)*

Set this keyword to an integer value indicating the print quality at which graphics are to be drawn to the printer. Note that the print quality is independent of the rendering quality (as set by the QUALITY keyword). Valid values are:

- 0 = Low
- 1 = Normal (this is the default)
- 2 = High

Generally, setting the print quality to a lower value will increase the speed of the printing job, but decrease the resolution; setting it to a higher value will cause the printing job to take more time, but will increase the resolution.

Note

Some printer drivers may not be able to support different printing qualities. In these cases, the setting of the PRINT_QUALITY property will be quietly ignored.

QUALITY *(Get, Set)*

Set this keyword to an integer value indicating the rendering quality at which graphics are to be drawn to this destination. Note that the rendering quality is independent of the print quality (as set by the PRINT_QUALITY keyword). Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

UNITS *(Get, Set)*

Set this keyword to indicate the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the drawable area on a page.

Note

If you change the value of the UNITS property (using the SetProperty method), IDL will convert the current value of the DIMENSIONS property to the new units.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

IDLgrPrinter::NewDocument

The IDLgrPrinter::NewDocument procedure method closes the current document (a page or group of pages), which causes any pending output to be sent to the printer, finishing the printer job.

Syntax

Obj -> [IDLgrPrinter::]NewDocument

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPrinter::NewPage

The IDLgrPrinter::NewPage procedure method issues a new page command to the printer.

Syntax

Obj -> [IDLgrPrinter::]NewPage

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrPrinter::SetProperty

The IDLgrPrinter::SetProperty procedure method sets the value of a property or group of properties for the printer.

Syntax

Obj -> [IDLgrPrinter::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrPrinter::Init followed by the word “Set” can be set using IDLgrPrinter::SetProperty.

Version History

Introduced: 5.0

IDLgrROI

The IDLgrROI object class is an object graphics representation of a region of interest.

Superclasses

This class is a subclass of IDLanROI.

Subclasses

None.

Creation

See IDLgrROI::Init.

Methods

Intrinsic Methods

The IDLgrROI object class has the following methods:

- IDLgrROI::Cleanup
- IDLgrROI::GetProperty
- IDLgrROI::Init
- IDLgrROI::PickVertex
- IDLgrROI::SetProperty

Inherited Methods

This class inherits the following methods:

- IDLanROI::AppendData
- IDLanROI::ComputeGeometry
- IDLanROI::ComputeMask
- IDLanROI::ContainsPoints
- IDLanROI::RemoveData
- IDLanROI::ReplaceData

- IDLanROI::Rotate
- IDLanROI::Scale
- IDLanROI::Translate

Version History

Introduced: 5.3

IDLgrROI::Cleanup

The IDLgrROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrROI::]Cleanup (In a subclass' Cleanup method only.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLgrROI::GetProperty

The IDLgrROI::GetProperty procedure method retrieves the value of a property or group of properties for the Object Graphics region.

Syntax

Obj -> [IDLgrROI::]GetProperty [, ALL=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

All keywords accepted by IDLanROI::GetProperty are also accepted by this method. Furthermore, any keyword to IDLgrROI::Init followed by the word (*Get*) can be retrieved using IDLgrROI::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable to contain an anonymous structure with the values of all of the properties associated with the state of this object. State information about the object may include things like color, line style, etc., but not vertex data or user values.

Note

The fields in this structure may change in subsequent releases of IDL.

XRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

YRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Version History

Introduced: 5.3

IDLgrROI::Init

The IDLgrROI::Init function method initializes an Object Graphics region of interest.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrROI' [, *X*[, *Y*[, *Z*]]] [, CLIP_PLANES{Get, Set}=*array*]
[, COLOR{Get, Set}=*vector*] [, /DOUBLE{Get, Set}] [, /HIDE{Get, Set}]
[, LINESTYLE{Get, Set}=*value*] [, NAME{Get, Set}=*string*]
[, PALETTE{Get, Set}=*objref*] [, STYLE{Get, Set}={ 0 | 1 | 2 }]
[, SYMBOL{Get, Set}=*objref*] [, THICK{Get, Set}=*points*{1.0 to 10.0}]
[, UVALUE{Get, Set}=*uvalue*] [, XCOORD_CONV{Get, Set}=*[s_0, s_1]*]
[, YCOORD_CONV{Get, Set}=*[s_0, s_1]*] [, ZCOORD_CONV{Get, Set}=*[s_0, s_1]*])

or

Result = Obj -> [IDLgrROI::]Init([*X*[, *Y*[, *Z*]]]) (*Only in a subclass' Init method.*)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Y

A vector providing the Y components of the vertices. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Z

A scalar or vector providing the Z components of the vertices. If not provided, Z values default to 0.0. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Keywords

Note

All keywords accepted by IDLanROI::Init are accepted by this method as well.

In addition, the following keywords are accepted:

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to an RGB or indexed color for drawing the region. The default color is [0, 0, 0].

DOUBLE *(Get, Set)*

Set this keyword to a non-zero value to indicate that data should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default. The DOUBLE property controls the precision used for storing the data in the (inherited)AppendData, Init, and (inherited)ReplaceData methods via the X, Y, and Z arguments and in SetProperty method via the (inherited)DATA keyword. IDL converts any data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the (inherited)DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

HIDE *(Get, Set)*

Set this keyword to a Boolean value indicating whether this region should be drawn:

- 0 = draw the region (the default)
- 1 = do not draw the region

LINESTYLE *(Get, Set)*

Set this keyword to the line style to be used to draw the region. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern. The valid values for the pre-defined line styles are:

- 0 = solid (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

NAME *(Get, Set)*

Set this keyword to a string to use as the name for this region.

PALETTE *(Get, Set)*

Set this keyword to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used for Object Graphics destinations using the RGB color model. In this case, if the color value for the region is specified as a color index value, this palette is used to look up the color for the region. If the PALETTE keyword is not set, the destination object PALETTE property is used, which defaults to a gray scale ramp.

STYLE *(Get, Set)*

Set this keyword to indicate the geometrical primitive to use to represent the region when displayed. Valid values include:

- 0 = points
- 1 = open polyline
- 2 = closed polyline (the default)

SYMBOL *(Get, Set)*

Set this keyword to reference an IDLgrSymbol object for the symbol used for display when STYLE = 0 (points). By default, a dot is used.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the size of the points, or the thickness of the lines, measured in points. The default is 1.0 points.

UVALUE *(Get, Set)*

Set this keyword to a user value of any type to contain any information you wish. Remember if you set this user value equal to a pointer or object reference, you must destroy the pointer or object reference explicitly when destroying this region.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[\ (-X_{min})/(X_{max} - X_{min}),\ 1.0/(X_{max} - X_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[\ (-Y_{min})/(Y_{max} - Y_{min}),\ 1.0/(Y_{max} - Y_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[\ (-Z_{min})/(Z_{max} - Z_{min}),\ 1.0/(Z_{max} - Z_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.3

CLIP_PLANES keyword: 5.6

IDLgrROI::PickVertex

The IDLgrROI::PickVertex function method picks a vertex of the region which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = *Obj* -> [IDLgrROI::]PickVertex(*Dest*, *View*, *Point* [, PATH=*objref*])

Return Value

Result

The return value is the index of the nearest region vertex. If two or more vertices are equally nearest to the point, the smallest index of those vertices is returned.

Arguments

Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

View

An object reference to the IDLgrView containing this region.

Point

A two-element vector, [*x*, *y*], representing the device location used for picking a nearest vertex.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected vertex is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

Introduced: 5.3

IDLgrROI::SetProperty

The IDLgrROI::SetProperty procedure method sets the value of a property or group of properties for the Object Graphics region.

Syntax

Obj -> [IDLgrROI::]SetProperty

Arguments

None.

Keywords

Note

Any keywords accepted by IDLanROI::SetProperty are also accepted by this method. Furthermore, any keywords to IDLgrROI::Init followed by the word *(Set)* can be set using IDLgrROI::SetProperty as well.

Version History

Introduced: 5.3

IDLgrROIGroup

The IDLgrROIGroup object class is an Object Graphics representation of a group of regions of interest.

Superclasses

This class is a subclass of IDLanROIGroup.

Subclasses

None.

Creation

See IDLgrROIGroup::Init.

Methods

Intrinsic Methods

The IDLgrROIGroup class has the following methods:

- IDLgrROIGroup::Add
- IDLgrROIGroup::Cleanup
- IDLgrROIGroup::GetProperty
- IDLgrROIGroup::Init
- IDLgrROIGroup::PickRegion
- IDLgrROIGroup::SetProperty

Inherited Methods

This class inherits the following methods:

- IDLanROIGroup::ContainsPoints
- IDLanROIGroup::ComputeMask
- IDLanROIGroup::GetProperty
- IDLanROIGroup::Rotate

- IDLanROIGroup::Scale
- IDLanROIGroup::Translate

Version History

Introduced: 5.3

IDLgrROIGroup::Add

The IDLgrROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLgrROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj -> [IDLgrROIGroup::]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLgrROI object class representing the region of interest to add to the group.

Keywords

Accepts all keywords accepted by the IDLanROIGroup::Add method.

Version History

Introduced: 5.3

IDLgrROIGroup::Cleanup

The IDLgrROIGroup::Cleanup procedure method performs all cleanup for an Object Graphics region of interest group object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrROIGroup::]Cleanup (In a subclass' Cleanup method only.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLgrROIGroup::GetProperty

The IDLgrROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj -> [IDLgrROIGroup::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

All keywords accepted by IDLanROIGroup::GetProperty are also accepted by this method. Furthermore, any keyword to IDLgrROIGroup::Init followed by the word (*Get*) can be retrieved using IDLgrROIGroup::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable. Upon return, ALL contains an anonymous structure with the values of all of the properties associated with the state of this object.

Note

The fields in this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

YRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Version History

Introduced: 5.3

IDLgrROIGroup::Init

The IDLgrROIGroup::Init function method initializes an Object Graphics region of interest group object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrROIGroup' [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*vector*] [, /HIDE{Get, Set}] [, NAME{Get, Set}=*string*] [, XCOORD_CONV{Get, Set}=*[s_0, s_1]*] [, YCOORD_CONV{Get, Set}=*[s_0, s_1]*] [, ZCOORD_CONV{Get, Set}=*[s_0, s_1]*])

or

Result = *Obj* -> [IDLgrROIGroup::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to an RGB or indexed color for drawing the region group. The default color is [0,0,0].

HIDE *(Get, Set)*

Set this keyword to a Boolean value indicating whether this region group should be drawn:

- 0 = draw the region group (the default)
- 1 = do not draw the region group

NAME *(Get, Set)*

Set this keyword to a string to use as the name for this region group.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[\ (-X_{min})/(X_{max} - X_{min}),\ 1.0/(X_{max} - X_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[\ (-Y_{min})/(Y_{max} - Y_{min}),\ 1.0/(Y_{max} - Y_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[\ (-Z_{min})/(Z_{max} - Z_{min}),\ 1.0/(Z_{max} - Z_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.3

CLIP_PLANES keyword: 5.6

IDLgrROIGroup::PickRegion

The IDLgrROIGroup::PickRegion function method picks a region within the group which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = *Obj* -> [IDLgrROIGroup::]PickRegion(*Dest*, *View*, *Point* [, PATH=*objref*])

Return Value

Result

The return value is the object reference of the nearest region. If two or more regions are equally nearest to the point, the one that was added to the region group first is returned.

Arguments

Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

View

An object reference to the IDLgrView containing this region.

Point

A two-element vector, [*x*, *y*], representing the device location to use for picking a nearest region.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected region is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

Introduced: 5.3

IDLgrROIGroup::SetProperty

The IDLgrROIGroup::Set Property procedure method sets the value of a property or group of properties for the region group.

Syntax

Obj -> [IDLgrROIGroup::]SetProperty

Arguments

None.

Keywords

Note

Any keywords to IDLgrROIGroup::Init followed by the word *(Set)* can be set using IDLgrROIGroup::SetProperty.

Version History

Introduced: 5.3

IDLgrScene

A scene object represents the entire scene to be drawn and serves as a container of IDLgrView or IDLgrViewgroup objects.

Superclasses

This class is a subclass of IDL_Container.

Subclasses

This class has no subclasses.

Creation

See "IDLgrScene::Init" on page 2905.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrScene::Add
- IDLgrScene::Cleanup
- IDLgrScene::GetByName
- IDLgrScene::GetProperty
- IDLgrScene::Init
- IDLgrScene::SetProperty

Inherited Methods

This class inherits the following methods:

- IDL_Container::Count
- IDL_Container::Get
- IDL_Container::IsContained
- IDL_Container::Move

Version History

Introduced: 5.0

IDLgrScene::Add

The IDLgrScene::Add function method verifies that the added item is an instance of an IDLgrView or IDLgrViewgroup object. If it is, IDLgrScene:Add adds the view or viewgroup to the specified scene.

Syntax

Obj -> [IDLgrScene::]Add, *View* [, POSITION=*index*]

Arguments

View

An instance of the IDLgrView or IDLgrViewgroup object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced: 5.0

IDLgrScene::Cleanup

The IDLgrScene::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrScene::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrScene::GetByName

The IDLgrScene::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj* `->` [IDLgrScene::]GetByName(*Name*)

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None.

Version History

Introduced: 5.0

IDLgrScene::GetProperty

The IDLgrScene::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj -> [IDLgrScene::]GetProperty [, ALL=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrScene::Init followed by the word “Get” can be retrieved using IDLgrScene::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Version History

Introduced: 5.0

IDLgrScene::Init

The IDLgrScene::Init function method initializes the scene object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrScene' [, COLOR{Get, Set}=*index or RGB vector*] [, /HIDE{Get, Set}] [, NAME{Get, Set}=*string*] [, /TRANSPARENT{Get, Set}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrScene::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrScene::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrScene::SetProperty are indicated by the word "Set" following the keyword.

HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

COLOR *(Get, Set)*

Set this keyword to the color to which the scene should be erased before drawing. The color may be specified as a color lookup table index or an RGB vector.

NAME

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

TRANSPARENT *(Get, Set)*

Set this keyword to disable window clearing. If this keyword is not set, the destination object in use by the scene is automatically erased when the scene is initialized.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

IDLgrScene::SetProperty

The IDLgrScene::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj -> [IDLgrScene::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrScene::Init followed by the word “Set” can be set using IDLgrScene::SetProperty.

Version History

Introduced: 5.0

IDLgrSurface

A surface object represents a shaded or vector representation of a mesh grid.

An IDLgrSurface object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See “IDLgrSurface::Init” on page 2914.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrSurface::Cleanup
- IDLgrSurface::GetCTM
- IDLgrSurface::GetProperty
- IDLgrSurface::Init
- IDLgrSurface::SetProperty

Version History

Introduced: 5.0

IDLgrSurface::Cleanup

The IDLgrSurface::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrSurface::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrSurface::GetCTM

The IDLgrSurface::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrSurface::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrSurface::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrSurface::GetProperty

The IDLgrSurface::GetProperty procedure method retrieves the value of a property or group of properties for the surface.

Syntax

Obj -> [IDLgrSurface::]GetProperty [, ALL=*variable*] [, DATA=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrSurface::Init followed by the word "Get" can be retrieved using IDLgrSurface::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

DATA

Set this keyword to a named variable that upon return will contain the surface data.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

YRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Version History

Introduced: 5.0

IDLgrSurface::Init

The IDLgrSurface::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrSurface' [, *Z* [, *X*, *Y*]] [, BOTTOM{Get, Set}=*index or RGB vector*] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB vector*] [, DATAX{Set}=*vector or 2-D array*] [, DATAY{Set}=*vector or 2-D array*] [, DATAZ{Set}=*2-D array*] [, DEPTH_OFFSET{Get, Set}=*value*] [, /DOUBLE{Get, Set}] [, /EXTENDED_LEGO{Get, Set}] [, /HIDDEN_LINES{Get, Set}] [, /HIDE{Get, Set}] [, LINESTYLE{Get, Set}=*value*] [, MAX_VALUE{Get, Set}=*value*] [, MIN_VALUE{Get, Set}=*value*] [, NAME{Get, Set}=*string*] [, PALETTE{Get, Set}=*objref*] [, /RESET_DATA{Set}] [, SHADE_RANGE{Get, Set}=*[index of darkest pixel, index of brightest pixel]*] [, SHADING{Get, Set}={0 | 1}] [, SHARE_DATA{Set}=*objref*] [, /SHOW_SKIRT{Get, Set}] [, SKIRT{Get, Set}=*Z value*] [, STYLE{Get, Set}={0 | 1 | 2 | 3 | 4 | 5 | 6}] [, TEXTURE_COORD{Get, Set}=*array*] [, /TEXTURE_HIGHRES{Get, Set}] [, /TEXTURE_INTERP{Get, Set}] [, TEXTURE_MAP{Get, Set}=*objref to IDLgrImage*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, UVALUE{Get, Set}=*value*] [, /USE_TRIANGLES{Get, Set}] [, VERT_COLORS{Get, Set}=*vector*] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*] [, ZERO_OPACITY_SKIP{Get, Set}={0 | 1}])

or

Result = *Obj* -> [IDLgrSurface::]Init([*Z* [, *X*, *Y*]]) (*Only in a subclass' Init method.*)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinates for a column of Z (e.g., X[0] specifies the X coordinate for Z[0, *]). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z (Xij specifies the X coordinate of Zij). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinates for a column of Z (e.g., Y[0] specifies the Y coordinate for Z[0, *]). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z (Yij specifies the Y coordinate of Zij). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is defined as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array indices of each element of Z. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Keywords

Properties retrievable via IDLgrSurface::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrSurface::SetProperty are indicated by the word “Set” following the keyword.

BOTTOM *(Get, Set)*

The color value used to draw the bottom surface. If not specified, or set to a negative scalar value, the bottom is drawn with the same color as the top. Setting a bottom color is only supported when the destination device uses RGB color mode.

CLIP_PLANES *(Get, Set)*

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to the color to be used as the foreground color for this model. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

DATAX *(Set)*

Set this keyword to a vector or a two-dimensional array specifying the X coordinates of the surface grid. This keyword is the same as the X argument described above. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

DATAY *(Set)*

Set this keyword to a vector or a two-dimensional array specifying the Y coordinates of the surface grid. This keyword is the same as the Y argument described above. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

DATAZ *(Set)*

Set this keyword to the two-dimensional array to display as a surface. This keyword is the same as the Z argument described above. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

DEPTH_OFFSET *(Get, Set)*

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

Research Systems suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFEST has no effect unless the value of the STYLE keyword is 2 or 6 (Filled or LegoFilled).

DOUBLE *(Get, Set)*

Set this keyword to a non-zero value to indicate that data provided by any of the X, Y, or Z arguments or DATAX, DATAY, or DATAZ keywords should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default.

IDL converts any value data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATAX, DATAY, or DATAZ parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATAX, DATAY, or DATAZ parameters is stored using a variable of type DOUBLE.

EXTENDED_LEGO *(Get, Set)*

Set this keyword to force the IDLgrSurface object to display the last row and column of data when lego display styles are selected.

HIDDEN_LINES *(Get, Set)*

Set this keyword to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

LINESTYLE *(Get, Set)*

Set this keyword to indicate the line style that should be used to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

MAX_VALUE *(Get, Set)*

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

MIN_VALUE *(Get, Set)*

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ''.

PALETTE *(Get, Set)*

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

RESET_DATA *(Set)*

Set this keyword to treat the data provided via one of the DATA[XYZ] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this keyword if the object on which the property is

being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This keyword has no effect if no new data is provided via a DATA property.

SHADE_RANGE *(Get, Set)*

Set this keyword to a two-element array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color element for the brightest pixel. This value is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

SHADING *(Get, Set)*

Set this keyword to an integer representing the type of shading to use if STYLE is set to 2 (Filled) or 6 (LegoFilled).

- 0 = Flat (default): The color has a constant intensity for each face of the surface, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

SHARE_DATA *(Set)*

Set this keyword to an object whose data is to be shared by this surface. A surface may only share data with another surface. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

SHOW_SKIRT *(Get, Set)*

Set this keyword to enable skirt drawing. The default is to disable skirt drawing.

SKIRT *(Get, Set)*

Set this keyword to the *Z* value at which a skirt is to be defined around the array. The *Z* value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given *Z* value, and the same *X* and *Y* values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see SHOW_SKIRT above). IDL converts, maintains, and returns this data as double-precision floating-point.

STYLE *(Get, Set)*

Set this keyword to and integer value that indicates the style to be used to draw the surface. Valid values are:

- 0 = Points
- 1 = Wire mesh (the default)
- 2 = Filled
- 3 = RuledXZ
- 4 = RuledYZ
- 5 = Lego
- 6 = LegoFilled: for outline or shaded and stacked histogram-style plots.

TEXTURE_COORD *(Get, Set)*

A 2 x *n* array of surface coordinate-texturemap coordinate pairs [*s*, *t*] at each vertex., containing the fill pattern array subscripts of each of the *n* polygon vertices. Use this keyword in conjunction with the TEXTURE_MAP keyword to warp images over the surface. To stretch (or shrink) the texture map to cover the surface mesh completely, set TEXTURE_COORD to a scalar. By default, IDL stretches (or shrinks) the texture map to cover the surface mesh completely, and sets TEXTURE_COORD to a scalar (-1).

Texture coordinates are normalized. This means that the *m* x *n* image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

Because of the way in which high-resolution textures require modified texture coordinates, if the TEXTURE_COORD keyword is used, TEXTURE_HIGHRES will be disabled.

TEXTURE_HIGHRES *(Get, Set)*

Set this keyword to cause texture tiling to be used as necessary to maintain the full pixel resolution of the original texture image. This is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic. If not set, and the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to the maximum resolution supported by the 3-D hardware on your system. The default value is 0.

Note

Because of the way in which high-resolution textures require modified texture coordinates, if you specify the TEXTURE_COORD keyword, high resolution textures (TEXTURE_HIGHRES) will be disabled.

TEXTURE_INTERP *(Get, Set)*

Set this keyword to a nonzero value to indicate that bilinear sampling is to be used with texture mapping. The default method is nearest-neighbor sampling.

TEXTURE_MAP *(Get, Set)*

Set this keyword to an instance of the IDLgrImage object class to be texture mapped onto the surface. If this keyword is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) By default, the texture map will be stretched (or shrunk) to cover the surface mesh completely.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrSurface object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function src = alpha and dst = 1 - alpha, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If a texture is provided without texture coordinates, IDLgrSurface generates its own texture mapping coordinates to map the texture onto the surface without resampling artifacts, even if the provided texture image does not have dimensions that are an exact power of two. If texture coordinates are provided, the image is resampled to the nearest larger dimensions that are exact powers of two.

Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note

Texture mapping is applied to all styles that are set by the STYLE property except Lego and LegoFilled.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. The default is 1.0 points.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object of which it is a user value.

USE_TRIANGLES *(Get, Set)*

Set this keyword to force the IDLgrSurface object to use triangles instead of quads to draw the surface and skirt.

VERT_COLORS *(Get, Set)*

Set this keyword to a vector of colors to be used to draw at each vertex. Color is interpolated between vertices if SHADING is set to 1 (Gouraud). If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the polygons are all drawn in the single color provided by the COLOR keyword. If this keyword is omitted or set to a scalar, vertex colors are removed and the surface is drawn in the color specified by the COLOR keyword.

Note

If the surface object is being rendered on a destination device that uses the Indexed color model, and the view that contains the surface also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert *X* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZERO_OPACITY_SKIP *(Get, Set)*

Set this keyword to gain finer control over the rendering of textured surface pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this keyword is set to 1, any texels are “skipped” and not rendered at all. If this keyword is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this keyword is 1.

Note

This keyword has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrSurface::SetProperty

The IDLgrSurface::SetProperty procedure method sets the value of a property or group of properties for the surface.

Syntax

Obj -> [IDLgrSurface::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrSurface::Init followed by the word “Set” can be set using IDLgrSurface::SetProperty.

Version History

Introduced: 5.0

IDLgrSymbol

A symbol object represents a graphical element that is plotted relative to a particular position.

Note

Seven predefined symbols are provided by IDL.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See “IDLgrSymbol::Init” on page 2930.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrSymbol::Cleanup
- IDLgrSymbol::GetProperty
- IDLgrSymbol::Init
- IDLgrSymbol::SetProperty

Version History

Introduced: 5.0

IDLgrSymbol::Cleanup

The IDLgrSymbol::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrSymbol::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrSymbol::GetProperty

The IDLgrSymbol::GetProperty procedure method retrieves the value of a property or group of properties for the symbol.

Syntax

Obj -> [IDLgrSymbol::]GetProperty [, ALL=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrSymbol::Init followed by the word “Get” can be retrieved using IDLgrSymbol::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Version History

Introduced: 5.0

IDLgrSymbol::Init

The IDLgrSymbol::Init function method initializes the plot symbol.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrSymbol' [, *Data*] [, COLOR{Get, Set}=*index or RGB vector*] [, DATA{Get, Set}=*integer or objref*] [, NAME{Get, Set}=*string*] [, SIZE{Get, Set}=*vector*] [, THICK{Get, Set}=*points*{1.0 to 10.0}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrSymbol::]Init([*Data*]) (*Only in a subclass' Init method.*)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Data

Either an integer value from the list shown below, or an object reference to either an IDLgrModel object or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = Arrow Head

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Keywords

Properties retrievable via IDLgrSymbol::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrSymbol::SetProperty are indicated by the word "Set" following the keyword.

COLOR *(Get, Set)*

Set this keyword to the color used to draw the symbol. The color may be specified as a color lookup table index or as an RGB vector. The default color is the color of the object for which this symbol is being used.

DATA *(Get, Set)*

Set this keyword to specify a symbol. This keyword is equivalent to the *Data* argument.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

SIZE *(Get, Set)*

Set this keyword to a one-, two-, or three-element vector describing the X, Y, and Z scaling factors to be applied to the symbol. The default is [1.0, 1.0, 1.0].

- If SIZE is specified as a scalar, then the X, Y, and Z scale factors are all equal to the scalar value.
- If SIZE is specified as a 2-element vector, then the X and Y scale factors are as specified by the vector, and the Z scale factor is 1.0.

- If SIZE is specified as a 3-element vector, then the X, Y, and Z scale factors are as specified by the vector.

IDL converts, maintains, and returns this data as double-precision floating-point.

THICK *(Get, Set)*

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to used to draw any lines that make up the symbol, in points. The default is 1.0 points.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

Data argument: 5.6

IDLgrSymbol::SetProperty

The IDLgrSymbol::SetProperty procedure method sets the value of a property or group of properties for the symbol.

Syntax

Obj -> [IDLgrSymbol::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrSymbol::Init followed by the word “Set” can be set using IDLgrSymbol::SetProperty.

Version History

Introduced: 5.0

IDLgrTessellator

A tessellator object decomposes a polygon description into a set of triangles. Use the tessellator object to convert complex and/or concave polygons into a form suitable for drawing with the IDLgrPolygon object. IDLgrPolygon can draw only convex polygons correctly.

The polygon contours may intersect each other and may be self-intersecting. The contours may be disjoint, overlapping, or contained within other contours. The contours may also be degenerate, may contain repeated points, and may or may not be closed. The order of the vertices may be either counter-clockwise or clockwise. For best results, the polygon contours should be coplanar.

The tessellator object uses the "odd-winding rule" to determine if a point is in the interior of the polygon and therefore contained in a triangle output by the tessellator. With this rule, a point is in the interior if it is circled an odd number of times as we travel around each of the contours.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

Specify polygon contours with calls to the IDLgrTessellator::AddPolygon method. After adding all the contours, use the IDLgrTessellator::Tessellate method to perform the tessellation and retrieve the resulting list of vertices and connectivity array.

If the polygon contours contain intersecting or self-intersecting contours, the tessellator may return vertices that were not in the original set of vertices specified with the IDLgrTessellator::AddPolygon method. These vertices are created by the intersecting contours.

If your vertex data also includes other information, such as a color for each vertex, then you may wish for this extra information to be created for any new vertices generated by the tessellator. Use the AUXDATA keywords for IDLgrTessellator::AddPolygon and IDLgrTessellator::Tessellate to pass in and retrieve your per-vertex data. The tessellator object interpolates the per-vertex data from neighboring vertices to create new per-vertex data for the new vertices it generates.

In the following example of handling per-vertex data with generated vertices, the polygon is a simple self-intersecting "bow-tie" polygon. It is submitted to the tessellator with four vertices, but the tessellator returns a fifth at the point of self-intersection. Color data for the four original vertices is also supplied, and the tessellator returns a fifth color.

```
PRO tessaux
    oTess = OBJ_NEW('IDLgrTessellator')
    colors = [[0,255,0],[0,255,0],[0,64,0],[0,64,0]]
    oTess->AddPolygon, [0,1,0,1], [0,0,1,1], AUXDATA=colors
    result = oTess->Tessellate(v, c, AUXDATA=aux)
    PRINT, v[*,4]
    PRINT, aux[*,4]
    oPoly = OBJ_NEW('IDLgrPolygon', v, POLYGONS=c, $
VERT_COLORS=aux, SHADING=1)
    XOBJVIEW, oPoly, /BLOCK
    OBJ_DESTROY, [oTess, oPoly]
END
```

The generated output will be:

```
0.500000     0.500000
  0    159      0
```

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See “IDLgrTessellator::Init” on page 2940.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrTessellator::AddPolygon
- IDLgrTessellator::Cleanup

- IDLgrTessellator::Init
- IDLgrTessellator::Reset
- IDLgrTessellator::Tessellate

Version History

Introduced: 5.0

IDLgrTessellator::AddPolygon

The IDLgrTessellator::AddPolygon procedure method adds a polygon to the tessellator object.

Syntax

Obj -> [IDLgrTessellator::]AddPolygon, *X* [, *Y*[, *Z*]] [, AUXDATA=*array of auxiliary data*] [, /INTERIOR] [, POLYGON=*array of polygon descriptions*]

Arguments

X

A 1 x *n*, 2 x *n*, or 3 x *n* array of polygon vertices.

Y

A vector of Y values. If *X* and *Y* are both specified, they must be one-dimensional vectors of the same length.

Z

A vector of Z values. If *X*, *Y*, and *Z* are all specified, they must all three be one-dimensional vectors of the same length. If no *Z* values are specified, the *Z* value for the polygon is set to 0.

Keywords

AUXDATA

Set this keyword to an array of auxiliary per-vertex data. This array must have dimensions [*m*,*n*] where m is the number of auxiliary data items per vertex and *n* is the number of vertices specified in the *X*, *Y*, and *Z* arguments. If you specify AUXDATA in any invocation of the AddPolygon method, you must specify it on all invocations of the method for the polygons to be tessellated together with the Tessellate method. Further, the value of m in the dimensions must be the same for all polygons. That is, all polygons must have the same number of auxiliary data items for each vertex.

POLYGON

Set this keyword to an array of polygon descriptions. A polygon description is an integer or longword array of the form: [*n*, i_0, i_1, ..., i_{n-1}], where *n* is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGON array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows you to add multiple polygons to the tessellator object with a single AddPolygon operation.

INTERIOR

Set this keyword to set a polygon to be an interior polygon, which is treated as a hole in the exterior polygons.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

Version History

Introduced: 5.0

AUXDATA keyword: 5.6

IDLgrTessellator::Cleanup

The IDLgrTessellator::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY,*Obj*

or

Obj -> [IDLgrTessellator::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrTessellator::Init

The IDLgrTessellator::Init function method initializes the tessellator object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrTessellator')

or

Result = *Obj* -> [IDLgrTessellator::]Init( ) (*Only in a subclass' Init method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrTessellator::Reset

The IDLgrTessellator::Reset procedure method resets the object's internal state. All previously added polygons are removed from memory and the object is prepared for a new tessellation task.

Syntax

Obj -> [IDLgrTessellator::]Reset

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrTessellator::Tessellate

The IDLgrTessellator::Tessellate function method performs the actual tessellation.

Syntax

Result = *Obj* -> [IDLgrTessellator::]Tessellate(*Vertices*, *Poly* [, AUXDATA=*variable*] [, /QUIET])

Arguments

If the tessellation succeeds, IDLgrTessellator::Tessellate returns 1 and the contents of Vertices and Poly are set to the results of the tessellation. If the tessellation fails, the function returns 0.

Vertices

A 2 x *n* array if all the input polygons were 2-D. A 3 x *n* array if all the input polygons were 3-D.

Poly

An array of polygon descriptions. A polygon description is an integer or longword array of the form: [*n*, i_0, i_1, ..., i_{n-1}], where *n* is the number of vertices that define the polygon, and i_0..i_{n-1} are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices.

Note

On output, the *Vertices* array can be used as the value of the DATA property, and the *Poly* array can be used as the value of the POLYGON property, of an IDLgrPolygon object.

Keywords

AUXDATA

Set this keyword to a named variable that receives the auxiliary data associated with each vertex returned in the Vertices argument. The data is an [*m*, *n*] array where m is the number of per-vertex auxiliary data items specified in the call(s) to the AddPolygon method, and n is the number of vertices returned in the Vertices argument. The type of the returned auxiliary data is the same as the type of the data supplied with the AUXDATA keyword in the last call to AddPolygon.

QUIET

Set this keyword to suppress warning and error message generation due to tessellation errors. !ERROR_STATE is not updated in the case of the return value being ‘0’ when the QUIET keyword is specified.

Version History

Introduced: 5.0

AUXDATA keywords: 5.6

IDLgrText

A text object represents one or more text strings that share common rendering attributes. An IDLgrText object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrText::Init" on page 2951.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrText::Cleanup
- IDLgrText::GetCTM
- IDLgrText::GetProperty
- IDLgrText::Init
- IDLgrText::SetProperty

Keywords

PALETTE

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Version History

Introduced: 5.0

IDLgrText::Cleanup

The IDLgrText::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrText::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrText::GetCTM

The IDLgrText::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrText::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the text object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrText::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrText::GetProperty

The IDLgrText::GetProperty procedure method retrieves the value of a property or group of properties for the text.

Syntax

Obj -> [IDLgrText::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrText::Init followed by the word "Get" can be retrieved using IDLgrText::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

XRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

YRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Note

Until the text is drawn to the destination object, the [XYZ]RANGE properties will only report the locations of the text. Use the GetTextDimensions method of the destination object to get the data dimensions of the text prior to a draw operation.

Version History

Introduced: 5.0

IDLgrText::Init

The IDLgrText::Init function method initializes the text object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrText' [, *String or vector of strings*] [, ALIGNMENT{Get, Set}=*value*{0.0 to 1.0}] [, BASELINE{Get, Set}=*vector*] [, CHAR_DIMENSIONS{Get, Set}=*[width, height]*] [, CLIP_PLANES{Get, Set}=*array*] [, COLOR{Get, Set}=*index or RGB vector*] [, /ENABLE_FORMATTING{Get, Set}] [, FONT{Get, Set}=*objref*] [, /HIDE{Get, Set}] [, LOCATIONS{Get, Set}=*array*] [, NAME{Get, Set}=*string*] [, /ONGLASS{Get, Set}] [, PALETTE{Get, Set}=*objref*] [, RECOMPUTE_DIMENSIONS{Get, Set}={0 | 1 | 2}] [, STRINGS{Get, Set}=*string or vector of strings*] [, UPDIR{Get, Set}=*vector*] [, UVALUE{Get, Set}=*value*] [, VERTICAL_ALIGNMENT{Get, Set}=*value*{0.0 to 1.0}] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, ZCOORD_CONV{Get, Set}=*vector*])

or

Result = Obj -> [IDLgrText::]Init([*String or vector of strings*]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

Note

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

Keywords

Properties retrievable via IDLgrText::GetProperty are indicated by the word “Get” following the keyword. Properties settable via IDLgrText::SetProperty are indicated by the word “Set” following the keyword.

ALIGNMENT *(Get, Set)*

Set this keyword to a floating-point value between 0.0 and 1.0 to indicate the requested horizontal alignment of the text baseline. An alignment of 0.0 (the default) left-justifies the text at the given position; an alignment of 1.0 right-justifies the text, and an alignment of 0.5 centers the text over the given position.

BASELINE *(Get, Set)*

Set this keyword to a two (or three) element vector describing the direction in which the baseline is to be oriented. Use this keyword in conjunction with the UPDIR keyword to specify the plane on which the text lies. The default BASELINE is [1.0,0,0] (i.e., parallel to the x-axis).

CHAR_DIMENSIONS *(Get, Set)*

Set this keyword equal to a two-element vector [*width*, *height*] indicating the dimensions (measured in data units) of a bounding box for each character, to be used when scaling text projected in three dimensions. If either *width* or *height* is zero, the text will be scaled such that if it were positioned halfway between the near and far clipping planes, it will appear at the point size associated with this text object’s font. The default value is [0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Note

If you set the CHAR_DIMENSIONS property to [0,0] (using the SetProperty method), indicating that IDL should calculate the text size, the value (returned by the GetProperty method) will not be updated to reflect the calculated size until you call either the Draw method or the GetTextDimensions method.

For example, if the VIEWPLANE_RECT of the view the text object is being rendered in is set equal to [0,0,10,10] (that is, it spans ten data units in each of the X and Y directions), setting the CHAR_DIMENSIONS property equal to [2, 3] will scale the text such that each character fills 20% of the X range and 30% of the Y range.

This property has no effect if the ONGLASS property is set equal to one.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

COLOR *(Get, Set)*

Set this keyword to the color to be used as the foreground color for the text. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

ENABLE_FORMATTING *(Get, Set)*

Set this keyword to indicate that the text object should honor embedded Hershey-style formatting codes within the strings. (Formatting codes are described in Appendix N, “Fonts”.) The default is not to honor the formatting codes.

FONT *(Get, Set)*

Set this keyword to an instance of an IDLgrFont object class to describe the font to use to draw this string. The default is 12 point Helvetica. See IDLgrFont for details.

Note

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a null object.

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

LOCATIONS *(Get, Set)*

Set this keyword to an array of one or more two- or three-element vectors specifying the coordinates (measured in data units) used to position the string(s). The default location for each string is [0,0,0]. Each vector is of the form [*x*, *y*] or [*x*, *y*, *z*]; if *z* is not provided, it is assumed to be zero. Each location corresponds to a string in the *String* argument; the number of locations should be equal the number of strings. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

ONGLASS *(Get, Set)*

Set this keyword to indicate that the text should be displayed “on the glass”. The default is projected 3-D text.

PALETTE *(Get, Set)*

Set this keyword equal to the object reference of a palette object (an instance of the IDLgrPalette object class). This keyword is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this keyword is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

RECOMPUTE_DIMENSIONS *(Get, Set)*

Set this keyword to one of the following values to indicate when this text object's character dimensions (refer to the CHAR_DIMENSIONS property) are to be recomputed automatically:

- 0 = Never recompute. Always use the character dimensions provided via the CHAR_DIMENSIONS property. If CHAR_DIMENSIONS is set to [0,0], compute once and re-use the resulting dimensions until the CHARACTER_DIMENSIONS are modified.
- 1 = Recompute, but reuse the current transformation matrix from the previous draw of this text object. If this is the first time the text object is drawn, compute the current transformation matrix. (This option is useful if the parent model of this text object is scaled for zooming, and the text is supposed to increase in size, rather having its data dimensions recomputed to ensure the font size is matched.)
- 2 = Recompute always, including the current transformation matrix.

STRINGS *(Get, Set)*

Set this keyword to the string (or vector of strings) associated with the text object. This keyword is the same as the *String* argument described above.

Set this keyword to the string (or vector of strings) associated with the text object. This keyword is the same as the *String* argument described above. If the number of strings matches the number of locations (as specified by the LOCATIONS property), the existing locations are used.

Note

If the number of strings *does not* match the number of locations, the number of locations is modified to match the number of strings, and the location value for each string is reset to [0,0,0].

UPDIR *(Get, Set)*

Set this keyword to a two (or three) element vector describing the vertical direction for the string. The *upward direction* is the direction defined by a vector pointing from the origin to the point specified. Use this keyword in conjunction with the BASELINE keyword to specify the plane on which the text lies; the direction specified by UPDIR should be orthogonal to the direction specified by BASELINE. The default UPDIR is [0.0, 1.0, 0.0] (i.e., parallel to the *Y* axis).

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

VERTICAL_ALIGNMENT *(Get, Set)*

Set this keyword to a floating-point value between 0.0 and 1.0 to indicate the requested vertical alignment of the text. An alignment of 0.0 (the default) bottom-justifies the text at the given location; an alignment of 1.0 top-justifies the text at the given location.

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrText::SetProperty

The IDLgrText::SetProperty procedure method sets the value of a property or group of properties for the text.

Syntax

Obj -> [IDLgrText::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrText::Init followed by the word “Set” can be set using IDLgrText::SetProperty.

Version History

Introduced: 5.0

IDLgrView

A view object represents a rectangular area in which graphics objects are drawn. It is a container for objects of the IDLgrModel class.

Superclasses

This class is a subclass of IDL_Container.

Subclasses

This class has no subclasses.

Creation

See "IDLgrView::Init" on page 2965.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrView::Add
- IDLgrView::Cleanup
- IDLgrView::GetByName
- IDLgrView::GetProperty
- IDLgrView::Init
- IDLgrView::SetProperty

Inherited Methods

This class inherits the following methods:

- IDL_Container::Count
- IDL_Container::Get
- IDL_Container::IsContained
- IDL_Container::Move

Version History

Introduced: 5.0

IDLgrView::Add

The IDLgrView::Add procedure method adds a child to this view.

Syntax

Obj -> [IDLgrView::]Add, *Model* [, POSITION=*index*]

Arguments

Model

An instance of the IDLgrModel object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced 5.0

IDLgrView::Cleanup

The IDLgrView::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrView::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced 5.0

IDLgrView::GetByName

The IDLgrView::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj* `->` [IDLgrView::]GetByName(*Name*)

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None.

Version History

Introduced 5.0

IDLgrView::GetProperty

The IDLgrView::GetProperty procedure method retrieves the value of the property or group of properties for the view.

Syntax

Obj -> [IDLgrView::]GetProperty [, ALL=*variable*] [, PARENT=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrView::Init followed by the word “Get” can be retrieved using IDLgrView::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

Version History

Introduced 5.0

IDLgrView::Init

The IDLgrView::Init function method initializes the view object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrView' [, COLOR{Get, Set}=*index or RGB vector*] [, DEPTH_CUE{Get, Set}=*[zbright, zdim]*] [, DIMENSIONS{Get, Set}=*[width, height]*] [, /DOUBLE {Get, Set}] [, EYE{Get, Set}=*distance*] [, LOCATION{Get, Set}=*[x, y]*] [, PROJECTION{Get, Set}={1 | 2}] [, /TRANSPARENT{Get, Set}] [, UNITS{Get, Set}={0 | 1 | 2 | 3}] [, UVALUE{Get, Set}=*value*] [, VIEWPLANE_RECT{Get, Set}=*[x, y, width, height]*] [, ZCLIP{Get, Set}=*[near, far]*])

or

Result = *Obj* -> [IDLgrView::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrView::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrView::SetProperty are indicated by the word "Set" following the keyword.

COLOR *(Get, Set)*

Set this keyword to the color for the view. This is the color to which the view area will be erased before its contents are drawn. The color may be specified as a color lookup table index or as an RGB vector. The default is [255, 255, 255] (white).

DEPTH_CUE *(Get, Set)*

Set this keyword to a two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color. Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

DIMENSIONS *(Get, Set)*

Set this keyword to a two-element vector of the form [*width*, *height*] specifying the dimensions of the viewport (the rectangle in which models are displayed on a graphics destination). By default, the viewport dimensions are set to [0, 0], which indicates that it will match the dimensions of the graphics destination to which it is drawn. The dimensions are measured in the units specified by the UNITS keyword.

DOUBLE *(Get, Set)*

The DOUBLE keyword parameter controls the precision used for rendering the entire contents of the view. If set, IDL calculates the transformations used for the modeling and view transforms using double-precision floating-point arithmetic. This allows the values specified for the VIEWPLANE_RECT, modeling transforms in IDLgrModel

objects, and coordinate data in atomic graphic objects to be used as double-precision before mapping to device coordinates.

Note

If this keyword is not specified, IDL uses single-precision floating-point arithmetic for these values which can cause loss of significance and incorrect rendering of data. Using this keyword may impact graphics performance and should only be used when handling data requiring double-precision.

EYE *(Get, Set)*

Set this keyword to specify the distance from the eyepoint to the viewplane (Z=0). The default is 4.0. The eyepoint is always centered within the viewplane rectangle. (That is, if the VIEWPLANE_RECT property is set equal to [0,0,1,1], the eyepoint will be at X=0.5, Y=0.5.) IDL converts, maintains, and returns this data as double-precision floating-point.

LOCATION *(Get, Set)*

Set this keyword to a two-element vector of the form [*x*, *y*] specifying the position of the lower left corner of the view. The default is [0, 0], measured in device units.

PROJECTION *(Get, Set)*

Set this keyword to an integer value indicating the type of projection to use within this view. All models displayed within this view will be projected using this type of projection. Valid values are described below.

- 1 = Orthogonal projection (default).
- 2 = Perspective: Indicates that all models are projected toward the eye (located at the origin), which is the apex of the viewing frustum. With a perspective projection, models that are farther away from the eye will appear smaller in the view than models that are nearer to the eye.

TRANSPARENT *(Get, Set)*

Set this keyword to disable the viewport erase, making the viewport transparent.

UNITS *(Get, Set)*

Set this keyword to specify the units of measure for this view. Valid values are:

- 0 = Device (default)
- 1 = Inches

- 2 = Centimeters
- 3 = Normalized: relative to the graphics destination's *rect*.

Note

If you set the UNITS property (using the SetProperty method) of a view without also setting the LOCATION and DIMENSIONS properties, IDL will use the existing size and location values in the new units, *without conversion*. This means that if your view's location and dimensions were previously measured in centimeters, and you change the value of UNITS to 1 (measurement in inches), the actual size of the view object will change.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this "user value" to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object to which the user value applies.

VIEWPLANE_RECT *(Get, Set)*

Set this keyword to a four-element vector of the form [*x*, *y*, *width*, *height*] to describe the bounds in x and y of the view volume. Objects within the view volume are projected into the viewport. These values are measured in normalized space. The default is [-1.0, -1.0, 2.0, 2.0] IDL converts, maintains, and returns this data as double-precision floating-point.

Note

The z bounds of the view volume are set via the ZCLIP keyword. The viewplane rectangle is always located at Z=0.

ZCLIP *(Get, Set)*

Set this keyword to a two element vector representing the near and far clipping planes to be applied to the objects in this view. The vector should take the form [*near*, *far*]. By default, these values are [1, -1]. IDL converts, maintains, and returns this data as double-precision floating-point.

Version History

Introduced 5.0

IDLgrView::SetProperty

The IDLgrView::SetProperty procedure method sets the value of the property or group of properties for the view.

Syntax

Obj -> [IDLgrView::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrView::Init followed by the word “Set” can be set using IDLgrView::SetProperty.

Version History

Introduced 5.0

IDLgrViewgroup

The IDLgrViewgroup object is a simple container object, very similar to the IDLgrScene object. It contains one or more IDLgrView objects and an IDLgrScene can contain one or more of these objects. This object is special in that it can also contain objects which do not have a Draw method (e.g. IDLgrPattern and IDLgrFont). An IDLgrViewgroup object cannot be returned by a call to the IDLgrWindow::Select method.

Superclasses

This class is a subclass of IDL_Container.

Subclasses

This class has no subclasses.

Creation

See IDLgrViewgroup::Init.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrViewgroup::Add
- IDLgrViewgroup::Cleanup
- IDLgrViewgroup::GetByName
- IDLgrViewgroup::GetProperty
- IDLgrViewgroup::Init
- IDLgrViewgroup::SetProperty

Inherited Methods

This class inherits the following methods:

- IDL_Container::Count

- IDL_Container::Get
- IDL_Container::IsContained
- IDL_Container::Move

Version History

Introduced: 5.1

IDLgrViewgroup::Add

The IDLgrViewgroup::Add function method verifies that the added item is not an instance of the IDLgrScene or IDLgrViewgroup object. If it is not, IDLgrViewgroup:Add adds the object to the specified viewgroup.

Syntax

Obj -> [IDLgrViewgroup::]Add, *Object* [, POSITION=*index*]

Arguments

Object

An instance of an object or a list of objects. Objects which subclass IDLgrScene or IDLgrViewgroup can not be added (avoiding circularity constraints). All other objects are allowed.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced: 5.1

IDLgrViewgroup::Cleanup

The IDLgrViewgroup::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY,*Obj*

or

Obj -> [IDLgrViewgroup::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrViewgroup::GetByName

The IDLgrViewgroup::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj* `->` [IDLgrViewgroup::]GetByName(*Name*)

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None.

Version History

Introduced: 5.1

IDLgrViewgroup::GetProperty

The IDLgrViewgroup::GetProperty procedure method retrieves the value of a property or group of properties for the viewgroup object.

Syntax

Obj -> [IDLgrViewgroup::]GetProperty [, ALL=*variable*] [, PARENT=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrViewgroup::Init followed by the word “Get” can be retrieved using IDLgrViewgroup::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

PARENT

Set this keyword to a named variable that will contain an object reference to the object that contains this viewgroup.

Version History

Introduced: 5.1

IDLgrViewgroup::Init

The IDLgrViewgroup::Init function method initializes the viewgroup object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrViewgroup' [, /HIDE{Get, Set}] [, NAME{Get, Set}=*string*] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrViewgroup::]Init( ) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrViewgroup::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrViewgroup::SetProperty are indicated by the word "Set" following the keyword.

HIDE *(Get, Set)*

Set this keyword to a boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

NAME *(Get, Set)*

Set this keyword to a string representing the name to be associated with this object. The default is the null string, ''.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You may use this value to contain any information you wish.

Version History

Introduced: 5.1

IDLgrViewgroup::SetProperty

The IDLgrViewgroup::SetProperty procedure method sets the value of a property or group of properties for the viewgroup.

Syntax

Obj -> [IDLgrViewgroup::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrViewgroup::Init followed by the word “Set” can be retrieved using IDLgrViewgroup::SetProperty.

Version History

Introduced: 5.1

IDLgrVolume

A volume object represents a mapping from a three-dimensional array of data to a three-dimensional array of voxel colors, which, when drawn, are projected to two dimensions.

An IDLgrVolume object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "IDLgrVolume::Init" on page 2986.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrVolume::Cleanup
- IDLgrVolume::ComputeBounds
- IDLgrVolume::GetCTM
- IDLgrVolume::GetProperty
- IDLgrVolume::Init
- IDLgrVolume::PickVoxel
- IDLgrVolume::SetProperty

Version History

Introduced: 5.0

IDLgrVolume::Cleanup

The IDLgrVolume::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrVolume::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrVolume::ComputeBounds

The IDLgrVolume::ComputeBounds procedure method computes the smallest bounding box that contains all voxels whose opacity lookup is greater than a given opacity value. The BOUNDS property is updated to the computed bounding box.

Syntax

Obj -> [IDLgrVolume::]ComputeBounds [, OPACITY=*value*] [, /RESET] [, VOLUMES=*int array*]

Arguments

None.

Keywords

OPACITY

Set this keyword to the opacity value to be used to determine which voxels are included within the bounding box. All voxels whose opacity lookup is greater than this value will be included. The default value is zero.

RESET

Set this keyword to cause the BOUNDS keyword of IDLgrVolume::Init to be reset to contain the entire volume.

VOLUMES

Set this keyword to an array of integers which select which volumes to consider when computing the bounding box. A non-zero value selects a volume to be searched. The default is to search all loaded volumes. For example: VOLUMES=[0,1] will cause ComputeBounds to search only the volume loaded in DATA1.

Version History

Introduced: 5.0

IDLgrVolume::GetCTM

The IDLgrVolume::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = *Obj* -> [IDLgrVolume::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Arguments

None.

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the volume object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVolume::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrVolume::GetProperty

The IDLgrVolume::GetProperty procedure method retrieves the value of a property or group of properties for the volume.

Syntax

Obj -> [IDLgrVolume::]GetProperty [, ALL=*variable*] [, PARENT=*variable*] [, VALID_DATA=*variable*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrVolume::Init followed by the word “Get” can be retrieved using IDLgrVolume::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

PARENT

Set this keyword equal to a named variable that will contain an object reference to the object that contains this object.

VALID_DATA

Set his keyword equal to a named variable that will contain an array of integers (one per volume, DATA0, DATA1, etc.) which have the value 1 if volume data has been loaded for that volume and 0 if that volume data is currently undefined.

XRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

YRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

ZRANGE

Set this keyword equal to a named variable that will contain a two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Version History

Introduced: 5.0

IDLgrVolume::Init

The IDLgrVolume::Init function method initializes the volume object. At least one volume must be specified, via arguments or keywords.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrVolume' [, *vol0* [, *vol1* [, *vol2* [, *vol3*]]]] [, AMBIENT{Get, Set}=*RGB vector*] [, BOUNDS{Get, Set}=*[xmin, ymin, zmin, xmax, ymax, zmax]*] [, CLIP_PLANES{Get, Set}=*array*] [, COMPOSITE_FUNCTION{Get, Set}={0 | 1 | 2 | 3}] [, CUTTING_PLANES{Get, Set}=*array*] [, DATA0{Get, Set}=*[d_x, d_y, d_z]*] [, DATA1{Get, Set}=*[d_x, d_y, d_z]*] [, DATA2{Get, Set}=*[d_x, d_y, d_z]*] [, DATA3{Get, Set}=*[d_x, d_y, d_z]*] [, DEPTH_CUE{Get, Set}=*[zbright, zdim]*] [, /HIDE{Get, Set}] [, HINTS{Get, Set}={0 | 1 | 2 | 3}] [, /INTERPOLATE{Get, Set}] [, /LIGHTING_MODEL{Get, Set}] [, NAME{Get, Set}=*string*] [, /NO_COPY{Get, Set}] [, OPACITY_TABLE0{Get, Set}=*256-element byte array*] [, OPACITY_TABLE1{Get, Set}=*256-element byte array*] [, RENDER_STEP{Get, Set}=*[x, y, z]*] [, RGB_TABLE0{Get, Set}=*256 x 3-element byte array*] [, RGB_TABLE1{Get, Set}=*256 x 3-element byte array*] [, /TWO_SIDED{Get, Set}] [, UVALUE{Get, Set}=*value*] [, VOLUME_SELECT{Get, Set}={0 | 1 | 2}] [, XCOORD_CONV{Get, Set}=*vector*] [, YCOORD_CONV{Get, Set}=*vector*] [, /ZBUFFER{Get, Set}] [, ZCOORD_CONV{Get, Set}=*vector*] [, ZERO_OPACITY_SKIP{Get, Set}={0 | 1}])

or

Result = *Obj* -> [IDLgrVolume::]Init([*vol0* [, *vol1* [, *vol2* [, *vol3*]]]]) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

vol_0

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol_1

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol_2

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol_3

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

Note

If two or more of the above arguments are specified, they must have matching dimensions.

Keywords

Properties retrievable via IDLgrVolume::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrVolume::SetProperty are indicated by the word "Set" following the keyword.

AMBIENT *(Get, Set)*

Use this keyword to set the color and intensity of the volume's base ambient lighting. Color is specified as an RGB vector. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING_MODEL is set.

BOUNDS *(Get, Set)*

Set this keyword to a six-element vector of the form [x_{min}, y_{min}, z_{min}, x_{max}, y_{max}, z_{max}], which represents the sub-volume to be rendered.

CLIP_PLANES (*Get, Set*)

Set this keyword to an array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A,B,C,D], where Ax+By+Cz+D = 0. Portions of this object

that fall in the half space Ax+By+Cz+D > 0 will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this keyword are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Note

Clipping planes are equivalent to cutting planes (refer to the CUTTING_PLANES keyword). The CUTTING_PLANES will be applied first, then the CLIP_PLANES (until a maximum number of planes is reached).

COMPOSITE_FUNCTION *(Get, Set)*

The composite function determines the value of a pixel on the viewing plane by analyzing the voxels falling along the corresponding ray, according to one of the following compositing functions:

- 0 = Alpha (default): Alpha-blending. The recursive equation

  ```
  dest' = src * srcalpha + dest * (1 - srcalpha)
  ```

  is used to compute the final pixel color.

- 1 = MIP: Maximum intensity projection. The value of each pixel on the viewing plane is set to the brightest voxel, as determined by its opacity. The most opaque voxel’s color appropriation is then reflected by the pixel on the viewing plane.

- 2 = Alpha sum: Alpha-blending. The recursive equation

  ```
  dest' = src + dest * ( 1 - srcalpha)
  ```

  is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.

- 3 = Average: Average-intensity projection. The resulting image is the average of all voxels along the corresponding ray.

CUTTING_PLANES *(Get, Set)*

Set this keyword to a floating-point array with dimensions (4, *n*) specifying the coefficients of *n* cutting planes. The cutting plane coefficients are in the form {{n_x, n_y, n_z, D}, ...} where $(n_x)X+(n_y)Y+(n_z)Z+ D > 0$, and ($X$, Y, Z) are the voxel coordinates. To clear the cutting planes, set this property to any scalar value (e.g. CUTTING_PLANES = 0). By default, no cutting planes are defined.

DATA0 *(Get, Set)*

Set this keyword to a three-element array of the format (d_x, d_y, d_z), which specifies a data volume. Setting this property is the same as including the *vol*$_0$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA1, DATA2, or DATA3, all existing data is removed from the object.

DATA1 *(Get, Set)*

Set this keyword to a three-element array of the format (d_x, d_y, d_z), which specifies a data volume. Setting this property is the same as including the *vol*$_1$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA2, or DATA3, all existing data is removed from the object.

DATA2 *(Get, Set)*

Set this keyword to a three-element array of the format (d_x, d_y, d_z), which specifies a data volume. Setting this property is the same as including the *vol*$_2$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA3, all existing data is removed from the object.

DATA3 *(Get, Set)*

Set this keyword to a three-element array of the format (d_x, d_y, d_z), which specifies a data volume. Setting this property is the same as including the *vol*$_3$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA2, all existing data is removed from the object.

Note

DATA0, DATA1, DATA2, and DATA3 sizes are dynamic.

DEPTH_CUE *(Get, Set)*

Set this keyword to a two-element floating-point array [*zbright, zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

HIDE *(Get, Set)*

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

HINTS *(Get, Set)*

Set this keyword to specify one of the following acceleration hints:

- 0 = Disables all acceleration hints (default).
- 1 = Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness.

A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.

- 2 = Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
- 3 = Selects the two acceleration options described above.

INTERPOLATE *(Get, Set)*

Set this keyword to indicate that Trilinear interpolation is to be used to determine the data value for each step on a ray. Setting this keyword improves the quality of images produced, at the cost of more computing time. especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

LIGHTING_MODEL *(Get, Set)*

Set this keyword to use the current lighting model during rendering in conjunction with a local gradient evaluation.

Note

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

NAME *(Get, Set)*

Set this keyword equal to a string containing the name associated with this object. The default is the null string, ' '.

NO_COPY *(Get, Set)*

Set this keyword to relocate volume data from the input variables to the volume object, leaving the input variables undefined. Only the DATA0 keyword and the *vol0* argument are affected. If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

OPACITY_TABLE0 *(Get, Set)*

Set this keyword to a 256-element byte array to specify an opacity table for DATA0. The default table is the linear ramp.

OPACITY_TABLE1 *(Get, Set)*

Set this keyword to a 256-element byte array to specify an opacity table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

RENDER_STEP *(Get, Set)*

Set this keyword to a three element vector of the form [*x*, *y*, *z*] to specify the stepping factor through the voxel matrix.

RGB_TABLE0 *(Get, Set)*

Set this keyword to a 256 x 3-element byte array to specify an RGB color table for DATA0. The default table is the linear ramp.

RGB_TABLE1 *(Get, Set)*

Set this keyword to a 256 x 3-element byte array to specify an RGB color table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

TWO_SIDED *(Get, Set)*

Set this keyword to force the lighting model to use a two-sided voxel gradient. The two-sided gradient is different from the one-sided gradient (default) in that the absolute value of the inner product of the light direction and the surface gradient is used instead of clamping to 0.0 for negative values.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

VOLUME_SELECT *(Get, Set)*

Set this keyword to an integer value to select the form of the volume to be rendered. The VOLUME_SELECT keyword is used to modify the `src` and `srcalpha` parameters for the COMPOSITE_FUNCTION keyword.

- 0 = render voxels from the 8bit DATA0 volume (the default)

```
src = RGB_TABLE0[DATA0]
srcalpha = OPACITY_TABLE0[DATA0]
```

- 1 = render voxels formed by modulating the RGBA components from DATA0 and DATA1 (after RGB and OPACITY table lookups).

```
src = (RGB_TABLE0[DATA0]*RGB_TABLE1[DATA1])/256
srcalpha=(OPACITY_TABLE0[DATA0]*OPACITY_TABLE1[DATA1])/256
```

- 2 = render voxels formed using a byte from DATA0 (red), DATA1 (green), DATA2(blue) and DATA3(alpha). The keywords OPACITY_TABLE0 and RGB_TABLE0, described above, are used to indirect the data from each volume before forming the RGBA pixel.

```
src=(RGB_TABLE[DATA0,0],RGB_TABLE[DATA1,1],RGB_TABLE[DATA2,2])/256
srcalpha = (OPACITY_TABLE0[DATA3])/256
```

XCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

YCOORD_CONV *(Get, Set)*

Set this keyword to a vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

ZBUFFER *(Get, Set)*

Set this keyword to clip the rendering to the current Z-buffer and then update the buffer. The default is to not modify the current Z-buffer.

ZCOORD_CONV *(Get, Set)*

Set this keyword to a vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]IDL converts, maintains, and returns this data as double-precision floating-point.

ZERO_OPACITY_SKIP *(Get, Set)*

Set this keyword to skip voxels with an opacity of 0. This keyword can increase the output contrast of MIP (MAXIMUM_INTENSITY) projections by allowing the background to show through. If this keyword is set, voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the keyword) continues to render voxels with an opacity of zero.

Obsolete Keywords

The following keywords are obsolete:

- CUTTING_PLANES

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrVolume::PickVoxel

The IDLgrVolume::PickVoxel function method computes the coordinates of the voxel projected to a location specified by the 2-D device coordinates point, [x_i, y_i], and the current Z-buffer. The function returns the volume indices as a a vector of three long integers. If the selected point is not within the volume, this function returns [-1,-1,-1].

Syntax

Result = *Obj* -> [IDLgrVolume::]PickVoxel (*Win*, *View*, *Point* [, PATH=*objref(s)*])

Arguments

Win

The IDLgrWindow object from which the Z-buffer is to be used.

View

The IDLgrView object that contains the volume.

Point

The [*x*, *y*] viewport coordinates of the point chosen.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a voxel coordinate. Each path object reference specified with this keyword must contain an alias. The voxel coordinate is computed for the version of the object falling within the specified path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.0

IDLgrVolume::SetProperty

The IDLgrVolume::SetProperty procedure method sets the value of a property or group of properties for the volume.

Syntax

Obj -> [IDLgrVolume::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrVolume::Init followed by the word “Set” can be set using IDLgrVolume::SetProperty.

Version History

Introduced: 5.0

IDLgrVRML

The IDLgrVRML object allows you to save the contents of an Object Graphics hierarchy into a VRML 2.0 format file. The graphics tree can only contain a single view due to limitations in the VRML specification. The resulting VRML file is interactive and allows you to explore the geometry interactively using a VRML browser.

Note

Objects or subclasses of this type can not be saved or restored.

Aspect ratios are difficult to duplicate as they can be browser dependent. The object is limited to the primitives supported by VRML. Texture maps (and images) will be inlined into the output file. While this will generate large VRML files, the files are fully self-contained.

Several entities cannot be translated perfectly. These include:

IDLgrImage objects

Rotation and Z buffer behavior are not completely supported. Image objects will be converted into texture mapped polygons. BLEND_FUNCTION is not completely supported (only binary srcAlpha,1-srcAlpha) This function is applied automatically if an alpha channel is present. It is also very browser dependent. Channel masks are not supported.

IDLgrPolygon and IDLgrSurface objects

Hidden line/hidden point display, color and vertex color blending with texture colors, and bottom color are not supported. Shading may be browser dependent. Front face culling is not supported and back face culling is only supported at the browser's discretion.

IDLgrLight objects

Lighting scope and intensity may be browser dependent.

IDLgrText objects

Text using the ONGLASS property is only supported for the initial view.

IDLgrViewgroup, IDLgrScene, IDLgrVolume objects

These objects are not supported.

IDLgrPalette objects

Palette objects are simulated using an RGB color model.

IDLgrPattern objects

Only solid or clear patterns are supported.

IDLgrFont, IDLgrSymbol objects

The THICK property is not supported.

IDLgrPolyline, IDLgrSymbol, IDLgrSurface, IDLgrPolygon and IDLgrPlot objects

Line attributes (thickness, linestyle) are not supported.

IDLgrView objects

Z-clipping control, aspect ratio preservation, the LOCATION property, and orthographic projections are not supported.

Destination objects

The COLOR_MODEL property is not fully supported in Indexed Color mode, when using a SHADER_RANGE (an RGB model will be substituted instead). The QUALITY property is not supported.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See IDLgrVRML::Init

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrVRML::Cleanup
- IDLgrVRML::Draw
- IDLgrVRML::GetDeviceInfo
- IDLgrVRML::GetFontnames
- IDLgrVRML::GetProperty
- IDLgrVRML::GetTextDimensions
- IDLgrVRML::Init
- IDLgrVRML::SetProperty

Version History

Introduced: 5.1

IDLgrVRML::Cleanup

The IDLgrVRML::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrVRML::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.1

IDLgrVRML::Draw

The IDLgrVRML::Draw procedure method draws the given picture to this graphics destination.

Syntax

Obj -> [IDLgrVRML::]Draw [, *Picture*]

Arguments

Picture

The view (an instance of an IDLgrView object) to be drawn. If the view has a LOCATION property, it is ignored.

Keywords

None.

Version History

Introduced: 5.1

IDLgrVRML::GetDeviceInfo

The IDLgrVRML::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj -> [IDLgrVRML::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None.

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_TEXTURE_DIMENSIONS* contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_VIEWPORT_DIMENSIONS* contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, *NAME* contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, *NUM_CPUS* contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, *VENDOR* contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, *VERSION* contains the version of the rendering device driver as a string.

Version History

Introduced: 5.1

MAX_NUM_CLIP_PLANES keyword: 5.6

IDLgrVRML::GetFontnames

The IDLgrVRML::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix N, "Fonts" for more information.

Syntax

Return = *Obj* ->[IDLgrVRML::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name, such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.1

IDLgrVRML::GetProperty

The IDLgrVRML::GetProperty procedure method retrieves the value of a property or group of properties for the VRML object.

Syntax

Obj -> [IDLgrVRML::]GetProperty [, ALL=*variable*]
[, SCREEN_DIMENSIONS=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrVRML::Init followed by the word “Get” can be retrieved using IDLgrVRML::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the retrievable properties associated with this object.

SCREEN_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this object associated. The screen dimensions are measured in device units.

Version History

Introduced: 5.1

IDLgrVRML::GetTextDimensions

The IDLgrVRML::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

Result = *Obj* ->[IDLgrVRML::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVRML::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.1

IDLgrVRML::Init

The IDLgrVRML::Init function method initializes the VRML object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrVRML' [, COLOR_MODEL{Get}={0 | 1}]
[, DIMENSIONS{Get, Set}=*[width, height]*] [, FILENAME{Get, Set}=*string*]
[, GRAPHICS_TREE{Get, Set}=*objref*] [, N_COLORS{Get}=*integer*{2 to 256}]
[, PALETTE{Get, Set}=*objref*] [, QUALITY{Get, Set}={0 | 1 | 2}]
[, RESOLUTION{Get, Set}=*[xres, yres]*] [, UNITS{Get, Set}={0 | 1 | 2 | 3}]
[, UVALUE{Get, Set}=*value*] [, WORLDINFO=*string array*]
[, WORLDTITLE=*string*])

or

Result = *Obj* -> [IDLgrVRML::]Init( ) (*Only in a subclass' Init method.*)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrVRML::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrVRML::SetProperty are indicated by the word "Set" following the keyword.

COLOR_MODEL *(Get)*

Set this keyword to the color model to be used for the buffer:

- 0=RGB (the default)
- 1=Color indexed.

DIMENSIONS *(Get, Set)*

Set this keyword to a two-element vector of the form [*width*, *height*] to specify the dimensions of the window in units specified by the UNITS property. The default is [640,480].

Note

The only use of this property is to support the use of normalized coordinates for the dimensions of the IDLgrView object passed to the IDLgrVRML::Draw method.

FILENAME *(Get, Set)*

Set this keyword to the name of a file into which the vector data will be saved. The default is `idl.wrl`.

GRAPHICS_TREE *(Get, Set)*

Set this keyword to an object reference of type IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

N_COLORS *(Get)*

Set this keyword to the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to indexed.

PALETTE *(Get, Set)*

Set this keyword to the object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the buffer’s color lookup table.

QUALITY *(Get, Set)*

Set this keyword to an integer indicating the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0=Low
- 1=Medium
- 2=High (the default)

RESOLUTION *(Get, Set)*

Set this keyword to a two-element vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel.

Note

This keyword is used for text scaling and partial aspect ratio preservation only. The default value is [0.0352778, 0.0352778] (72 DPI).

UNITS *(Get, Set)*

Set this keyword to indicate the units of measure for the DIMENSIONS property. Valid values are:

- 0=Device (the default)
- 1=Inches
- 2=Centimeters
- 3=Normalized (relative to 1600 x 1200).

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this user value to contain any information you wish.

WORLDINFO

Set this keyword to a list of strings for the info field of the VRML WorldInfo node. The default is the null string, ''.

WORLDTITLE

Set this keyword to a string containing the title for the VRML WorldInfo node, TITLE field. The default is `'IDL VRML file'`.

Version History

Introduced: 5.1

IDLgrVRML::SetProperty

The IDLgrVRML::SetProperty procedure method sets the value of a property or group of properties for the VRML world.

Syntax

Obj -> [IDLgrVRML::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrVRML::Init followed by the word “Set” can be retrieved using IDLgrVRML::SetProperty.

Version History

Introduced: 5.1

IDLgrWindow

A window object is a representation of an on-screen area on a display device that serves as a graphics destination.

Note

Objects or subclasses of this type can not be saved or restored.

Note on Window Size Limits

The OpenGL libraries IDL uses impose limits on the maximum size of a drawable area. The limits are device-dependent — they depend both on your graphics hardware and the setting of the RENDERER property. Currently, the smallest maximum drawable area on any IDL platform is 1280 x 1024 pixels; the limit on your system may be larger.

Superclasses

This class has no superclass.

Subclasses

This class has no subclasses.

Creation

See “IDLgrWindow::Init” on page 3030.

Methods

Intrinsic Methods

This class has the following methods:

- IDLgrWindow::Cleanup
- IDLgrWindow::Draw
- IDLgrWindow::Erase
- IDLgrWindow::GetContiguousPixels
- IDLgrWindow::GetDeviceInfo

- IDLgrWindow::GetFontnames
- IDLgrWindow::GetProperty
- IDLgrWindow::GetTextDimensions
- IDLgrWindow::Iconify
- IDLgrWindow::Init
- IDLgrWindow::PickData
- IDLgrWindow::Read
- IDLgrWindow::Select
- IDLgrWindow::SetCurrentCursor
- IDLgrWindow::SetProperty
- IDLgrWindow::Show

Version History

Introduced: 5.0

IDLgrWindow::Cleanup

The IDLgrWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLgrWindow::]Cleanup (*Only in subclass' Cleanup method*.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrWindow::Draw

The IDLgrWindow::Draw procedure method draws the specified scene or view object to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj -> [IDLgrWindow::]Draw [, *Picture*] [, CREATE_INSTANCE={1 | 2}] [, /DRAW_INSTANCE]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that this scene or view is the changing part of a drawing. It is overlaid on the result of the most recent CREATE_INSTANCE draw.

Version History

Introduced: 5.0

IDLgrWindow::Erase

The IDLgrWindow::Erase procedure method erases the entire contents of the window.

Syntax

Obj -> [IDLgrWindow::]Erase [, COLOR=*index or RGB vector*]

Arguments

None.

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as an RGB vector. The default erase color is white.

Version History

Introduced: 5.0

IDLgrWindow::GetContiguousPixels

The IDLgrWindow::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Return = *Obj* `->` [IDLgrWindow::]GetContiguousPixels()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrWindow::GetDeviceInfo

The IDLgrWindow::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=0 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj -> [IDLgrWindow::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None.

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

Introduced: 5.0

MAX_NUM_CLIP_PLANES keyword: 5.6

IDLgrWindow::GetFontnames

The IDLgrWindow::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix N, "Fonts" for more information.

Syntax

Return = *Obj* -> [IDLgrWindow::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.0

IDLgrWindow::GetProperty

The IDLgrWindow::GetProperty procedure method retrieves the value of a property or group of properties for the window.

Syntax

Obj -> [IDLgrWindow::]GetProperty [, ALL=*variable*] [, IMAGE_DATA=*variable*] [, RESOLUTION=*variable*] [, SCREEN_DIMENSIONS=*variable*] [, ZBUFFER_DATA=*variable*]

Arguments

None.

Keywords

Any keyword to IDLgrWindow::Init followed by the word "Get" can be retrieved using IDLgrWindow::GetProperty. To retrieve a property, set the associated keyword equal to a named variable that will contain the property value.

In addition, the following keywords are available:

ALL

Set this keyword to a named variable that will contain an anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

IMAGE_DATA

Set this keyword to a named variable that will contain a byte array representing the image that is currently displayed in the window. If the window object uses an RGB color model, the returned array will have dimensions (3, *winXSize*, *winYSize*), or (4, *winXSize, winYSize*) if an alpha channel is included. If the window object uses an Indexed color model, the returned array will have dimensions (*winXSize*, *winYSize*). See "IDLgrWindow::Read" on page 3038 for more information.

RESOLUTION

Set this keyword to a named variable that will contain a vector of the form [*xres*, *yres*] reporting the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

SCREEN_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this window is associated. The screen dimensions are measured in device units.

Note

The maximum screen dimension size depends on the graphics device.

ZBUFFER_DATA

Set this keyword to a named variable that will contain a float array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Version History

Introduced: 5.0

IDLgrWindow::GetTextDimensions

The IDLgrWindow::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

Result = *Obj* ->[IDLgrWindow::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values are the distance to travel (parallel to the UPDIR direction) from the baseline to reach the bottom of all the descenders for the string; the values will be negative or 0. This keyword is only valid if *TextObj* is of the class IDLgrText.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrWindow::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

Introduced: 5.0

IDLgrWindow::Iconify

The IDLgrWindow::Iconify procedure method iconifies or de-iconifies the window.

Note

Iconification under window systems is solely handled by the window manager; client applications, such as IDL, do not have the capability to manage icons. The Iconify method provides a hint to the window manager, which applies the information as it sees fit.

Syntax

Obj -> [IDLgrWindow::]Iconify, *IconFlag*

Arguments

IconFlag

Set *IconFlag* to 1 (one) to iconify the window or to 0 (zero) to restore the window. If the window is already restored, it is brought to the front of the window stack.

Keywords

None.

Version History

Introduced: 5.0

IDLgrWindow::Init

The IDLgrWindow::Init function method initializes the window object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrWindow' [, COLOR_MODEL{Get}={0 | 1}] [, DIMENSIONS{Get, Set} =*[width, height]*] [, GRAPHICS_TREE{Get, Set}=*objref of type IDLgrScene, IDLgrViewgroup, or IDLgrView*] [, LOCATION{Get, Set}=*[x, y]*] [, N_COLORS{Get}=*integer*{2 to 256}] [, PALETTE{Get, Set}=*objref*] [, QUALITY{Get, Set}={0 | 1 | 2}] [, RENDERER{Get}={0 | 1}] [, RETAIN{Get}={0 | 1 | 2}] [, TITLE{Get, Set}=*string*] [, UNITS{Get, Set}={0 | 1 | 2 | 3}] [, UVALUE{Get, Set}=*value*])

or

Result = *Obj* -> [IDLgrWindow::]Init( ) (*Only in a subclass' Init method*.)

X Windows Keywords: [, DISPLAY_NAME{Get}=*string*]

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

None.

Keywords

Properties retrievable via IDLgrWindow::GetProperty are indicated by the word "Get" following the keyword. Properties settable via IDLgrWindow::SetProperty are indicated by the word "Set" following the keyword.

COLOR_MODEL *(Get)*

Set this keyword to the color model to be used for the window:

- 0 = RGB (default)
- 1 = Color Index

Note

For some X11 display situations, IDL may not be able to support a color index model destination object in object graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations.

DIMENSIONS *(Get, Set)*

Set this keyword to a two-element vector of the form [*width*, *height*] to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the value of the “Default Window Width” and “Default Window Height” preferences set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE, the DIMENSIONS property is set equal to one quarter of the screen size. There are limits on the maximum size of an IDLgrWindow object; see “Note on Window Size Limits” on page 3015 for details.

Note

Changing DIMENSIONS properties is merely a request and may be ignored for various reasons.

DISPLAY_NAME *(Get) (X Only)*

Set this keyword to the name of the X Windows display on which the window is to appear.

GRAPHICS_TREE *(Get, Set)*

Set this keyword to an object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

LOCATION *(Get, Set)*

Set this keyword to a two-element vector of the form [*x*, *y*] to specify the location of the upper lefthand corner of the window relative to the display screen, in units specified by the UNITS property. By default, the window is positioned at one of four quadrants on the display screen, and the location is measured in device units.

Note

Changing LOCATION properties is merely a request and may be ignored for various reasons. LOCATION may be adjusted to take into account window decorations.

N_COLORS *(Get)*

Set this keyword to the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Indexed (1). This keyword is ignored if COLOR_MODEL is set to RGB (0).

Note

If COLOR_MODEL is set to Color Index (1), setting N_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the IDLgrWindow::GetProperty method. The actual number of available colors depends on your system and also on how you have used IDL.

PALETTE *(Get, Set)*

Set this keyword to the object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table, applicable if the Indexed color model is used.

QUALITY *(Get, Set)*

Set this keyword to an integer indicating the rendering quality at which graphics are to be drawn to this destination. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default).

RENDERER *(Get)*

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of an IDLgrWindow object; see "Note on Window Size Limits" on page 3015 for details.

RETAIN *(Get)*

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the "Backing Store" preference set in the IDL Development Environment's (IDLDE) Preferences dialog. If there is no preference file for the IDLDE (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

- 0 = No backing store.
- 1 = The server or window system is requested to provide the backing store. Note that requesting backing store from the server is only a request; backing store may not be provided in all situations.
- 2 = Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN keyword of IDLgrWindow::GetProperty. IDL may also alter the RENDERER keyword while attempting to provide backing store.

In IDL Object Graphics, it is almost always best to disable backing store (that is, set the RETAIN property equal to zero). This is because drawing to an off-screen pixmap (which is what happens when backing store is enabled) almost always bypasses any hardware graphics acceleration that may be available, causing all rendering to be done in software. To ensure that windows are redrawn properly, enable the generation of expose events on the WIDGET_DRAW window and redraw the window explicitly when an expose event is received.

Note

If you are using software rendering (that is, the RENDERER property is set equal to one), IDL will refresh the window automatically regardless of the setting of the RETAIN property.

TITLE *(Get, Set)*

Set this keyword equal to a string that represents the title of the window.

UNITS *(Get, Set)*

Set this keyword to indicate the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the screen.

Note

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units.

UVALUE *(Get, Set)*

Set this keyword to a value of any type. You can use this “user value” to contain any information you wish. Remember that if you set the user value equal to a pointer or object reference, you should destroy the pointer or object reference explicitly when destroying the object it is a user value of.

Version History

Introduced: 5.0

IDLgrWindow::PickData

The IDLgrWindow::PickData function method maps a point in the two-dimensional device space of the window to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the window's device space "hits" a graphic object, or zero if no object was "hit". PickData returns -1 if the point selected falls outside of the specified view or window.

Syntax

Result = *Obj* -> [IDLgrWindow::]PickData(*View*, *Object*, *Location*, *XYZLocation* [, DIMENSIONS=*[w,h]*] [, PATH=*objref(s)*] [, PICK_STATUS=*variable*])

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Location

A two-element vector [*x*, *y*] specifying the location in the window's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the LOCATION or DIMENSIONS properties (this is only possible with IDLgrAxis, IDLgrImage, and IDLgrText objects), these transformations will *not* be included in the data coordinates returned by the PickData function. This means that you may need to re-apply the transformation accomplished by specifying LOCATION or DIMENSIONS once you have retrieved the data coordinates with PickData. This situation does not occur if you transform the axis, text, or image object using the [XYZ]COORD_CONV properties.

Keywords

DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates [*x*, *y*] specified in the *Location* argument, and will occupy the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))
```

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions [*3*, *w*, *h*].

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table A-30: PICK_STATUS Keyword Values

Version History

Introduced: 5.0

PICK_STATUS keyword: 5.6

IDLgrWindow::Read

The IDLgrWindow::Read function method reads an image from a window. The returned value is an instance of the IDLgrImage object class.

Syntax

Result = *Obj* -> [IDLgrWindow::]Read()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDLgrWindow::Select

The IDLgrWindow::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

Result = Obj -> [IDLgrWindow::]Select(*Picture, XY* [, DIMENSIONS=*[width, height]*] [, UNITS={0 | 1 | 2 | 3}])

Arguments

Picture

The view or scene (an instance of the IDLgrView, IDLgrViewgroup, or IDLgrScene class) whose children are among the candidates for selection.

If the first argument is a scene, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the last object drawn will appear at a lower index in the list.

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

Keywords

DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify that the selection box will have a width *w* and a height *h*, and will be centered about the coordinates [*x*, *y*] specified in the *XY* argument. The box occupies the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/1), y+(h/2))
```

Any object that intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination.

Version History

Introduced: 5.0

IDLgrWindow::SetCurrentCursor

The IDLgrWindow::SetCurrentCursor procedure method sets the current cursor image to be used while positioned over a drawing area.

Syntax

Obj-> [IDLgrWindow::]SetCurrentCursor [, *CursorName*] [, IMAGE=*16 x 16 bitmap*] [, MASK=*16 x 16 bitmap*] [, HOTSPOT=*[x, y]*]

X Windows Keywords: [, STANDARD=*index*]

Arguments

CursorName

A string that specifies which built-in cursor to use. This argument is ignored if any keywords to this routine are set. This string can either be a name provided to the REGISTER_CURSOR routine or one of the following:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

Keywords

IMAGE

Set this keyword to a 16x16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the “hot spot” can be provided via the HOTSPOT keyword.

MASK

When the IMAGE keyword is set, the MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are “masked out”.

HOTSPOT

Set this keyword to a two-element vector specifying the [*x*, *y*] pixel offset of the cursor “hot spot”, the point which is considered to be the mouse position, from the upper left corner of the cursor image. This parameter is only applicable if IMAGE is provided. The cursor image is displayed top-down (the first row is displayed at the top).

STANDARD (X Only)

Set this keyword to an X11 cursor font index to change the appearance of the cursor in the IDL graphics window to a glyph in this font. On non-X platforms, setting this keyword displays the crosshair cursor.

Version History

Introduced: 5.0

CursorName argument: 5.6

IDLgrWindow::SetProperty

The IDLgrWindow::SetProperty procedure method sets the value of a property or group of properties for the window.

Syntax

Obj -> [IDLgrWindow::]SetProperty

Arguments

None.

Keywords

Any keyword to IDLgrWindow::Init followed by the word “Set” can be set using IDLgrWindow::SetProperty.

Version History

Introduced: 5.0

IDLgrWindow::Show

The IDLgrWindow::Show procedure method exposes or hides a window.

Syntax

Obj -> [IDLgrWindow::]Show, *Position*

Arguments

Position

Set this argument equal to a non-zero value to expose the window, or to 0 to hide the window.

Keywords

None.

Version History

Introduced: 5.0

TrackBall

A TrackBall object translates widget events from a draw widget (created with the WIDGET_DRAW function) into transformations that emulate a virtual trackball (for transforming object graphics in three dimensions).

This object class is implemented in the IDL language. Its source code can be found in the file `trackball__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

This class has no superclasses.

Subclasses

This class has no subclasses.

Creation

See "TrackBall::Init" on page 3046.

Methods

Intrinsic Methods

This class has the following methods:

- TrackBall::Init
- TrackBall::Reset
- TrackBall::Update

Version History

Introduced: 5.0

TrackBall::Init

The TrackBall::Init function method initializes the TrackBall object.

Syntax

Obj = OBJ_NEW('TrackBall', *Center*, *Radius* [, AXIS={0 | 1 | 2}] [, /CONSTRAIN] [, MOUSE={1 | 2 | 4}])

or

Result = *Obj* -> [TrackBall::]Init(*Center*, *Radius*) (*Only in a subclass' Init method*.)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Center

A two-element vector, [*X*, *Y*], specifying the center coordinates of the trackball. *X* and *Y* should be specified in device units.

Radius

The radius of the trackball, specified in device units.

Keywords

AXIS

Set this keyword to an integer value to indicate the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.
- 2 = Rotate only around the *Z* axis (this is the default).

CONSTRAIN

Set this keyword to indicate that the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

Version History

Introduced: 5.0

TrackBall::Reset

The TrackBall::Reset procedure method resets the state of the TrackBall object.

Syntax

Obj -> [TrackBall::]Reset, *Center*, *Radius* [, AXIS={0 | 1 | 2}] [, /CONSTRAIN] [, MOUSE={1 | 2 | 4}]

Arguments

Center

A two-element vector, [*X*, *Y*], specifying the center coordinates of the trackball. *X* and *Y* should be specified in device units.

Radius

The radius of the trackball, specified in device units.

Keywords

AXIS

Set this keyword to an integer value to indicate the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.s
- 2 = Rotate only around the *Z* axis (this is the default).

CONSTRAIN

Set this keyword to indicate that the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

Version History

Introduced: 5.0

TrackBall::Update

The TrackBall::Update function method updates the state of the TrackBall object based on the information contained in the input widget event structure. The return value is nonzero if a transformation matrix is calculated as a result of the event, or zero otherwise.

Syntax

Result = *Obj* -> [TrackBall::]Update(*sEvent* [, MOUSE={1 | 2 | 4}] [, TRANSFORM=*variable*] [, /TRANSLATE])

Arguments

sEvent

The widget event structure.

Keywords

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

TRANSFORM

Set this keyword to a named variable that will contain a 4 x 4 element floating-point array if a new transformations matrix is calculated as a result of the widget event.

TRANSLATE

Set this keyword to indicate that the trackball movement should be constrained to translation in the *X*-*Y* plane rather than rotation about an axis.

Example

The example code below provides a skeleton for a widget-based application that uses the TrackBall object to interactively change the orientation of graphics.

Create a trackball centered on a 512x512 pixel drawable area, and a view containing the model to be manipulated:

```
xdim = 512
ydim = 512
wBase = WIDGET_BASE()
wDraw = WIDGET_DRAW(wBase, XSIZE=xdim, YSIZE=ydim, $
    GRAPHICS_LEVEL=2, /BUTTON_EVENTS, $
    /MOTION_EVENTS, /EXPOSE_EVENTS, RETAIN=0 )
WIDGET_CONTROL, wBase, /REALIZE
WIDGET_CONTROL, wDraw, GET_VALUE=oWindow

oTrackball = OBJ_NEW('Trackball', [xdim/2.,ydim/2.], xdim/2.)
oView = OBJ_NEW('IDLgrView')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
XMANAGER, 'TrackEx', wBase
```

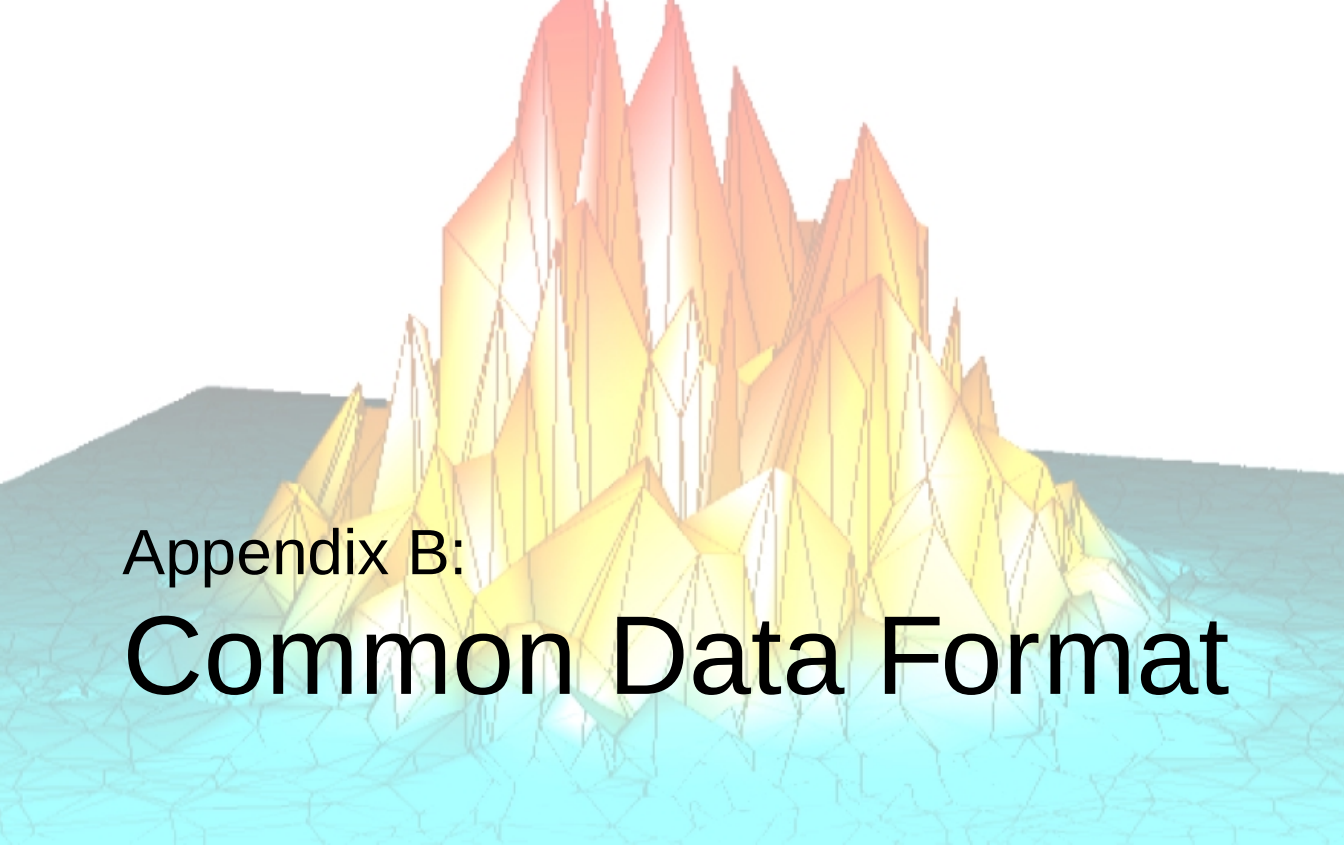
You must handle the trackball updates in the widget event-handling code. As the trackball transformation changes, update the transformation for the model object, and redraw the view:

```
PRO TrackEx_Event, sEvent
...
bHaveXform = oTrackball->Update( sEvent, TRANSFORM=TrackXform )
IF (bHaveXform) THEN BEGIN
oModel->GetProperty, TRANSFORM=ModelXform
oModel->SetProperty, TRANSFORM=ModelXform # TrackXform
oWindow->Draw, oView
ENDIF
...
END
```

For a complete example, see the file `surf_track.pro`, located in the `examples/visual` subdirectory of the IDL distribution. The SURF_TRACK procedure uses IDL widgets to create a graphical user interface to an object tree, creates a surface object from user-specified data (or from default data, if none is specified), and places the surface object in an IDL draw widget. The SURF_TRACK interface allows the user to specify several attributes of the object hierarchy via pulldown menus.

Version History

Introduced: 5.0



Appendix B: Common Data Format

The following topics are covered in this appendix:

Overview 3054
Variables and Attributes 3055
CDF File Options 3057
Creating CDF Files 3058
Alphabetical Listing of CDF Routines . . 3060

Overview

The Common Data Format is a file format that facilitates the storage and retrieval of multi-dimensional scientific data. This version of IDL supports CDF 2.6r7. IDL's CDF routines all begin with the prefix "CDF_".

CDF is a product of the National Space Science Data Center (NSSDC). General information about CDF, including the "frequently-asked-questions" (FAQ) list, software, and CDF's IDL library (an alternative interface between CDF and IDL) are available on the World Wide Web at:

```
http://nssdc.gsfc.nasa.gov/cdf/cdf_home.html
```

If you do not have access to the WWW you can get CDF information via ftp at:

```
ftp://nssdc.gsfc.nasa.gov/pub/cdf/FAQ.doc
```

For assistance via e-mail, send a message to the internet address:

```
cdfsupport@nssdca.gsfc.nasa.gov
```

Note

This version of IDL supports CDF V2.6r7. Note that CDF V2.6 files are not readable by previous versions of CDF.

Variables and Attributes

Information in a CDF file consists of attributes (metadata) and collections of data records (variables).

Variables

IDL can create CDF files representing any data that can be stored in a zero- to eight-dimensional array. CDF supports two distinct types of variables, *rVariables* and *zVariables*. For reasons of efficiency, CDF uses variances to indicate whether data is unique between records and dimensions. For example, consider a data set of simultaneous surface temperatures at a variety of locations, the IDL code for creating the CDF file is included at the end of this section. A variable representing “GMT time” will vary from record to record, but not dimension to dimension (since all data are taken simultaneously). On the other hand, a variable such as longitude may not vary from record to record, but will vary from dimension to dimension. Record variance is set using the REC_VARY and REC_NOVARY keywords to CDF_VARCREATE, while dimensional variance is set through the *DimVary* argument to CDF_VARCREATE. In both cases, the default is varying data.

rVariables

rVariables (or regular variables) are multidimensional arrays of values, each having the same dimensions. That is, all *rVariables* in a CDF must have the same number of dimensions and dimension sizes. In IDL, the *rVariable* dimension sizes are declared when the CDF file is first created with CDF_CREATE. In the example at the end of this section, all variables except time are *rVariables*.

zVariables

zVariables (The *z* doesn’t stand for anything—the CDF people just like the letter z) are multidimensional arrays of values of the same data type. *zVariables* can have different dimensionality from other *zVariables* and *rVariables*. In general, *zVariables* are much more flexible, and therefore easier to use, than *rVariables*.

For more discussion on CDF variables, see section 1.5 (“Organizing Your Data in CDF”) of the version 2.6 *CDF User’s Guide*.

Attributes

Attributes can contain auxiliary information about an entire CDF file (*global scope* attributes or gAttributes), or about particular CDF variables (*variable scope* attributes or *rAttributes*/*zAttributes* depending on variable type). CDF attributes can be scalar or vector in nature, and of any valid datatype. In the case of vector, or multiple entry, attributes the user must keep track of the entry numbers (in CDF terms these are the gEntry, rEntry, or zEntry numbers depending on attribute type). For example, every rVariable in a CDF file might have an rAttribute named “Date”. A vector *zVariable* might have a *zAttribute* named “Location” with values such as [“Melbourne Beach”, “Crowley”, ...]. A global attribute “MODS” might be used to keep track of the modification history of a CDF file (see “CDF_ATTPUT” on page 3072). Note however, that variables cannot have multiple attributes with the same names. In IDL, CDF attributes are created with CDF_ATTPUT and retrieved with CDF_ATTGET.

For more on CDF variables, see section 1.6 (“Attributes”) of the version 2.6 *CDF User’s Guide*. Certain standard attributes are required for a file to conform to the NSSDC standard. For a description of these attributes see section 2.6.1 (“Standard Attributes”) of the Version 2.6 *CDF User’s Guide.*

Specifying Attributes and Variables

Variables and attributes can be referred to either by name or by their ID numbers in most CDF routines. For example, in the CDF_VARCREATE command shown in the example under “Type Conversion” on page 3059, the following command would have been equivalent:

```
; Reference by variable ID:
CDF_VARCREATE, fileid, varid, '12'
```

CDF File Options

File Type

The SINGLE_FILE and MULTI_FILE keywords to CDF_CREATE allow CDFs to be written as either:

1. all data in a single file, or
2. a separate file for each variable, plus a master file for global information.

The default is MULTI_FILE. For more discussion on CDF file format options, see section 1.4.1 of the version 2.6 *CDF User's Guide*.

Data Encodings/Decodings

Keywords to CDF_CREATE allow files to be written in a variety of data encoding and decoding options. (For example, the /SUN_ENCODING keyword creates a file in the SUN native encoding scheme). The default encoding/decoding is network (XDR). All CDF encodings and decodings can be written or read on all platforms, but matching the encoding with the architecture used provides the best performance. If you work in a single-platform environment most of the time, select HOST_ENCODING for maximum performance. If you know that the CDF file will be transported to a computer using another architecture, specify the encoding for the target architecture or specify NETWORK_ENCODING (the default). Specifying the target architecture provides maximum performance on that architecture; specifying NETWORK_ENCODING provides maximum flexibility.

For more on CDF encoding/decoding methods and combinations, see sections 2.2.7 ("Encoding") and 2.2.8 ("Decoding") of the version 2.6 *CDF User's Guide*.

Creating CDF Files

The following list details the basic IDL commands needed to create a new CDF file:

- CDF_CREATE: Call this procedure to begin creating a new file. CDF_CREATE contains a number of keywords which affect the internal format of the new CDF file.
- CDF_VARCREATE: Define the variables to be used in the file.
- CDF_ATTPUT: Optionally, use attributes to describe the data.
- CDF_VARPUT: Write the appropriate data to the CDF file.
- CDF_CLOSE: Close the file.

Note

On Windows, CDF routines can save and retrieve data sets greater than 64 KB in size.

Reading CDF Files

The following commands are the basic commands needed to read data from a CDF file:

- CDF_OPEN: Open an existing CDF file.
- CDF_INQUIRE: Call this function to find the general information about the contents of the CDF file.
- CDF_CONTROL: Call this function to obtain further information about the CDF file
- CDF_VARINQ: Retrieve the names, types, sizes, and other information about the variables in the CDF file.
- CDF_VARGET: Retrieve the variable values.
- CDF_ATTINQ: Optionally, retrieve the names, scope and other information about the CDFs attributes.
- CDF_ATTGET: Optionally, retrieve the attributes.
- CDF_CLOSE: Close the file.
- If the structure of the CDF file is already known, the inquiry routines do not need to be called—only CDF_OPEN, CDF_ATTGET, CDF_VARGET, and CDF_CLOSE would be needed.

Type Conversion

Values are converted to the appropriate type before being written to a CDF file. For example, in the commands below, IDL converts the string “12” to a floating-point 12.0 before writing it:

```
varid=CDF_VARCREATE(fileid, 'VarName',['VARY','VARY'],$
   DIM=[2,3+5],/CDF_FLOAT)
CDF_VARPUT, fileid, 'VarName', '12' ; Reference by variable ID
```

Example: Creating a CDF File

The following is a simple example demonstrates the basic procedure used in creating a CDF file. See “Variables and Attributes” on page 3055 for a discussion of the variances used in this example. See the documentation for individual CDF routines for more specific examples.

```
id = CDF_CREATE('Temperature.cdf', [2,3], /CLOBBER )
att_id = CDF_ATTCREATE(id, 'Title', /GLOBAL)
CDF_ATTPUT, id, att_id, 0, 'My Fancy CDF'
att1_id = CDF_ATTCREATE(id, 'Planet', /GLOBAL)
CDF_ATTPUT, id, 'Planet', 0, 'Mars'
time_id = CDF_VARCREATE(id, 'Time', ['NOVARY', 'NOVARY'], $
   /REC_VARY)
att2_id = CDF_ATTCREATE(id, 'Time Standard', /VARIABLE_SCOPE)
; times are every half hour starting a 8 am GMT.
CDF_ATTPUT, id, att2_id, time_id, 'GMT'
FOR I=0,9 DO CDF_VARPUT, id, time_id, 8.+ 0.5 * I, rec_start=I
temp_id = CDF_VARCREATE(id, 'Temp', ['VARY', 'VARY'], $
   /REC_VARY, /ZVAR, DIMENSIONS=[2,3])
long_id = CDF_VARCREATE(id, 'Longitude', ['VARY', 'VARY'], $
   /REC_NOVARY)
lat_id = CDF_VARCREATE(id, 'Latitude', ['VARY', 'VARY'], $
   /REC_NOVARY)
; write 10 temperature records:
CDF_VARPUT, id, temp_id, FINDGEN(2, 3, 10)
; create longitudes:
CDF_VARPUT, id, long_id, [[10.0, 12.0], [8.0, 6.0], [3.0, 2.0]]
; create latitudes:
CDF_VARPUT, id, lat_id, [[40.0, 42.0], [38.0, 34.0],[30.0, 31.0]]
CDF_CLOSE, id
```

Alphabetical Listing of CDF Routines

The remainder of this chapter is an alphabetical listing of CDF Routines.

CDF_ATTCREATE

The CDF_ATTCREATE function creates a new attribute in the specified Common Data Format file. If successful, the attribute ID is returned.

Syntax

Result = CDF_ATTCREATE(*Id*, *Attribute_Name* [, /GLOBAL_SCOPE] [, /VARIABLE_SCOPE])

Return Value

Returns the attribute ID.

Arguments

Id

The CDF ID of the file for which a new attribute is created, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute_Name

A string containing the name of the attribute to be created.

Keywords

GLOBAL_SCOPE

Set this keyword to make the scope of the attribute global. This is the default.

VARIABLE_SCOPE

Set this keyword to indicate that the attribute's scope is per variable.

Examples

```
id = CDF_OPEN('test') ; Create a CDF file.
xx = CDF_ATTCREATE(id, 'Attribute-1', /GLOBAL_SCOPE)
CDF_ATTRENAME, id, 'Attribute-1', 'My Favorite Attribute'
PRINT, CDF_ATTNUM(id, 'My Favorite Attribute')
CDF_CLOSE, id ; Close the CDF file.
```

Version History

Introduced: Pre 4.0

CDF_ATTDELETE

The CDF_ATTDELETE procedure deletes an attribute from the specified CDF file. Note that the attribute's entries are also deleted, and that the attributes that numerically follow the deleted attribute within the CDF file are automatically renumbered.

Syntax

CDF_ATTDELETE, *Id*, *Attribute* [, *EntryNum*] [, /ZVARIABLE]

Arguments

ID

The CDF ID of the file containing the *Attribute* to be deleted, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute

A string containing the name or zero-based attribute number of the attribute to be deleted.

EntryNum

The entry number to delete. If EntryNum is not specified, the entire attribute is deleted. If the attribute is variable in scope, this is either the name or number of the variable the attribute is to be associated with. If the attribute is global in scope, this is the actual gEntry. It is the user's responsibility to keep track of valid gEntry numbers. Normally, gEntry numbers will begin with 0 or 1 and will increase up to MAXGENTRY (as reported in the GET_ATTR_INFO structure returned by CDF_CONTROL), but this is not required.

Keywords

ZVARIABLE

If EntryNum is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that EntryNum is an rVariable ID. Note: the attribute must have a scope of VARIABLE_SCOPE.

Examples

```
cid = CDF_CREATE('DEMOattdelete')
attr1_id = CDF_ATTCREATE(cid, 'GLOBAL_ATTR1', /GLOBAL_SCOPE)
attr2_id = CDF_ATTCREATE(cid, 'GLOBAL_ATTR2', /GLOBAL_SCOPE)
attr3_id = CDF_ATTCREATE(cid, 'VAR_ATTR1', /VARIABLE_SCOPE)
attr4_id = CDF_ATTCREATE(cid, 'VAR_ATTR2', /VARIABLE_SCOPE)

; Check the number of attributes:
info = CDF_INQUIRE(cid)
HELP, info.natts

; Delete the first and third attributes:
CDF_ATTDELETE, cid, 'GLOBAL_ATTR1'
; The attribute numbers are zero-based and automatically
; renumbered
CDF_ATTDELETE, cid, 1

; Select the new first attribute:
CDF_ATTINQ, cid, 0, name, scope, MaxEntry, MaxZentry
HELP, name, scope

CDF_DELETE, cid
```

IDL Output

```
<Expression>    LONG      =            4

NAME            STRING    = 'GLOBAL_ATTR2'
SCOPE           STRING    = 'GLOBAL_SCOPE'
```

Version History

Introduced: 4.0.1b

See Also

CDF_ATTCREATE, CDF_ATTGET, CDF_ATTEXISTS, CDF_ATTINQ, CDF_ATTPUT, CDF_ATTRENAME

CDF_ATTEXISTS

The CDF_ATTEXISTS function determines whether a given attribute exists in the specified CDF file. Attributes may be specified by name or number.

Syntax

Result = CDF_ATTEXISTS(*Id*, *Attribute* [, *EntryNum*] [, /ZVARIABLE])

Return Value

Returns TRUE (1) if the specified attribute exists or FALSE (0) if it does not exist

Arguments

Id

The CDF ID of the file containing the Attribute to be checked, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute

A string containing the name or zero-based attribute number of the attribute to be checked.

EntryNum

The entry number to confirm. If EntryNum is not specified, the entire file is searched for the specified attribute. If the attribute is variable in scope, this is either the name or number of the variable the attribute is to be associated with. If the attribute is global in scope, this is the actual gEntry. It is the user's responsibility to keep track of valid gEntry numbers. Normally gEntry numbers will begin with 0 or 1 and will increase up to MAXGENTRY (as reported in the GET_ATTR_INFO structure returned by CDF_CONTROL), but this is not required.

Keywords

ZVARIABLE

If EntryNum is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that EntryNum is an rVariable ID. Note: the attribute must have a scope of VARIABLE_SCOPE.

Examples

Create a function to test an attribute's existence and return a string:

```
FUNCTION exists, cdfid, attname_or_number
IF CDF_ATTEXISTS(cdfid, attname_or_number) THEN $
   RETURN,' Attribute Exists' ELSE $
   RETURN,' Attribute Does Not Exist'
END

; Create a CDF with 2 attributes:
cdfid = CDF_CREATE('DEMOattexists')
attr1_id = CDF_ATTCREATE(cdfid, 'GLOBAL_ATT' , /GLOBAL_SCOPE)
attr2_id = CDF_ATTCREATE(cdfid, 'VARIABLE_ATT', /VARIABLE_SCOPE)

; Check the existence of the two attributes, plus a third that
; does not exist:
PRINT, EXISTS(cdfid, attr1_id)
PRINT, EXISTS(cdfid, 1)
PRINT, EXISTS(cdfid, 'BAD ATTR')

CDF_DELETE, cdfid
```

IDL Output

```
Attribute Exists
Attribute Exists
Attribute Does Not Exist
```

Version History

Introduced: 4.0.1b

See Also

CDF_ATTCREATE, CDF_ATTGET, CDF_ATTDELETE, CDF_ATTINQ, CDF_ATTPUT, CDF_ATTRENAME

CDF_ATTGET

The CDF_ATTGET procedure reads an attribute entry from a CDF file.

Syntax

CDF_ATTGET, *Id*, *Attribute*, *EntryNum*, *Value* [, CDF_TYPE= *variable*] [, /ZVARIABLE]

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute

A string containing the name of the attribute *or* the attribute number to be written.

EntryNum

The entry number. If the attribute is variable in scope, this is either the name or number of the variable the attribute is to be associated with. If the attribute is global in scope, this is the actual gEntry. It is the user's responsibility to keep track of valid gEntry numbers. Normally, gEntry numbers will begin with 0 or 1 and will increase up to MAXGENTRY (as reported in the GET_ATTR_INFO structure returned by CDF_CONTROL), but this is not required.

Value

A named variable in which the value of the attribute is returned.

Keywords

CDF_TYPE

Set this keyword equal to a named variable that will contain the CDF type of the attribute entry, returned as a scalar string. Possible returned values are: CDF_CHAR, CDF_UCHAR, CDF_INT1, CDF_BYTE, CDF_UINT1, CDF_UINT2, CDF_INT2, CDF_UINT4, CDF_INT4, CDF_REAL4, CDF_FLOAT, CDF_REAL8, CDF_DOUBLE, or CDF_EPOCH. If the type cannot be determined, "UNKNOWN" is returned.

Note that, as is true with variable data, attribute entries of type CDF_INT1, CDF_BYTE, CDF_UINT2, and CDF_UINT4 are converted into IDL supported datatypes (for example, data of type CDF_UINT2, data of the C-type unsigned short, is converted into IDL's INT, a signed integer. So, an attribute that is 65535 as a CDF_UINT2 will appear as INT = -1 in IDL). In these cases, pay special attention to the return values.

ZVARIABLE

If EntryNum is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that EntryNum is an rVariable ID. Note: the attribute must have a scope of VARIABLE_SCOPE.

Examples

```
; Open the CDF file created in the CDF_ATTPUT example:
id = CDF_OPEN('foo')
CDF_ATTGET, id, 'Att2', 'Var2', x
PRINT, X, FORMAT='("[",9(X,F3.1,","),X,F3.1,"]")'
CDF_CLOSE, id ; Close the CDF file.
```

IDL Output

```
[ 0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0]
```

This is the expected output, since this attribute was created with a call to FINDGEN.

Version History

Introduced: Pre 4.0

CDF_ATTINQ

The CDF_ATTINQ procedure obtains information about a specified attribute in a Common Data Format file.

Syntax

CDF_ATTINQ, *Id*, *Attribute*, *Name*, *Scope*, *MaxEntry* [, *MaxZEntry*]

Arguments

Id

The CDF ID of the file containing the desired attribute, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute

A string containing either the name or number of the attribute to be inquired.

Name

A named variable in which the name of the attribute is returned.

Scope

A named variable in which a string, describing the scope of the attribute, is returned. This string will have one of the following values: “GLOBAL_SCOPE”, “VARIABLE_SCOPE”, “GLOBAL_SCOPE_ASSUMED”, or “VARIABLE_SCOPE_ASSUMED”.

MaxEntry

A named variable in which the maximum rVariable entry number for this attribute is returned.

MaxZEntry

A named variable in which the maximum zVariable entry number for this attribute is returned.

Keywords

None.

Examples

```
cdfid= CDF_OPEN('/cdrom/ozone.8.20.92')
CDF_ATTINQ, cdfid, 0, name, scope, maxentry, maxzentry
PRINT, name, scope, maxentry, maxzentry
```

Version History

Introduced: Pre 4.0

CDF_ATTNUM

The CDF_ATTNUM function returns the attribute number associated with a particular attribute in a Common Data Format file.

Syntax

Result = CDF_ATTNUM(*Id*, *Attribute_Name*)

Return Value

Returns the attribute number.

Arguments

Id

The CDF ID for the file that contains the desired attribute, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute_Name

A string containing the name of the attribute.

Keywords

None.

Examples

See the example for “CDF_ATTPUT” on page 3072.

Version History

Introduced: Pre 4.0

CDF_ATTPUT

The CDF_ATTPUT procedure writes an attribute entry to a Common Data Format file, or attaches an attribute to a CDF variable. If the specified entry already exists, it is overwritten.

Syntax

CDF_ATTPUT, *Id*, *Attribute*, *EntryNum*, *Value* [, /ZVARIABLE]

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Attribute

A string containing either the name or number of the attribute to be written.

EntryNum

The entry number. If the attribute is variable in scope, this is either the name or number of the variable the attribute is to be associated with. If the attribute is global in scope, this is the actual gEntry. It is the user's responsibility to keep track of valid gEntry numbers. Normally gEntry numbers will begin with 0 or 1 and will increase up to MAXGENTRY (as reported in the GET_ATTR_INFO structure returned by CDF_CONTROL), but this is not required.

Value

The value(s) to be written.

Keywords

ZVARIABLE

If EntryNum is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that EntryNum is an rVariable ID. Note: the attribute must have a scope of VARIABLE_SCOPE.

Examples

Example 1

```
Id= CDF_CREATE('foo', /SUN_ENCODING, /HOST_DECODING, $
   /ROW_MAJOR)   ; no dimensions.
dummy= CDF_VARCREATE(id, 'Var1', /CDF_INT4, /REC_VARY)
v2= CDF_VARCREATE(id, 'Var2', /CDF_FLOAT, /REC_NOVARY)
dummy= CDF_ATTCREATE(id, 'Title', /VARIABLE)
global_dummy = CDF_ATTCREATE(id,'Date',/GLOBAL)
dummy= CDF_ATTCREATE(id, 'Att2', /VARIABLE)
CDF_ATTPUT, id, 'Title', 'Var1', 'Temperature at surface'
CDF_ATTPUT, id, 'Title', v2, 'Time of recording'
CDF_ATTPUT, id, 'Date',1,'July 4, 1996'
CDF_ATTPUT, id, 'Att2', 'Var2', FINDGEN(10)

; Rename the "Att2" attribute to "Attribute2":
CDF_ATTRENAME, Id, 'Att2', 'Attribute2'

; Verify the attribute number (zero-based) of Attribute2
PRINT, CDF_ATTNUM(id, 'Attribute2')

; Close the CDF file. This file is used in the CDF_ATTGET example.
CDF_CLOSE, id
```

IDL Output

```
1
```

Example 2

The following example uses the Global attribute “MODS” to keep track of the modification history of a CDF file named `mods.cdf`.

```
id = CDF_CREATE('mods.cdf', /CLOBBER)
cid = CDF_ATTCREATE(id, 'MODS', /GLOBAL_SCOPE)
CDF_ATTPUT, id, cid, 0, 'Original Version'
CDF_CLOSE, id

; Next, reopen the CDF file and make modifications:
id = CDF_OPEN('mods.cdf')
CDF_CONTROL, id, ATTRIBUTE='MODS', GET_ATTR_INFO=ginfo

;Use CDF_CONTROL to get the MAXGENTRY used.
CDF_ATTPUT, id, cid, ginfo.maxgentry+1,'Second Version'

;Insert the new gEntry at MAXGENTRY+1.
CDF_CLOSE, id
```

```
; Reopen the CDF file again and make more modifications:
id = CDF_OPEN('mods.cdf')
CDF_CONTROL, id, ATTRIBUTE='MODS', GET_ATTR_INFO=ginfo
CDF_ATTPUT, id, cid, ginfo.maxgentry+1, 'Third Version'
CDF_CLOSE, id

;Reopen the CDF file again and make a modification in the
;MAXGENTRY + 2 spot (skipping an entry number).
id = CDF_OPEN('mods.cdf')
CDF_CONTROL, id, ATTRIBUTE='MODS', GET_ATTR_INFO=ginfo
CDF_ATTPUT, id, cid, ginfo.maxgentry+2, 'Fourth Version'

; Now, examine the CDF file to review its modification history.
; Since the gENTRY numbers have a gap in them, we can check each
; attribute with the CDF_ATTEXISTS function. This is a good idea
; if you do not know for certain that the attribute entries are
; serially numbered.

CDF_CONTROL, id, ATTRIBUTE='MODS', GET_ATTR_INFO=ginfo
  FOR I=0, ginfo.maxgentry DO BEGIN
   IF CDF_ATTEXISTS(id, cid, I) THEN BEGIN
     CDF_ATTGET, id, cid, I, gatt
     PRINT, I, gatt, FORMAT='("Attribute: MODS (gENTRY #",i1,") = ",A)'
   ENDIF ELSE BEGIN
     PRINT, I, FORMAT='("Attribute: MODS (gENTRY #",i1,") $
       Does not exist")'
   ENDELSE
  ENDFOR
CDF_CLOSE, id
```

IDL Output

```
Attribute: MODS (gENTRY #0) = Original Version
Attribute: MODS (gENTRY #1) = Second Version
Attribute: MODS (gENTRY #2) = Third Version
Attribute: MODS (gENTRY #3) Does not exist
Attribute: MODS (gENTRY #4) = Fourth Version
```

Version History

Introduced: Pre 4.0

CDF_ATTRENAME

The CDF_ATTRENAME procedure is used to rename an existing attribute in a Common Data Format file.

Syntax

CDF_ATTRENAME, *Id*, *OldAttr*, *NewName*

Arguments

Id

The CDF ID of the file containing the desired attribute, returned from a previous call to CDF_OPEN or CDF_CREATE.

OldAttr

A string containing the current name of the attribute *or* the attribute number to be renamed.

NewName

A string containing the new name for the attribute.

Keywords

None.

Examples

See the example for “CDF_ATTPUT” on page 3072.

Version History

Introduced: Pre 4.0

CDF_CLOSE

The CDF_CLOSE procedure closes the specified Common Data Format file. The CDF's data buffers are flushed, all of the CDF's open files are closed, and the CDF identifier is freed. You *must* use CDF_CLOSE to close a CDF file to guarantee that all modifications you have made are actually written to disk.

Syntax

CDF_CLOSE, *Id*

Arguments

Id

The CDF ID of the file to be closed, returned from a previous call to CDF_OPEN or CDF_CREATE.

Keywords

None.

Examples

```
; Open a file:
id = CDF_OPEN('open_close.cdf'
; ... Other CDF_ commands go here.
; Close the cdf file.
CDF_CLOSE, id
```

Version History

Introduced: Pre 4.0

CDF_COMPRESSION

The CDF_COMPRESSION procedure sets or returns the compression mode for a CDF file and/or variables. Compression parameters should be set before values are written to the CDF file.

Special Note About Temporary File Location

CDF creates temporary files whenever files/variables are compressed or uncompressed. By default, these files are created in the current directory. UNIX users can set the environment variable CDF_TMP to set the temporary directory explicitly.

Syntax

CDF_COMPRESSION, Id [, GET_COMPRESSION=*variable*] [, GET_GZIP_LEVEL=*variable*] [, GET_VAR_COMPRESSION=*variable*] [, GET_VAR_GZIP_LEVEL=*variable*] [, SET_COMPRESSION={0 | 1 | 2 | 3 | 5}] [, SET_GZIP_LEVEL=*integer*{1 to 9}] [, SET_VAR_COMPRESSION={0 | 1 | 2 | 3 | 5}] [, SET_VAR_GZIP_LEVEL=*integer*{1 to 9}] [, VARIABLE=*variable name or index*] [, /ZVARIABLE]

Arguments

Id

The CDF ID of the file being compressed or queried, as returned from a previous call to CDF_OPEN or CDF_CREATE. Note that CDF compression only works for single-file CDF files (see CDF_CREATE).

Keywords

GET_COMPRESSION

Set this keyword to a named variable to retrieve the compression type used for the single-file CDF file. Note that individual CDF variables may compression types different that the one for the rest of the CDF file.

GET_GZIP_LEVEL

Set this keyword to a named variable in which the current GZIP effort level (1-9) for the CDF file is returned. If the compression type for the file is not GZIP (5), then a value of zero is returned.

GET_VAR_COMPRESSION

Set this keyword to a named variable to retrieve the compression type for the variable identified by the VARIABLE keyword.

GET_VAR_GZIP_LEVEL

Set this keyword to a named variable in which the GZIP effort level (1-9) for variable specified by the VARIABLE keyword is returned. If the compression type for the variable is not GZIP (5), then a value of zero is returned.

SET_COMPRESSION

Set this keyword to the compression type to be used for the single-file CDF file. Note that individual CDF variables may use compression types different than the one for the rest of the CDF file. Valid compression types are:

- 0 = No Compression
- 1 = Run-Length Encoding
- 2 = Huffman
- 3 = Adaptive Huffman
- 5 = GZIP (see the optional GZIP_LEVEL keyword)

SET_GZIP_LEVEL

This keyword is used to indicate the desired effort for the GZIP compression. This effort must be expressed as a scalar in the range (1-9). If GZIP_LEVEL is not specified upon entry then the default effort level is taken to be 5. If the SET_GZIP_LEVEL keyword is set to a valid value, and the keyword SET_COMPRESSION is not specified, the SET_COMPRESSION is set to GZIP (5).

SET_VAR_COMPRESSION

Set this keyword to the compression type for the variable identified by the VARIABLE keyword. If the variable is a zVariable, and is referred to by index in the VARIABLE keyword, then the keyword ZVARIABLE must be set. The desired variable compression should be set before variable data is added with CDF_VARPUT. Valid compression types are:

- 0 = No Compression
- 1 = Run-Length Encoding
- 2 = Huffman

- 3 = Adaptive Huffman
- 5 = GZIP (see the optional GZIP_LEVEL keyword)

SET_VAR_GZIP_LEVEL

Set this keyword to the GZIP effort level (1-9). If the compression type for the variable is not GZIP (5), no action is performed.

VARIABLE

Set this keyword to the name of a variable or a variable index to set the current variable. This keyword is mandatory when queering/setting the compression parameters of a rVariable or zVariable. Note that if VARIABLE is set to the index of a zVARIABLE, the ZVARIABLE keyword must also be set. If ZVARIABLE is not set, the variable is assumed to be an rVariable.

ZVARIABLE

Set this keyword if the current variable is a zVARIABLE and is referred to by index in the VARIABLE keyword. For example:

```
CDF_COMPRESSION, id, VARIABLE=0, /ZVARIABLE,$
   GET_VAR_COMPRESSION=vComp
```

Examples

```
; Create a  CDF file and define the compression.
; Compression only works on Single-File CDFs:
id=CDF_CREATE('demo.cdf',[10,20],/CLOBBER,/SINGLE_FILE)
CDF_COMPRESSION,id,SET_COMPRESSION=1 ; (Run-length encoding)
att_id=CDF_ATTCREATE(id, 'Date',/GLOBAL)
CDF_ATTPUT,id,'Date',att_id,systime()

; Change the compression type for the file to GZIP by using
; SET_GZIP_LEVEL:
CDF_COMPRESSION,id,SET_GZIP_LEVEL=7

; Retrieve compression information:
CDF_COMPRESSION,id,GET_GZIP_LEVEL=glevel,GET_COMPRESSION=gcomp
HELP,glevel,gcomp

; Create and compress an rVariable:
rid=CDF_VARCREATE(id,'rvar0',[1,1],/CDF_FLOAT)
CDF_COMPRESSION,id,SET_VAR_COMPRESSION=2,VARIABLE='rvar0'
CDF_VARPUT,id,'rvar0',findgen(10,20,5)
```

```
CDF_COMPRESSION,id,GET_VAR_COMPRESSION=v_comp,VARIABLE=rid,GET_VAR
_GZIP_LEVEL=v_glevel
HELP,v_comp,v_glevel

; Create and compress a  zVariable:
zid=CDF_varcreate(id,'zvar0',[1,1,1],DIM=[10,20,30],/ZVARIABLE,$
   /CDF_DOUBLE)

; You can set a compression and check it in the same call:
CDF_COMPRESSION,id,SET_VAR_GZIP_LEVEL=9,VARIABLE=zid,/ZVARIABLE,$
   GET_VAR_GZIP_LEVEL=v_gzip
HELP,v_gzip

CDF_VARPUT,id,zid,dindgen(10,20,30),/ZVARIABLE

; File and variable keywords can be combined in the same call
; (Set calls are processed before Get calls)
CDF_COMPRESSION,id,GET_VAR_COMPRESSION=v_comp,VARIABLE='zvar0',$
   /ZVARIABLE, SET_COMPRESSION=2,GET_COMPRESSION=file_comp
HELP,file_comp,v_comp

CDF_DELETE,id
```

IDL Output

```
GLEVEL          LONG      =            7
GCOMP           LONG      =            5

V_COMP          LONG      =            2
V_GLEVEL        LONG      =            0
```

(Note that V_GLEVEL is 0, since the variable compression is not GZIP.)

```
V_GZIP          LONG      =            9

FILE_COMP       LONG      =            2
V_COMP          LONG      =            5
```

Version History

Introduced: 5.3

See Also

CDF_CONTROL, CDF_CREATE, CDF_OPEN, CDF_VARNUM

CDF_CONTROL

The CDF_CONTROL procedure allows you to obtain or set information for a Common Data Format file, its variables, and its attributes.

Syntax

CDF_CONTROL, *Id* [, ATTRIBUTE=*name or number*]
[, GET_ATTR_INFO=*variable*] [, GET_CACHESIZE=*variable*]
[, GET_COPYRIGHT=*variable*] [, GET_FILENAME=*variable*]
[, GET_FORMAT=*variable*] [, GET_NEGTOPOSFP0_MODE=*variable*]
[, GET_NUMATTRS=*variable*] [, GET_READONLY_MODE=*variable*]
[, GET_RVAR_CACHESIZE=*variable*] [, GET_VAR_INFO=*variable*]
[, GET_ZMODE=*variable*] [, GET_ZVAR_CACHESIZE=*variable*]
[, SET_CACHESIZE=*value*] [, SET_EXTENDRECS=*records*]
[, SET_INITIALRECS=*records*] [, /SET_NEGTOPOSFP0_MODE]
[, SET_PADVALUE=*value*] [, /SET_READONLY_MODE]
[, SET_RVAR_CACHESIZE=*value*{See Note}]
[, SET_RVARS_CACHESIZE=*value*{See Note}] [, SET_ZMODE={0 | 1 | 2}]
[, SET_ZVAR_CACHESIZE=*value*{See Note}]
[, SET_ZVARS_CACHESIZE=*value*{See Note}] [, VARIABLE=*name or index*]
[, /ZVARIABLE]

Note: Use only with MULTI_FILE CDF files

Arguments

Id

The CDF ID of the file being changed or queried, as retuned from a previous call to CDF_OPEN or CDF_CREATE.

Keywords

ATTRIBUTE

Makes the attribute specified the current attribute. Either an attribute name or an attribute number may be specified.

GET_ATTR_INFO

Set this keyword to a named variable that will contain information about the current attribute. Information is returned in the form of a structure with the following tags:

```
{ NUMGENTRIES:0L, NUMRENTRIES:0L, NUMZENTRIES:0L,
  MAXGENTRY:0L, MAXRENTRY:0L, MAXZENTRY:0L }
```

The first three tags contain the number of globals, rVariables, and zVariables associated with the attribute. MAXGENTRY contains the highest index used, and the last two tags contain the highest variable ids that were used when setting the attribute's value.

Note that an attribute must be set before GET_ATTR_INFO can be used. For example:

```
CDF_CONTROL, id, ATTRIBUTE='ATT1', GET_ATTR_INFO=X
```

GET_CACHESIZE

Set this keyword to a named variable that will be set equal to the number of 512-byte cache buffers being used for the current `.cdf` file. For discussion about using caches with CDF files, see section 2.1.4 ("Caching Scheme") of the version 2.6 *CDF User's Guide*.

GET_COPYRIGHT

Set this keyword to a named variable that will contain the copyright notice of the CDF library now being used by IDL (as opposed to the library that was used to write the current CDF).

GET_FILENAME

Set this keyword to a named variable that will contain the pathname of the current `.cdf` file.

GET_FORMAT

Set this keyword to a named variable that will contain a string describing the CDF Format of the current CDF file. Possible formats are SINGLE_FILE and MULTI_FILE, and can only be set with the CDF_CREATE procedure. For example:

```
id = CDF_CREATE('single', /SINGLE_FILE)
CDF_CONTROL, id, GET_FORMAT = cdfformat
HELP, cdfformat
```

IDL prints:

```
CDFFORMAT       STRING    = 'SINGLE_FILE'
```

GET_NEGTOPOSFP0_MODE

Set this keyword to a named variable that will be set equal to the CDF negative to positive floating point 0.0 (NEGtoPOSfp0) mode. In NEGtoPOSfp0 mode, values equal to -0.0 will be converted to 0.0 whenever encountered. By CDF convention, a returned value of -1 indicates that this feature is enabled, and a returned value of zero indicates that this feature is disabled.

GET_NUMATTRS

Set this keyword to a named variable that will contain a two-element array of longs. The first value will contain the number of attributes with global scope; the second value will contain the number of attributes with variable scope. NOTE: attributes with GLOBAL_SCOPE_ASSUMED scope will be included in the global scope count and attributes with VARIABLE_SCOPE_ASSUMED will be included in the count of attributes with variable scope.

Note that you can obtain the total number of attributes using the CDF_INQUIRE routine.

GET_RVAR_CACHESIZE

Set this keyword to a named variable that will be set equal to the number of 512-byte cache buffers being used for the current MULTI_FILE format CDF and the rVariable indicated by the VARIABLE keyword. This keyword should only be used for MULTI_FILE CDF files. For discussion about using caches with CDF files, see section 2.1.4 (“Caching Scheme”) of the version 2.6 *CDF User’s Guide*.

GET_READONLY_MODE

Set this keyword to a named variable that will be set equal to the CDF read-only mode. By CDF convention, a returned value of -1 indicates that the file is in read-only mode, and a returned value of zero indicates that the file is not in read-only mode.

GET_VAR_INFO

Set this keyword to a named variable that will contain information about the current variable. For detailed information about the returned values, consult section 2.3.8 (“RECORDS”) of the version 2.6 *CDF User’s Guide*. Information is returned in the form of a structure with the following tags:

```
{ EXTENDRECS:0L, MAXALLOCREC:0L, MAXREC:0L,
   MAXRECS:0L, NINDEXENTRIES:0L, NINDEXRECORDS:0L,
   PADVALUE:<as appropriate> }
```

The EXTENDRECS field will contain the number of records by which the current variable will be extended whenever a new record needs to be added.

The MAXALLOCREC field will contain the maximum record number (zero-based) allocated for the current variable. Records can only be allocated for NOVARY zVariables in SINGLE_FILE format CDFs. When these conditions are not met, the value is set to -1.

The MAXREC field will contain the maximum record number for the current variable. For variables with a record variance of NOVARY, this will be at most zero. A value of -1 indicates that no records have been written.

The MAXRECS field will contain the maximum record number (zero-based) of all variables of this type (rVariable or zVariable) in the current CDF. A value of -1 indicates that no records have been written.

The NINDEXENTRIES field will contain the number of index entries for the current variable in the current CDF. This value is -1 unless the current CDF is of SINGLE_FILE format, and the variable is a zVariable.

The NINDEXRECORDS field will contain the number of index records for the current variable in the current CDF. This value is -1 unless the current CDF is of SINGLE_FILE format, and the variable is a zVariable.

The PADVALUE field will contain the value being used to fill locations that are not explicitly filled by the user. If a PADVALUE is not specified, CDF_CONTROL returns an error.

For example:

```
fid = CDF_CREATE('test.cdf')
varid = CDF_VARCREATE(fid, 'test')
CDF_CONTROL, fid, GET_VAR_INFO=info, VARIABLE='test'
```

IDL Prints:

```
% CDF_CONTROL: Function completed but
NO_PADVALUE_SPECIFIED: A pad value has not been specified.
```

GET_ZMODE

Set this keyword to a named variable that will be set equal the zMode of the current CDF. In a non-zero zMode, CDF rVariables are temporarily replaced with zVariables. The possible return values are:

- 0 = zMode is off.
- 1 = zMode is on in zMode/1, indicating that the dimensionality and variances of the variables will stay the same.
- 2 = zMode is on in zMode/2, indicating that those dimensions with false variances (NOVARY) will be eliminated.

For Information about zModes, consult Section 2.1.2 of the version 2.6 *CDF User's Guide*.

GET_ZVAR_CACHESIZE

Set this keyword to a named variable that will be set equal to the number of 512-byte cache buffers being used in the current MULTI_FILE format CDF and the zVariable indicated by the VARIABLE keyword. This keyword should only be used with MULTI_FILE CDF files. For discussion about using caches with CDF files, see section 2.1.4 ("Caching Scheme") of the version 2.6 *CDF User's Guide*.

SET_CACHESIZE

Set this keyword equal to the desired number of 512-byte cache buffers to used for the current `.cdf` file. For discussion about using caches with CDF files, see section 2.1.4 ("Caching Scheme") of the version 2.6 *CDF User's Guide*.

SET_EXTENDRECS

Set this keyword equal to the number of additional physical records that should be added to the current variable whenever it needs to be extended.

SET_INITIALRECS

Set this keyword equal to the number of records that should be initially written to the current variable. Note that this keyword should be set *before* writing any data to the variable.

SET_NEGTOPOSFP0_MODE

Set this keyword to a non-zero value to put the current CDF file into negative to positive floating point 0.0 (NEGtoPOSfp0) mode. In this mode, values equal to -0.0 will be converted to 0.0 whenever encountered. Setting this keyword equal to zero takes the current CDF file out of NEGtoPOSfp0 mode.

SET_PADVALUE

Set this keyword equal to the pad value for the current variable.

SET_READONLY_MODE

Set this keyword to a non-zero value to put the current CDF file into read-only mode. Set this keyword equal to zero to take the current CDF file out of read-only mode.

SET_RVAR_CACHESIZE

Set this keyword equal to the desired number of 512-byte cache buffers to used for the rVariable file specified by the VARIABLE keyword. This keyword should only be used with MULTI_FILE CDF files. For discussion about using caches with CDF files, see section 2.1.4 (“Caching Scheme”) of the version 2.6 *CDF User’s Guide.*

SET_RVARS_CACHESIZE

Set this keyword equal to the desired number of 512-byte cache buffers to used for all rVariable files in the current CDF file or files. This keyword should only be used with MULTI_FILE CDF files. For discussion about using caches with CDF files, see section 2.1.4 (“Caching Scheme”) of the version 2.6 *CDF User’s Guide*.

SET_ZMODE

Set this keyword to change the zMode of the current CDF. In a non-zero zMode, CDF rVariables are temporarily replaced with zVariables. Set this keyword to one (1) to change to zMode/1, in which the dimensionality and variances of the variables stay the same. Set this keyword to two (2) to change to zMode/2, in which those dimensions with false variances (NOVARY) are eliminated. For Information about zModes, consult Section 2.1.2 of the version 2.6 *CDF User’s Guide.*

SET_ZVAR_CACHESIZE

Set this keyword equal to the desired number of 512-byte cache buffers to used for the zVariable’s file specified by the VARIABLE keyword. This keyword should only be used with MULTI_FILE CDF files. For discussion about using caches with CDF files, see section 2.1.4 (“Caching Scheme”) of the version 2.6 *CDF User’s Guide.*

SET_ZVARS_CACHESIZE

Set this keyword equal to the desired number of 512-byte cache buffers to used for all zVariable files in the current CDF. This keyword should only be used with MULTI_FILE CDF files. For discussion about using caches with CDF files, see section 2.1.4 (“Caching Scheme” of the version 2.6 *CDF User’s Guide*.

VARIABLE

Set this keyword to a name or index to set the current variable. The following example specifies that the variable MyData should have 20 records written to it initially:

```
CDF_CONTROL, id, VAR='MyData', SET_INITIALRECS=20
```

Note that if VARIABLE is set to the index of a zVariable, the ZVARIABLE keyword *must* also be set. If ZVARIABLE is not set, the variable is assumed to be an rVariable.

ZVARIABLE

Set this keyword to TRUE if the current variable is a zVariable and is referred to by index. For example:

```
CDF_CONTROL, id, VARIABLE=0, /ZVARIABLE, GET_VAR_INFO=V
```

Version History

Introduced: Pre 4.0

See Also

CDF_CREATE, CDF_INQUIRE

CDF_CREATE

The CDF_CREATE function creates a new Common Data Format file with the given filename and dimensions.

Note that when you create a CDF file, you must specify both encoding and decoding methods. Encoding specifies the method used to write data to the CDF file. Decoding specifies the method used to retrieve data from the CDF file and pass it to an application (IDL, for example). Encoding and decoding methods are specified by setting the *XXX*_ENCODING and *XXX*_DECODING keywords to CDF_CREATE. If no decoding method is specified, the decoding method is set to be the same as the encoding method.

All CDF encodings and decodings can be written or read on all platforms, but matching the encoding with the architecture used provides the best performance. If you work in a single-platform environment most of the time, select HOST_ENCODING for maximum performance. If you know that the CDF file will be transported to a computer using another architecture, specify the encoding for the target architecture or specify NETWORK_ENCODING (the default). Specifying the target architecture provides maximum performance on that architecture; specifying NETWORK_ENCODING provides maximum flexibility.

For more discussion on CDF encoding/decoding methods and combinations, see sections 2.2.7 (“Encoding”) and 2.2.8 (“Decoding”) of the version 2.6 *CDF User’s Guide*.

Syntax

Result = CDF_CREATE(*Filename*, [*Dimensions*] [, /CLOBBER] [, /MULTI_FILE | , /SINGLE_FILE] [, /COL_MAJOR | , /ROW_MAJOR])

Encoding Keywords (pick one):
[, /ALPHAOSF1_ENCODING]
[, /ALPHAVMSD_ENCODING]
[, /ALPHAVMSG_ENCODING]
[, /DECSTATION_ENCODING]
[, /HOST_ENCODING]
[, /HP_ENCODING]
[, /IBMRS_ENCODING]
[, /IBMPC_ENCODING]
[, /MAC_ENCODING]
[, /NETWORK_ENCODING]
[, /NEXT_ENCODING]

[, /SGI_ENCODING]
[, /SUN_ENCODING]

Decoding Keywords (pick one):
[, /ALPHAOSF1_DECODING]
[, /ALPHAVMSD_DECODING]
[, /ALPHAVMSG_DECODING]
[, /DECSTATION_DECODING]
[, /HOST_DECODING]
[, /HP_DECODING]
[, /IBMRS_DECODING]
[, /IBMPC_DECODING]
[, /MAC_DECODING]
[, /NETWORK_DECODING]
[, /NEXT_DECODING]
[, /SGI_DECODING]
[, /SUN_DECODING]

Return Value

Returns the CDF ID for the new file.

Arguments

Filename

A scalar string containing the name of the file to be created. Note that if the desired filename has a `.cdf` ending, you can omit the extension and specify just the first part of the filename. For example, specifying `"mydata"` would open the file `mydata.cdf`.

Dimensions

A vector of values specifying size of each rVariable dimension. If no dimensions are specified, the file will contain a single scalar per record (i.e., a 0-dimensional CDF).

Keywords

CLOBBER

Set this keyword to erase the existing file (if the file already exists) before creating the new version.

Note that if the existing file has been corrupted, the CLOBBER operation may fail, causing IDL to display an error message. In this case you must manually delete the existing file from outside IDL.

COL_MAJOR

Set this keyword to use column major (IDL-like) array ordering for variable storage.

MULTI_FILE

Set this keyword to cause all CDF control information and attribute entry data to be placed in one `.cdf` file, with a separate file created for each defined variable. If the variable in an rVariable, then the variable files will have extensions of `.v0`, `.v1`, *etc.*; zVariables will be stored in files with extensions of `.z0`, `.z1`, *etc*. This is the default format, and is usually more efficient than the SINGLE_FILE format. See section 2.2.7 (“Format”) in the version 2.6 *CDF User’s Guide* for more information. If both SINGLE_FILE and MULTI_FILE are set the file will be created in the MULTI_FILE format.

MULTI_FILE Example:

```
id=CDF_CREATE('multi', /MULTI_FILE)
CDF_CONTROL, id, GET_FORMAT=cdf_format
HELP, cdf_format
```

IDL prints:

```
CDF_FORMAT      STRING    = 'MULTI_FILE'
```

ROW_MAJOR

Set this keyword to specify row major (C-like) array ordering for variable storage. This is the default.

SINGLE_FILE

Set this keyword to cause all CDF information (control information, attribute entry data, variable data, etc.) to be written to a single `.cdf` file. The default is to use the MULTI_FILE format where a separate file is created for each variable. See section 2.2.7 (“Format”) of the version 2.6 *CDF User’s Guide* for more information.

Encoding Keywords

Select one of the following keywords to specify the type of encoding:

ALPHAOSF1_ENCODING

Set this keyword to indicate DEC ALPHA/OSF1 data encoding.

ALPHAVMSD_ENCODING

Set this keyword to indicate DEC ALPHA/VMS data encoding using Digital's D_FLOAT representation.

ALPHAVMSG_ENCODING

Set this keyword to indicate DEC ALPHA/VMS data encoding using Digital's G_FLOAT representation.

DECSTATION_ENCODING

Set this keyword to select Decstation (MIPSEL) data encoding.

HOST_ENCODING

Set this keyword to select that the file will use native data encoding.

HP_ENCODING

Set this keyword to select HP 9000 data encoding.

IBMPC_ENCODING

Set this keyword to select IBM PC data encoding.

IBMRS_ENCODING

Set this keyword to select IBM RS/6000 series data encoding.

MAC_ENCODING

Set this keyword to select Macintosh data encoding.

NETWORK_ENCODING

Set this keyword to select network-transportable data encoding (XDR). This is the default method.

NEXT_ENCODING

Set this keyword to select NeXT data encoding.

SGI_ENCODING

Set this keyword to select SGI (MIPSEB) data encoding (Silicon Graphics Iris and Power series).

SUN_ENCODING

Set this keyword to select SUN data encoding.

Decoding Keywords

Select one of the following keywords to specify the type of decoding:

ALPHAOSF1_DECODING

Set this keyword to indicate DEC ALPHA/OSF1 data decoding.

ALPHAVMSD_DECODING

Set this keyword to indicate DEC ALPHA/VMS data decoding using Digital's D_FLOAT representation.

ALPHAVMSG_DECODING

Set this keyword to indicate DEC ALPHA/VMS data decoding using Digital's G_FLOAT representation.

DECSTATION_DECODING

Set this keyword to select Decstation (MIPSEL) data decoding.

HOST_DECODING

Set this keyword to select that the file will use native data decoding.

HP_DECODING

Set this keyword to select HP 9000 data decoding.

IBMPC_DECODING

Set this keyword to select IBM PC data decoding.

IBMRS_DECODING

Set this keyword to select IBM RS/6000 series data decoding.

MAC_DECODING

Set this keyword to select Macintosh data decoding.

NETWORK_DECODING

Set this keyword to select network-transportable data decoding (XDR). This is the default method.

NEXT_DECODING

Set this keyword to select NeXT data decoding.

SGI_DECODING

Set this keyword to select SGI (MIPSEB) data decoding (Silicon Graphics Iris and Power series).

SUN_DECODING

Set this keyword to select SUN data decoding.

Examples

Use the following command to create a 10-element by 20-element CDF using network encoding and Sun decoding:

```
id = CDF_CREATE('cdf_create.cdf', [10,20], /NETWORK_ENCODING, $
   /SUN_DECODING)
; ... other cdf commands ...
CDF_CLOSE, id ; close the file.
```

Now suppose that we decide to use HP_DECODING instead. We can use the CLOBBER keyword to delete the existing file when creating the new file:

```
id = CDF_CREATE('cdf_create.cdf', [10,20], /NETWORK_ENCODING, $
   /HP_DECODING, /CLOBBER)
; ... other cdf commands ...
CDF_CLOSE, id ; close the file.
```

The new file is written over the existing file. Use the following command to delete the file:

```
CDF_DELETE, id
```

Version History

Introduced: Pre 4.0

CDF_DELETE

The CDF_DELETE procedure deletes the specified Common Data Format file. Files deleted include the original `.cdf` file and the `.v0`, `.v1`, etc. files if they exist.

Syntax

CDF_DELETE, *Id*

Arguments

Id

The CDF ID of the file to be deleted, returned from a previous call to CDF_OPEN or CDF_CREATE.

Keywords

None.

Examples

```
id = CDF_OPEN('open_close.cdf'); Open a file.
; ... other CDF_ commands ...
CDF_DELETE, id ; Close and Delete the cdf file.
```

Version History

Introduced: Pre 4.0

CDF_DOC

The CDF_DOC procedure retrieves general documentation information about a Common Data Format file.

Syntax

CDF_DOC, *Id*, *Version*, *Release*, *Copyright* [, INCREMENT=*variable*]

Arguments

Id

A CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Version

A named variable in which the version number of the CDF library that created the CDF is returned.

Release

A named variable in which the release number of the CDF library that created the CDF is returned.

Copyright

A named variable in which the copyright notice of the CDF library that created the CDF is returned.

Keywords

INCREMENT

Set this keyword to a named variable that will contain the increment of the CDF library that created the specified CDF file.

Examples

```
id=CDF_CREATE('VersionCheck')   ; Create a CDF file.
CDF_DOC, id, vers, rel, copy, INCREMENT=incr
PRINT,'File Written Using CDF', vers, rel, incr, $
   FORMAT='(A,I1,".",I1,"r",I2)'
CDF_CLOSE, id ; Close the CDF file.
```

IDL Output

```
File Written Using CDF2.6
```

Version History

Introduced: Pre 4.0

CDF_ENCODE_EPOCH

The CDF_ENCODE_EPOCH function encodes a CDF_EPOCH variable into a string. Four different string formats are available. The default (EPOCH=0) is the standard CDF format, which may be parsed by the CDF_PARSED_EPOCH function or broken down with the CDF_EPOCH procedure.

Syntax

Result = CDF_ENCODE_EPOCH(*Epoch* [, EPOCH={0 | 1 | 2 | 3}])

Return Value

Returns a string containing the encoded CDF_EPOCH variable.

Arguments

Epoch

The double-precision CDF_EPOCH value to be encoded. For more information about CDF_EPOCH values, see section 2.2.10 (“Data Types”) of the version 2.6 *CDF User’s Guide*.

Keywords

EPOCH

Set this keyword to indicate the type of output desired,

- Set EPOCH=0 to select output of the standard type, which is described in CDF_PARSE_EPOCH.
- Set EPOCH=1 to select output of the type `yyyymodd.ttttttt` where: `yyyy` is the year, `mo` is the month (1-12), `dd` is the day of the month (1-31), and `ttttttt` is the fraction of the day (e.g. 2500000 at 6 am).
- Set EPOCH=2 to select output of the type `yyyymoddhhmmss` where: `yyyy` is the year, `mo` is the month (1-12), `dd` is the day of the month (1-31), `hh` is the hour (0-23), `mm` is the minute (0-59), and `ss` is the second (0-59).

- Set EPOCH=3 to select output of the type `yyyy-mo-ddThh:mm:ss.cccZ` where: `yyyy` is the year, `mo` is the month (1-12), `dd` is the day of the month (1-31), `hh` is the hour (0-23), `mm` is the minute (0-59), `ss` is the second (0-59), and `ccc` is the millisecond (0-999). The characters `T` and `Z` are the CDF_EPOCH type 3 place holders.

Examples

```
epoch_string = '04-Dec-1995 20:19:18.176'
epoch = CDF_PARSE_EPOCH(epoch_string)
HELP, epoch_string, epoch

; Create encode strings:
encode0 = CDF_ENCODE_EPOCH(test_epoch, EPOCH=0)
encode1 = CDF_ENCODE_EPOCH(test_epoch, EPOCH=1)
encode2 = CDF_ENCODE_EPOCH(test_epoch, EPOCH=2)
encode3 = CDF_ENCODE_EPOCH(test_epoch, EPOCH=3)

; Compare encoding formats:
HELP, encode0, encode1, encode2, encode3
```

IDL Output

```
EPOCH_STRING    STRING    = '04-Dec-1995 20:19:18.176'
EPOCH           DOUBLE    =    6.2985328e+13

ENCODE0         STRING    = '04-Dec-1995 20:19:18.176'
ENCODE1         STRING    = '19951204.8467381'
ENCODE2         STRING    = '19951204201918'
ENCODE3         STRING    = '1995-12-04T20:19:18.176Z'
```

Version History

Introduced: 4.0.1b

See Also

CDF_EPOCH, CDF_PARSE_EPOCH

CDF_EPOCH

The CDF_EPOCH procedure computes or breaks down CDF_EPOCH values in a CDF file. When computing an epoch, any missing value is considered to be zero.

If you supply a value for the Epoch argument and set the BREAKDOWN_EPOCH keyword, CDF_EPOCH will compute the values of the Year, Month, Day, etc. and insert the values into the named variables you supply. If you specify the Year (and optionally, the Month, Day, etc.) and set the COMPUTE_EPOCH keyword, CDF_EPOCH will compute the epoch and place the value in the named variable supplied as the Epoch parameter.

Note

You must set either the BREAKDOWN_EPOCH or COMPUTE_EPOCH keyword.

Syntax

CDF_EPOCH, *Epoch*, *Year* [, *Month*, *Day*, *Hour*, *Minute*, *Second*, *Milli*] [, /BREAKDOWN_EPOCH] [, /COMPUTE_EPOCH]

Arguments

Epoch

The Epoch value to be broken down, or a named variable into which the computed epoch will be placed. The Epoch value is the number of milliseconds since `01-Jan-0000 00:00:00.000`

Note

"Year zero" is a convention chosen by NSSDC to measure epoch values. This date is more commonly referred to as 1 BC. Remember that 1 BC was a leap year.

Year

The year (such as 1992) or a named variable.

Month

The month (1-12) or a named variable. You can also set the Month argument equal to zero, in which case the Day argument can take on any value between 1-366; this number is interpreted as the "Day of the Year" rather than a "Day of the Month".

Day

The day (1-31) or a named variable. If the Month argument is set equal to zero, Day can be set to any value between 1-366.

Hour

The hour (0-23) or a named variable.

Minute

The minute (0-59) or a named variable.

Second

The second (0-59) or a named variable.

Milli

The millisecond (0-999) or a named variable. If Hour, Minute, and Second are all set equal to zero, Milli is interpreted as the “Millisecond of the Day” and can be any value between 0 and 86400000.

Keywords

BREAKDOWN_EPOCH

If this keyword is set, Epoch is a value which will broken down and the resulting Year, Month, Day, etc. are returned in the remaining parameters which must be named variables.

COMPUTE_EPOCH

If this keyword is set, Epoch is a named variable into which the epoch is placed and the other parameters are values which will be used to compute the epoch.

Examples

To compute the epoch value of September 20, 1992 at 3:00 am:

```
CDF_EPOCH, MergeDate, 1992, 9, 20, 3, /COMPUTE_EPOCH
```

To break down the given epoch value into standard date components:

```
CDF_EPOCH, 4.7107656e13, yr, mo, dy, hr, mn, sc, milli, /BREAK
```

Version History

Introduced: Pre 4.0

CDF_ERROR

The CDF_ERROR function returns a a short explanation of a given status code returned from a Common Data Format file.

Syntax

Result = CDF_ERROR(*Status*)

Return Value

Returns a string containing a status code explanation.

Arguments

Status

The status code to be explained.

Keywords

None.

Version History

Introduced: Pre 4.0

CDF_EXISTS

The CDF_EXISTS function returns true if the Common Data Format (CDF) scientific data format library is supported on the current IDL platform.

This routine is written in the IDL language. Its source code can be found in the file `cdf_exists.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CDF_EXISTS( )

Return Value

Returns a 1 (True) if the library is supported or a 0 (False) if the library is not supported.

Arguments

None.

Keywords

None.

Examples

The following IDL command prints an error message if the CDF library is not available:

```
IF CDF_EXISTS() EQ 0 THEN PRINT, 'CDF not supported.'
```

Version History

Introduced: Pre 4.0

CDF_INQUIRE

The CDF_INQUIRE function returns global information about the Common Data Format file. The tags of this structure are described below.

Syntax

Result = CDF_INQUIRE(*Id*)

Return Value

This information is returned in a structure of the form:

```
{ NDIMS:0L, DECODING:"", ENCODING:"", MAJORITY:"", MAXREC:0L, $
  NVARS:0L, NZVARS:0L, NATTS:0L, DIM:LONARR(NDIMS) }
```

Explanation of the Structure Tags

The structure returned by this function consists of the following tags:

Tag	Description
NDIMS	The longword integer specifying the number of dimensions in the rVariables in the current CDF.
DECODING	A string describing the decoding type set in the CDF file, such as 'MAC_DECODING' or 'ALPHAVMSD_ENCODING'.
ENCODING	A string describing the type of encoding used in the CDF file, such as 'NETWORK_ENCODING' or 'SUN_ENCODING'.
MAJORITY	A string describing the majority used in the CDF file. The majority will be either row ('ROW_MAJOR') or column ('COL_MAJOR').
MAXREC	A longword integer specifying the highest record number written in the rVariables in the current CDF. The MAXREC field will contain the value -1 if no rVariables have yet been written to the CDF.
NVARS	A longword integer specifying the number of rVariables (regular variables) in the CDF.

Table B-1: CDF_INQUIRE Structure Tags

Tag	Description
NZVARS	A longword integer specifying the number of zVariables in the CDF.
NATTS	A longword integer specifying the number of attributes in the CDF. Note that the number returned in this field includes both global and variable attributes. You can use the GET_NUMATTR keyword to the CDF_CONTROL routine to determine the number of each.
DIM	A vector where each element contains the corresponding dimension size for the rVariables in the current CDF. For 0-dimensional CDF's, this argument contains a single element (a zero).

Table B-1: CDF_INQUIRE Structure Tags (Continued)

Arguments

Id

A CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Keywords

None.

Examples

```
cdfid = CDF_CREATE('CDFinquire', /HP_ENCODING, /MAC_DECODING)
attr1_id = CDF_ATTCREATE(cdfid, 'GLOBAL_ATT', /GLOBAL_SCOPE)
attr2_id = CDF_ATTCREATE(cdfid,'VARIABLE_ATT', /VARIABLE_SCOPE)
CDF_CONTROL, cdfid, GET_NUMATTRS = num_attrs
PRINT, 'This CDF has ', num_attrs(0), $
   'Global attribute(s) and ', num_attrs(1), $
   'Variable attribute(s).', $
   FORMAT='(A,I2,A,I2,A)'

inquire = CDF_INQUIRE(cdfid)
HELP, inquire, /STRUCT
CDF_DELETE, cdfid ; Delete the CDF file.
```

IDL Output

```
This CDF has  1 Global attribute(s) and  1 Variable attribute(s).

** Structure <4003e0c0>, 9 tags, length=48, refs=1:
   NDIMS           LONG                 0
   DECODING        STRING    'MAC_DECODING'
   ENCODING        STRING    'HP_ENCODING'
   MAJORITY        STRING    'ROW_MAJOR'
   MAXREC          LONG                -1
   NVARS           LONG                 0
   NZVARS          LONG                 0
   NATTS           LONG                 2
   DIM             LONG      Array(1)
```

Version History

Introduced: Pre 4.0

CDF_CONTROL, CDF_DOC, CDF_LIB_INFO

CDF_LIB_INFO

The CDF_LIB_INFO procedure returns information about the CDF Library being used by this version of IDL. Information about the version of CDF used to create a particular CDF file can be obtained through CDF_DOC.

Syntax

CDF_LIB_INFO [, COPYRIGHT =*variable*] [, INCREMENT=*variable*] [, RELEASE=*variable*] [, SUBINCREMENT=*variable*] [, VERSION=*variable*]

Arguments

None.

Keywords

COPYRIGHT

A named variable in which the copyright notice of the CDF library that this version of IDL is using will be returned.

INCREMENT

A named variable in which the incremental number of the CDF library that this version of IDL is using will be returned.

RELEASE

A named variable in which the release number of the CDF library that this version of IDL is using will be returned.

SUBINCREMENT

A named variable in which the sub incremental character of the CDF library that this version of IDL is using will be returned.

VERSION

A named variable in which the version number of the CDF library that this version of IDL is using will be returned.

Examples

```
CDF_LIB_INFO, VERSION=V, RELEASE=R, COPYRIGHT=C, $
   INCREMENT=I
PRINT, 'IDL ', !version.release, 'uses CDF Library ', $
   V, R, I, FORMAT='(A,A,A,I1,".",I1,".",I2,A)'
PRINT, C
```

IDL Output

```
IDL 5.0 uses CDF Library 2.6
NSSDC Common Data Format (CDF)
(C) Copyright 1990-1995 NASA/GSFC
National Space Science Data Center
NASA/Goddard Space Flight Center
Greenbelt, Maryland 20771 USA

CDF_DOC

CDF_OPEN

The CDF_OPEN function opens an existing Common Data Format file.

Syntax

Result = CDF_OPEN(*Filename*)

Return Value

If successful, the CDF ID for the file is returned.

Arguments

Filename

A scalar string containing the name of the file to be created. Note that if the desired filename has a `.cdf` ending, you can omit the extension and specify just the first part of the filename. For example, specifying "mydata" would open the file `mydata.cdf`.

Keywords

None.

Examples

```
id = CDF_OPEN('open_close.cdf')   ; Open a file.
; ... other CDF_ commands ...
CDF_CLOSE, id ; Close the cdf file.
```

Version History

Introduced: Pre 4.0

CDF_PARSE_EPOCH

The CDF_PARSE_EPOCH function parses a properly-formatted input string into a double-precision value properly formatted for use as a CDF_EPOCH variable. CDF_EPOCH variables may be unparsed into a variety of formats using the CDF_ENCODE_EPOCH function.

Syntax

Result = CDF_PARSE_EPOCH(*Epoch_string*)

Return Value

Returns the double-precision value of the input string.

Arguments

Epoch_string

A formatted string that will be parsed into a double precision value suitable to be used as a CDF_EPOCH value. The format expected by CDF_PARSE_EPOCH (the CDF standard) is dd-mmm-yyyy hh:mm:ss.ccc where:

- dd is the day of the month, 1-31.
- mmm is the month, Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, or Dec.
- yyyy is the year, A.D.
- hh is the hour, 0-23.
- mm is the minute, 0-59.
- ss is the second, 0-59, and
- ccc is the millisecond, 0-999.

For more information about CDF_EPOCH values, see section 2.2.10 (“Data Types”) of the version 2.6 *CDF User’s Guide*.

Keywords

None.

Examples

```
test_string = '04-Dec-1995 20:19:18.176'
test_epoch = CDF_PARSE_EPOCH(test_string)
HELP, test_string, test_epoch
PRINT, CDF_ENCODE_EPOCH(test_epoch, EPOCH=0)
```

IDL Output

```
TEST_STRING     STRING    = '04-Dec-1995 20:19:18.176'
TEST_EPOCH      DOUBLE    =    6.2985328e+13

04-Dec-1995 20:19:18.176
```

Version History

Introduced: 4.0.1b

See Also

CDF_ENCODE_EPOCH, CDF_EPOCH

CDF_VARCREATE

The CDF_VARCREATE function creates a new variable in a Common Data Format file.

Syntax

Result = CDF_VARCREATE(*Id*, *Name* [, *DimVary*] [, /CDF_BYTE | , /CDF_CHAR | , /CDF_DOUBLE | , /CDF_EPOCH | , /CDF_FLOAT | , /CDF_INT1 | , /CDF_INT2 | , /CDF_INT4 | , /CDF_REAL4 | , /CDF_REAL8 | , /CDF_UCHAR | , /CDF_UINT1 | , /CDF_UINT2 | , /CDF_UINT4] [, ALLOCATERECS=*records*] [, DIMENSIONS=*array*] [, NUMELEM=*characters*] [, /REC_NOVARY | , /REC_VARY] [, /ZVARIABLE])

Return Value

Returns the variable of the type specified by the chosen keyword.

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Name

A string containing the name of the variable to be created.

DimVary

A one-dimensional array containing one element per CDF dimension. If the element is non-zero or the string 'VARY', the variable will have variance in that dimension. If the element is zero or the string 'NOVARY' then the variable will have no variance with that dimension. If the variable is zero-dimensional, this argument may be omitted.

Keywords

You must specify the type variable being created. This is done by setting one of the following keywords:

- CDF_BYTE
- CDF_CHAR
- CDF_DOUBLE
- CDF_EPOCH
- CDF_FLOAT
- CDF_INT1
- CDF_INT2
- CDF_INT4
- CDF_REAL4
- CDF_REAL8
- CDF_UCHAR
- CDF_UINT1
- CDF_UINT2
- CDF_UINT4

If no type is specified, CDF_FLOAT is assumed.

Although all CDF variable types are supported within the file, IDL has full support only for the following CDF data types: CDF_DOUBLE, CDF_EPOCH, CDF_FLOAT, CDF_INT2, CDF_INT4, CDF_REAL4, CDF_REAL8, and CDF_UCHAR.

ALLOCATERECS

Set this keyword equal to the desired number of pre-allocated records for this variable in a SINGLE_FILE CDF file. Pre-allocating records ensure that variable data is stored contiguously in the CDF file. For discussion about allocating records, see section 2.3.8 (“Records”) of the version 2.6 *CDF User’s Guide*.

DIMENSIONS

Set this keyword to create a new zVariable with the specified dimensions. For example:

```
id = CDF_CREATE("cdffile.cdf", [100] )
zid = CDF_VARCREATE(id, "Zvar", [1,1,1], DIM=[10,20,30])
```

NUMELEM

The number of elements of the data type at each variable value. This keyword only has meaning for string data types (CDF_CHAR, CDF_UCHAR). This is the number of characters in the string. The default is 1.

REC_NOVARY

If this keyword is set, all records will contain the same information.

REC_VARY

If this keyword is set, all records will contain unique data. This is the default.

ZVARIABLE

A variable is assumed to be a zVariable if its dimensions are specified by the DIMENSIONS keyword. Set this keyword to create a zero-dimensional zVariable. For example:

```
id = CDF_CREATE("cdffile.cdf", [100] )
zid = CDF_VARCREATE(id, "Zvar", /ZVARIABLE)
```

Examples

Example 1

In this example, we create a CDF file to record the data retrieved from an array of temperature and salinity detectors. There is a 3 x 4 array of detectors at two depths, 10.0 meters and 20.2 meters:

```
id = CDF_CREATE("temp_salinity.cdf", [3,4], /NETWORK_ENCODING, $
   /SUN_DECODING, /CLOBBER)
temp_id =CDF_VARCREATE(id, "Temperature", ['Vary', 'Vary'], $
   /REC_VARY,/CDF_FLOAT)
depth_id = CDF_VARCREATE(id, "Depth", [0,0], /REC_VARY,
/CDF_FLOAT)
sal_id = CDF_VARCREATE(id, "Salinity", [1,1], /REC_VARY, $
   /CDF_DOUBLE)

; Create and fill the UNITS attribute:
units_att = CDF_ATTCREATE(id, 'UNITS', /VARIABLE)
CDF_ATTPUT, id, 'UNITS', 'Depth', 'Meters'
CDF_ATTPUT, id, 'UNITS', temp_id, 'Kelvin'
CDF_ATTPUT, id, units_att, sal_id, 'Percent'

; Create and write some fictitous data:
data1 = 20.0 + FINDGEN(3,4)
CDF_VARPUT, id, varid, data1
; IDL will handle the type conversion, CDF will set all values
; of this record to a depth of 10.0.
CDF_VARPUT, id, depth_id, '10.0'
CDF_VARPUT, id, depth_id, 20.2,rec_start=1
; Set the second depth.
```

```
CDF_VARPUT, id, sal_id, DINDGEN(3,4)/10.0
; Make more fictitous data.

; Demostrate the non-variance of depth by retrieving the
; values. On the first pass, use CDF_VARGET1 to retrieve
; single values:
CDF_VARGET1, id, depth_id, pth_0   ; Get single values.
CDF_VARGET1, id, depth_id, depth_1, REC_START=1
; Get single values.
HELP, depth_0, depth_1

; Now retrieve the full depth records:
CDF_VARGET, id, depth_id, depth, REC_COUNT=2

;Examine the depth variable:
HELP, depth
PRINT, depth
```

IDL Output

```
DEPTH_0         FLOAT     =       10.0000
DEPTH_1         FLOAT     =       20.2000

DEPTH           FLOAT     = Array(3, 4, 2)

10.0000      10.0000      10.0000
10.0000      10.0000      10.0000
10.0000      10.0000      10.0000
10.0000      10.0000      10.0000

20.2000      20.2000      20.2000
20.2000      20.2000      20.2000
20.2000      20.2000      20.2000
20.2000      20.2000      20.2000
```

Example 2

In this example, we create a variable, setting the data type from a string variable, which could have been returned by the DATATYPE keyword to a CDF_VARINQ call:

```
VARTYPE = 'CDF_FLOAT'

; Use the _EXTRA keyword and the CREATE_STRUCT function to
; make the appropriate keyword.

VarId = CDF_VARCREATE(Id, 'Pressure', [1,1], $
   NUMELEM=2, _EXTRA=CREATE_STRUCT(VARTYPE,1))
CDF_CLOSE, id ; Close the CDF file.
```

Version History

Introduced: Pre 4.0

CDF_VARDELETE

The CDF_VARDELETE procedure deletes a variable from a SINGLE_FILE CDF file. Note that the variable's entries are also deleted, and that the variables that numerically follow the deleted variable within the CDF file are automatically renumbered. CDF rVariables and zVariables are counted separately within CDF files. Attempting to delete a variable from a MULTI_FILE format CDF file will result in a warning message.

Syntax

CDF_VARDELETE, *Id*, *Variable* [, /ZVARIABLE]

Arguments

Id

The CDF ID of the file containing the Variable to be deleted, returned from a previous call to CDF_OPEN or CDF_CREATE.

Variable

A string containing the name of the variable to be deleted OR the variable number to be deleted. Variable numbers are 0-based in IDL. zVariables and rVariables are counted separately in CDF files.

Keywords

ZVARIABLE

Set this keyword if the Variable is a zVariable and was passed by number. The default is to assume that Variable is an rVariable.

Examples

```
cid = CDF_CREATE('DEMOvardelete',/SINGLE_FILE)

; Create 3 zVariables and 1 rVariable:
var1_id = CDF_VARCREATE(cid, 'rVAR1', /CDF_FLOAT)
var2_id = CDF_VARCREATE(cid, 'zVAR1', /CDF_INT4, /REC_NOVARY, $
   /ZVARIABLE)
var3_id = CDF_VARCREATE(cid, 'zVAR2', /CDF_CHAR, [2,10], $
   NUMELEM=10, DIM=[5,5])
var4_id = CDF_VARCREATE(cid, 'zVAR3' ,/CDF_REAL8, /ZVARIABLE)

; Check the number of variables:
info = CDF_INQUIRE(cid)
HELP, info.nzvars, info.nvars

; Delete the first and third zvariables:
CDF_VARDELETE, cid, 'zVAR1', /ZVARIABLE
CDF_VARDELETE, cid, 1, /ZVARIABLE

; CAUTION: Remember the variable numbers are zero-based
; and are automatically renumbered.

info = CDF_INQUIRE(cid)
HELP, info.nzvars, info.nvars
varinfo = CDF_VARINQ(cid, 0, /ZVARIABLE)
; check on zVAR2
HELP, varinfo, /STRUCTURE

CDF_DELETE, cid
```

IDL Output

```
<Expression>    LONG      =            3
<Expression>    LONG      =            1

<Expression>    LONG      =            1
<Expression>    LONG      =            1

CDF_ATTDELETE, CDF_CONTROL, CDF_VARCREATE, CDF_VARINQ

CDF_VARGET

The CDF_VARGET procedure reads multiple values from a Common Data Format file variable. By default, all elements of a record are read. If INTERVAL and/or OFFSET are specified but no COUNT is specified, CDF_VARGET attempts to get as many elements of each record as possible.

Syntax

CDF_VARGET, *Id*, *Variable*, *Value* [, COUNT=*vector*] [, INTERVAL=*vector*] [, OFFSET=*vector*] [, REC_COUNT=*records*] [, REC_INTERVAL=*value*] [, REC_START=*record*] [, /STRING{data in CDF file must be type CDF_CHAR or CDF_UCHAR}] [, /ZVARIABLE]

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE

Variable

A string containing the name of the variable *or* the variable number being read.

Value

A named variable in which the values of the variable are returned.

Keywords

COUNT

An optional vector containing the counts to be used in reading Value. The default is to read all elements in each record, taking into account INTERVAL and OFFSET.

INTERVAL

A vector specifying the interval between values in each dimension. The default value is 1 for each dimension.

OFFSET

A vector specifying the array indices within the specified record(s) at which to begin writing. OFFSET is a 1-dimensional array containing one element per CDF dimension. The default value is zero for each dimension.

REC_COUNT

The number of records to read. The default is 1.

REC_INTERVAL

The interval between records when reading multiple records. The default value is 1.

REC_START

The record number at which to start reading. The default is 0.

STRING

Set this keyword to return CDF_CHAR and CDF_UCHAR data from the CDF file into *Value* as string data rather than byte data. This keyword is ignored if the data in the CDF file is not of type CDF_CHAR or CDF_UCHAR.

ZVARIABLE

If *Variable* is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that *Variable* is an rVariable ID.

Examples

```
; Create a CDF file,  and make a few variables:
id = CDF_CREATE('DEMOvargets')
vid1 = CDF_VARCREATE(id, 'VAR1', /CDF_CHAR, NUMELEM=15)
vid2=CDF_VARCREATE(id, 'VAR2', /CDF_UCHAR, NUMELEM=10)
CDF_VARPUT, id, vid1, BINDGEN(15, 2)+55, COUNT=2
CDF_VARPUT, id, vid2, ['IDLandCDF ', 'AreWayCool'

; Retrieve the CDF_CHAR array as byte data:
CDF_VARGET, id,'VAR1',var1_byte,REC_COUNT=2
HELP, var1_byte

;Retrieve the CDF_CHAR array as string data:
CDF_VARGET, id, 'VAR1', var1_string, REC_COUNT=2, /STRING
HELP, var1_string
```

```
; For demonstration purposes, use the 'VAR2' variable number to
; access 'VAR2' for the duration of this example:

var2num = CDF_VARNUM(id, 'VAR2')
HELP, var2num

; Rename 'VAR2' to 'VAR_STRING_2':
CDF_VARRENAME, id, var2num, 'VAR_STRING_2'

; Examine VAR_STRING_2 with CDF_VARINQ:
VAR2_INQ = CDF_VARINQ(id, var2num)
HELP, VAR2_INQ, /STRUCTURE

; Read in and print out VAR_STRING_2:
CDF_VARGET, id, var2num, var2_string, /STRING, REC_COUNT=2
PRINT, var2_string

CDF_DELETE, id ; Delete the CDF file
```

IDL Output

```
% CDF_VARGET: Warning: converting data to unsigned bytes
```

This warning message indicates that the data was stored in the CDF file with type CDF_CHAR (signed 1-byte characters), but was retrieved by IDL with type BYTE (unsigned byte). To turn this warning message off, set !QUIET=1.

```
VAR1_BYTE       BYTE      = Array(15,  2)

VAR1_STRING     STRING    = Array(2)

VAR2NUM         LONG      =            1

** Structure <400b1600>, 6 tags, length=33, refs=1:
   IS_ZVAR         INT                   0

IDLandCDF  AreWayCool
```

Version History

Introduced: Pre 4.0

CDF_VARGET1

The CDF_VARGET1 procedure reads one value from a CDF file variable.

Syntax

CDF_VARGET1, *Id*, *Variable*, *Value* [, OFFSET=*vector*] [, REC_START=*record*]
[, /STRING{data in CDF file must be type CDF_CHAR or CDF_UCHAR}]
[, /ZVARIABLE]

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Variable

A string containing the name or number of the variable to be read.

Value

A named variable in which the value of the variable is returned.

Keywords

OFFSET

A vector specifying the array indices within the specified record(s) at which to begin reading. OFFSET is a 1-dimensional array containing one element per CDF dimension. The default value is 0 for each dimension.

REC_START

The record number at which to start reading. The default is 0.

STRING

Set this keyword to return CDF_CHAR and CDF_UCHAR data from the CDF file into Value as string data rather than byte data. This keyword is ignored if the data in the CDF file is not of type CDF_CHAR or CDF_UCHAR.

ZVARIABLE

If Variable is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that Variable is an rVariable ID.

Examples

See the example for “CDF_VARCREATE” on page 3112.

Version History

Introduced: Pre 4.0

CDF_VARINQ

The CDF_VARINQ function returns a structure containing information about the specified variable in a Common Data Format file.

Syntax

Result = CDF_VARINQ(*Id*, *Variable* [, /ZVARIABLE])

Return Value

The returned structure has the form:

```
{ IS_ZVAR:0, NAME:"", DATATYPE:"", NUMELEM:0L, $
   RECVAR:"", DIMVAR:BYTARR(...) [, DIM:LONARR(...)]}
```

Note

The DIM field is included in the structure only if IS_ZVAR is one.

Explanation of the Structure Tags

The following table provides structure tag information.

Tag	Description
IS_ZVAR	This field will contain a 1 if the variable is a zVariable or a 0 if it is an rVariable.
NAME	The name of the variable.
DATATYPE	A string describing the data type of the variable. The string has the form 'CDF_XXX' where XXX is FLOAT, DOUBLE, EPOCH, UCHAR, etc.
NUMELEM	The number of elements of the data type at each variable value. This is always 1 except in the case of string type variables (CDF_CHAR, CDF_UCHAR).
RECVAR	A string describing the record variance of the variable. This is either the string 'VARY' or 'NOVARY'.

Table B-2: CDF_VARINQ Structure Tags

Tag	Description
DIMVAR	An array of bytes. The value of each element is zero if there is no variance with that dimension and one if there is variance. For zero-dimensional CDFs, DIMVAR will have one element whose value is zero.
DIM	An array of longs. The value of each element corresponds to the dimension of the variable. This field is only included in the structure if the variable is a zVariable.

Table B-2: CDF_VARINQ Structure Tags (Continued)

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Variable

A string containing the name or number of the variable being inquired.

Keywords

ZVARIABLE

If Variable is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that Variable is an rVariable ID.

Examples

See the example for "CDF_VARGET" on page 3120.

Version History

Introduced: Pre 4.0

CDF_VARNUM

The CDF_VARNUM function returns the variable number associated with a given variable name in a Common Data Format file.

Syntax

Result = CDF_VARNUM(*Id*, *VarName* [, *IsZVar*])

Retrun Value

Returns the variable number of a specified variable name. If the specified variable cannot be found in the CDF file, CDF_VARNUM returns the scalar -1.

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

VarName

A string containing the name of the variable.

IsZVar

A named variable into which CDF_VARNUM will place a 1 to indicate that the referenced variable is a zVariable or a 0 to indicate that it is an rVariable.

Keywords

None.

Examples

See the example for “CDF_VARGET” on page 3120.

Version History

Introduced: Pre 4.0

CDF_VARPUT

The CDF_VARPUT procedure writes a value to a variable in a Common Data Format file. This function provides equivalent functionality to the C routines CDFvarPut and CDFvarHyperPut.

Syntax

CDF_VARPUT, *Id*, *Variable*, *Value* [, COUNT=*vector*] [, INTERVAL=*vector*] [, OFFSET=*vector*] [, REC_INTERVAL=*value*] [, REC_START=*record*] [, /ZVARIABLE]

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

Variable

A string containing the name or number of the variable being written.

Value

The value to write. If the value has 1 more dimension than the CDF, multiple records will be written.

Keywords

COUNT

An optional vector containing the counts to be used in writing Value. Note that counts do not have to match the dimensions of Value. The default count is to use the dimensions of *Value*.

INTERVAL

A vector specifying the interval between values in each dimension. The default value is 1 in each dimension.

OFFSET

A vector specifying the array indices within the specified record(s) at which to begin writing. OFFSET is a 1-dimensional array containing one element per CDF dimension. The default value is zero in each dimension.

REC_INTERVAL

The interval between records being written when writing multiple records. The default value is 1.

REC_START

The record number at which to start writing. The default is 0.

ZVARIABLE

If *Variable* is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that *Variable* is an rVariable ID.

Examples

```
id= CDF_CREATE('mycdf', [5,10], /NETWORK_ENCODING, /ROW_MAJOR)
varid= CDF_VARCREATE(id, 'V1', [1,1], /CDF_FLOAT, /REC_VARY)
```

To write the value 42.0 into record 12, third row, fourth column:

```
CDF_VARPUT, id, varid, 42, REC_START=12, OFFSET=[2,3]
```

To write 3 records, skipping every other record, starting at record 2, writing every other entry of each record. Note that in this example we write 25 values into each record written:

```
CDF_VARPUT, id, varid, FINDGEN(5,5,3), INTERVAL=[2,1], $
   REC_INTERVAL=2, REC_START=2
CDF_DELETE, id
```

Version History

Introduced: Pre 4.0

CDF_VARRENAME

The CDF_VARRENAME procedure renames an existing variable in a Common Data Format file.

Syntax

CDF_VARRENAME, *Id*, *OldVariable*, *NewName* [, /ZVARIABLE]

Arguments

Id

The CDF ID, returned from a previous call to CDF_OPEN or CDF_CREATE.

OldVariable

A string containing the current name of the variable *or* the variable number to be renamed.

NewName

A string containing the new name for the variable.

Keywords

ZVARIABLE

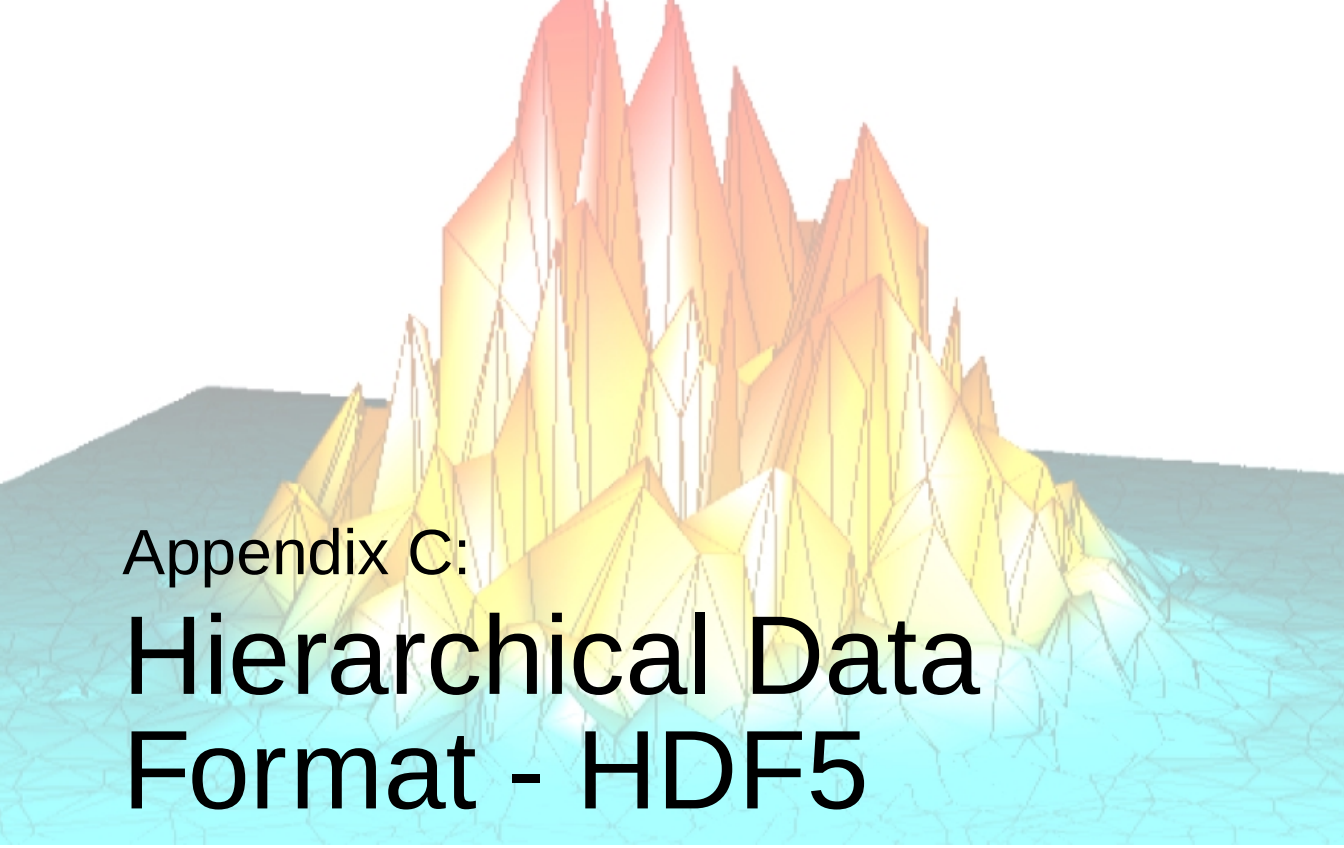
If OldVariable is a variable ID (as opposed to a variable name) and the variable is a zVariable, set this flag to indicate that the variable ID is a zVariable ID. The default is to assume that OldVariable is an rVariable ID.

Examples

See the example for "CDF_VARGET" on page 3120.

Version History

Introduced: Pre 4.0



Appendix C: Hierarchical Data Format - HDF5

This chapter details the interface routines for the Hierarchical Data Format version 5. This version of IDL supports HDF 5. The following topics are covered in this chapter:

Overview 3132
The HDF5 Format 3133
The IDL HDF5 Library 3134
IDL HDF5 Limitations 3136
Example Code - Reading an Image 3137
Example Code - Reading a Subselection 3138
Alphabetical Listing of HDF5 Routines . 3140

Overview

IDL's HDF5 library consists of a dynamically-loadable module (DLM) that provides access to the HDF5 library. HDF5 is the Hierarchical Data Format, developed by the National Center for Supercomputing Applications (NCSA). The HDF5 file format is designed for scientific data consisting of a hierarchy of datasets and attributes (or metadata). The HDF5 library is a set of C functions that provide an interface for reading, writing, and querying of HDF5 files. The IDL HDF5 DLM is a set of built-in IDL functions and procedures that provide access to the underlying C library.

For more information on HDF5 see:

`http://hdf.ncsa.uiuc.edu/HDF5/`

The HDF5 Format

Hierarchical Data Format files are organized in a hierarchical structure. The two primary structures are:

- The HDF5 group — a grouping structure containing instances of zero or more groups or datasets, together with supporting metadata.
- The HDF5 dataset — a multidimensional array of data elements, together with supporting metadata.

HDF attributes are small named datasets that are attached to primary datasets, groups, or named datatypes.

HDF4 versus HDF5

HDF5 was designed to address some of the limitations of the HDF4 format, in addition to providing new functionality.

The limitations of the HDF4 format included:

- A file cannot store more than 20,000 complex objects and cannot be larger than 2 gigabytes;
- The data models are inconsistent, there are too many object types, and datatypes are too restrictive;
- The C library source was old and complex, did not support parallel I/O effectively, and was not threadsafe.

The new HDF5 includes the following improvements:

- Larger files may be stored and more objects per file may be included.
- A more comprehensive data model with two basic structures: multidimensional datasets and groups.
- Simpler, better-engineered library and API, with support for parallel I/O and threads.

Note

The HDF5 format is not compatible with HDF4, although a conversion routine (`h4toh5`) is available from NCSA (`http://hdf.ncsa.uiuc.edu/h4toh5/`).

The IDL HDF5 Library

The IDL HDF5 library consists of an almost direct mapping between the HDF5 library functions and the IDL functions and procedures. The relationship between the IDL routines and the HDF5 library is described in the following subsections.

Routine Names

The IDL routine names are typically identical to the HDF5 function names, with the exception that an underscore is added between the prefix and the actual function. For example, the C function `H5get_libversion()` is implemented by the `IDL` function `H5_GET_LIBVERSION`.

The IDL HDF5 library contains the following function categories:

Prefix	Category	Purpose
H5	Library	General library tasks
H5A	Attribute	Manipulate attribute datasets
H5D	Dataset	Manipulate general datasets
H5F	File	Create, open, and close files
H5G	Group	Handle groups of other groups or datasets
H5I	Identifier	Query object identifiers
H5R	Reference	Reference identifiers
H5S	Dataspace	Handle dataspace dimensions and selection
H5T	Datatype	Handle dataset element information

Table C-1: HDF Function Categories

Functions Versus Procedures

HDF5 functions that only return an error code are typically implemented as IDL procedures. An example is `H5F_CLOSE`, which takes a single file identifier number as the argument and closes the file. HDF5 functions that return values are implemented as IDL functions. An example is `H5F_OPEN`, which takes a filename as the argument and returns a file identifier number.

Error Handling

All HDF5 functions that return an error or status code are checked for failure. If an error occurs, the HDF5 error handling code is called to retrieve the internal HDF5 error message. This error message is printed to the output window, and program execution stops.

Dimension Order

HDF5 uses C row-major ordering instead of IDL column-major ordering. For row major, the first listed dimension varies slowest, while for column major the first listed dimension varies fastest. The IDL HDF5 library handles this difference by automatically reversing the dimensions for all functions that accept lists of dimensions.

Note

Only the order in which the dimensions are listed is affected; in both the HDF5 file and in IDL memory, the layout of the data is identical.

For example, an HDF5 file may be known to contain a dataset with dimensions [5][10][50], either as declared in the C code, or from the output from the `h5dump` utility. When this dataset is read into IDL, the array will have the dimensions listed as [50, 10, 5], using the output from the IDL help function.

Note

In both the C program used to create the file and in IDL memory after reading the dataset, the values with dimension 50 will be contiguous.

IDL HDF5 Limitations

The IDL HDF5 library currently has the following limitations:

- Conversion cannot be forced from the HDF5 datatype to a different IDL type (such as single-precision instead of double), although data can be converted after reading from the file.
- Only the first (or top) error message from the HDF5 error stack is printed.
- Variable-length and opaque datatypes are currently ignored.
- The low-level property interface (H5P) is not exposed.
- Write capability is currently not provided.

Example Code - Reading an Image

The following example opens up the `hdf5_test.h5` file and reads in a sample image. It is assumed that the user already knows the dataset name, either from using `h5dump`, or the `H5G_GET_MEMBER_NAME` function.

```
pro ex_read_hdf5

   ; Open the HDF5 file.
   file_id = H5F_OPEN('hdf5_test.h5')

   ; Open the image dataset within the file.
   ; This is located within the /images group.
   ; We could also have used H5G_OPEN to open up the group first.
   dataset_id1 = H5D_OPEN(file_id, '/images/Eskimo')

   ; Read in the actual image data.
   image = H5D_READ(dataset_id1)

   ; Open up the dataspace associated with the Eskimo image.
   dataspace_id = H5D_GET_SPACE(dataset_id1)

   ; Retrieve the list of dimensions, so we can set the
   ;window size.
   dimensions = H5S_GET_SIMPLE_EXTENT_DIMS(dataspace_id)

   ; Now open and read the color palette associated with
   ; this image.
   dataset_id2 = H5D_OPEN(file_id, '/images/Eskimo_palette')
   palette = H5D_READ(dataset_id2)

   ; Close all our identifiers so we don't leak resources.
   H5S_CLOSE, dataspace_id
   H5D_CLOSE, dataset_id1
   H5D_CLOSE, dataset_id2
   H5F_CLOSE, file_id

   ; Display the data.
   DEVICE, DECOMPOSED=0
   WINDOW, XSIZE=dimensions[0], YSIZE=dimensions[1]
   TVLCT, palette[0,*], palette[1,*], palette[2,*]

   ; We need to use /ORDER since the image is stored
   ; top-to-bottom.
   TV, image, /ORDER

end
```

Example Code - Reading a Subselection

The following example reads only a portion of the previous image, using the dataspace keywords to H5D_READ.

```
pro ex_read_hdf5_select

   ; Open the HDF5 file.
   file_id = H5F_OPEN('hdf5_test.h5')

   ; Open the image dataset within the file.
   dataset_id1 = H5D_OPEN(file_id, '/images/Eskimo')

   ; Open up the dataspace associated with the Eskimo image.
   dataspace_id = H5D_GET_SPACE(dataset_id1)

   ; Now choose our hyperslab. We will pick out only the central
   ; portion of the image.
   start = [100, 100]
   count = [200, 200]
   ; Be sure to use /RESET to turn off all other
   ; selected elements.
   H5S_SELECT_HYPERSLAB, dataspace_id, start, count,
      STRIDE=[2, 2], /RESET

   ; Create a simple dataspace to hold the result. If we
   ; didn't supply
   ; the memory dataspace, then the result would be the same size
   ; as the image dataspace, with zeroes everywhere except our
   ; hyperslab selection.
   memory_space_id = H5S_CREATE_SIMPLE(count)

   ; Read in the actual image data.
   image = H5D_READ(dataset_id1, FILE_SPACE=dataspace_id, $
      MEMORY_SPACE=memory_space_id)

   ; Now open and read the color palette associated with
   ; this image.
   dataset_id2 = H5D_OPEN(file_id, '/images/Eskimo_palette')
   palette = H5D_READ(dataset_id2)

   ; Close all our identifiers so we don't leak resources.
   H5S_CLOSE, memory_space_id
   H5S_CLOSE, dataspace_id
   H5D_CLOSE, dataset_id1
   H5D_CLOSE, dataset_id2
   H5F_CLOSE, file_id
```

```
        ; Display the data.
        DEVICE, DECOMPOSED=0
        WINDOW, XSIZE=count[0], YSIZE=count[1]
        TVLCT, palette[0,*], palette[1,*], palette[2,*]

        ; We need to use /ORDER since the image is stored
        ; top-to-bottom.
    TV, image, /ORDER

end
```

Alphabetical Listing of HDF5 Routines

An alphabetical listing of the HDF5 Routines and their information follows.

H5_CLOSE

The H5_CLOSE procedure flushes all data to disk, closes file identifiers, and cleans up memory. This routine closes IDL's link to its HDF5 libraries. This procedure is used automatically by IDL when RESET_SESSION is issued, but it may also be called if the user desires to free all HDF5 resources.

Syntax

H5_CLOSE

Arguments

None.

Keywords

None.

Version History

Introduced 5.6

See Also

H5_OPEN

H5_GET_LIBVERSION

The H5_GET_LIBVERSION function returns the current version of the HDF5 library used by IDL.

Syntax

Result = H5_GET_LIBVERSION( )

Return Value

Returns a string in the form of '*maj.min.rel*', where *maj* is the major number, *min* is the minor number, and *rel* is the release number. An example would be '1.4.3', representing HDF5 version 1.4.3.

H5_OPEN

H5_OPEN

The H5_OPEN procedure initializes IDL's HDF5 library. This procedure is issued automatically by IDL when one of IDL's HDF5 routines is used.

Note

This routine is provided for diagnostic purposes only. You do not need to use this routine while working with IDL's HDF5 routines.

Syntax

H5_OPEN

Arguments

None.

Keywords

None.

Version History

Introduced 5.6

See Also

H5_CLOSE, H5_GET_LIBVERSION

H5_PARSE

The H5_PARSE function recursively descends through an HDF5 file or group and creates an IDL structure containing object information and data.

Note

This function is not part of the standard HDF5 interface, but is provided as a programming convenience.

Syntax

Result = H5_PARSE (*File* [, /READ_DATA])

or

Result = H5_PARSE (*Loc_id*, *Name* [, FILE=*string*] [, PATH=*string*] [, /READ_DATA])

Return Value

The *Result* is an IDL structure containing the parsed file or group. The fields within each structure in *Result* depend upon the object type.

Structure Fields Common to All Object Types

Field	Description
_NAME	Object name, or the filename if at the top level
_ICONTYPE	Name of associated icon, used by H5_BROWSER
_TYPE	Object type, such as GROUP, DATASET, DATATYPE, ATTRIBUTE, or LINK

Table C-2: Structure Fields Common to All Object Types

Additional Fields for Groups, Datasets, and Named Datatypes

Field	Description
_FILE	The filename to which the object belongs
_PATH	Full path to the group, dataset, or datatype within the file

Table C-3: Additional Fields for Groups, Datasets, and Named Datatypes

Additional Fields for Groups

Field	Description
_COMMENT	Comment string

Table C-4: Additional Fields for Groups

Additional Fields for Datasets, Attributes, and Named Datatypes

Field	Description
_DATATYPE	Datatype class, such as H5T_INTEGER
_STORAGESIZE	Size of each value in bytes
_PRECISION	Precision of each value in bits

Table C-5: Additional Fields for Datasets, Attributes, and Named Datatypes

Field	Description
_SIGN	For integers, either 'signed' or 'unsigned'; otherwise a null string

Table C-5: Additional Fields for Datasets, Attributes, and Named Datatypes

Additional Fields for Datasets and Attributes

Field	Description
_DATA	Data values stored in the object
_NDIMENSIONS	Number of dimensions in the dataspace
_DIMENSIONS	List of dataspace dimensions
_NELEMENTS	Total number of elements in the dataspace

Table C-6: Additional Fields for Datasets and Attributes

Groups, datasets, datatypes, and attributes will be stored as substructures within *Result*. The tag names for these substructures are constructed from the actual object name by converting all non-alphanumeric characters to underscores, and converting all characters to uppercase.

Arguments

File

A string giving the name of the file to parse.

Loc_id

An integer giving the file or group identifier to access.

Name

A string giving the name of the group, dataset, or datatype within *Loc_id* to parse.

Keywords

FILE

Set this optional keyword to a string giving the filename associated with the Loc_id. This keyword is used for filling in the _FILE field within the returned structure, and is not required. The FILE keyword is ignored if the *File* argument is provided.

PATH

Set this optional keyword to a string giving the full path associated with the *Loc_id*. This keyword is used for filling in the _PATH field within the returned structure, and is not required. The PATH keyword is ignored if the *File* argument is provided.

READ_DATA

If this keyword is set, then all data from datasets is read in and stored in the returned structure. If READ_DATA is not provided then the _DATA field for datasets will be set to the string '<unread>'.

Note

For attribute objects all data is automatically read and stored in the structure.

Example

The following example shows how to parse a file, and then prints out the parsed structure.

```
File = FILEPATH('hdf5_test.h5', SUBDIR=['examples','data'])
Result = H5_PARSE(File)
help, Result, /STRUCTURE
```

When the above commands are entered, IDL prints:

```
** Structure <5f24468>, 13 tags, length=6872, data length=6664,
refs=1:
   _NAME STRING    'D:\RSI\idl56\examples\data\hdf5_test.h5'
   _ICONTYPE       STRING    'hdf'
   _TYPE       STRING    'GROUP'
   _FILE       STRING    'D:\RSI\idl56\examples\data\hdf5_test.h5'
   _PATH       STRING    '/'
   _COMMENT        STRING    ''
   _2D_INT_ARRAY   STRUCT    -> <Anonymous> Array[1]
   A_NOTE          STRUCT    -> <Anonymous> Array[1]
   SL_TO_3D_INT_ARRAY
   STRUCT    -> <Anonymous> Array[1]
```

```
   ARRAYS          STRUCT    -> <Anonymous> Array[1]
   DATATYPES       STRUCT    -> <Anonymous> Array[1]
   IMAGES          STRUCT    -> <Anonymous> Array[1]
   LINKS           STRUCT    -> <Anonymous> Array[1]
```

Now print out the structure of a dataset within the "Images" group:

```
help, Result.images.eskimo, /STRUCTURE
```

IDL prints:

```
** Structure <16f1ca0>, 20 tags, length=840, data length=802,
refs=2:
   _NAME           STRING    'Eskimo'
   _ICONTYPE       STRING    'binary'
   _TYPE           STRING    'DATASET'
   _FILE           STRING
'D:\RSI\debug\examples\data\hdf5_test.h5'
   _PATH           STRING    '/images'
   _DATA           STRING    '<unread>'
   _NDIMENSIONS    LONG                 2
   _DIMENSIONS     ULONG64   Array[2]
   _NELEMENTS      ULONG64                   389400
   _DATATYPE       STRING    'H5T_INTEGER'
   _STORAGESIZE    ULONG                1
   _PRECISION      LONG                 8
   _SIGN           STRING    'unsigned'
   CLASS           STRUCT    -> <Anonymous> Array[1]
   IMAGE_VERSION   STRUCT    -> <Anonymous> Array[1]
   IMAGE_SUBCLASS  STRUCT    -> <Anonymous> Array[1]
   IMAGE_COLORMODEL
                   STRUCT    -> <Anonymous> Array[1]
   IMAGE_MINMAXRANGE
                   STRUCT    -> <Anonymous> Array[1]
   IMAGE_TRANSPARENCY
                   STRUCT    -> <Anonymous> Array[1]
   PALETTE         STRUCT    -> <Anonymous> Array[1]
```

Version History

H5_BROWSER

H5A_CLOSE

The H5A_CLOSE procedure closes the specified attribute and releases resources used by it. After this routine is used, the attribute's identifier is no longer available until the H5A_OPEN routines are used again to specify that attribute. Further use of the attribute identifier is illegal.

Syntax

H5A_CLOSE, *Attribute_id*

Arguments

Attribute_id

An integer representing the attribute's identifier to be closed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_OPEN_NAME, H5A_OPEN_IDX

H5A_GET_NAME

The H5A_GET_NAME function retrieves an attribute name given the attribute identifier number.

Syntax

Result = H5A_GET_NAME(*Attribute_id*)

Return Value

Returns a string containing the attribute name.

Arguments

Attribute_id

An integer representing the attribute's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_GET_SPACE, H5A_GET_TYPE

H5A_GET_NUM_ATTRS

The H5A_GET_NUM_ATTRS function returns the number of attributes attached to a group, dataset, or a named datatype.

Syntax

Result = H5A_GET_NUM_ATTRS(*Loc_id*)

Return Value

Returns an integer representing the number of attributes.

Arguments

Loc_id

An integer representing the identifier of the group, dataset, or named datatype to query.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_OPEN_IDX

H5A_GET_SPACE

The H5A_GET_SPACE function returns the identifier number of a copy of the dataspace for an attribute.

Syntax

Result = H5A_GET_SPACE(*Attribute_id*)

Return Value

Returns an integer representing the dataspace's identifier. This identifier can be released with the H5S_CLOSE.

Arguments

Attribute_id

An integer representing the attribute's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_GET_NAME, H5A_GET_TYPE, H5S_CLOSE

H5A_GET_TYPE

The H5A_GET_TYPE function returns the identifier number of a copy of the datatype for an attribute.

Syntax

Result = H5A_GET_TYPE(*Attribute_id*)

Return Value

Returns an integer representing the datatype identifier. This identifier should be released with the H5T_CLOSE.

Arguments

Attribute_id

An integer representing the attribute identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_GET_SPACE, H5A_GET_NAME, H5T_CLOSE

H5A_OPEN_IDX

The H5A_OPEN_IDX function opens an existing attribute by the index of that attribute within an HDF5 file.

Syntax

Result = H5A_OPEN_IDX(*Loc_id*, *Index*)

Return Value

Returns an integer representing the attribute's identifier number.

Arguments

Loc_id

An integer representing the identifier of the group, dataset, or named datatype containing the attribute within.

Index

An integer representing the zero-based index of the attribute to be accessed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_OPEN_NAME, H5A_GET_NUM_ATTRS, H5A_GET_NAME, H5A_CLOSE

H5A_OPEN_NAME

The H5A_OPEN_NAME function opens an existing attribute by the name of that attribute within an HDF5 file.

Syntax

Result = H5A_OPEN_NAME(*Loc_id*, *Name*)

Return Value

Returns an integer representing the attribute's identifier number.

Arguments

Loc_id

An integer representing the identifier of the group, dataset, or named datatype containing the attribute within.

Name

A string representing the name of the attribute to be accessed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_OPEN_IDX, H5A_CLOSE

H5A_READ

The H5A_READ function reads the data within an attribute, converting from the HDF5 file datatype into the HDF5 memory datatype, and finally into the corresponding IDL datatype.

Syntax

Result = H5A_READ(*Attribute_id*)

Return Value

Returns an IDL variable containing all of the attribute's data. For details on different return types and storage mechanisms, see the H5D_READ function.

Arguments

Attribute_id

An integer representing the attribute's identifier to be read.

Keywords

None.

Version History

Introduced 5.6

See Also

H5A_OPEN_NAME, H5A_OPEN_IDX, H5A_CLOSE, H5D_READ

H5D_CLOSE

The H5D_CLOSE procedure closes the specified dataset and releases its used resources. After this routine is used, the dataset's identifier is no longer available until the H5D_GET_SPACE is used again to specify that dataset.

Syntax

H5D_CLOSE, *Dataset_id*

Arguments

Dataset_id

An integer representing the dataset's identifier to be closed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5D_OPEN

H5D_GET_SPACE

The H5D_GET_SPACE function returns an identifier number for a copy of the dataspace for a dataset.

Syntax

Result = H5D_GET_SPACE(*Dataset_id*)

Return Value

Returns an integer representing the dataspace's identifier. This identifier can be released with the H5S_CLOSE.

Arguments

Dataset_id

An integer representing the dataset's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_CLOSE, H5D_GET_STORAGE_SIZE, H5D_GET_TYPE

H5D_GET_STORAGE_SIZE

The H5D_GET_STORAGE_SIZE function returns the amount of storage in bytes required for a dataset. For chunked datasets, this value is the number of allocated chunks times the chunk size.

Note

This function does not typically need to be called, as IDL will automatically allocate the necessary memory when reading data.

Syntax

Result = H5D_GET_STORAGE_SIZE(*Dataset_id*)

Return Value

Returns an integer representing the amount of storage in bytes.

Arguments

Dataset_id

An integer representing the dataset's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_CLOSE, H5D_GET_SPACE, H5D_GET_TYPE

H5D_GET_TYPE

The H5D_GET_TYPE function returns an identifier number for a copy of the datatype for a dataset.

Syntax

Result = H5D_GET_TYPE(*Dataset_id*)

Return Value

Returns an integer representing the datatype's identifier. This identifier can be released with the H5T_CLOSE.

Arguments

Dataset_id

An integer representing the dataset's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_CLOSE, H5D_GET_SPACE, H5D_GET_STORAGE_SIZE

H5D_OPEN

The H5D_OPEN function opens an existing dataset within an HDF5 file.

Syntax

Result = H5D_OPEN(*Loc_id*, *Name*)

Return Value

Returns an integer representing the dataset's identifier. This identifier can be released with the H5D_CLOSE.

Arguments

Loc_id

An integer representing the identifier of the file or group containing the dataset.

Name

A string representing the name of the dataset to be accessed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5D_CLOSE

H5D_READ

The H5D_READ function reads the data within a dataset, converting from the HDF5 file datatype into the HDF5 memory datatype, and finally into the corresponding IDL datatype.

Syntax

Result = H5D_READ(*Dataset_id* [, FILE_SPACE=*id*] [, MEMORY_SPACE=*id*])

Return Value

Returns an IDL variable containing the specified data. The different return types and storage mechanisms are described below.

Note

The dimensions for the *Result* variable are constructed using the following precedence rules:

If MEMORY_SPACE is specified, then the dimensions of the MEMORY_SPACE are used.

If only FILE_SPACE is specified, then the dimensions of the FILE_SPACE are used.

If neither MEMORY_SPACE nor FILE_SPACE are specified, then the dimensions are taken from the *Dataset_id*.

Arguments

Dataset_id

An integer representing the dataset's identifier to be read.

Keywords

FILE_SPACE

Set this keyword to the file dataspace identifier that should be used when reading the dataset. The FILE_SPACE keyword may be used to define hyperslabs or elements for

subselection within the dataset. The default is zero (in HDF5 this is equivalent to H5S_ALL), which indicates that the entire dataspace should be read.

MEMORY_SPACE

Set this keyword to the memory dataspace identifier that should be used when copying the data from the file into memory. The MEMORY_SPACE keyword may be used to define hyperslabs or elements in which to place the data. The default is zero (in HDF5 this is equivalent to H5S_ALL), which indicates that the memory dataspace is identical to the file dataspace.

Return Type

When reading in HDF5 datasets, the datatype is first set to the native HDF5 types. These native types are then converted to IDL types as shown in the following table:

HDF5 Class	HDF5 Datatype	IDL Type
H5T_INTEGER H5T_BITFIELD H5T_ENUM	H5T_NATIVE_UINT8	Byte
	H5T_NATIVE_INT16	Integer
	H5T_NATIVE_UINT16	Unsigned integer
	H5T_NATIVE_INT32	Long integer
	H5T_NATIVE_UINT32	Unsigned long integer
	H5T_NATIVE_INT64	64-bit Integer
	H5T_NATIVE_UINT64	Unsigned 64-bit integer
H5T_REFERENCE	H5T_STD_REF_OBJ	Unsigned 64-bit integer
H5T_FLOAT	H5T_NATIVE_FLOAT	Floating point
	H5T_NATIVE_DOUBLE	Double-precision floating
H5T_STRING	H5T_C_S1	String
H5T_TIME	H5T_C_S1	String
H5T_COMPOUND	(Member datatypes)	Structure
H5T_ARRAY	(Super datatype)	(Super type)

Table C-7: HDF and IDL Datatypes

Note

Multidimensional datasets are returned in IDL row major order, with the fastest-varying dimensions listed first. HDF5 uses C column major order, with the fastest-varying dimensions listed last. In both cases, the memory layout for data elements is identical (i.e. no transpose is needed), only the order of the dimensions is reversed.

Note

For the H5T_ARRAY datatype the array dimensions are concatenated with the dataset dimensions, with the array dimensions varying more rapidly.

Note

Structure tag names are constructed from H5T_COMPOUND member names by switching to uppercase and converting all non-alphanumeric characters to underscores.

H5D_CLOSE, H5D_OPEN, H5A_READ, H5S_CREATE_SIMPLE, H5S_SELECT_ELEMENTS, H5S_SELECT_HYPERSLAB

H5F_CLOSE

The H5F_CLOSE procedure closes the specified file and releases resources used by it. After this routine is used, the file's identifier is no longer available until the H5F_CLOSE routine is used again to specify that file.

Syntax

H5F_CLOSE, *File_id*

Arguments

File_id

An integer representing the file's identifier to be closed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5F_OPEN

H5F_IS_HDF5

The H5F_IS_HDF5 function determines if a file is in the HDF5 format.

Syntax

Result = H5F_IS_HDF5(*Filename*)

Return Value

Returns an integer of 1 if the file is in the HDF5 format, 0 if otherwise.

Arguments

Filename

A string representing the name of the files to be checked.

Keywords

None.

Version History

Introduced 5.6

See Also

H5F_OPEN

H5F_OPEN

The H5F_OPEN function opens an existing HDF5 file.

Syntax

Result = H5F_OPEN(*Filename*)

Return Value

Returns an integer representing the file identifier number. This identifier can be released with the H5F_CLOSE.

Arguments

Filename

A string representing the name of the file to be accessed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5F_CLOSE, H5F_IS_HDF5

H5G_CLOSE

The H5G_CLOSE procedure closes the specified group and releases resources used by it. After this routine is used, the group's identifier is no longer available until the H5F_OPEN routine is used again to specify that group.

Syntax

H5G_CLOSE, *Group_id*

Arguments

Group_id

An integer representing the group's identifier to be closed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5G_OPEN

H5G_GET_COMMENT

The H5G_GET_COMMENT function retrieves a comment string from a specified object.

Syntax

Result = H5G_GET_COMMENT(*Loc_id*, *Name*)

Return Value

Returns a string containing the comment, or a null string if no comment exists.

Arguments

Loc_id

An integer representing the identifier of the file or group.

Name

A string representing the name of the object for which to retrieve the comment.

Keywords

None.

Version History

Introduced 5.6

See Also

H5G_GET_OBJINFO

H5G_GET_LINKVAL

The H5G_GET_LINKVAL function returns the name of the object pointed to by a symbolic link.

Syntax

Result = H5G_GET_LINKVAL(*Loc_id*, *Name*)

Return Value

Returns a string containing the name of the object pointed to by a symbolic link.

Arguments

Loc_id

An integer representing the identifier of the file or group.

Name

A string representing the name of the symbolic link for which to retrieve the link value.

Keywords

None.

Version History

Introduced 5.6

See Also

H5G_GET_OBJINFO

H5G_GET_MEMBER_NAME

The H5G_GET_MEMBER_NAME function retrieves the name of an object within a group, by its zero-based index.

Note

This function is not part of the standard HDF5 interface, but is provided as a programming convenience. The H5Giterate() C function is used to retrieve the name.

Syntax

Result = H5G_GET_MEMBER_NAME(*Loc_id*, *Name*, *Index*)

Return Value

Returns a string containing the object's name.

Arguments

Loc_id

An integer representing the identifier of the file or group.

Name

A string representing the name of the group in which to retrieve the member name.

Index

An integer representing the zero-based index of the object for which to retrieve the name.

Keywords

None.

Version History

Introduced 5.6

See Also

H5G_GET_NMEMBERS

H5G_GET_NMEMBERS

The H5G_GET_NMEMBERS function returns the number of objects within a group.

Note

This function is not part of the standard HDF5 interface, but is provided as a programming convenience. The H5Giterate() C function is used to retrieve the number of members.

Syntax

Result = H5G_GET_NMEMBERS(*Loc_id*, *Name*)

Return Value

Returns an integer representing the number of objects.

Arguments

Loc_id

An integer representing the identifier of the file or group.

Name

A string representing the name of the group for which to retrieve the number of members.

Keywords

None.

Version History

Introduced 5.6

See Also

H5G_GET_MEMBER_NAME

H5G_GET_OBJINFO

The H5G_GET_OBJINFO function retrieves information from a specified object.

Syntax

Result = H5G_GET_OBJINFO(*Loc_id*, *Name* [, /FOLLOW_LINK])

Return Value

Returns a structure of the name H5F_STAT containing the following fields:

FILENO

This field contains two integers which, along with the OBJNO field, uniquely identify the object among all open HDF5 files.

OBJNO

This field contains two integers which, along with the FILENO field, uniquely identify the object among all open HDF5 files. If all four values in FILENO and OBJNO are the same between two objects, then these two objects are the same.

NLINK

The number of hard links to the object. If this field is zero, then the object is a symbolic link.

TYPE

A string representing the object type. Possible values are:

- ‘LINK’
- ‘GROUP’
- ‘DATASET’
- ‘TYPE’
- ‘UNKNOWN’

MTIME

The modification time for the object, in seconds since 1 January 1970.

Tip

You can convert the MTIME field from seconds to a date/time string using SYSTIME(*0, mtime*). See SYSTIME for more information.

LINKLEN

If the object is a symbolic link (and the FOLLOW_LINK keyword is not set), then this field will contain the length in characters of the link value. The link value itself may be retrieved using H5D_GET_LINKVAL.

Arguments

Loc_id

An integer representing the identifier of the file or group.

Name

A string representing the name of the object for which to retrieve the information structure.

Keywords

FOLLOW_LINK

If *Name* is a symbolic link, then set this keyword to follow the symbolic link and retrieve information about the linked object. The default is to return information about the symbolic link itself.

Version History

Introduced 5.6

See Also

H5G_GET_LINKVAL

H5G_OPEN

The H5G_OPEN function opens an existing group within an HDF5 file.

Syntax

Result = H5G_OPEN(*Loc_id*, *Name*)

Return Value

Returns an integer representing the group's identifier number. This identifier can be released with the H5G_CLOSE.

Arguments

Loc_id

An integer representing the identifier of the file or group containing the group to be accessed.

Name

A string representing the name of the group to be accessed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5G_CLOSE

H5I_GET_TYPE

The H5I_GET_TYPE function returns the object's type.

Syntax

Result = H5I_GET_TYPE(*Obj_id*)

Return Value

Returns a string representing the object type. Possible return values include:

- 'FILE'
- 'GROUP'
- 'DATATYPE'
- 'DATASPACE'
- 'DATASET'
- 'ATTR'
- 'BADID'

Arguments

Obj_id

An integer representing the object's identifier for which to return the type.

Keywords

None.

Version History

Introduced 5.6

H5R_DEREFERENCE

The H5R_DEREFERENCE function opens a reference and returns the object identifier.

Syntax

Result = H5R_DEREFERENCE(*Loc_id*, *Reference*)

Return Value

The *Result* is an integer giving the identifier number. This identifier should be released using the appropriate close procedure.

Arguments

Loc_id

An integer giving the identifier in which the reference dataset is located.

Reference

An integer giving the reference number to open.

Keywords

None.

Version History

Introduced 5.6

See Also

H5R_GET_OBJECT_TYPE

H5R_GET_OBJECT_TYPE

The H5R_GET_OBJECT_TYPE function returns the type of object that an object reference points to.

Syntax

Result = H5R_GET_OBJECT_TYPE(*Loc_id*, *Reference*)

Return Value

The *Result* is a string giving the object type. Possible return values include:

- ‘FILE’
- ‘GROUP’
- ‘DATASET’
- ‘DATASPACE’
- ‘DATASET’
- ‘ATTR’
- ‘BADID’

Arguments

Loc_id

An integer giving the identifier in which the reference dataset is located.

Reference

An integer giving the reference number to query.

Keywords

None.

Version History

Introduced 5.6

See Also

H5R_DEREFERENCE

H5S_CLOSE

The H5S_CLOSE procedure releases and terminates access to a dataspace. After this routine is used, the dataspace's identifier is no longer available.

Warning

Failure to release a dataspace using this procedure will result in resource leaks.

Syntax

H5S_CLOSE, *Dataspace_id*

Arguments

Dataspace_id

An integer representing the dataspace's identifier to close.

Keywords

None.

Version History

Introduced 5.6

See Also

H5D_GET_SPACE

H5S_COPY

The H5S_COPY function copies an existing dataspace.

Syntax

Result = H5S_COPY(*Dataspace_id*)

Return Value

Returns an integer representing the dataspace's identifier number. The dataspace identifier can be released with the H5S_CLOSE.

Arguments

Dataspace_id

An integer representing the dataspace identifier to copy.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_CREATE_SIMPLE, H5S_CLOSE

H5S_CREATE_SIMPLE

The H5S_CREATE_SIMPLE function creates a simple dataspace.

Syntax

Result = H5S_CREATE_SIMPLE(*Dimensions* [, MAX_DIMENSIONS=*vector*])

Return Value

Returns an integer representing the dataspace's identifier number. This dataspace identifier can be released with the H5S_CLOSE.

Arguments

Dimensions

Set this argument to a vector containing the dimensions for the dataspace.

Note

The *Dimensions* argument should be specified in IDL's row-major order. Internally, the dimensions will be reversed to match HDF5/C's column-major order.

Keywords

MAX_DIMENSIONS

Set this keyword to a vector containing the maximum dimensions for the dataspace. The MAX_DIMENSIONS must have the same number of elements as the *Dimensions* argument. If MAX_DIMENSIONS is omitted then the maximum dimensions are set to *Dimensions*. You can use a value of -1 in MAX_DIMENSIONS to indicate an unlimited dimension.

Note

The MAX_DIMENSIONS keyword should be specified in IDL's row-major order. Internally, the dimensions will be reversed to match HDF5/C's column-major order.

Version History

Introduced 5.6

See Also

H5S_CLOSE, H5S_COPY

H5S_GET_SELECT_BOUNDS

The H5S_GET_SELECT_BOUNDS function retrieves the coordinates of the bounding box containing the current dataspace selection.

Syntax

Result = H5S_GET_SELECT_BOUNDS(*Dataspace_id*)

Return Value

Returns an (*m* x 2) array, where *m* is the number of dimensions (or rank) of the dataspace. The first row in the array is the starting coordinates of the bounding box, while the second row is the ending coordinates.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SIMPLE_EXTENT_NPOINTS, H5S_GET_SELECT_NPOINTS, H5S_GET_SELECT_ELEM_NPOINTS, H5S_GET_SELECT_HYPER_NBLOCKS

H5S_GET_SELECT_ELEM_NPOINTS

The H5S_GET_SELECT_ELEM_NPOINTS function determines the number of element points in the current dataspace selection.

Syntax

Result = H5S_GET_SELECT_ELEM_NPOINTS(*Dataspace_id*)

Return Value

Returns an integer representing the number of element points.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_BOUNDS, H5S_GET_SELECT_HYPER_NBLOCKS, H5S_GET_SELECT_NPOINTS, H5S_GET_SIMPLE_EXTENT_NPOINTS

H5S_GET_SELECT_ELEM_POINTLIST

The H5S_GET_SELECT_ELEM_POINTLIST function returns a list of the element points in the current dataspace selection.

Syntax

Result = H5S_GET_SELECT_ELEM_POINTLIST(*Dataspace_id* [, START=*value*] [, NUMBER=*value*])

Return Value

The *Result* is an (*m* x *n*) array, where *m* is the number of dimensions (or rank) of the dataspace, and *n* is the number of selected points. Each row contains the coordinates for an element selection point.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

START

Set this keyword to an integer representing the point to start with, counting from 0. The default is START = 0.

NUMBER

Set this keyword to an integer representing the number of element points to return. The default is NUMBER = (N - START), where N is the total number of element points in the selection.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_ELEM_NPOINTS, H5S_GET_SELECT_NPOINTS

H5S_GET_SELECT_HYPER_BLOCKLIST

The H5S_GET_SELECT_HYPER_BLOCKLIST function returns a list of the hyperslab blocks in the current dataspace selection.

Syntax

Result = H5S_GET_SELECT_HYPER_BLOCKLIST(*Dataspace_id* [, START=*value*] [, NUMBER=*value*])

Return Value

Returns an (*m* x 2*n*) array, where *m* is the number of dimensions (or rank) of the dataspace. The 2*n* rows of *Result* contain the list of blocks. The first row contains the start coordinates of the first block, followed by the next row which contains the opposite corner coordinates, followed by the next row which contains the start coordinates of the second block, etc.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

START

Set this keyword to an integer representing the block to start with, counting from 0. The default is START = 0.

NUMBER

Set this keyword to an integer representing the number of blocks to return. The default is NUMBER = (N - START), where N is the total number of blocks in the selection.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_HYPER_NBLOCKS, H5S_GET_SELECT_NPOINTS

H5S_GET_SELECT_HYPER_NBLOCKS

The H5S_GET_SELECT_HYPER_NBLOCKS function determines the number of hyperslab blocks in the current dataspace selection.

Syntax

Result = H5S_GET_SELECT_HYPER_NBLOCKS(*Dataspace_id*)

Return Value

Returns an integer representing the number of blocks.

Arguments

Dataspace_id

An integer representing the dataspace identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_BOUNDS, H5S_GET_SELECT_ELEM_NPOINTS, H5S_GET_SELECT_NPOINTS, H5S_GET_SIMPLE_EXTENT_NPOINTS

H5S_GET_SELECT_NPOINTS

The H5S_GET_SELECT_NPOINTS function determines the number of elements in a dataspace selection.

Syntax

Result = H5S_GET_SELECT_NPOINTS(*Dataspace_id*)

Return Value

Returns an integer representing the number of elements.

Arguments

Dataspace_id

An integer representing the dataspace identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_BOUNDS, H5S_GET_SELECT_ELEM_NPOINTS, H5S_GET_SELECT_HYPER_NBLOCKS, H5S_GET_SIMPLE_EXTENT_NPOINTS

H5S_GET_SIMPLE_EXTENT_DIMS

The H5S_GET_SIMPLE_EXTENT_DIMS function returns the dimension sizes for a dataspace.

Syntax

Result = H5S_GET_SIMPLE_EXTENT_DIMS(*Dataspace_id*
[, MAX_DIMENSIONS=*variable*])

Return Value

Returns a vector containing the dimension sizes.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

MAX_DIMENSIONS

Set this keyword to a named variable to return the maximum dimension sizes for the dataspace.

Version History

Introduced 5.6

See Also

H5S_GET_SIMPLE_EXTENT_NDIMS,
H5S_GET_SIMPLE_EXTENT_NPOINTS, H5S_GET_SIMPLE_EXTENT_TYPE

H5S_GET_SIMPLE_EXTENT_NDIMS

The H5S_GET_SIMPLE_EXTENT_NDIMS function determines the number of dimensions (or rank) of a dataspace.

Syntax

Result = H5S_GET_SIMPLE_EXTENT_NDIMS(*Dataspace_id*)

Return Value

Returns an integer representing the number of dimensions.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SIMPLE_EXTENT_DIMS, H5S_GET_SIMPLE_EXTENT_NPOINTS, H5S_GET_SIMPLE_EXTENT_TYPE

H5S_GET_SIMPLE_EXTENT_NPOINTS

The H5S_GET_SIMPLE_EXTENT_NPOINTS function determines the number of elements in a dataspace.

Syntax

Result = H5S_GET_SIMPLE_EXTENT_NPOINTS(*Dataspace_id*)

Return Value

Returns an integer representing the number of elements.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SIMPLE_EXTENT_DIMS, H5S_GET_SIMPLE_EXTENT_NDIMS, H5S_GET_SIMPLE_EXTENT_TYPE

H5S_GET_SIMPLE_EXTENT_TYPE

The H5S_GET_SIMPLE_EXTENT_TYPE function returns the current class of a dataspace.

Syntax

Result = H5S_GET_SIMPLE_EXTENT_TYPE(*Dataspace_id*)

Return Value

Returns a string containing the class. Possible values are:

- ‘H5S_SCALAR’
- ‘H5S_SIMPLE’
- ‘H5S_COMPLEX’
- ‘H5S_NO_CLASS’

Arguments

Dataspace_id

An integer representing the dataspace’s identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SIMPLE_EXTENT_DIMS, H5S_GET_SIMPLE_EXTENT_NDIMS, H5S_GET_SIMPLE_EXTENT_NPOINTS

H5S_IS_SIMPLE

The H5S_IS_SIMPLE function determines whether a dataspace is a simple dataspace.

Syntax

Result = H5S_IS_SIMPLE(*Dataspace_id*)

Return Value

Returns an integer of 1 if the dataspace is simple and 0 if it is not.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

H5S_OFFSET_SIMPLE

The H5S_OFFSET_SIMPLE procedure sets the selection offset for a simple dataspace. The offset allows the same shaped selection to be moved to different locations within the dataspace.

Syntax

H5S_OFFSET_SIMPLE, *Dataspace_id*, *Offset*

Arguments

Dataspace_id

An integer representing the dataspace's identifier on which to set the selection offset.

Offset

An *m*-element vector of integers, where *m* is the number of dataspace dimensions, containing the offsets.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_BOUNDS, H5S_SELECT_ELEMENTS, H5S_SELECT_HYPERSLAB

H5S_SELECT_ALL

The H5S_SELECT_ALL procedure selects the entire extent of a dataspace.

Syntax

H5S_SELECT_ALL, *Dataspace_id*

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be selected.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_NPOINTS, H5S_SELECT_ELEMENTS, H5S_SELECT_HYPERSLAB, H5S_SELECT_NONE

H5S_SELECT_ELEMENTS

The H5S_SELECT_ELEMENTS procedure selects array elements to be included in the selection for a dataspace.

Syntax

H5S_SELECT_ELEMENTS, *Dataspace_id, Coordinates* , /RESET

Arguments

Dataspace_id

An integer representing the dataspace's identifier on which to set the selection.

Coordinates

An *m*-element vector, or an (*m* x *n*) array, where *m* is the number of dimensions (or rank) of the dataspace, and *n* is the number of selected points. Each row contains the coordinates for an element selection point.

Keywords

RESET

Set this keyword to replace the existing selection with the new *Coordinates*. The default is RESET = 0 which adds the new selection to the existing selection.

Note

The RESET keyword must be set (/RESET or RESET = 1) or the H5S_SELECT_ELEMENTS routine will result in an error message. This error message comes from the HDF5 library, which forces a default of RESET = 0 but insists on this keyword being set for this routine to work.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_ELEM_NPOINTS, H5S_GET_SELECT_ELEM_POINTLIST, H5S_GET_SELECT_NPOINTS, H5S_SELECT_HYPERSLAB

H5S_SELECT_HYPERSLAB

The H5S_SELECT_HYPERSLAB procedure selects a hyperslab region to be included in the selection for a dataspace.

Note

If all of the elements in the selected hyperslab region are already selected, then a new hyperslab region is not created.

Syntax

H5S_SELECT_HYPERSLAB, *Dataspace_id*, *Start*, *Count*, [, BLOCK=*vector*] [, /RESET] [, STRIDE=*vector*]

Arguments

Dataspace_id

An integer representing the dataspace's identifier on which to set the selection.

Start

An *m*-element vector of integers, where *m* is the number of dataspace dimensions, containing the starting location for the hyperslab.

Count

An *m*-element vector of integers containing the number of blocks to select in each dimension.

Keywords

BLOCK

Set this keyword to an *m*-element vector of integers containing the size of a block. The default is a single element in each dimension (for example BLOCK is set to a vector of all 1's).

RESET

Set this keyword to replace the existing selection with the new selection. The default is RESET=0 which adds the new selection to the existing selection.

STRIDE

Set this keyword to an *m*-element vector of integers containing the number of elements to move in each dimension when selecting blocks. The default is to move a single element in each dimension (for example STRIDE is set to a vector of all 1's). STRIDE values must be greater than zero.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_HYPER_BLOCKLIST, H5S_GET_SELECT_HYPER_NBLOCKS, H5S_GET_SELECT_NPOINTS, H5S_SELECT_ELEMENTS

H5S_SELECT_NONE

The H5S_SELECT_NONE procedure resets the dataspace selection region to include no elements.

Syntax

H5S_SELECT_NONE, *Dataspace_id*

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be reset.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_NPOINTS, H5S_SELECT_ALL, H5S_SELECT_ELEMENTS, H5S_SELECT_HYPERSLAB

H5S_SELECT_VALID

The H5S_SELECT_VALID function verifies that the selection is within the extent of a dataspace.

Syntax

Result = H5S_SELECT_VALID(*Dataspace_id*)

Return Value

Returns an integer of 1 if the selection is within the dataspace and 0 if it is not.

Arguments

Dataspace_id

An integer representing the dataspace's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5S_GET_SELECT_NPOINTS, H5S_SELECT_ELEMENTS, H5S_SELECT_HYPERSLAB

H5T_CLOSE

The H5T_CLOSE procedure releases the specified datatype's identifier and releases resources used by it. After this routine is used, the datatype's identifier is no longer available until the H5T_OPEN routine is used again to specify that datatype.

Syntax

H5T_CLOSE, *Datatype_id*

Arguments

Datatype_id

An integer representing the datatype's identifier to be closed.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_OPEN

H5T_COMMITTED

The H5T_COMMITTED function determines whether a datatype is a named datatype or a transient type.

Syntax

Result = H5T_COMMITTED(*Datatype_id*)

Return Value

Returns an integer of 1 if the datatype is named and 0 if the datatype is transient.

Arguments

Datatype_id

An integer representing the datatyped identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

H5T_COPY

The H5T_COPY function copies an existing datatype. The returned type is transient and unlocked.

Syntax

Result = H5T_COPY(*Datatype_id*)

Return Value

Returns an integer representing the datatype's identifier number. This identifier can be released with the H5T_CLOSE procedure.

Arguments

Datatype_id

An integer representing the datatype's identifier to be copied.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_CLOSE, H5T_OPEN

H5T_EQUAL

The H5T_EQUAL function determines whether two datatype identifiers refer to the same datatype.

Syntax

Result = H5T_EQUAL(*Datatype_id1*, *Datatype_id2*)

Return Value

Returns an integer of 1 if the identifiers refer to the same datatype and 0 if they do not.

Arguments

Datatype_id1

An integer representing the first datatype identifier.

Datatype_id2

An integer representing the second datatype identifier.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_COPY

H5T_GET_ARRAY_DIMS

The H5T_GET_ARRAY_DIMS function returns the dimension sizes for an array datatype object.

Syntax

Result = H5T_GET_ARRAY_DIMS(*Datatype_id* [, PERMUTATIONS=*variable*])

Return Value

Returns a vector containing the dimension sizes.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

PERMUTATIONS

Set this keyword to a named variable in which to return the dimension permutations (C versus FORTRAN).

Version History

Introduced 5.6

See Also

H5T_GET_ARRAY_NDIMS

H5T_GET_ARRAY_NDIMS

The H5T_GET_ARRAY_NDIMS function determines the number of dimensions (or rank) of an array datatype object.

Syntax

Result = H5T_GET_ARRAY_NDIMS(*Datatype_id*)

Return Value

Returns an integer representing the number of dimensions.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_ARRAY_DIMS

H5T_GET_CLASS

The H5T_GET_CLASS function returns the datatype's class.

Syntax

Result = H5T_GET_CLASS(*Datatype_id*)

Return Value

Returns a string containing the datatype's class. Possible return values include:

- 'H5T_INTEGER'
- 'H5T_FLOAT'
- 'H5T_TIME'
- 'H5T_STRING'
- 'H5T_BITFIELD'
- 'H5T_OPAQUE'
- 'H5T_COMPOUND'
- 'H5T_REFERENCE'
- 'H5T_ENUM'
- 'H5T_VLEN'
- 'H5T_ARRAY'
- 'H5T_NO_CLASS'

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_SIZE, H5T_GET_SUPER

H5T_GET_CSET

The H5T_GET_CSET function returns the character set type of a string datatype.

Syntax

Result = H5T_GET_CSET(*Datatype_id*)

Return Value

Returns a string containing the character set type. Possible values are:

- ‘ASCII’ — US ASCII
- ‘ERROR’

Arguments

Datatype_id

An integer representing the datatype’s identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

H5T_GET_EBIAS

The H5T_GET_EBIAS function returns the exponent bias of a floating-point type.

Syntax

Result = H5T_GET_EBIAS(*Datatype_id*)

Return Value

Returns an integer representing the exponent bias.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_FIELDS

H5T_GET_FIELDS

The H5T_GET_FIELDS function retrieves information about the positions and sizes of bit fields within a floating-point datatype.

Syntax

Result = H5T_GET_FIELDS(*Datatype_id*)

Return Value

Returns a structure named H5T_GET_FIELDS containing the following tags:

TYPE_ID

The datatype's identifier *Datatype_id*.

SIGN_POS

The position of the floating-point sign bit.

EXP_POS

The bit position of the exponent.

EXP_SIZE

The size of the exponent in bits.

MAN_POS

The bit position of the mantissa.

MAN_SIZE

The size of the mantissa in bits.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_EBIAS, H5T_GET_INPAD, H5T_GET_NORM, H5T_GET_OFFSET, H5T_GET_ORDER, H5T_GET_PAD, H5T_GET_PRECISION

H5T_GET_INPAD

The H5T_GET_INPAD function returns the padding method for unused internal bits within a floating-point datatype.

Syntax

Result = H5T_GET_INPAD(*Datatype_id*)

Return Value

Returns an integer representing the padding method. Possible values are:

- 0 — Background set to zeroes
- 1 — Background set to ones
- 2 — Background left unchanged

Arguments

Datatype_id

An integer representing the datatype identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_FIELDS

H5T_GET_MEMBER_CLASS

The H5T_GET_MEMBER_CLASS function returns the datatype class of a compound datatype member.

Syntax

Result = H5T_GET_MEMBER_CLASS(*Datatype_id*, *Member*)

Return Value

Returns a string containing the datatype class. Possible values are:

- ‘H5T_INTEGER’
- ‘H5T_FLOAT’
- ‘H5T_TIME’
- ‘H5T_STRING’
- ‘H5T_BITFIELD’
- ‘H5T_OPAQUE’
- ‘H5T_COMPOUND’
- ‘H5T_REFERENCE’
- ‘H5T_ENUM’
- ‘H5T_VLEN’
- ‘H5T_ARRAY’
- ‘H5T_NO_CLASS’

Arguments

Datatype_id

An integer representing the datatype’s identifier to be queried.

Member

An integer representing the member index, starting at zero.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_MEMBER_NAME, H5T_GET_MEMBER_OFFSET, H5T_GET_MEMBER_TYPE, H5T_GET_NMEMBERS

H5T_GET_MEMBER_NAME

The H5T_GET_MEMBER_NAME function returns the datatype name of a compound datatype member.

Syntax

Result = H5T_GET_MEMBER_NAME(*Datatype_id*, *Member*)

Return Value

Returns a string containing the datatype name.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Member

An integer representing the member index, starting at zero.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_MEMBER_CLASS, H5T_GET_MEMBER_OFFSET, H5T_GET_MEMBER_TYPE, H5T_GET_NMEMBERS

H5T_GET_MEMBER_OFFSET

The H5T_GET_MEMBER_OFFSET function returns the byte offset of a field within a compound datatype.

Syntax

Result = H5T_GET_MEMBER_OFFSET(*Datatype_id*, *Member*)

Return Value

Returns an integer representing the byte offset.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Member

An integer representing the member index, starting at zero.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_MEMBER_CLASS, H5T_GET_MEMBER_NAME, H5T_GET_MEMBER_TYPE, H5T_GET_NMEMBERS

H5T_GET_MEMBER_TYPE

The H5T_GET_MEMBER_TYPE function returns the datatype identifier for a specified member within a compound datatype.

Syntax

Result = H5T_GET_MEMBER_TYPE(*Datatype_id*, *Member*)

Return Value

Returns an integer representing the datatype identifier. This identifier should be closed using H5T_CLOSE.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Member

An integer representing the member index, starting at zero.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_MEMBER_CLASS, H5T_GET_MEMBER_NAME, H5T_GET_MEMBER_OFFSET, H5T_CLOSE, H5T_GET_NMEMBERS

H5T_GET_NMEMBERS

The H5T_GET_NMEMBERS function returns the number of fields in a compound datatype.

Syntax

Result = H5T_GET_NMEMBERS(*Datatype_id*)

Return Value

Returns an integer representing the number of fields.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_MEMBER_CLASS, H5T_GET_MEMBER_NAME, H5T_GET_MEMBER_OFFSET, H5T_GET_MEMBER_TYPE

H5T_GET_NORM

The H5T_GET_NORM function returns the mantissa normalization of a floating-point datatype.

Syntax

Result = H5T_GET_NORM(*Datatype_id*)

Return Value

Returns a string containing the mantissa normalization. Possible values are:

- ‘IMPLIED’ — Most-significant bit of mantissa not stored, always 1
- ‘MSBSET’ — Most-significant bit of mantissa is always 1
- ‘NORM’ — Mantissa is not normalized
- ‘ERROR’

Arguments

Datatype_id

An integer representing the datatype’s identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_FIELDS

H5T_GET_OFFSET

The H5T_GET_OFFSET function returns the bit offset of the first significant bit in an atomic datatype. The offset is the number of bits of padding that follows the significant bits (for big endian) or precedes the significant bits (for little endian).

Syntax

Result = H5T_GET_OFFSET(*Datatype_id*)

Return Value

Returns an integer representing the bit offset.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_FIELDS

H5T_GET_ORDER

The H5T_GET_ORDER function returns the byte order of an atomic datatype.

Syntax

Result = H5T_GET_ORDER(*Datatype_id*)

Return Value

Returns a string representing the byte order. Possible values are:

- ‘LE’ — Little endian
- ‘BE’ — Big endian
- ‘VAX’ — VAX mixed ordering
- ‘NONE’
- ‘ERROR’

Arguments

Datatype_id

An integer representing the datatype’s identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_INPAD, H5T_GET_PAD, H5T_GET_PRECISION

H5T_GET_PAD

The H5T_GET_PAD function returns the padding method of the least significant bit (*lsb*) and most significant bit (*msb*) of an atomic datatype.

Syntax

Result = H5T_GET_PAD(*Datatype_id*)

Return Value

Returns a two-element vector [*lsb*, *msb*]. Possible values are:

- 0 — Background set to zeroes
- 1 — Background set to ones
- 2 — Background left unchanged.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_INPAD, H5T_GET_ORDER, H5T_GET_PRECISION

H5T_GET_PRECISION

The H5T_GET_PRECISION function returns the precision in bits of an atomic datatype. The precision is the number of significant bits which, unless padded, is 8 times larger than the byte size from H5T_GET_CSET.

Syntax

Result = H5T_GET_PRECISION(*Datatype_id*)

Return Value

Returns an integer representing the bit precision.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_INPAD, H5T_GET_ORDER, H5T_GET_PAD, H5T_GET_SIZE

H5T_GET_SIGN

The H5T_GET_SIGN function returns the sign type for an integer datatype.

Syntax

Result = H5T_GET_SIGN(*Datatype_id*)

Return Value

Returns an integer representing the sign type. Possible values are:

- -1 — Error
- 0 — Unsigned integer type
- 1 — Two's complement signed integer type

Arguments

Datatype_id

An integer representing the datatype’s identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_ORDER, H5T_GET_PAD, H5T_GET_PRECISION

H5T_GET_SIZE

The H5T_GET_SIZE function returns the size of a datatype in bytes.

Syntax

Result = H5T_GET_SIZE(*Datatype_id*)

Return Value

Returns an integer representing the datatype's size.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_CLASS, H5T_GET_SUPER

H5T_GET_STRPAD

The H5T_GET_STRPAD function returns the padding method for a string datatype.

Syntax

Result = H5T_GET_STRPAD(*Datatype_id*)

Return Value

Returns a string containing the padding method. Possible values are:

- ‘NULLTERM’ — Null terminate (like C)
- ‘NULLPAD’ — Pad with zeroes
- ‘SPACEPAD’ — Pad with spaces (like FORTRAN)
- ‘ERROR’

Arguments

Datatype_id

An integer representing the datatype’s identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_CSET, H5T_GET_SIZE

H5T_GET_SUPER

The H5T_GET_SUPER function returns the base datatype from which a datatype is derived.

Syntax

Result = H5T_GET_SUPER(*Datatype_id*)

Return Value

Returns an integer representing the base datatype's identifier number. This identifier can be released with the H5T_CLOSE.

Arguments

Datatype_id

An integer representing the datatype's identifier to be queried.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_GET_CLASS, H5T_GET_SIZE

H5T_IDLTYPE

The H5T_IDLTYPE function returns the IDL type code corresponding to a datatype.

Note

This function is not part of the standard HDF5 interface, but is provided as a programming convenience.

Syntax

Result = H5T_IDLTYPE(*Datatype_id*
[, ARRAY_DIMENSIONS=*variable*][, STRUCTURE=*variable*])

Return Value

The *Result* is an integer giving the IDL type code.

Note

For a list of IDL type codes and their definitions, see "IDL Type Codes" in the *IDL Reference Guide* manual under the SIZE function.

Arguments

Datatype_id

An integer giving the datatype identifier for which to return the IDL type code.

Keywords

ARRAY_DIMENSIONS

Set this keyword to a named variable in which to return a vector containing the array dimensions, if the datatype is an array. If the datatype is not an array, then a scalar value of 0 is returned.

STRUCTURE

Set this keyword to a named variable in which to return the IDL structure definition, if the datatype is a compound datatype. If the datatype is not compound, then a scalar value of 0 is returned.

Version History

Introduced 5.6

See Also

H5T_MEMTYPE

H5T_MEMTYPE

The H5T_MEMTYPE function returns the native memory datatype corresponding to a file datatype.

Note

This function is not part of the standard HDF5 interface, but is provided as a programming convenience.

Syntax

Result = H5T_MEMTYPE(*Datatype_id*)

Return Value

The *Result* is an integer giving the datatype identifier. If the file datatype is not immutable, then the memory datatype identifier should be closed using H5T_CLOSE.

Note

For a list of IDL type codes and their definitions, see "IDL Type Codes" in the *IDL Reference Guide* manual under the SIZE function.

Arguments

Datatype_id

An integer giving the file datatype identifier for which to return the memory datatype.

Keywords

None.

Version History

Introduced 5.6

See Also

H5T_IDLTYPE

H5T_OPEN

The H5T_OPEN function opens a named datatype.

Syntax

Result = H5T_OPEN(*Loc_id*, *Name*)

Return Value

Returns an integer representing the datatype's identifier number. This identifier can be released with the H5T_CLOSE.

Arguments

Loc_id

An integer representing the identifier of the file or group containing the datatype.

Name

A string representing the name of the datatype to be accessed.

Keywords

None.

Version History

Introduced 5.6

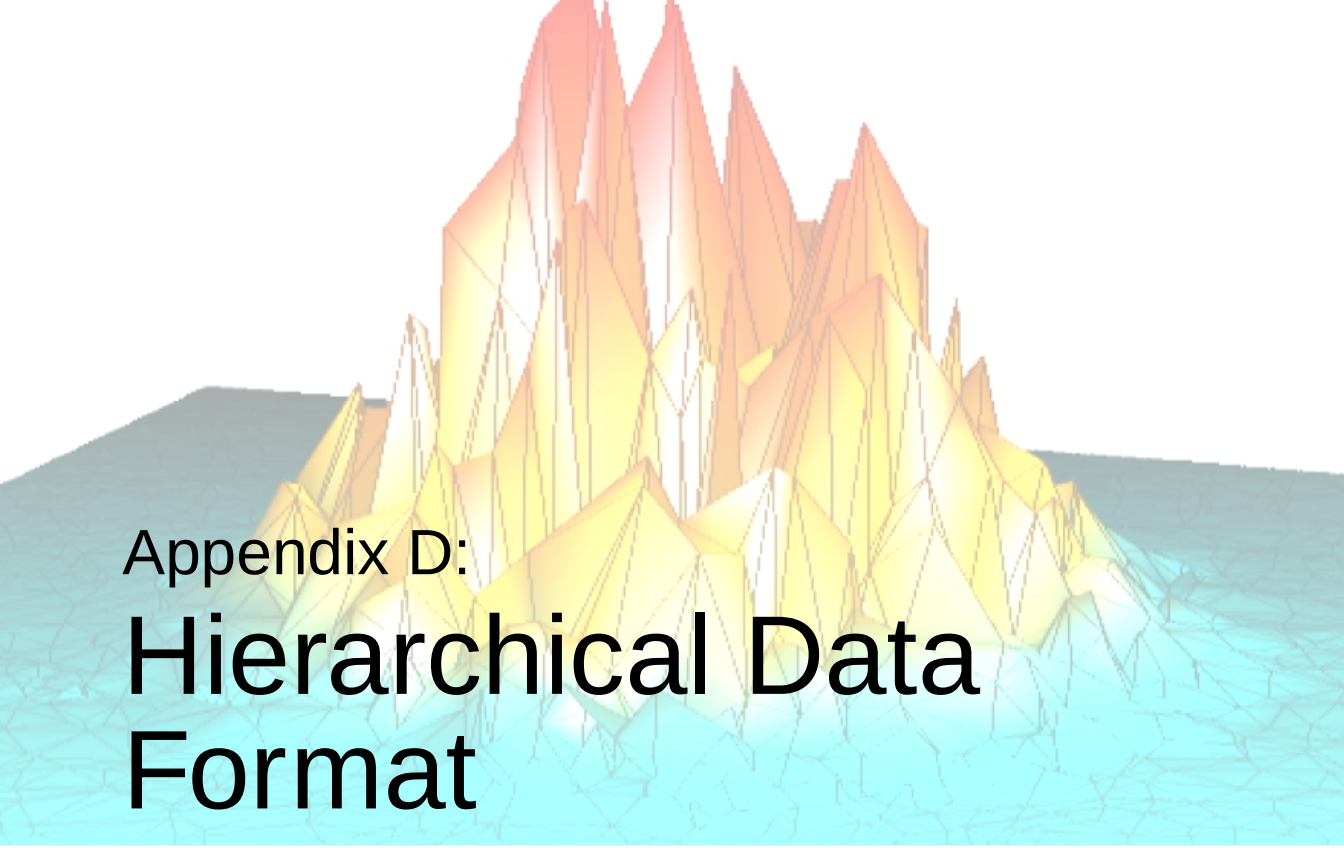
H5T_CLOSE



Appendix D: Hierarchical Data Format

The following topics are covered in this appendix:

Overview 3240
HDF Interfaces 3241
Creating HDF Files 3243
HDF Scientific Dataset ID Numbers . . . 3245
Alphabetical Listing of HDF Routines . . 3249

Overview

The Hierarchical Data Format (HDF) is a multi-object file format that facilitates the transfer of various types of data between machines and operating systems. HDF is a product of the National Center for Supercomputing Applications (NCSA). HDF is designed to be flexible, portable, self-describing and easily extensible for future enhancements or compatibility with other standard formats. The HDF library contains interfaces for storing and retrieving images and multi-dimensional scientific data. This version of IDL supports HDF 4.1r5.

Note

On the AIX platform, the HDF library supports version 4.1r3.

IDL's HDF routines all begin with the prefix "HDF_".

Further information about HDF can be found on the World Wide Web at the HDF Information Server:

```
http://hdf.ncsa.uiuc.edu
```

Alternately, you can send e-mail to:

```
hdfhelp@ncsa.uiuc.edu.
```

HDF Interfaces

There are two basic interfaces to HDF files: the single-file application interface and the multiple-file application interface. These interfaces support eight different types (or “models”) of data access. The table below lists the different models and the names of the IDL routines that access those models. Each model is described in more detail after the table.

Model	IDL Routine Name Prefix
24-bit raster	HDF_DF24_
annotation data	HDF_DFAN_
palette data	HDF_DFP_
8-bit raster	HDF_DFR8_
scientific data	HDF_SD_
multi-file scientific data	HDF_SD_
VData	HDF_VD_
VGroup	HDF_VG_

Table D-1: Data Access Models and Routine Prefixes

Single File Application Interfaces

In this mode, access is limited to one file at a time. This interface supports the 8-bit raster, 24-bit raster, palette, scientific data, and annotation models. The interfaces are described in more detail after the table.

- 8-bit Raster Model: The HDF_DFR8_ routines access 8-bit images.
- Palette Model: The HDF_DFP_ routines are used to work with the HDF_DFR8_ routines to manipulate palettes associated with 8-bit HDF images.
- 24-bit Raster Model: The HDF_DFR24_ routines access 24-bit images.
- Scientific Data Models (SDs): Used to manipulate arrays of arbitrary dimension and type. Under this model, an array accompanied by a record of its data type, dimensions and descriptors is called a Scientific Dataset (SD).

- Annotation Model: The annotation model is used to describe the contents of the file through such items as labels, data descriptors, and dimension scales.
- Vdata Model: This interface allows for the creation of customized tables. Each table consists of a series of Vdata records whose values are stored in fixed length fields. As described in more detail in the Vdata example below, a Vdata can contain three kinds of identifying information: a Vdata name, Vdata Class, and multiple Vdata field names. The Vdata model is accessed through the routines that begin with the HDF_VD_ prefix.
- Vgroup Model: A collection of one or more data objects, Vdata sets, or Vgroups is known as a Vgroup. Each Vgroup can be given a Vgroup name and Vgroup class. The Vgroup model is accessed through the routines that begin with the HDF_VG_ prefix.

Multi-File Application Interface

The HDF_SD_ routines allow operations on more than one file at a time. This multi-file interoperability is achieved through HDF's use of a modified version of the NetCDF library. IDL's interface to HDF's multi-file capability is the HDF_SD_SETEXTFILE routine.

Creating HDF Files

The following IDL commands should be used to create a new HDF file:

- HDF_OPEN: Call this procedure first to open an HDF file. The CREATE keyword must be set if you want to create a new file instead of opening an existing one.
- HDF_DFAN_ADDFDS: Optionally, add a file description.
- HDF_DFAN_ADDFID: Optionally, add a file annotation.

Adding Data to an HDF File

The routines used to add data to an HDF file vary based on the interface model being used:

- To add an 8-bit image (with or without a palette), use HDF_DFR8_ADDIMAGE or DFR8_PUTIMAGE.
- To add a palette, use HDF_DFP_ADDPAL or HDF_DFP_PUTPAL.
- To add a 24-bit image, use HDF_DF24_ADDIMAGE or HDF_DF24_PUTIMAGE.
- To add a Multi-File Scientific Dataset, use the following commands:
  - HDF_SD_CREATE or HDF_SD_SELECT to create an SDS or select an existing one.
  - HDF_SD_DIMSET to set dimension information.
  - HDF_SD_ATTRSET to set attribute information.
  - HDF_SD_SETINFO to insert optional information about the data.
  - HDF_SD_ADDDATA to insert the data.
  - HDF_SD_SETEXTFILE to move the data to an external file (optional).
  - HDF_SD_ENDACCESS to end access to the SDS.
- To add a Vdata, use the following commands:
  - HDF_VD_ATTACH to get a Vdata identifier.
  - HDF_VD_SETINFO to write information about the Vdata (optional).
  - HDF_VD_FDEFINE to prepare non-trivial fields (optional).
  - HDF_VD_WRITE to write the Vdata.

- To add a Vdata to a Vgroup, use the following commands:
  - HDF_VG_ATTACH to get a Vgroup identifier.
  - HDF_VG_SETINFO to set the Vgroup name and class (optional).
  - HDF_VG_INSERT to add the Vdata to a Vgroup.
  - HDF_VG_DETACH to close the Vgroup.
  - HDF_CLOSE to close the file.

HDF Examples

Two example files that demonstrate the use of the HDF routines can be found in the `examples/data_access/sdf` subdirectory of the IDL distribution. The file `hdf_info.pro` prints a summary of basic information about an HDF file. The file `hdf_rdwr.pro` creates a new HDF file and then reads the information back from that file.

HDF Scientific Dataset ID Numbers

IDL's HDF_SD_ routines can accept two different types of ID numbers. Documentation for these routines in the *IDL Reference Guide* refers to these ID numbers as the SD_ID and SDS_ID arguments.

The SD_ID is the Scientific Dataset interface ID. There is only one SD_ID per HDF file. For each actual dataset used, you will also need an SDS_ID, which is the ID for the particular dataset.

Some routines, such as HDF_SD_ATTRFIND, accept either an SD_ID or an SDS_ID. In these cases, the documentation refers to the ID as an S_ID, meaning that either type of ID is accepted.

IDL and HDF Data Types

HDF and IDL support many different data types. Many of the HDF routines allow you to perform a data type conversion "on the fly" by setting keywords such as FLOAT. When the data type desired is not explicitly specified, IDL uses the conversions shown in the following tables. Note that single-precision floating-point is the default data type and that the complex data type is not supported.

When writing IDL data to an HDF file, IDL data types are converted to the HDF data types shown in the following table:

IDL Data Type	HDF Data Type
BYTE	DFNT_UINT8 (IDL bytes are unsigned)
INT	DFNT_INT16
UINT	DFNT_UINT16
LONG	DFNT_INT32
ULONG	DFNT_UINT32
FLOAT	DFNT_FLOAT32
DOUBLE	DFNT_DOUBLE
STRING	DFNT_CHAR8

Table D-2: Type Conversions when Writing IDL Data to an HDF File

When reading data from an HDF file, HDF data types are converted to the IDL data types shown in the following table:

HDF Data Type	IDL Data Type
DFNT_CHAR8 or DFNT_UCHAR8	STRING
DFNT_INT8 or DFNT_UINT8	BYTE
DFNT_INT16	INT
DFNT_UINT16	UINT
DFNT_INT32	LONG
DFNT_UINT32	ULONG
DFNT_FLOAT32 or DFNT_NONE	FLOAT
DFNT_DOUBLE	DOUBLE

Table D-3: Type Conversions when Reading HDF Data into IDL

HDF type codes for the supported HDF data types are shown in the table below:

HDF Data Type	Type Code
DFNT_UCHAR8	3
DFNT_CHAR8	4
DFNT_FLOAT32	5
DFNT_DOUBLE	6
DFNT_INT8	20
DFNT_UINT8	21
DFNT_INT16	22
DFNT_UINT16	23
DFNT_INT32	24
DFNT_UINT32	25

Table D-4: HDF Data Type Codes

Common HDF Tag Numbers

The following table lists common HDF tag numbers and their meanings.

Tag Number	Meaning
030	Version Identifier
100	File Identifier
101	File Description
102	Tag Identifier
103	Tag Description
104	Data Identifier Label
105	Data Identifier Annotation
106	Number Type
107	Machine Type
200	Obsolete
201	Obsolete
202	Obsolete
203	Obsolete
204	Obsolete
300	RIG Image Dimension
301	Raster Image Look Up Table (LUT)
302	Raster Image
303	Compressed Raster Image
306	Raster Image Group (RIG)
307	RIG LUT Dimension
308	RIG Matte Dimension
309	Raster Image Matte Data

Table D-5: Common HDF Tag Numbers

Tag Number	Meaning
310	Raster Image Color Correction
311	Raster Image Color Format
312	Raster Image Aspect Ratio
400	Composite Image Descriptor
500	XY Position
602	Vector Image - Tek4014 Stream
603	Vector Image - Tek4105 Stream
701	SD Dimension Record
702	SD Data
703	SD Scales
704	SD Labels
705	SD Units
706	SD Formats
707	SD Max/Min
708	SD Coordinates
710	SD Link
720	SD Descriptor (NDG)
731	SD Calibration Information
732	SD Fill Value
1962	Vdata Description
1963	Vdata
1965	Vgroup

Table D-5: Common HDF Tag Numbers (Continued)

Alphabetical Listing of HDF Routines

The remainder of this chapter is an alphabetical listing of HDF Routines.

Note

The routines HDF_BROWSER and HDF_READ, introduced in IDL version 5.1, allow you to read HDF data files and import data into IDL using a graphical user interface. Using these two routines, you can avoid the need to use most of the rest of IDL's HDF interface. HDF_BROWSER and HDF_READ are discussed in the *IDL Reference Guide*.

HDF_AN_ANNLEN

This function returns the number of characters contained in the HDF AN annotation specified by the annotation identifier *ann_id*.

Syntax

Result = HDF_AN_ANNLEN(*ann_id*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ann_id

Annotation identifier returned by HDF_AN_CREATE, HDF_AN_CREATEF, or HDF_AN_SELECT.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_ANNLIST

This function obtains a list of identifiers of the annotations that are of the type specified by the parameter annot_type and are attached to the object identified by its tag, *obj_tag*, and its reference number, *obj_ref*.

Syntax

Result = HDF_AN_ANNLIST(*an_id*, *annot_type*, *obj_tag*, *obj_ref*, *ann_list*)

Return Value

Returns SUCCEED (0) or FAIL (-1) otherwise.

Arguments

an_id

HDF AN interface identifier returned by HDF_AN_START.

annot_type

Type of the annotation. Since this routine is implemented only to obtain the identifiers of data annotations and not file annotations, the valid values of *annot_type* are:

- 0 = data label
- 1 = data description

obj_tag

HDF tag of the object.

obj_ref

HDF reference number of the object.

ann_list

A named variable that will contain the annotation identifiers.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_ATYPE2TAG

This function returns the HDF tag that corresponds to the annotation type specified by the parameter *annot_type*.

Syntax

Result = HDF_AN_ATYPE2TAG(*annot_type*)

Return Value

Returns the HDF annotation tag (*ann_tag*) if successful, or not found (0) otherwise.

Arguments

annot_type

Type of the annotation. The following table lists the valid values of *annot_type* in the left column and the corresponding values for the returned annotation tag on the right.

Annotation Type	HDF Annotation Tag
0 = Data Label (AN_DATA_LABEL)	104 (DFTAG_DIL)
1= Data Description (AN_DATA_DESC)	105 (DFTAG_DIA)
2 = File Label (AN_FILE_LABEL)	100 (DFTAG_FID)
3 = File Description (AN_FILE_DESC)	101 (DFTAG_FD)

Table D-6: Valid annot_type and ann_tag values.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_CREATE

This function creates an HDF AN data annotation of type *annot_type* for the object specified by its HDF tag, *obj_tag*, and its HDF reference number, *obj_ref*. Use HDF_AN_CREATEF to create a file annotation. Currently, the user must write to a newly-created annotation before creating another annotation of the same type. Creating two consecutive annotations of the same type causes the second call to HDF_AN_CREATE to return FAIL (-1).

Syntax

Result = HDF_AN_CREATE(*an_id*, *obj_tag*, *obj_ref*, *annot_type*)

Return Value

Returns the data annotation identifier (*ann_id*) if successful or FAIL (-1) otherwise.

Arguments

an_id

HDF_AN_ INTERFACE identifier returned by HDF_AN_START.

obj_tag

HDF tag of the object to be annotated.

obj_ref

HDF reference number of the object to be annotated.

annot_type

Type of the data annotation.

The returned data annotation identifier can represent either a data label or a data description. Valid values for annot_type are:

- 0 = data label
- 1 = data description

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_CREATEF

This function creates an HDF AN file annotation of the type specified by the parameter *annot_type*. Use HDF_AN_CREATE to create a data annotation. Currently, the user must write to a newly-created annotation before creating another annotation of the same type. Creating two consecutive annotations of the same type causes the second call to HDF_AN_CREATE to return FAIL (-1)

Syntax

Result = HDF_AN_CREATEF(*an_id*, *annot_type*)

Return Value

Returns the file annotation identifier (*ann_id*) if successful or FAIL (-1) otherwise.

Arguments

an_id

HDF_AN_ INTERFACE identifier returned by HDF_AN_START.

annot_type

Type of the file annotation. The file annotation identifier returned can either represent a file label or a file description. Valid values for *annot_type* are:

- 2 = file label
- 3 = file description

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_END

This procedure terminates access to the HDF AN interface identified by *an_id*, which is previously initialized by a call to HDF_AN_START. Note that there must be one call to HDF_AN_END for each call to HDF_AN_START.

Syntax

HDF_AN_END, *an_id*

Arguments

an_id

HDF AN interface identifier returned by HDF_AN_START.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_ENDACCESS

This procedure terminates access to the annotation identified by the parameter ann_id. Note that there must be one call to HDF_AN_ENDACCESS for every call to HDF_AN_SELECT, HDF_AN_CREATE or HDF_AN_CREATEF.

Syntax

HDF_AN_ENDACCESS, *ann_id*

Arguments

ann_id

Annotation identifier returned by HDF_AN_CREATE, HDF_AN_CREATEF or HDF_AN_SELECT.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_FILEINFO

This function retrieves the total number of the four kinds of annotations and stores them in the appropriate parameters. Note that the numbers of data labels and descriptions refer to the total number of data labels and data descriptions in the file, not for a specific object. Use HDF_AN_NUMANN to determine these numbers for a specific object. This function is generally used to find the range of acceptable indices for HDF_AN_SELECT calls.

Syntax

Result = HDF_AN_FILEINFO(*an_id*, *n_file_labels*, *n_file_descs*, *n_data_labels*, *n_data_descs*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

an_id

HDF AN interface identifier returned by HDF_AN_START.

n_file_labels

A named variable that will contain the number of file labels.

n_file_descs

A named variable that will contain the number of file descriptions.

n_data_labels

A named variable that will contain the total number of data labels of all data objects in the file.

n_data_descs

A named variable that will contain the total number of data descriptions of all data objects in the file.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_GET_TAGREF

This function retrieves the HDF tag and reference number of the annotation identified by its index and by its annotation type.

Syntax

Result = HDF_AN_GET_TAGREF(*an_id*, *index*, *annot_type*, *ann_tag*, *ann_ref*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

an_id

HDF AN interface identifier returned by HDF_AN_START.

index

Index of the annotation. This parameter is a nonnegative integer and is less than the total number of annotations of type *annot_type* in the file. Use HDF_AN_FILEINFO to obtain the total number of annotations of each type in the file.

annot_type

Type of the annotation. The following table lists the valid values of the parameter annot_type in the left column, and the corresponding values of the parameter ann_tag in the right column.

Annotation Type	HDF Annotation Tag
0 = Data Label (AN_DATA_LABEL)	104 (DFTAG_DIL)
1= Data Description (AN_DATA_DESC)	105 (DFTAG_DIA)
2 = File Label (AN_FILE_LABEL)	100 (DFTAG_FID)
3 = File Description (AN_FILE_DESC)	101 (DFTAG_FD)

Table D-7: Valid annot_type and ann_tag values.

ann_tag

A named variable that will contain the HDF tag of the annotation.

ann_ref

A named variable that will contain the HDF reference number of the annotation.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_ID2TAGREF

This function retrieves the HDF tag/reference number pair of the HDF AN annotation identified by its annotation identifier.

Syntax

Result = HDF_AN_ID2TAGREF(*ann_id*, *ann_tag*, *ann_ref*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ann_id

HDF AN annotation identifier returned by HDF_AN_SELECT, HDF_AN_CREATE or HDF_AN_CREATEF.

ann_tag

A named variable that will contain the HDF tag of the annotation. Possible values returned in ann_tag are:

- 104 = data label (DFTAG_DIL)
- 105 = data description (DFTAG_DIA)
- 100 = file label (DFTAG_FID)
- 101 = file description (DFTAG_FD)

ann_ref

A named variable that will contain the HDF reference number of the annotation.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_NUMANN

This function returns the total number of HDF AN annotations that are of a given type and that are attached to the object identified by its HDF tag and its HDF reference number.

Syntax

Result = HDF_AN_NUMANN(*an_id*, *annot_type*, *obj_tag*, *obj_ref*)

Return Value

Returns the number of annotations or FAIL (-1) otherwise.

Arguments

an_id

HDF AN interface identifier returned by HDF_AN_START.

annot_type

Type of the annotation. The following table lists the valid values of the parameter annot_type in the left column, and the corresponding values of the parameter ann_tag in the right column.

Annotation Type	HDF Annotation Tag
0 = Data Label (AN_DATA_LABEL)	104 (DFTAG_DIL)
1 = Data Description (AN_DATA_DESC)	105 (DFTAG_DIA)
2 = File Label (AN_FILE_LABEL)	100 (DFTAG_FID)
3 = File Description (AN_FILE_DESC)	101 (DFTAG_FD)

Table D-8: Valid annot_type and ann_tag values.

obj_tag

HDF tag of the object.

obj_ref

HDF reference number of the object. Since this routine is implemented only to obtain the total number of data annotations and not file annotations, the valid values of annot_type are:

- 0 = data label
- 1 = data description

To obtain the total number of file annotations or all data annotations, use HDF_AN_FILEINFO.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_READANN

This function reads the HDF AN annotation identified by the annotation identifier and stores the annotation into a variable.

Syntax

Result = HDF_AN_READANN(*ann_id*, *annotation* [, LENGTH=*characters*])

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ann_id

Annotation identifier returned by HDF_AN_CREATE, HDF_AN_CREATEF or HDF_AN_SELECT.

annotation

A named variable that will contain the annotation.

Keywords

LENGTH

Specifies the number of characters to be read from the annotation argument. If LENGTH is not set, or LENGTH is greater than the number of characters in annotation, then the entire annotation is read.

Version History

Introduced: 5.2

HDF_AN_SELECT

This function obtains the HDF AN identifier of the annotation specified by its index and by its annotation type.

Syntax

Result = HDF_AN_SELECT(*an_id*, *index*, *annot_type*)

Return Value

Returns the annotation identifier (*ann_id*) if successful or FAIL (-1) otherwise.

Arguments

an_id

HDF_AN_ INTERFACE identifier returned by HDF_AN_START.

index

Location of the annotation in the file. This parameter is a nonnegative integer and is less than the total number of annotations of type annot_type in the file minus 1. Use HDF_AN_FILEINFO to obtain the total number of annotations of each type in the file.

annot_type

Type of the annotation. Valid values of annot_type are:

- 0 = data labels
- 1 = data descriptions
- 2 = file labels
- 3 = file descriptions

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_START

This function initializes the HDF AN interface for the specified file. A call to HDF_AN_START is required before any HDF AN functions can be invoked. HDF_AN_START is used with the HDF_AN_END function to define the extent of an HDF AN session. A call to HDF_AN_END is required for each call to HDF_AN_START.

Syntax

Result = HDF_AN_START(*file_id*)

Return Value

Returns the HDF AN interface identifier (an_id) if successful or FAIL (-1) otherwise.

Arguments

file_id

File identifier returned by HDF_OPEN. Note that each call to HDF_OPEN *must* be terminated with a call to HDF_CLOSE.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_TAG2ATYPE

This function returns the HDF AN annotation type that corresponds to the specified HDF annotation tag.

Syntax

Result = HDF_AN_TAG2ATYPE(*ann_tag*)

Return Value

Returns the annotation type if successful or FAIL (-1) otherwise.

Arguments

ann_tag

HDF tag of the annotation.

The following table lists the valid values of ann_tag in the left column and the corresponding values of the returned annotation type in the right column.

Annotation Type	HDF Annotation Tag
0 = Data Label (AN_DATA_LABEL)	104 (DFTAG_DIL)
1= Data Description (AN_DATA_DESC)	105 (DFTAG_DIA)
2 = File Label (AN_FILE_LABEL)	100 (DFTAG_FID)
3 = File Description (AN_FILE_DESC)	101 (DFTAG_FD)

Table D-9: Valid annot_type and ann_tag values.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_TAGREF2ID

This function returns the HDF AN identifier of the annotation specified by its HDF tag and its HDF reference number.

Syntax

Result = HDF_AN_TAGREF2ID(*an_id*, *ann_tag*, *ann_ref*)

Return Value

Returns the annotation identifier (*ann_id*) if successful or FAIL (-1) otherwise.

Arguments

an_id

HDF_AN_ INTERFACE identifier returned by HDF_AN_START.

ann_tag

HDF tag of the annotation. Valid values are:

- 104 = data label (DFTAG_DIL)
- 105 = data description (DFTAG_DIA)
- 100 = file label (DFTAG_FID)
- 101 = file description (DFTAG_FD)

ann_ref

HDF reference number of the annotation.

Keywords

None.

Version History

Introduced: 5.2

HDF_AN_WRITEANN

This function writes the annotation text provided in the parameter *annotation* to the HDF AN annotation specified by the parameter *ann_id*.

Syntax

Result = HDF_AN_WRITEANN(*ann_id*, *annotation* [, LENGTH=*characters*])

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ann_id

Annotation identifier returned by HDF_AN_CREATE, HDF_AN_CREATEF, or HDF_AN_SELECT.

annotation

Text or IDL variable to be written as the annotation.

Keywords

LENGTH

Length of the annotation text to be written. If not specified, the entire annotation will be written. If the keyword LENGTH is set, then only LENGTH characters of the annotation will be written. If the annotation has already been written, HDF_AN_WRITEANN will overwrite the current text.

Version History

Introduced: 5.2

HDF_BROWSER

See HDF_BROWSER in the *IDL Reference Guide.*

HDF_CLOSE

The HDF_CLOSE procedure closes the HDF file associated with the given file handle.

Syntax

HDF_CLOSE, *FileHandle*

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

HDF_OPEN

HDF_DELDD

The HDF_DELDD procedure deletes a tag or reference from the list of data descriptors in an HDF file.

Syntax

HDF_DELDD, *FileHandle*, *Tag*, *Ref*

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

Tag

The data descriptor tag to delete.

Ref

The data descriptor reference number to delete.

Keywords

None.

Version History

Introduced: Pre 4.0

HDF_DF24_ADDIMAGE

The HDF_DF24_ADDIMAGE procedure writes a 24-bit raster image to an HDF file. The interlace is set automatically based upon the dimensions of the image being written: ARR(3, Width, Height) for pixel interlace, ARR(Width, 3, Height) for scan-line interlace, and ARR(Width, Height, 3) for scan-plane interlace.

Note

HDF_DF24_ADDIMAGE chooses an interlace based upon the location of the '3'-sized dimension. For 3x3xN, 3xNx3 and Nx3x3 images, if the first '3' encountered is supposed to be a width or height, HDF_DF24_ADDIMAGE will choose the 'wrong' interlace. However, as long as one reads in the image using the same interlace, the image will be read correctly anyway. Avoid writing 24-bit-deep raster images with a width or height of 3 pixels.

Note

Input data is converted to bytes before being written to the file, as images in the DF24 HDF model are necessarily byte images.

Syntax

HDF_DF24_ADDIMAGE, *Filename*, *Image* [, /FORCE_BASELINE{useful only if QUALITY<25}] [, /JPEG | , /RLE] [, QUALITY=*value*{0 to 100}]

Arguments

Filename

A scalar string containing the name of the file to be written.

Image

A 3-dimensional array of values representing the 3 planes (Red, Green, and Blue) of the 24-bit image. One of the dimensions *must* be 3 (e.g., a 3 x 100 x 100 array).

Keywords

FORCE_BASELINE

Set this keyword to force the JPEG quantization tables to be constrained to the range 1 to 255. This provides full baseline compatibility with external JPEG applications, but only makes a difference if the QUALITY keyword is set to a value less than 25. The default is TRUE.

JPEG

Set this keyword to compress the image being added using the JPEG (Joint Photographic Expert Group) method. Note that JPEG compression is *lossy*; see WRITE_JPEG in the *IDL Reference Guide* for more information about when this method is appropriate. (In other words, using JPEG compression to reduce the size of an image changes the values of the pixels and hence may alter the meaning of the corresponding data.) Setting either the QUALITY or the FORCE_BASELINE keyword implies this method.

QUALITY

Set this keyword equal to the JPEG “quality” desired. This value should be in the range 0 (terrible image quality but excellent compression) to 100 (excellent image quality but minimum compression). The default is 75. Setting this keyword implies that the JPEG keyword is set. Lower values of QUALITY produce higher compression ratios and smaller files.

RLE

Set this keyword to store the image using run length compression. RLE compression is lossless, and is recommended for images where data retention is critical.

Version History

Introduced: 4.0

See Also

WRITE_JPEG in the *IDL Reference Guide*.

HDF_DF24_GETIMAGE

The HDF_DF24_GETIMAGE procedure reads a 24-bit raster image from an HDF file. The default is to use the same format for reading as that used in writing the image. Note: it is slower to read an image in a different interlace than the one in which the image was originally written.

Syntax

HDF_DF24_GETIMAGE, *Filename*, *Image* [, /LINE | , /PIXEL | , /PLANE]

Arguments

Filename

A scalar string containing the name of the file to be read.

Image

A named variable in which the image data is returned.

Keywords

LINE

Set this keyword to force the image to be read with scan-line interlace.

PIXEL

Set this keyword to force the image to be read with pixel interlace.

PLANE

Set this keyword to force the image to be read with scan-plane interlace.

Version History

Introduced: 4.0

HDF_DF24_GETINFO

The HDF_DF24_GETINFO procedure retrieves information about the current 24-bit HDF image.

Syntax

HDF_DF24_GETINFO, *Filename*, *Width*, *Height*, *Interlace*

Arguments

Filename

A string containing the name of the file to be read.

Width

A named variable in which the width of the image is returned.

Height

A named variable in which the height of the image is returned.

Interlace

A named variable in which the interface method is returned. The returned value is 0 for pixel interlacing, 1 for scan-line interlacing, and 2 for scan-plane interlacing.

Keywords

None.

Examples

```
; Open the file myhdf.hdf:
h = HDF_OPEN('myhdf.hdf')
; Return information about the 24-bit image:
HDF_DF24_GETINFO, 'myhdf.hdf', width, height, interlace
; Print information about the returned variables:
HELP, width, height, interlace
HDF_CLOSE('myhdf.hdf') ; Close the HDF file.
```

IDL Output

If the image were 536 by 412 pixels, and scan-line interlaced, IDL would print:

```
WIDTH LONG = 536
HEIGHT LONG = 412
INTERLACE LONG = 1
```

For a more detailed example, see the file `hdf_info.pro`, located in the `examples/data_access/sdf` subdirectory of the IDL distribution.

Version History

Introduced: 4.0

See Also

HDF_DF24_GETIMAGE, HDF_DF24_LASTREF, HDF_DF24_NIMAGES, HDF_DF24_READREF, HDF_DF24_RESTART

HDF_DF24_LASTREF

The HDF_DF24_LASTREF function returns the reference number of the most recently read or written 24-bit image in an HDF file.

Syntax

Result = HDF_DF24_LASTREF( )

Return Value

Returns the reference number of the most recently read or written image.

Arguments

None.

Keywords

None.

Examples

```
; Open an HDF file.
h=HDF_OPEN('myhdf.hdf')
PRINT, HDF_DF24_LASTREF()
; IDL prints 0, meaning that the call was successful,
; but no reference number was available.

; Create a 3D array, representing a 24-bit image:
a = BINDGEN(3,100,100)

; Write the 24-bit image to the file:
HDF_DF24_ADDIMAGE, 'myhdf.hdf', a

PRINT, HDF_DF24_LASTREF()
; IDL prints a reference number for the last operation
; (for example, 2). Note the reference number is not
; simply a 1-based "image number"; the reference number
; could easily be "2" or "3", etc.

; Write another image to the file:
HDF_DF24_ADDIMAGE, 'myhdf.hdf', a
```

```
; Print the last reference number:
PRINT, HDF_DF24_LASTREF()
PRINT, HDF_DF24_NIMAGES('myhdf.hdf')
; IDL prints "2" because we've written two images to the file.
; Close the file
HDF_CLOSE, h
```

Version History

Introduced: 4.0

See Also

HDF_DF24_ADDIMAGE, HDF_DF24_GETIMAGE, HDF_DF24_GETINFO, HDF_DF24_NIMAGES, HDF_DF24_READREF, HDF_DF24_RESTART, HDF_DFR8_LASTREF

HDF_DF24_NIMAGES

The HDF_DF24_NIMAGES function returns the number of 24-bit images in an HDF file.

Syntax

Result = HDF_DF24_NIMAGES(*Filename*)

Return Value

Returns the number of images in the file or -1 if the specified file is invalid or damaged

Arguments

Filename

A string containing the name of the file to be searched.

Keywords

None.

Examples

```
; Open HDF file:
h = HDF_OPEN('myhdf.hdf')
; Return the number of 24-bit images in the file:
number = HDF_DF24_NIMAGES('myhdf.hdf')
; Print information about the returned value. If there were five
; images in the file, IDL would print NUMBER LONG = 5
HELP, number
; Close the HDF file:
HDF_CLOSE, h
```

Version History

Introduced: 4.0

See Also

HDF_DF24_GETIMAGE, HDF_DF24_GETINFO, HDF_DF24_READREF, HDF_DF24_RESTART, HDF_DFR8_NIMAGES

HDF_DF24_READREF

The HDF_DF24_READREF procedure sets the reference number of the image in an HDF file to be read by the next call to HDF_DF24_GETIMAGE.

Syntax

HDF_DF24_READREF, *Filename*, *Refno*

Arguments

Filename

A scalar string containing the name of the file to be read.

Refno

The reference number for a 24-bit raster image.

Keywords

None.

Version History

Introduced: 4.0

HDF_DF24_RESTART

The HDF_DF24_RESTART procedure causes the next call to HDF_DF24_GETIMAGE to read the first 24-bit image in the HDF file.

Syntax

HDF_DF24_RESTART

Arguments

None.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFAN_ADDFDS

The HDF_DFAN_ADDFDS procedure adds a file description to an HDF file.

Syntax

HDF_DFAN_ADDFDS, *Filename*, *Description*

Arguments

Filename

A scalar string containing the name of the file to be written.

Description

A string or a array of bytes containing the information to be written.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFAN_ADDFID

The HDF_DFAN_ADDFID procedure adds a file annotation to an HDF file. A file can have multiple annotations added.

Syntax

HDF_DFAN_ADDFID, *Filename*, *Label*

Arguments

Filename

A scalar string containing the name of the file to be written.

Label

A string containing the annotation string.

Keywords

None.

Examples

```
; Open the HDF file:
filename = 'FID.hdf'
hid = HDF_OPEN(filename,/CREATE)
; Write two file annotations:
HDF_DFAN_ADDFID, filename, 'File Annotation #1'
HDF_DFAN_ADDFID, filename, 'File Annotation #2'
; Read the two annotations back:
HDF_DFAN_GETFID, filename, fid1
HDF_DFAN_GETFID, filename, fid2
HELP, fid1, fid2
; Try to read a non-existent FID:
HDF_DFAN_GETFID, filename, fid3
; Read the FIRST fid again, using the FIRST keyword:
HDF_DFAN_GETFID, filename, fid4, /FIRST
HELP, fid4
; Close the HDF file:
HDF_CLOSE, hid
```

IDL Output

```
FID1            STRING    = 'File Annotation #1'
FID2            STRING    = 'File Annotation #2'

% HDF_DFAN_GETFID: Could not read ID length

FID4            STRING    = 'File Annotation #1'
```

Version History

Introduced: 4.0

HDF_DFAN_GETDESC

The HDF_DFAN_GETDESC procedure reads the description for the given tag and reference number in an HDF file.

Syntax

HDF_DFAN_GETDESC, *Filename*, *Tag*, *Ref*, *Description* [, /STRING]

Arguments

Filename

A scalar string containing the name of the file to be read.

Tag

The tag number.

Ref

The reference number.

Description

A named variable in which the description is returned as a vector of bytes.

If a description does not exist, the *Description* variable will contain either a 0L (long-integer zero) or a blank string, and a warning message will be printed. Warning messages can be suppressed by setting the !QUIET system variable to a non-zero value.

Keywords

STRING

Set this keyword to return the description as a string rather than a vector of bytes.

Examples

```
desc1 = 'FILE DESCRIPTION NUMBER 1'
tag_image = 302
file = 'DEMOdesc.hdf'
fid = HDF_OPEN(file, /CREATE)
HDF_DFR8_ADDIMAGE, file, DIST(10)
HDF_DFAN_PUTDESC, file, tag_image, HDF_DFR8_LASTREF(), desc1
; Read the description and return a vector of bytes:
HDF_DFAN_GETDESC, file, tag_image, HDF_DFR8_LASTREF(), out_desc1
HELP, out_desc1
PRINT, STRING(out_desc1)
; Read the description and return an IDL string variable:
HDF_DFAN_GETDESC, file, tag_image, HDF_DFR8_LASTREF(), $
    out_desc2, /STRING
HELP, out_desc2
HDF_CLOSE, fid
```

IDL Output

```
OUT_DESC1       BYTE      = Array(25)

FILE DESCRIPTION NUMBER 1

OUT_DESC2       STRING    = 'FILE DESCRIPTION NUMBER 1'
```

Version History

Introduced: 4.0

See Also

HDF_DFAN_PUTDESC

HDF_DFAN_GETFDS

The HDF_DFAN_GETFDS procedure reads the next available file description from an HDF file.

Syntax

HDF_DFAN_GETFDS, *Filename*, *Description* [, /FIRST] [, /STRING]

Arguments

Filename

A string containing the name of the file to be read.

Description

A named variable in which the description is returned. By default, the description is returned as a vector of bytes. Set the STRING keyword to return the description as a string.

If a description does not exist, the *Description* variable will contain either a 0L (long-integer zero) or a blank string, and a warning message will be printed. Warning messages can be suppressed by setting the !QUIET system variable to a non-zero value.

Keywords

FIRST

Set this keyword to read the first file description in the file. If FIRST is not set, the next available file description (which can be the first file description) will be read.

STRING

Set this keyword to return *Description* as a string instead of a vector of bytes.

Examples

```
filename = 'DEMOfds.hdf'
fds1 = 'FILE DESCRIPTION NUMBER 1'
fds2 = 'SHORT FDS 2'
; Create an HDF file:
fid = HDF_OPEN(filename, /CREATE)
; Add first file description:
HDF_DFAN_ADDFDS, filename, fds1
; Add second file description:
HDF_DFAN_ADDFDS, filename, fds2
; Get the first file description:
HDF_DFAN_GETFDS, filename, out_fds1, /FIRST
HELP, out_fds1
PRINT, STRING(out_fds1)
; Get the second file description:
HDF_DFAN_GETFDS, filename, out_fds2, /STRING
HELP, out_fds2
; Close the HDF file:
HDF_CLOSE, fid
```

IDL Output

```
OUT_FDS1        BYTE      = Array(25)

FILE DESCRIPTION NUMBER 1

OUT_FDS2        STRING    = 'SHORT FDS 2'
```

Version History

Introduced: 4.0

See Also

HDF_DFAN_ADDFDS, HDF_DFAN_ADDFID, HDF_DFAN_GETDESC, HDF_DFAN_GETFID

HDF_DFAN_GETFID

The HDF_DFAN_GETFID procedure reads the next available file annotation from an HDF file.

Syntax

HDF_DFAN_GETFID, *Filename*, *Label* [, /FIRST]

Arguments

Filename

A scalar string containing the name of the file to be read.

Label

A named variable in which the annotation is returned as a string.

Keywords

FIRST

Set this keyword to read the first annotation in the file. Otherwise, the next available annotation is read (which may be the first annotation).

Examples

For an example using this routine, see “HDF_DFAN_ADDFID” on page 3288.

Version History

Introduced: 4.0

HDF_DFAN_GETLABEL

The HDF_DFAN_GETLABEL procedure reads the label for the given tag-reference pair in an HDF file.

Syntax

HDF_DFAN_GETLABEL, *Filename*, *Tag*, *Ref*, *Label*

Arguments

Filename

A scalar string that contains the name of the file to be read.

Tag

The tag number.

Ref

The reference number.

Label

A named variable in which the label is returned as a string.

Keywords

None.

Examples

```
fid = HDF_OPEN('test.hdf', /ALL)
label = 'TEST LABEL'
tag = 105 ; The annotation tag.
ref = 2 ; Choose a reference number.
; Write the label:
HDF_DFAN_PUTLABEL, 'test.hdf', tag, ref, label
; Read back the label:
HDF_DFAN_GETLABEL, 'test.hdf', tag, ref, outl
HELP, outl ; They look the same...
; OUTL            STRING    = 'TEST LABEL'
; Close the HDF file:
HDF_CLOSE, fid
```

Version History

Introduced: 4.0

See Also

HDF_DFAN_GETDESC, HDF_DFAN_LABLIST, HDF_DFAN_PUTDESC, HDF_DFAN_PUTLABEL

HDF_DFAN_LABLIST

The HDF_DFAN_LABLIST function retrieves a list of the reference numbers and the corresponding labels for a given tag in an HDF file.

Syntax

Result = HDF_DFAN_LABLIST(*Filename*, *Tag*, *Reflist*, *Labellist* [, LISTSIZE=*value*] [, MAXLABEL=*value*] [, STARTPOS=*value*] [, /STRING])

Return Value

If successful, the number of entries found is returned.

Arguments

Filename

A scalar string containing the name of the file to be read.

Tag

The tag number.

Reflist

A named variable in which an array of reference numbers associated with the given tag is returned.

Labellist

A named variable in which an array of labels is returned. Unless the STRING keyword is set, *Labellist* will contain an N_ELEMENTS(*Reflist*) by MAXLABEL array of bytes. Note that array elements containing labels that are shorter than MAXLABEL will be padded with zeroes.

Keywords

LISTSIZE

Set the maximum size of the *Reflist* and *Labellist* returned. The default is to read all references present, or 20 if the inquiry to obtain the number of references fails.

MAXLABEL

Use this keyword to override the default label length of 16.

STARTPOS

Use this keyword to set the default starting position in the *Reflist* array.

STRING

Set this keyword to return an array of strings rather than an array of bytes. If STRING is set, the MAXLABEL keyword is ignored and full-length strings are returned.

Examples

```
tag_image = 302
file = 'DEMOlablist.hdf'
n_images = HDF_DFAN_LABLIST(file, tag_image, refs, list, /STRING)
help, n_images, refs, list
PRINT, list(0)
; Find all the compressed images:
tag_image_comp = 303
n_comp_images = HDF_DFAN_LABLIST(file, tag_image_comp, $
   refs, list, MAXLABEL=5)
HELP, n_comp_images, refs, list
```

IDL Output

```
N_IMAGES        LONG      =            2
REFS            INT       = Array(2)
LIST            STRING    = Array(2)

SAMPLE IMAGE LABEL

N_COMP_IMAGES   LONG      =            3
REFS            INT       = Array(3)
LIST            BYTE      = Array(5, 3)
```

Version History

Introduced: 4.0

See Also

HDF_DFAN_GETLABEL, HDF_DFAN_PUTLABEL

HDF_DFAN_LASTREF

The HDF_DFAN_LASTREF function returns the reference number of the most recently read or written annotation in an HDF file.

Syntax

Result = HDF_DFAN_LASTREF( )

Return Value

Returns the reference number of the most recently read or written annotation.

Arguments

None.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFAN_PUTDESC

The HDF_DFAN_PUTDESC procedure writes a description for the given tag and reference number in an HDF file.

Bugs

Attempting to overwrite an existing description with a longer one fails.

Overwriting an existing description with a shorter description succeeds, but the description length is unchanged and garbage characters are left at the end of the description.

Syntax

HDF_DFAN_PUTDESC, *Filename*, *Tag*, *Ref*, *Description*

Arguments

Filename

A scalar string containing the name of the file to be written.

Tag

The tag number.

Ref

The reference number.

Description

A string or array of bytes containing the information to be written.

If a description does not exist, the *Description* variable will contain either a 0L (long-integer zero) or a blank string, and a warning message will be printed. Warning messages can be suppressed by setting the !QUIET system variable to a non-zero value.

Keywords

None.

Examples

See the example for "HDF_DFAN_GETDESC" on page 3290.

Version History

Introduced: 4.0

HDF_DFAN_PUTLABEL

The HDF_DFAN_PUTLABEL procedure writes a label for the given tag and reference number in an HDF file.

Bugs

Due to a problem in the HDF version 4.0 library, attempting to rewrite a label fails. For example:

```
file = 'blah.hdf' ; Specify a file
; Specify tag and reference numbers:
tag = 105 & ref = 40
; Make label "XXXX":
HDF_DFAN_PUTLABEL, file, tag, ref, 'XXXX'
; Label now "YY":
HDF_DFAN_PUTLABEL, file, tag, ref, 'YY'
; Delete the file:
OPENU, unit, file, /DELETE, /GET & CLOSE, unit
; Now try to re-use label "XXXX":
HDF_DFAN_PUTLABEL, file, tag, ref, 'XXXX'
```

IDL Output

```
% HDF_DFAN_PUTLABEL: Failed to write label
% Execution halted at:  $MAIN$
```

Syntax

HDF_DFAN_PUTLABEL, *Filename*, *Tag*, *Ref*, *Label*

Arguments

Filename

A scalar string containing the name of the file to be written.

Tag

The tag number.

Ref

The reference number.

Label

A string containing the description to write.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_ADDPAL

The HDF_DFP_ADDPAL procedure appends a palette to an HDF file.

Syntax

HDF_DFP_ADDPAL, *Filename*, *Palette*

Arguments

Filename

A scalar string containing the name of the file to be written.

Palette

A vector or array containing palette data. Palettes must be either [3, 256] arrays or 786-element vectors.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_GETPAL

The HDF_DFP_GETPAL procedure reads the next available palette from an HDF file.

Syntax

HDF_DFP_GETPAL, *Filename*, *Palette*

Arguments

Filename

A scalar string containing the name of the file to be read.

Palette

A named variable in which the palette data is returned.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_LASTREF

The HDF_DFP_LASTREF function returns the reference number of the most recently read or written palette in an HDF file.

Syntax

Result = HDF_DFP_LASTREF( )

Return Value

Returns the reference number of the most recently read or written palette.

Arguments

None.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_NPALS

The HDF_DFP_NPALS function returns the number of palettes present in an HDF file. This number includes palettes associated with RIS8 (8-bit raster) images.

Syntax

Result = HDF_DFP_NPALS(*Filename*)

Return Value

Returns the number of palettes.

Arguments

Filename

A scalar string containing the name of the desired HDF file.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_PUTPAL

The HDF_DFP_PUTPAL procedure appends a palette to an HDF file.

Syntax

HDF_DFP_PUTPAL, *Filename*, *Palette* [, /DELETE] [, /OVERWRITE]

Arguments

Filename

A scalar string containing the name of the file to be written.

Palette

A vector or array containing palette data. Palettes must be either [3, 256] arrays or 786-element vectors.

Keywords

DELETE

Set this keyword to delete the HDF file (if it exists) and create a new HDF file with the specified palette as its first object.

Note

The HDF file must be closed before the DELETE keyword is specified. Attempting to delete an open HDF file will result in an error.

OVERWRITE

Set this keyword to overwrite the previous palette with the one specified by *Palette*.

Examples

```
; Create HDF file:
id = HDF_OPEN('test.hdf', /CREATE, /RDWR)
; Add a palette:
HDF_DFP_PUTPAL,'test.hdf'', FINDGEN(3,256)
; Print number of palettes:
PRINT, HDF_DFP_NPALS('test.hdf')
```

```
; Append a palette:
HDF_DFP_PUTPAL,'test.hdf',findgen(3,256)
; Print the number of palettes:
PRINT, HDF_DFP_NPALS('test.hdf')
; Overwrite the last palette:
HDF_DFP_PUTPAL, 'test.hdf', FINDGEN(3,256), /OVERWRITE
; Print the number of palettes:
PRINT, HDF_DFP_NPALS('test.hdf')
; An attempt to delete a file and add a new palette
; without first closing the HDF file fails:
HDF_DFP_PUTPAL, 'test.hdf', $
   FINDGEN(3,256), /DELETE
; Close the HDF file:
HDF_CLOSE, id
; Delete file and add a new palette:
HDF_DFP_PUTPAL, 'test.hdf', FINDGEN(3,256), /DELETE
; Print the number of palettes:
PRINT, HDF_DFP_NPALS('test.hdf')
```

IDL Output

```
1

2

2

% HDF_DFP_PUTPAL: Could not write palette
% Execution halted at:  $MAIN$

1
```

Version History

Introduced: 4.0

HDF_DFP_READREF

The HDF_DFP_READREF procedure sets the reference number of the palette in an HDF file to be read by the next call to HDF_DFP_GETPAL.

Syntax

HDF_DFP_READREF, *Filename*, *Refno*

Arguments

Filename

A scalar string containing the name of the file to be read.

Refno

The reference number of a palette.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_RESTART

The HDF_DFP_RESTART procedure causes the next call to HDF_DFR8_GETPAL to read from the first palette in an HDF file.

Syntax

HDF_DFP_RESTART

Arguments

None.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFP_WRITEREF

The HDF_DFP_WRITEREF procedure sets the reference number for the next palette to be written to an HDF file. Normally, the HDF library automatically chooses a reference number for the palette. This procedure allows you to override that choice.

Syntax

HDF_DFP_WRITEREF, *Filename*, *Refno*

Arguments

Filename

A scalar string containing the name of the file to be read.

Refno

The new reference number.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFR8_ADDIMAGE

The HDF_DFR8_ADDIMAGE procedure appends an 8-bit raster image to the specified HDF file.

Note

Input data is converted to bytes before being written to the file, as images in the DFR8 HDF model are necessarily byte images.

Syntax

HDF_DFR8_ADDIMAGE, *Filename*, *Image* [, /FORCE_BASELINE{useful only if QUALITY<25}] [, /JPEG | , /RLE] [[, /IMCOMP] , PALETTE=*vector or array*] [, QUALITY=*value*]

Arguments

Filename

A scalar string containing the name of the file to be written.

Image

A two-dimensional array containing the image data. If this array is not byte-type data, it is converted to bytes before writing.

Keywords

FORCE_BASELINE

Set this keyword to force the JPEG quantization tables to be constrained to the range 1...255. This provides full baseline compatibility with external JPEG applications, but only makes a difference if the QUALITY keyword is set to a value less than 25. The default is TRUE.

JPEG

Set this keyword to compress the image being added using the JPEG (Joint Photographic Expert Group) method. Note that JPEG compression is *lossy*; see WRITE_JPEG in the *IDL Reference Guide* for more information about when this method is appropriate. (In other words, using JPEG compression to reduce the size of

an images changes the values of the pixels and hence may alter the meaning of the corresponding data.) Setting either the QUALITY or the FORCE_BASELINE keywords implies this method.

IMCOMP

Set this keyword to store the image using imcomp data compression. Note that you *must* specify a palette. Note also that the JPEG and RLE compression methods are far superior; imcomp data compression should only be used if the images will be viewed on monitors with a very small number of colors (monochrome or 16-color).

PALETTE

Set this keyword to a vector or array containing valid palette data. Palettes must be either [3, 256] arrays or 786-element vectors. Set PALETTE equal to zero to specify that no palette be used. If the PALETTE keyword is not specified, the current palette (which may be no palette, if a palette has not been specified elsewhere or if the null palette has been explicitly specified with HDF_DFR8_SETPALETTE) will be used.

Note that if a palette is specified, it becomes the current palette, even if a default palette has been specified with HDF_DFR8_SETPALETTE.

Note also that if IMCOMP data reduction is used, you *must* specify a valid palette with the PALETTE keyword. It is not sufficient to set the current palette via other means.

QUALITY

Set this keyword equal to the JPEG “quality” desired. This value should be in range 0 (terrible image quality but excellent compression) to 100 (excellent image quality but minimum compression). The default is 75. Setting this keyword implies that the JPEG keyword is set. Lower values of QUALITY produce higher compression ratios and smaller files.

RLE

Set this keyword to store the image using run length compression. RLE compression is lossless, and is recommended for images where data retention is critical.

Examples

Assuming that we start with a file, `new.hdf`, with no 8-bit raster images, images could be appended and overwritten, with the following commands:

```
; Write the first image to the file:
HDF_DFR8_ADDIMAGE, 'new.hdf', Image1
; Append 2nd image:
HDF_DFR8_ADDIMAGE, 'new.hdf', Image2
; Append 3rd image:
HDF_DFR8_ADDIMAGE, 'new.hdf', Image3
; Use HDF_DFR8_PUTIMAGE to erase all previous images and
; write a new image at the first position in the file:
HDF_DFR8_PUTIMAGE, 'new.hdf', Image4
; Append 2nd image:
HDF_DFR8_ADDIMAGE, 'new.hdf', Image5
```

Version History

Introduced: 4.0

See Also

HDF_DFR8_GETIMAGE, HDF_DFR8_PUTIMAGE, WRITE_JPEG (in the *IDL Reference Guide*).

HDF_DFR8_GETIMAGE

The HDF_DFR8_GETIMAGE procedure retrieves an image and optionally, its palette, from an HDF file.

Syntax

HDF_DFR8_GETIMAGE, *Filename*, *Image* [, *Palette*]

Arguments

Filename

A scalar string containing the name of the file to be read.

Image

A named variable in which the image is returned.

Palette

A named variable in which the palette is returned as a 3-element by 256-element byte array. If the image does not have an associated palette, this variable is returned as 0.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFR8_GETINFO

The HDF_DFR8_GETINFO procedure retrieves information about the current 8-bit HDF image.

Syntax

HDF_DFR8_GETINFO, *Filename*, *Width*, *Height*, *Has_Palette*

Arguments

Filename

A string containing the name of the file to be read.

Width

A named variable in which the width of the image is returned.

Height

A named variable in which the height of the image is returned.

Has_Palette

A named variable in which 1 is returned if a palette is present. Otherwise, 0 is returned.

Keywords

None.

Examples

```
; Open the file myhdf.hdf:
h = HDF_OPEN('myhdf.hdf')
; Retrieve info about an image:
HDF_DFR8_GETINFO, 'myhdf.hdf', width, height, has_palette
; Print info about returned variables:
HELP, width, height, has_palette
; Close the HDF file:
HDF_CLOSE('myhdf.hdf')
```

IDL Output

```
WIDTH LONG = 536
HEIGHT LONG = 412
HAS_PALETTE LONG = 1
```

For a more detailed example, see the file `hdf_info.pro`, located in the `examples/data_access/sdf` subdirectory of the IDL distribution.

Version History

Introduced: 4.0

See Also

HDF_DFR8_GETIMAGE, HDF_DFR8_NIMAGES, HDF_DFR8_READREF, HDF_DFR8_RESTART

HDF_DFR8_LASTREF

The HDF_DFR8_LASTREF function returns the reference number of the most recently read or written 8-bit image in an HDF file.

Syntax

Result = HDF_DFR8_LASTREF( )

Return Value

Returns the reference number of the most recently read or written image.

Arguments

None.

Keywords

None.

Examples

```
h = HDF_OPEN('myhdf.hdf') ; Open an hdf file.
;IDL prints "0", meaning that the call was successful,
; but no reference number was available:
PRINT, HDF_DFR8_LASTREF()
;Create a 2D array representing an 8-bit image:
a = BINDGEN(100,100)
; Write the image to the file:
HDF_DFR8_ADDIMAGE, 'myhdf.hdf', a
;IDL prints the reference number for the last 8-bit image
; operation (for example, "2"). Note the reference number
; is not simply a 1-based "image number"; it could easily be
; "2" or "3" for the first operation on the file:
PRINT, HDF_DFR8_LASTREF()
HDF_DFR8_ADDIMAGE, 'myhdf.hdf', a ; Add another image.
; IDL prints "2", because we've put two 8-bit images in the file:
PRINT, HDF_DFR8_NIMAGES('myhdf.hdf')
HDF_CLOSE, h ; Close the file.
```

Version History

Introduced: 4.0

See Also

HDF_DFR8_ADDIMAGE, HDF_DFR8_GETIMAGE, HDF_DFR8_GETINFO, HDF_DFR8_LASTREF, HDF_DFR8_NIMAGES, HDF_DFR8_READREF, HDF_DFR8_RESTART

HDF_DFR8_NIMAGES

The HDF_DFR8_NIMAGES function returns the number of 8-bit images in the specified HDF file.

Syntax

Result = HDF_DFR8_NIMAGES(*Filename*)

Return Value

Returns the number of 8-bit images in the given HDF file. The function returns -1 if the specified file is invalid or damaged.

Arguments

Filename

A string containing the name of the file to be read.

Keywords

None.

Examples

```
; Open the file myhdf.hdf:
h = HDF_OPEN('myhdf.hdf')
; Retrieve the number of 8-bit images in the file into a variable:
number = HDF_DFR8_NIMAGES('myhdf.hdf')
HDF_CLOSE, h ; Close the file.
```

Version History

Introduced: 4.0

See Also

HDF_DFR8_GETIMAGE, HDF_DFR8_GETINFO, HDF_DFR8_READREF
HDF_DFR8_RESTART

HDF_DFR8_PUTIMAGE

The HDF_DFR8_PUTIMAGE procedure writes an 8-bit raster image as the first image in an HDF file. If there are images in the file, this procedure erases all other 8-bit and 24-bit images and writes *Image* as the first image in the file.

Note

Input data is converted to bytes before being written to the file, as images in the DFR8 HDF model are necessarily byte images.

Syntax

HDF_DFR8_PUTIMAGE, *Filename*, *Image* [, /FORCE_BASELINE{useful only if QUALITY<25}] [[, /IMCOMP] , PALETTE=*vector or array*] [, /JPEG | , /RLE] [, QUALITY=*value*]

Arguments

Filename

A scalar string containing the name of the file to be written.

Image

A two-dimensional array containing the image data. If this array is not byte-type data, it is converted to bytes before writing.

Keywords

FORCE_BASELINE

Set this keyword to force the JPEG quantization tables to be constrained to the range 1...255. This provides full baseline compatibility with external JPEG applications, but only makes a difference if the QUALITY keyword is set to a value less than 25. The default is TRUE.

JPEG

Set this keyword to compress the image being added using the JPEG (Joint Photographic Expert Group) method. Note that JPEG compression is *lossy*; see WRITE_JPEG in the *IDL Reference Guide* for more information about when this

method is appropriate. (In other words, using JPEG compression to reduce the size of an images changes the values of the pixels and hence may alter the meaning of the corresponding data.) Setting either the QUALITY or the FORCE_BASELINE keywords implies this method.

IMCOMP

Set this keyword to store the image using imcomp data compression. Note that you *must* specify a palette. Note also that the JPEG and RLE compression methods are far superior; imcomp data compression should only be used if the images will be viewed on monitors with a very small number of colors (monochrome or 16-color).

PALETTE

Set this keyword to a vector or array containing valid palette data. Palettes must be either [3, 256] arrays or 786-element vectors. Set PALETTE equal to zero to specify that no palette be used. If the PALETTE keyword is not specified, the current palette (which may be no palette, if a palette has not been specified elsewhere or if the null palette has been explicitly specified with HDF_DFR8_SETPALETTE) will be used.

Note that if a palette is specified, it becomes the current palette, even if a default palette has been specified with HDF_DFR8_SETPALETTE.

Note also that if IMCOMP data reduction is used, you *must* specify a valid palette with the PALETTE keyword. It is not sufficient to set the current palette via other means.

QUALITY

Set this keyword equal to the JPEG “quality” desired. This value should be in range 0 (terrible image quality but excellent compression) to 100 (excellent image quality but minimum compression). The default is 75. Setting this keyword implies that the JPEG keyword is set. Lower values of QUALITY produce higher compression ratios and smaller files.

RLE

Set this keyword to store the image using run length compression. RLE compression is lossless, and is recommended for images where data retention is critical.

Version History

Introduced: 4.0

See Also

HDF_DFR8_ADDIMAGE, HDF_DFR8_GETIMAGE, WRITE_JPEG (in the *IDL Reference Guide*).

HDF_DFR8_READREF

The HDF_DFR8_READREF procedure sets the reference number of the image to be read from an HDF file by the next call to HDF_DFR8_GETIMAGE.

Syntax

HDF_DFR8_READREF, *Filename*, *Refno*

Arguments

Filename

A scalar string containing the name of the file to be read.

Refno

A reference number for an 8-bit raster image.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFR8_RESTART

The HDF_DFR8_RESTART procedure causes the next call to HDF_DFR8_GETIMAGE to read from the first image in the HDF file.

Syntax

HDF_DFR8_RESTART

Arguments

None.

Keywords

None.

Version History

Introduced: 4.0

HDF_DFR8_SETPALETTE

The HDF_DFR8_SETPALETTE procedure sets the current palette to be used for subsequent images in an HDF file. The current palette will be used when adding images with the HDF_DFR8_ADDIMAGE routine.

Syntax

HDF_DFR8_SETPALETTE, *Palette*

Arguments

Palette

A 768-element byte array of palette data. This array be a vector (e.g., `BYTARR(768)`) or a two-dimensional array (e.g., `BYTARR(3, 256)`).

Set the Palette array to the integer zero to set the current palette to no palette.

Keywords

None.

Version History

Introduced: 4.0

HDF_DUPDD

The HDF_DUPDD procedure generates new references to existing data in an HDF file.

Syntax

HDF_DUPDD, *FileHandle*, *NewTag*, *NewRef*, *OldTag*, *OldRef*

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

NewTag

An integer tag for new data descriptor.

NewRef

An integer reference number for the new data descriptor.

OldTag

The integer tag of data descriptor to duplicate.

OldRef

The reference number of data descriptor to duplicate.

Keywords

None.

Version History

Introduced: Pre 4.0

HDF_EXISTS

The HDF_EXISTS function returns True if the HDF scientific data format library is supported on the current IDL platform.

This routine is written in the IDL language. Its source code can be found in the file `hdf_exists.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = HDF_EXISTS( )

Return Value

Returns a 1 (True) if the library is supported or a 0 (False) if the library is not supported.

Arguments

None.

Keywords

None.

Examples

The following IDL command prints an error message if the HDF library is not available:

```
IF HDF_EXISTS() EQ 0 THEN PRINT, 'HDF not supported.'
```

Version History

Introduced: Pre 4.0

HDF_GR_ATTRINFO

This function retrieves the name, data type, and number of values of the attribute for the HDF data object identified by the parameter obj_id.

Syntax

Result = HDF_GR_ATTRINFO(*obj_id*, *attr_index*, *name*, *data_type*, *count*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

obj_id

Raster image identifier (ri_id), returned by HDF_GR_CREATE or HDF_GR_SELECT, or HDF GR interface identifier (gr_id), returned by HDF_GR_START.

attr_index

Index of the attribute. The value of this parameter can be obtained using HDF_GR_FINDATTR, HDF_GR_NAMETOINDEX or HDF_GR_REFTOINDEX, depending on available information. Valid values range from 0 to the total number of attributes attached to the object minus 1. The total number of attributes attached to the file can be obtained using the routine HDF_GR_FILEINFO. The total number of attributes attached to an image can be obtained using the routine HDF_GR_GETIMINFO.

name

A named variable in which the name of the attribute is returned.

data_type

A named variable in which the attribute data type is returned. See “IDL and HDF Data Types” on page 3245.

count

A named variable in which the number of attributes is returned.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_CREATE

This function creates an HDF GR raster image. Once a raster image has been created, it is not possible to change its name, data type, dimension sizes or number of pixel components. However, it is possible to create a raster image and close the file before writing any data values to it. Later, the values can be added to or modified in the raster image, which then can be obtained using HDF_GR_SELECT.

Note

On creation, any interlace mode may be set. This mode will be used until the file is closed. If the resulting file is reopened, the interlace mode will revert to pixel-interlace (0). Data can still be read in any interlace mode using the INTERLACE keyword to HDF_GR_READIMAGE. This is a limitation of the current HDF library.

Syntax

Result = HDF_GR_CREATE(*gr_id*, *name*, *ncomp*, *data_type*, *interlace_mode*, *dim_sizes*)

Return Value

Returns a raster image identifier if successful or FAIL (-1) otherwise.

Arguments

gr_id

GR interface identifier returned by HDF_GR_START.

name

Name of the raster image. The length of the name should not be longer than 256 characters.

ncomp

Number of pixel components in the image. This parameter must have a value of at least 1.

data_type

Type of the image data. This parameter can be any of the data types supported by the HDF library. See “IDL and HDF Data Types” on page 3245.

interlace_mode

Interlace mode of the image data. Valid values are:

- 0 = Pixel interlace
- 1 = Line interlace
- 2 = Component interlace

dim_sizes

Array of sizes for each dimension of the image. The dimensions must be specified and their values must be greater than 0.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_END

This procedure terminates the HDF GR interface session identified by the parameter *gr_id*. HDF_GR_END, together with HDF_GR_START, define the extent of a HDF GR interface session. HDF_GR_END disposes of the internal structures initialized by the corresponding call to HDF_GR_START. There must be a call to HDF_GR_END for each call to HDF_GR_START; failing to provide one may cause loss of data. HDF_GR_START and HDF_GR_END do not manage file access; use HDF_OPEN and HDF_CLOSE to open and close HDF files. HDF_OPEN must be called before HDF_GR_START and HDF_CLOSE must be called after HDF_GR_END. Failure to properly close the HDF file with HDF_GR_END and HDF_CLOSE may result in lost data or corrupted HDF files.

Syntax

HDF_GR_END, *gr_id*

Arguments

gr_id

HDF GR interface identifier returned by HDF_GR_START.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_ENDACCESS

This procedure terminates access to the raster image identified by the parameter *ri_id* and disposes of the raster image identifier. This access is initiated by either HDF_GR_SELECT or HDF_GR_CREATE. There must be a call to HDF_GR_ENDACCESS for each call to HDF_GR_SELECT or HDF_GR_CREATE; failing to provide this will result in loss of data.

Syntax

HDF_GR_ENDACCESS, *ri_id*

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_FILEINFO

This function retrieves the number of raster images and the number of global attributes for the HDF GR interface identified by the parameter *gr_id*, and stores them into the parameters *n_images* and *n_file_attrs*, respectively. The term “global attributes” refers to attributes that are assigned to the file instead of individual raster images. These attributes are created by HDF_GR_SETATTR with the object identifier parameter set to a HDF GR interface identifier (*gr_id*) rather than a raster image identifier (*ri_id*). HDF_GR_FILEINFO is useful in finding the range of acceptable indices for HDF_GR_SELECT calls.

Syntax

Result = HDF_GR_FILEINFO(*gr_id*, *n_images*, *n_file_attrs*)

Return Value

Returns SUCCEED (or 0) if successful or FAIL (-1) otherwise.

Arguments

gr_id

HDF GR interface identifier returned by HDF_GR_START.

n_images

A named variable that will contain the number of raster images in the file.

n_file_attrs

A named variable that will contain the number of global attributes in the file.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_FINDATTR

This function finds the index of an HDF data object's attribute given its attribute name. HDF_GR_FINDATTR returns the index of the attribute whose name is specified by the parameter *attr_name* for the object identified by the parameter *obj_id*.

Syntax

Result = HDF_GR_FINDATTR(*obj_id*, *attr_name*)

Return Value

Returns the index of the attribute if successful or FAIL (-1) otherwise.

Arguments

obj_id

Raster image identifier (*ri_id*), returned by HDF_GR_CREATE or HDF_GR_SELECT, or HDF GR interface identifier (*gr_id*), returned by HDF_GR_START.

attr_name

Name of the attribute.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_GETATTR

This function obtains all values of the HDF GR attribute that is specified by its index, *attr_index*, and is attached to the object identified by the parameter *obj_id*.

Syntax

Result = HDF_GR_GETATTR(*obj_id*, *attr_index*, *values*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

obj_id

Raster image identifier (*ri_id*), returned by HDF_GR_CREATE or HDF_GR_SELECT, or HDF GR interface identifier (*gr_id*), returned by HDF_GR_START.

attr_index

Index of the attribute.

The value of the parameter *attr_index* can be obtained by using HDF_GR_FINDATTR, HDF_GR_NAMETOINDEX, or HDF_GR_REFTOINDEX, depending on available information. Valid values of *attr_index* range from 0 to the total number of attributes of the object - 1. The total number of attributes attached to the file can be obtained using the routine HDF_GR_FILEINFO. The total number of attributes attached to the image can be obtained using the routine HDF_GR_GETIMINFO. HDF_GR_GETATTR only reads all values assigned to the attribute and not a subset.

values

A named variable that will contain the attribute values.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_GETCHUNKINFO

This function retrieves chunking information about the HDF GR raster image identified by the parameter *ri_id* into the parameters *dim_length* and *flag*. Note that only chunk dimensions are retrieved; compression information is not available with this function.

Syntax

Result = HDF_GR_GETCHUNKINFO(*ri_id*, *dim_length*, *flag*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

dim_length

A named variable that will contain the array of chunk dimensions.

flag

A named variable that will contain the compression/chunk flag.

The value returned in the parameter *flag* indicates if the raster image is not chunked, chunked, or chunked and compressed. The following table shows the possible values of the parameter *flag* and the corresponding characteristics of the raster image.

Values of flag = Raster Image Characteristics

- -1 = Not chunked
- 0 = Chunked and not compressed
- 1 = Chunked and compressed with either the run-length encoding (RLE), Skipping Huffman or GZIP compression algorithms

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_GETIMINFO

This function retrieves general information about an HDF GR raster image. HDF_GR_GETIMINFO retrieves the name, number of components, data type, interlace mode, dimension sizes, and number of attributes of the raster image identified by the parameter *ri_id*. It also retrieves the number of attributes attached to the image into the parameter *num_attrs*.

Syntax

Result = HDF_GR_GETIMINFO(*ri_id*, *gr_name*, *ncomp*, *data_type*, *interlace_mode*, *dim_sizes*, *num_attrs*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

gr_name

A named variable that will contain the name of the raster image.

ncomp

A named variable that will contain the number of components in the raster image.

data_type

A named variable that will contain the data type of the raster image data. The valid values of the parameter *data_type* are listed in “IDL and HDF Data Types” on page 3245.

interlace_mode

A named variable that will contain the interlace mode of the stored raster image data.

- 0 = Pixel interlace
- 1 = Line interlace
- 2 = Component interlace

dim_sizes

A named variable that will contain the sizes of the raster image dimensions.

num_attrs

A named variable that will contain the number of attributes attached to the raster image.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_GETLUTID

This function gets the identifier of the HDF GR palette attached to the raster image identified by the parameter *ri_id*.

Syntax

Result = HDF_GR_GETLUTID(*ri_id*, *pal_index*)

Return Value

Returns the palette identifier if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

pal_index

Index of the palette. Currently, only one palette can be assigned to a raster image, which means that pal_index should always be set to 0.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_GETLUTINFO

This function retrieves the number of pixel components, data type, interlace mode, and number of color lookup table entries of the palette identified by the parameter *pal_id*.

Syntax

Result = HDF_GR_GETLUTINFO(*pal_id*, *ncomp*, *data_type*, *interlace_mode*, *num_entries*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

pal_id

Palette identifier returned by HDF_GR_GETLUTID.

ncomp

A named variable in which the number of components in the palette is returned.

data_type

A named variable in which the HDF data type of the palette is returned. See “IDL and HDF Data Types” on page 3245 for a description of the HDF data types.

interlace_mode

A named variable in which the interlace mode of the stored palette data is returned.

- 0 = Pixel interlace
- 1 = Line interlace
- 2 = Component interlace

num_entries

A named variable in which the number of color lookup table entries in the palette is returned.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_IDTOREF

This function returns the HDF reference number of the raster image identified by the parameter *ri_id*. This routine is commonly used for the purpose of annotating the raster image or including the raster image within an HDF Vgroup.

Syntax

Result = HDF_GR_IDTOREF(*ri_id*)

Return Value

Returns the HDF reference number of the raster image if successful or not found (0) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_SELECT or HDF_GR_CREATE.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_LUTTOREF

This function returns the HDF reference number of the palette identified by the parameter *pal_id*. This function is commonly used for the purpose of annotating the palette or including the palette within a HDF Vgroup.

Syntax

Result = HDF_GR_LUTTOREF(*pal_id*)

Return Value

Returns the reference number of the palette if successful or not found (0) otherwise.

Arguments

pal_id

Palette identifier returned by HDF_GR_GETLUTID.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_NAMETOINDEX

This function returns the index of the raster image named *gr_name* for the HDF GR interface identified by the parameter *gr_id*.

The value of index can be passed into HDF_GR_SELECT to obtain the raster image identifier (ri_id).

Syntax

Result = HDF_GR_NAMETOINDEX(*gr_id*, *gr_name*)

Return Value

Returns the index of the raster image if successful or FAIL (-1) otherwise.

Arguments

gr_id

HDF_GR_ interface identifier returned by HDF_GR_START.

gr_name

Name of the raster image.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_READIMAGE

This function reads the subsample of the HDF GR raster image specified by the parameter *ri_id* into the variable *data*.

Syntax

Result = HDF_GR_READIMAGE(*ri_id*, *data* [, EDGE=*array*] [, /INTERLACE] [, START=*array*] [, STRIDE=*array*])

Return Value

Returns the specified variable containing the image subsample.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT

data

A named variable that will contain the image data.

Keywords

EDGE

Array specifying the number of values to be read along each dimension. The default is to read the entire specified image.

INTERLACE

Set this keyword to force data to be returned in INTERLACE mode. The default is pixel-interlacing (0) other possible values are 1 (line) and 2 (component).

START

Array specifying the starting location from where raster image data is read. Valid values of each element in the array are 0 to the size of the corresponding raster image dimension minus 1. The default is to read starting at the first pixel in each dimension (start = [0,0]).

STRIDE

Array specifying the interval between the values that will be read along each dimension. The default is for contiguous reading along each dimension (stride = [1,1]).

Note

The correspondence between the elements in the array *start* and the array *data* dimensions in the HDF GR interface is different from that in the HDF SD interface. The array *stride* specifies the reading pattern along each dimension. For example, if one of the elements of the array stride is 1, then every element along the corresponding dimension of the array data will be read. If one of the elements of the array *stride* is 2, then every other element along the corresponding dimension of the array data will be read, and so on. The correspondence between elements of the array *stride* and the dimensions of the array *data* is the same as described above for the array *start*. Each element of the array *edges* specifies the number of data elements to be read along the corresponding dimension. The correspondence between the elements of the array *edges* and the dimensions of the array *data* is the same as described above for the array *start*.

Version History

Introduced: 5.2

HDF_GR_READLUT

This function reads the palette specified by the parameter *pal_id* into the *pal_data* variable.

Syntax

Result = HDF_GR_READLUT(*pal_id*, *pal_data* [, /INTERLACE])

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

pal_id

Palette identifier returned by HDF_GR_GETLUTID.

pal_data

A named variable that will contain the palette data.

Keywords

INTERLACE

Set this keyword to force pal_data to be returned in INTERLACE mode. The default is pixel-interlacing (0) other possible values are 1 (line) and 2 (component).

Version History

Introduced: 5.2

HDF_GR_REFTOINDEX

This function returns the index of the HDF GR raster image specified by the parameter *gr_ref*.

Syntax

Result = HDF_GR_REFTOINDEX(*gr_id*, *gr_ref*)

Return Value

Returns the index of the image if successful or FAIL (-1) otherwise.

Arguments

gr_id

HDF GR interface identifier returned by HDF_GR_START.

gr_ref

Reference number of the raster image.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_SELECT

This function obtains the identifier of the HDF GR raster image specified by its index.

Syntax

Result = HDF_GR_SELECT(*gr_id*, *index*)

Return Value

Returns the raster image identifier if successful or FAIL (-1) otherwise.

Arguments

gr_id

HDF GR interface identifier returned by HDF_GR_START.

index

Index of the raster image in the file. Valid values range from 0 to the total number of raster images in the file minus 1. The total number of the raster images in the file can be obtained by using HDF_GR_FILEINFO.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_SETATTR

This function attaches the attribute to the HDF GR object specified by the parameter *obj_id*. The attribute is defined by its name, data type, number of attribute values, and the attribute values. HDF_GR_SETATTR provides a generic way for users to define metadata. It implements the label = value data abstraction. If an HDF GR interface identifier (*gr_id*) is specified as the parameter *obj_id*, a global attribute is created that applies to all objects in the file. If a raster image identifier (*ri_id*) is specified as the parameter *obj_id*, an attribute is attached to the specified raster image. Attribute values are passed in the parameter values. The number of attribute values is defined by the parameter count. If more than one value is stored, all values must have the same data type. If an attribute with the given name, data type and number of values exists, it will be overwritten. Currently, the only predefined attribute is the fill value, identified by the attribute name “FillValue”.

Syntax

Result = HDF_GR_SETATTR(*obj_id*, *attr_name*, *data_type*, *count*, *values*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

obj_id

Raster image identifier (ri_id), returned by HDF_GR_CREATE or HDF_GR_SELECT or HDF GR interface identifier (gr_id), returned by HDF_GR_START.

attr_name

Name of the attribute (string).

data_type

Data type of the attribute (integer). Can be any data type supported by the HDF library. These data types are listed under “IDL and HDF Data Types” on page 3245.

count

Number of values in the attribute.

values

The attribute value.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_SETCHUNK

This function makes the HDF GR raster image specified by the parameter *ri_id* a chunked raster image according to the chunking and compression information provided in the parameters *comp_type* and *comp_prm*. Data can be compressed using run-length encoding (RLE), Skipping Huffman or GZIP compression algorithms.

Syntax

Result = HDF_GR_SETCHUNK(*ri_id*, *dim_length*, *comp_type*, *comp_prm*)

Return Value

Returns SUCCEED (or 0) if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

dim_length

Chunk dimensions array.

comp_type

Type of compression. Valid types are:

- 0 = uncompressed data
- 1 = data compressed using the RLE compression algorithm
- 3 = data compressed using the Skipping Huffman compression algorithm
- 4 = data compressed using the GZIP compression algorithm.

comp_prm

Compression parameters array. Specifies the compression parameters for the Skipping Huffman and GZIP compression methods. It contains only one element, which is set to the skipping size for Skipping Huffman compression or the deflate level for GZIP compression (1-9).

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_SETCHUNKCACHE

This function allows the user to set the maximum number of chunks to be cached (*maxcache*). If HDF_GR_SETCHUNKCACHE is not called, *maxcache* is set to the number of chunks along the fastest changing dimension.

Syntax

Result = HDF_GR_SETCHUNKCACHE(*ri_id*, *maxcache*, *flags*)

Return Value

Returns the value of *maxcache* if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

maxcache

Maximum number of chunks to cache.

flags

Currently, the only HDF allowed value for flags is zero (cache all).

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_SETCOMPRESS

This function specifies the type of compression for the specified HDF GR raster image.

Syntax

Result = HDF_GR_SETCOMPRESS(*ri_id*, *comp_type*, *comp_prm*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

comp_type

Compression method for the image data. Valid values are:

- 0 = no compression
- 1 = RLE run-length encoding
- 3 = Skipping Huffman compression
- 4 = GZIP compression
- 6 = JPEG compression

comp_prm

Compression parameters. If Skipping Huffman is used, set *comp_parm* to the skipping size (the size in bytes of the data elements). If GZIP compression is used, set *comp_parm* to an integer ranging from 1 (fastest) to 9 (most compressed).

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_SETEXTERNALFILE

This function causes the specified HDF GR raster image be written to the specified external file, at the specified offset. Data can be moved only once for any given raster image, and it is the user's responsibility to make sure the external data file is kept with the “original” file. If the raster image already exists, its data will be moved to the external file. Space occupied by the data in the primary file will not be released. If the raster image does not exist, its data will be written to the external file during the subsequent calls to HDF_GR_WRITEDATA.

Syntax

Result = HDF_GR_SETEXTERNALFILE(*ri_id*, *filename*, *offset*)

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

filename

Name of the external file.

offset

Offset in bytes from the beginning of the external file to where the data will be written.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_START

This function initializes the HDF GR interface for the specified file. This function is used with the HDF_GR_END procedure to define the extent of the HDF GR interface session. As with the start routines in the other interfaces, HDF_GR_START initializes the internal interface structures needed for the remaining HDF_GR_ routines. Use the general purpose routines HDF_OPEN and HDF_CLOSE to manage file access. The HDF_GR_ routines will not open and close HDF files.

Note

Failure to use HDF_CLOSE properly may result in lost data or corrupted HDF files.

Syntax

Result = HDF_GR_START(*file_id*)

Return Value

Returns the HDF GR interface identifier if successful or FAIL (-1) otherwise.

Arguments

file_id

File identifier returned by HDF_OPEN.

Keywords

None.

Version History

Introduced: 5.2

HDF_GR_WRITEIMAGE

This function writes the subsample of the raster image data stored in the variable data to the specified raster image. The subsample is defined by the values of the parameters start, stride and edge. The array start specifies the starting location of the subsample to be written. Valid values of each element in the array start are 0 to the size of the corresponding raster image dimension - 1.

Note

The correspondence between elements in the array start and the raster image dimensions in the HDF GR interface is different from that in the HDF SD interface. The array stride specifies the writing pattern along each dimension. For example, if one of the elements of the array stride is 1, then every element along the corresponding dimension of the array data will be written. If one of the elements of the stride array is 2, then every other element along the corresponding dimension of the array data will be written, and so on. The correspondence between elements of the array stride and the dimensions of the array data is the same as described above for the array start. Each element of the array edges specifies the number of data elements to be written along the corresponding dimension. The correspondence between the elements of the array edges and the dimensions of the array data is the same as described above for the array start.

Syntax

Result = HDF_GR_WRITEIMAGE(*ri_id*, *data* [, EDGE=*array*] [, INTERLACE={0 | 1 | 2}] [, START=*array*] [, STRIDE=*array*])

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

ri_id

Raster image identifier returned by HDF_GR_CREATE or HDF_GR_SELECT.

data

The image data to be written.

Keywords

EDGE

Array containing the number of data elements that will be written along each dimension. If not specified, all data will be written.

INTERLACE

Set this keyword to a scalar value to select the interlace mode of the input data. Valid values are:

- 0 = Pixel interlace
- 1 = Line interlace
- 2 = Component interlace

HDF_GR_WRITEIMAGE will write the data in the correct interlace mode the raster image is in.

START

Array containing the two-dimensional coordinate of the initial location for the write. If not specified, the write starts at the first pixel in each dimension (start=[0,0]).

STRIDE

Array containing the number of data locations the current location is to be moved forward before each write. If not specified, data is written contiguously (stride = [1,1]).

Note

See HDF_GR_READIMAGE for further description of the EDGE, START, and STRIDE keywords.

Version History

Introduced: 5.2

HDF_GR_WRITELUT

This function writes a palette with the specified number of pixel components, data type of the palette data, interlace mode, and number of entries in the palette. The palette data itself is stored in the *pal_data* variable. The data types supported by HDF are listed in “IDL and HDF Data Types” on page 3245.

Currently, only “old-style” palettes are supported, i.e ncomp = 3, num_entries = 256, data_type = uint8.

Syntax

Result = HDF_GR_WRITELUT(*pal_id*, *pal_data* [, DATA_TYPE=*value*] [, INTERLACE_MODE={0 | 1 | 2}] [, NENTRIES=*value*])

Return Value

Returns SUCCEED (0) if successful or FAIL (-1) otherwise.

Arguments

pal_id

Palette identifier returned by HDF_GR_GETLUTID.

ncomp

Number of components in the palette. Must have a value of at least 1.

pal_data

Palette data to be written.

Keywords

data_type

Data type of the palette data. Can be any of the data types supported by the HDF library. The default is UINT8.

interlace_mode

Interlace mode of the stored palette data. Valid values are:

- 0 = Pixel Interlaced (the default)
- 1 = Line Interlaced
- 2 = Component Interlaced

num_entries

Number of entries in the palette.

Version History

Introduced: 5.2

HDF_HDF2IDLTYPE

This function converts an HDF data type code into an IDL variable type code. See the IDL SIZE function and tables 3-2 through 3-4 in *Scientific Data Formats* for actual values.

Syntax

Result = HDF_HDF2IDLTYPE(*hdftypecode*)

Return Value

Returns the IDL variable type code (See SIZE). A return value of zero means the type could not be mapped.

Arguments

hdftypecode

An HDF data type code (long).

Keywords

None.

Examples

```
PRINT, HDF_HDF2IDLTYPE( 6 )
```

Version History

Introduced: 5.2

See Also

HDF_IDL2HDFTYPE

HDF_IDL2HDFTYPE

This function converts an IDL variable type code into an HDF data type code. See the IDL SIZE function and tables 3-2 through 3-4 in *Scientific Data Formats* for actual values.

Syntax

Result = HDF_IDL2HDFTYPE(*idltypecode*)

Return Value

Returns the HDF data type code. A return value of zero means the type could not be mapped.

Arguments

idltypecode

An IDL variable type code (long).

Keywords

None.

Examples

```
iType = SIZE(5.0d,/TYPE)
PRINT, HDF_IDL2HDFTYPE( iType )
```

Version History

Introduced: 5.2

See Also

HDF_HDF2IDLTYPE

HDF_ISHDF

The HDF_ISHDF function determines whether or not a specified file in an HDF file.

Warning

This routine bases its judgement as to whether or not a file is an HDF file on the first few bytes of the file. Therefore, it is possible that HDF_ISHDF will identify the file as an HDF file, but HDF_OPEN will not be able to open the file (because it is corrupted).

Syntax

Result = HDF_ISHDF(*Filename*)

Return Value

Returns true (1) if the file is an HDF file and false (0) if the file either is not an HDF file or does not exist.

Arguments

Filename

A scalar string containing the name of the file to be tested.

Keywords

None.

Version History

Introduced: Pre 4.0

HDF_LIB_INFO

The HDF_LIB_INFO procedure returns information about the HDF Library being used by this version of IDL, or information about the version of HDF used to create a particular HDF file.

Syntax

HDF_LIB_INFO, [*FileHandle*] [, MAJOR=*variable*] [, MINOR=*variable*] [, RELEASE=*variable*] [, VERSION=*variable*]

Arguments

FileHandle

The HDF filehandle returned from a previous call to HDF_OPEN.

Keywords

MAJOR

Set this keyword equal to a named variable that will contain the major version number of the HDF library currently in use by IDL. If the *FileHandle* argument is supplied, the variable will contain the major version number of the HDF library used by that particular HDF file.

MINOR

Set this keyword equal to a named variable that will contain the minor version number of the HDF library currently in use by IDL. If the *FileHandle* argument is supplied, the variable will contain the minor version number of the HDF library used by that particular HDF file.

RELEASE

Set this keyword equal to a named variable that will contain the release number of the HDF library currently in use by IDL. If the *FileHandle* argument is supplied, the variable will contain the release number of the HDF library used by that particular HDF file.

VERSION

Set this keyword equal to a named variable that will contain the version number text string of the HDF library currently in use by IDL. If the *FileHandle* argument is supplied, the variable will contain the version number text string of the HDF library used by that particular HDF file.

Examples

Example 1

```
HDF_LIB_INFO, MAJOR=MAJOR, MINOR=MINOR, VERSION=VER, RELEASE=REL
PRINT, 'IDL ', !version.release, ' uses HDF Library ', $
   MAJOR, MINOR, REL, FORMAT='(A,A,A,I1,".",I1,"r",I1,A)'
PRINT, VER
```

IDL Output

```
IDL 5.3 uses HDF Library 4.1r3
NCSA HDF Version 4.1 Release 3, May 1999
```

Example 2

The following example tests the version of HDF used to create a particular file. Note that the strings returned will depend solely upon the version of the HDF library used to create the file. In this example, it is the same as the library compiled into the current version of IDL since it is the current IDL that is creating the file.

```
file='example.hdf'
id=HDF_OPEN(file, /CREATE)
HDF_LIB_INFO, id, VERSION=VER
PRINT, 'The file ', file,' was created with : ', VER
HDF_CLOSE, id
```

IDL Output

```
The file example.hdf was created with :
NCSA HDF Version 4.1 Release 3, May 1999
```

Version History

Introduced: 5.1

HDF_NEWREF

The HDF_NEWREF function returns the next available reference number for an HDF file.

Syntax

Result = HDF_NEWREF(*FileHandle*)

Return Value

Returns the next available reference number.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

Keywords

None.

Version History

Introduced: Pre 4.0

HDF_NUMBER

The HDF_NUMBER function returns the number of tags in an HDF file or the number of references associated with a given tag.

Syntax

Result = HDF_NUMBER(*FileHandle* [, TAG=*integer*])

Return Value

Returns either the number of tags in the file or the number of references associated with the specified tag.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

Keywords

TAG

Set this keyword to an integer tag number or the string `'*'`. If this keyword is set to a tag number, HDF_NUMBER returns the number of references associated with the given tag. If this keyword is set to the string `'*'`, or is not specified, HDF_NUMBER returns the total number of tags in the HDF file.

Version History

Introduced: Pre 4.0

HDF_OPEN

The HDF_OPEN function opens or creates an HDF file for reading and/or writing.

Note that any combination of the READ, WRITE and CREATE keywords is valid.

Syntax

Result = HDF_OPEN(*Filename* [, /ALL] [, /CREATE] [, NUM_DD=*value*] [, /RDWR] [, /READ] [, /WRITE])

Return Value

If successful, a non-zero file handle (a longword integer) is returned. Longword -1 is returned on failure.

Arguments

Filename

A scalar string containing the name of the file to be opened.

Keywords

ALL

Set this keyword to create a new HDF file with read and write access. Setting this keyword is equivalent to:

```
HDF_OPEN(filename, /READ, /WRITE, /CREATE)
```

CREATE

Set this keyword to create a new HDF file.

NUM_DD

Use this keyword to override the machine default for the number of data descriptors to be allocated per DD block. For example:

```
H = HDF_OPEN('foo.hdf',/CREATE,/WRITE, NUM_DD=100)
```

RDWR

Set this keyword to open file with both read and write access. Setting this keyword is equivalent to:

```
HDF_OPEN(filename, /READ, /WRITE)
```

READ

Set this keyword to open the file with read access.

WRITE

Set this keyword to open the file with write access.

Version History

Introduced: Pre 4.0

HDF_PACKDATA

This function packs a set IDL variable into an array of raw byte data. It is useful in constructing the input to multi-field HDF Vdata writing routines, such as those found in HDF-EOS, from a set of IDL variables. The packed data is output as an array of bytes which is organized as a number of records. Each record consists of one or more data fields. A record is defined using the HDF_TYPE and HDF_ORDER keywords. These define the record layout in terms of HDF data types. This function first converts the input arrays into the type defined by the HDF_TYPE keyword using IDL type conversion rules. The function then walks through the input IDL arrays and copies the values into output array. There must be as many entries in the HDF_TYPE and HDF_ORDER keywords as there are data arguments. The function will output as many complete records as can be created from the input data arrays or the value of the NREC keyword, whichever is smaller.

Syntax

Result = HDF_PACKDATA(*data1* [, *data2* [, *data3* [, *data4* [, *data5* [, *data6* [, *data7* [, *data8*]]]]]]] [, HDF_ORDER=*array*] [, HDF_TYPE=*array*] [, NREC=*records*])

Return Value

Returns a 2-D BYTE array of packed data. The trailing dimension corresponds to each record in the input data.

Arguments

data1...data8

These arguments specify IDL arrays to be packed. The arguments are first converted to the types specified by HDF_TYPE. If the corresponding HDF_ORDER value is greater than one, more than one value will be read from the input array and placed in the packed array for each record. Strings are output as fixed width fields. If an input string is longer than its HDF_ORDER value, it is truncated before being packed. If an input string is shorter than its HDF_ORDER value, the extra space is filled with the value 0.

Keywords

HDF_ORDER

Set this keyword to an array the same length as the number of data fields. The value in the array is equal to the number of elements in the data argument for each record. In the case of strings, this is the length (in characters) of the string to be packed. A value of zero is interpreted as one element. The default for this keyword is an array of ones.

HDF_TYPE

Set this keyword to an array the same length as the number of data fields. The value in the array is an HDF data type for each argument. The IDL variables are converted to these types before being packed into the output array. The default for this keyword is an array of the value 5 (an HDF 32 bit float). See "IDL and HDF Data Types" on page 3245 for valid values.

NREC

Set this keyword to the number of records to be packed. The default is to pack as many complete records as can be formed by all of the input arrays.

Examples

See HDF_UNPACKDATA.

Version History

Introduced: 5.2

See Also

HDF_UNPACKDATA, EOS_PT_WRITELEVEL, HDF_VD_WRITE

HDF_READ

See HDF_READ in the *IDL Reference Guide*.

HDF_SD_ADDDATA

The HDF_SD_ADDDATA procedure writes a hyperslab of values to an SD dataset. By default, the output data is transposed. This transposition puts the data in column order, which is more efficient in HDF than row order (which is more efficient in IDL). In the rare cases where it is necessary to write the data without transposing, set the NOREVERSE keyword. The OFFSET, COUNT, and STRIDE keywords are similarly affected by the NOREVERSE keyword.

Syntax

HDF_SD_ADDDATA, *SDS_ID*, *Data* [, COUNT=*vector*] [, /NOREVERSE] [, START=*vector*] [, STRIDE=*vector*]

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD_SELECT or HDF_SD_CREATE.

Data

The data to be written.

Keywords

COUNT

Set this keyword to a vector of counts (i.e., the number of items) to be written in each dimension. The default is to write all available data. Use caution when using this keyword. See the second example, below.

NOREVERSE

Set this keyword to prevent HDF_SD_ADDDATA's transposition of *Data* and any vectors specified by keywords into column order.

START

Set this keyword to a vector that contains the starting position for the data. The default position is [0, 0, ..., 0].

STRIDE

Set this keyword to a vector that contains the strides, or sampling intervals, between accessed values of the NetCDF variable. The default stride vector is that for a contiguous write: [0, 0, ..., 0].

Examples

The following example writes a 230-element by 380-element byte image to an SD dataset, then reads it back as a 70 by 100 image starting at (40, 20), sampling every other Y pixel and every third X pixel:

```
start = [40, 20] ; Set the start vector.
count = [70, 100] ; Set the count vector.
stride = [2, 3] ; Set the stride vector.
image = DIST(230, 380) ; Create the image.
TV, image ; Display the image.
; Create a new HDF file in SD mode:
sd_id = HDF_SD_START('image.hdf', /CREATE)
; Define a new SD dataset:
sds_id = HDF_SD_CREATE(sd_id, 'image', [230, 380], /BYTE)
HDF_SD_ADDDATA, sds_id, image ; Write the image into the dataset.
HDF_SD_GETDATA, sds_id, full ; Retrieve the full image.
; Retrieve the sub-sampled image:
HDF_SD_GETDATA, sds_id, small, COUNT=count, $
   START=start, STRIDE=stride
HDF_SD_ENDACCESS, sds_id
HDF_SD_END, sd_id
HELP, full, small ; Print information about the images.
ERASE ; Erase the window.
TV, full; Display the full image.
TV, small ; Display the sub-sampled image.
```

IDL prints:

```
FULL   BYTE = Array(230, 380)
SMALL  BYTE = Array(70, 100)
```

Continuing with our example, suppose we want to write the center 50 by 100 pixels of the image to the file. You might be tempted to try:

```
HDF_SD_ADDDATA, sds_id, image, START=[90, 90], COUNT=[50,100]
```

You will find, however, that this captures the lower left-hand corner of the original image, rather than the center. To write the data from the center, subset the original image, choosing the data from the center:

```
HDF_SD_ADDDATA, sds_id, image(90:139, 90:189), START=[90, 90],$
   COUNT=[50,100] ; This is the correct way to add the data.
HDF_SD_ENDACCESS, sds_id ; End SD access.
HDF_SD_END, sd_id ; Close the file.
```

Version History

Introduced: 4.0

HDF_SD_GETDATA

HDF_SD_ATTRFIND

The HDF_SD_ATTRFIND function locates the index of an HDF attribute given its name. The attribute can be global or from a specific dataset. If an attribute is located, its index is returned. Otherwise, -1 is returned. Once an attribute's index is known, the HDF_SD_ATTRINFO function can be used to read that attribute.

Syntax

Result = HDF_SD_ATTRFIND(*S_ID*, *Name*)

Arguments

S_ID

An SD interface ID as returned by HDF_SD_START (i.e., a global attribute's "SD_ID"), or HDF_SD_SELECT/HDF_SD_CREATE (i.e., a dataset's "SDS_ID").

Name

A string containing the name of the attribute whose index is to be returned.

Keywords

None.

Examples

```
; Open an HDF file and start the SD interface:
sd_id = HDF_SD_START('demo.hdf')
; Find "TITLE", a global attribute:
gindex = HDF_SD_ATTRFIND(sd_id, 'TITLE')
; Get the ID for the first dataset:
sds_id = HDF_SD_SELECT(sd_id, 1)
; Read attribute info:
HDF_SD_ATTRINFO,sd_id,gindex, NAME=name, TYPE=type, COUNT=count
; Print info about the returned variables:
HELP, type, count, name
; Find the "LOCATION" dataset attribute:
dindex = HDF_SD_ATTRFIND(sds_id, 'LOCATION')
; Read attribute info:
HDF_SD_ATTRINFO,sds_id,dindex,NAME=name,TYPE=type,COUNT=count
```

IDL Output

```
TYPE STRING = 'STRING'
COUNT LONG = 8
NAME STRING = 'TITLE'
```

Version History

Introduced: 4.0

HDF_SD_ATTRINFO, HDF_SD_ATTRSET, HDF_SD_SELECT

HDF_SD_ATTRINFO

The HDF_SD_ATTRINFO procedure reads or retrieves information about an SD attribute. The attribute can be global or from a specific dataset. If an attribute is not present, an error message is printed.

Syntax

HDF_SD_ATTRINFO, *S_ID*, *Attr_Index* [, COUNT=*variable*] [, DATA=*variable*] [, HDF_TYPE=*variable*] [, NAME=*variable*] [, TYPE=*variable*]

Arguments

S_ID

An SD interface ID as returned by HDF_SD_START (i.e., a global attribute's "SD_ID"), or HDF_SD_SELECT/HDF_SD_CREATE (i.e., a dataset's "SDS_ID").

Attr_Index

The attribute index, can either be obtained by calling HDF_SD_ATTRFIND if a particular attribute name is known or can be obtained with a 0-based index sequentially referencing the attribute.

Keywords

COUNT

Set this keyword to a named variable in which the total number of values in the specified attribute is returned.

DATA

Set this keyword to a named variable in which the attribute data is returned.

HDF_TYPE

Set this keyword to a named variable in which the HDF type of the attribute is returned as a scalar string. Possible returned values are DFNT_NONE, DFNT_CHAR8, DFNT_FLOAT32, DFNT_FLOAT64, DFNT_INT8, DFNT_INT16, DFNT_INT32, DFNT_UINT8, DFNT_UINT16, and DFNT_UINT32.

NAME

Set this keyword to a named variable in which the name of the attribute is returned.

TYPE

Set this keyword to a named variable in which the IDL type of the attribute is returned as a scalar string. Possible returned values are BYTE, INT, LONG, FLOAT, DOUBLE, STRING, or UNKNOWN.

Examples

```
; Open an HDF file and start the SD interface:
sd_id = HDF_SD_START('demo.hdf')
; Find a global attribute:
gindex = HDF_SD_ATTRFIND(sd_id, 'TITLE')
; Retrieve attribute info:
HDF_SD_ATTRINFO, sd_id, gindex, NAME=n, TYPE=t, COUNT=c, $
   DATA=d, HDF_TYPE=h
; Print information about the returned variables:
HELP, n, t, c, h
; Return the SD dataset ID for the first dataset (index 0):
sds_id = HDF_SD_SELECT(sd_id, 0)
; Find a dataset attribute:
dindex = HDF_SD_ATTRFIND(sds_id, 'LOCATION')
; Retrieve attribute info:
HDF_SD_ATTRINFO,SDS_ID, dindex, NAME=n, TYPE=t, COUNT=c, DATA=d
; Print information about the new returned variables:
HELP, n, t, c, d
```

IDL Output

```
N STRING = 'TITLE'
T STRING = 'STRING'
C LONG = 17
D STRING = '5th Ave Surf Shop'
H STRING = 'DFNT_CHAR8'

N STRING = 'LOCATION'
T STRING = 'STRING'
C LONG = 15
D STRING = 'MELBOURNE BEACH'
```

HDF_SD_ATTRFIND, HDF_SD_ATTRSET, HDF_SD_CREATE, HDF_SD_SELECT, HDF_SD_START

HDF_SD_ATTRSET

The HDF_SD_ATTRSET procedure writes attributes to an open HDF SD dataset. If no data type is specified, the data type is taken from the *Values* argument.

Syntax

HDF_SD_ATTRSET, *S_ID*, *Attr_Name*, *Values* [, *Count*] [, /BYTE] [, /DFNT_CHAR8] [, /DFNT_FLOAT32] [, /DFNT_FLOAT64] [, /DFNT_INT8] [, /DFNT_INT16] [, /DFNT_INT32] [, /DFNT_UINT8] [, /DFNT_UINT16] [, /DFNT_UINT32] [, /DOUBLE] [, /FLOAT] [, /INT] [, /LONG] [, /SHORT] [, /STRING]

Arguments

S_ID

An SD interface ID as returned by HDF_SD_START (i.e., a global attribute's "SD_ID"), or HDF_SD_SELECT/HDF_SD_CREATE (i.e., a dataset's "SDS_ID").

Attr_Name

A string containing the name of the attribute to be written.

Values

The attribute values to be written.

Count

An optional integer argument specifying how many items are to be written. Count must be less than or equal to the number of elements in the Values argument.

Keywords

BYTE

Set this keyword to indicate that the attribute is composed of bytes. Data will be stored with the HDF DFNT_UINT8 data type. Setting this keyword is the same as setting the DFNT_UINT8 keyword.

DFNT_CHAR8

Set this keyword to create an attribute of HDF type DFNT_CHAR8. Setting this keyword is the same as setting the STRING keyword.

DFNT_FLOAT32

Set this keyword to create an attribute of HDF type DFNT_FLOAT32. Setting this keyword is the same as setting the FLOAT keyword.

DFNT_FLOAT64

Set this keyword to create an attribute of HDF type DFNT_FLOAT64. Setting this keyword is the same as setting the DOUBLE keyword.

DFNT_INT8

Set this keyword to create an attribute of HDF type DFNT_INT8.

DFNT_INT16

Set this keyword to create an attribute of HDF type DFNT_INT16. Setting this keyword is the same as setting either the INT keyword or the SHORT keyword.

DFNT_INT32

Set this keyword to create an attribute of HDF type DFNT_INT32. Setting this keyword is the same as setting the LONG keyword.

DFNT_UINT8

Set this keyword to create an attribute of HDF type DFNT_UINT8. Setting this keyword is the same as setting the BYTE keyword.

DFNT_UINT16

Set this keyword to create an attribute of HDF type DFNT_UINT16.

DFNT_UINT32

Set this keyword to create an attribute of HDF type DFNT_UINT32.

DOUBLE

Set this keyword to indicate that the attribute is composed of double-precision floating-point values. Data will be stored with the HDF DFNT_FLOAT64 data type. Setting this keyword is the same as setting the DFNT_FLOAT64 keyword.

FLOAT

Set this keyword to indicate that the attribute is composed of single-precision floating-point values. Data will be stored with the HDF DFNT_FLOAT32 data type. Setting this keyword is the same as setting the DFNT_FLOAT32 keyword.

INT

Set this keyword to indicate that the attribute is composed of 2-byte integers. Data will be stored with the HDF DFNT_INT16 data type. Setting this keyword is the same as setting either the SHORT keyword or the DFNT_INT16 keyword.

LONG

Set this keyword to indicate that the attribute is composed of longword integers. Data will be stored with the HDF DFNT_INT32 data type. Setting this keyword is the same as setting the DFNT_INT32 keyword.

SHORT

Set this keyword to indicate that the attribute is composed of 2-byte integers. Data will be stored with the HDF DFNT_INT16 data type. Setting this keyword is the same as setting either the INT keyword or the DFNT_INT16 keyword.

STRING

Set this keyword to indicate that the attribute is composed of strings. Data will be stored with the HDF DFNT_CHAR8 data type. Setting this keyword is the same as setting the DFNT_CHAR8 keyword.

Examples

```
fid = HDF_OPEN('demo.hdf', /ALL) ; Create a new HDF file.
sd_id = HDF_SD_START('demo.hdf', /RDWR) ; Start the SD interface.
; Create a global attribute:
HDF_SD_ATTRSET, sd_id, 'TITLE', 'MY TITLE GLOBAL', 16
; Create another global attribute:
HDF_SD_ATTRSET, sd_id, 'RANGE', [-99.88,55544.2], /DOUBLE
; Create a dataset:
SDS_ID = HDF_SD_CREATE(sd_id, 'var1', [10,20], /FLOAT)
; Add a dataset attribute:
HDF_SD_ATTRSET, SDS_ID, 'TITLE', 'MY TITLE SD_ID', 15
; Find the recently-created RANGE attribute:
index=HDF_SD_ATTRFIND(sd_id, 'RANGE')
; Retrieve data from RANGE:
HDF_SD_ATTRINFO,sd_id,index,NAME=atn,COUNT=atc,TYPE=att,DATA=d
; Print information about the returned variables:
HELP, atn, atc, att
; Print the data returned in variable d with the given format:
PRINT, d, FORMAT='(F8.2,x,F8.2)'
HDF_SD_ENDACCESS, sds_id ; End access to the HDF file.
HDF_SD_END, sd_id
HDF_CLOSE, fid
```

IDL Output

```
ATN STRING = 'RANGE'
ATC LONG = 2
ATT STRING = 'DOUBLE'

-99.88 55544.20
```

Version History

Introduced: 4.0

HDF_SD_ATTRFIND, HDF_SD_ATTRINFO, HDF_SD_CREATE, HDF_SD_SELECT

HDF_SD_CREATE

The HDF_SD_CREATE function creates and defines a Scientific Dataset (SD) for an HDF file. Keywords can be set to specify the data type. If no keywords are present a floating-point dataset is created.

Syntax

Result = HDF_SD_CREATE(*SD_ID*, *Name*, *Dims* [, /BYTE] [, /DFNT_CHAR8] [, /DFNT_FLOAT32] [, /DFNT_FLOAT64] [, /DFNT_INT8] [, /DFNT_INT16] [, /DFNT_INT32] [, /DFNT_UINT8] [, /DFNT_UINT16] [, /DFNT_UINT32] [, /DOUBLE] [, /FLOAT] [, HDF_TYPE=*type*] [, /INT] [, /LONG] [, /SHORT] [, /STRING])

Return Value

The returned value of this function is the SDS ID of the newly-created dataset.

Arguments

SD_ID

An SD ID as returned by HDF_SD_START.

Name

A string containing the name of the variable to be created.

Dims

A 1-based vector specifying the dimensions of the variable. If an UNLIMITED dimension is desired, set the last vector element to zero or a negative number.

Keywords

BYTE

Set this keyword to indicate that the dataset is composed of bytes. Data will be stored with the HDF DFNT_UINT8 data type. Setting this keyword is the same as setting the DFNT_UINT8 keyword.

DFNT_CHAR8

Set this keyword to create a data set of HDF type DFNT_CHAR8. Setting this keyword is the same as setting the STRING keyword.

DFNT_FLOAT32

Set this keyword to create a data set of HDF type DFNT_FLOAT32. Setting this keyword is the same as setting the FLOAT keyword.

DFNT_FLOAT64

Set this keyword to create a data set of HDF type DFNT_FLOAT64. Setting this keyword is the same as setting the DOUBLE keyword.

DFNT_INT8

Set this keyword to create a data set of HDF type DFNT_INT8.

DFNT_INT16

Set this keyword to create a data set of HDF type DFNT_INT16. Setting this keyword is the same as setting either the INT keyword or the SHORT keyword.

DFNT_INT32

Set this keyword to create a data set of HDF type DFNT_INT32. Setting this keyword is the same as setting the LONG keyword.

DFNT_UINT8

Set this keyword to create a data set of HDF type DFNT_UINT8. Setting this keyword is the same as setting the BYTE keyword.

DFNT_UINT16

Set this keyword to create a data set of HDF type DFNT_UINT16.

DFNT_UINT32

Set this keyword to create a data set of HDF type DFNT_UINT32.

DOUBLE

Set this keyword to indicate that the dataset is composed of double-precision floating-point values. Data will be stored with the HDF DFNT_FLOAT64 data type. Setting this keyword is the same as setting the DFNT_FLOAT64 keyword.

FLOAT

Set this keyword to indicate that the dataset is composed of single-precision floating-point values. Data will be stored with the HDF DFNT_FLOAT32 data type. Setting this keyword is the same as setting the DFNT_FLOAT32 keyword.

HDF_TYPE

Set this keyword to the type of data set to create. Valid values are: DFNT_CHAR8, DFNT_FLOAT32, DFNT_FLOAT64, DFNT_INT8, DFNT_INT16, DFNT_INT32, DFNT_UINT8, DFNT_UINT16, DFNT_UINT32.

For example:

```
type = HDF_IDL2HDFTYPE(SIZE(myData, /type))
sds_id = HDF_SD_CREATE(f_id, "name", dims, HDF_TYPE=type)
```

INT

Set this keyword to indicate that the dataset is composed of 2-byte integers. Data will be stored with the HDF DFNT_INT16 data type. Setting this keyword is the same as setting either the SHORT keyword or the DFNT_INT16 keyword.

LONG

Set this keyword to indicate that the dataset is composed of longword integers. Data will be stored with the HDF DFNT_INT32 data type. Setting this keyword is the same as setting the DFNT_INT32 keyword.

SHORT

Set this keyword to indicate that the dataset is composed of 2-byte integers. Data will be stored with the HDF DFNT_INT16 data type. Setting this keyword is the same as setting either the INT keyword or the DFNT_INT16 keyword.

STRING

Set this keyword to indicate that the dataset is composed of strings. Data will be stored with the HDF DFNT_CHAR8 data type. Setting this keyword is the same as setting the DFNT_CHAR8 keyword.

Examples

```
; Create a new HDF file:
sd_id = HDF_SD_START('test.hdf', /CREATE)
; Create an dataset that includes an unlimited dimension:
sds_id = HDF_SD_CREATE(sd_id, 'var1', [9,40,0], /SHORT)
```

The example for HDF_SD_ATTRSET also demonstrates the use of this routine.

Version History

Introduced: 4.0

HDF_OPEN, HDF_SD_ENDACCESS, HDF_SD_SELECT

HDF_SD_DIMGET

The HDF_SD_DIMGET procedure retrieves information about an SD dataset dimension.

Syntax

HDF_SD_DIMGET, *Dim_ID* [, /COUNT] [, COMPATIBILITY=*variable*] [, /FORMAT] [, /LABEL] [, /NAME] [, /NATTR] [, /SCALE] [, /TYPE] [, /UNIT]

Arguments

Dim_ID

A dimension ID as returned by HDF_SD _DIMGETID.

Keywords

COUNT

Set this keyword to return the dimension size.

COMPATIBILITY

Set this keyword to a named variable that will contain a string indicating the dimensional compatibility of the current dimension. Possible values are “BW_COMP” (backwards compatible), “BW_INCOMP” (backwards incompatible), or “FAIL” (the information is unavailable). For further information about dimensional compatibilities, see the HDF User’s Guide, and the BW_INCOMP keyword of HDF_SD_DIMSET. By default, IDL writes HDF files in “BW_COMP” mode.

FORMAT

Set this keyword to return the dimension format description string.

LABEL

Set this keyword to return the dimension label description string.

NAME

Set this keyword to return the dimension name.

NATTR

Set this keyword to return the number of attributes for the dimension.

SCALE

Set this keyword to return the scale of the dimension.

TYPE

Set this keyword to return a string describing the data's type (i.e., 'BYTE').

UNIT

Set this keyword to return the dimension unit description string.

Examples

For an example using this routine, see the example for HDF_SD_DIMSET.

Version History

Introduced: 4.0

See Also

HDF_SD_CREATE, HDF_SD_DIMGETID, HDF_SD_DIMSET, HDF_SD_SELECT

HDF_SD_DIMGETID

The HDF_SD_DIMGETID function returns a dimension ID given a dataset's "SDS_ID" and a dimension number.

Syntax

Result = HDF_SD_DIMGETID(*SDS_ID*, *Dimension_Number*)

Return Value

Returns the dimension identifier.

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD _SELECT or HDF_SD_CREATE.

Dimension_Number

A zero-based dimension number. The dimension number must be greater than or equal to 0 and less than the maximum dimension number, or *rank*.

Keywords

None.

Examples

For an example illustrating this routine, see the documentation for HDF_SD_DIMSET.

Version History

Introduced: 4.0

See Also

HDF_SD_CREATE, HDF_SD_DIMGET, HDF_SD_DIMSET, HDF_SD_SELECT

HDF_SD_DIMSET

The HDF_SD_DIMSET procedure sets the scale and data strings for an SD dimension.

Syntax

HDF_SD_DIMSET, *Dim_ID* [, /BW_INCOMP] [, FORMAT=*string*] [, LABEL=*string*] [, NAME=*string*] [, SCALE=*vector*] [, UNIT=*string*]

Arguments

Dim_ID

A dimension ID as returned by HDF_SD _DIMGETID.

Keywords

BW_INCOMP

Set this keyword to write SD dimensions in the “new” (HDF4.1 and later) style. Versions of HDF prior to HDF 4.0 beta 2 were inefficient in the use of SD dimensions. HDF now uses a new internal representation of SD dimensions. If the BW_INCOMP keyword is not set, or is explicitly set equal to zero, the current version of HDF writes SD dimensions in both the pre-HDF 4.0 format AND the “new” format. This default behavior is called the BW_COMP dimensional compatibility representation.

Setting the BW_INCOMP keyword causes the current dimension to be written in only the “new” (HDF4.1 and later) format. Depending on your HDF file, using this new format can reduce the size of the HDF by up to a factor of 2, but at the expense of incompatibility with pre HDF 4.0 beta 2 applications (IDL version 4, for example). The COMPATIBILITY keyword of HDF_SD_DIMGET can be used to check the dimensional compatibility of an HDF dimension.

Note

Future versions of HDF will recognize *only* the “new” (BW_INCOMP) dimensional representation.

FORMAT

A string for the dimension format.

LABEL

A string for the dimension label.

NAME

A string for the dimension name.

SCALE

A vector containing the dimension scale values.

UNIT

A string for the dimension unit.

Examples

```
; Initialize the SD interface:
sd_id = HDF_SD_START('myhdf.hdf', /RDWR)
; Create 3 dimensions:
sds_id = HDF_SD_CREATE(sd_id, 'var1', [10,20,0], /LONG)
; Select the first dimension:
dim_id=HDF_SD_DIMGETID(sds_id,0)
; Set the data strings and scale for the first dimension:
HDF_SD_DIMSET, dim_id, NAME='d1', LABEL='l1', $
   FORMAT='f1', UNIT='u1', SCALE=FINDGEN(10)
HDF_SD_ENDACCESS, sds_id
; Close the HDF file to ensure everything is written:
HDF_SD_END, sd_id
; Reopen the file:
sd_id = HDF_SD_START('myhdf.hdf')
; Select the first dimension:
dim_id = HDF_SD_DIMGETID(sds_id,0)
; Retrieve the information:
HDF_SD_DIMGET, dim_id, NAME=d1, LABEL=l1, FORMAT=f1, $
   UNIT=u1, SCALE=sc, COUNT=cnt, NATTR=natt, TYPE=type
; Print information about the returned variables:
HELP, d1, l1, f1, u1, sc, cnt, natt, type
; Close the SD interface:
HDF_SD_ENDACCESS,sds_id
HDF_SD_END, sd_id
```

IDL Output

```
D1 STRING = 'd1'
L1 STRING = 'l1'
F1 STRING = 'f1'
U1 STRING = 'u1'
SC FLOAT = Array(10)
CNT LONG = 10
NATT LONG = 3
TYPE STRING = 'FLOAT'
```

Version History

Introduced: 4.0

See Also

HDF_SD_CREATE, HDF_SD_DIMGET, HDF_SD_DIMGETID, HDF_SD_SELECT

HDF_SD_END

The HDF_SD_END procedure closes the SD interface to an HDF file. Failure to close the file without a call to HDF_SD_END results in the loss of any changed or added SD data. Therefore, HDF_SD_END calls should always be paired with calls to HDF_SD_START. Before HDF_SD_END is called, all access to SD datasets should be terminated with calls to HDF_SD_ENDACCESS.

Syntax

HDF_SD_END, *SD_ID*

Arguments

SD_ID

An SD interface ID as returned by HDF _SD_START.

Keywords

None.

Examples

```
; Open a new HDF file:
sd_id = HDF_SD_START('test.hdf', /CREATE)
; Various commands could now be used to access SD data
; in the HDF file.
; When done with datasets, access should be ended with
; calls to HDF_SD_ENDACCESS:
HDF_SD_ENDACCESS, sds_id_1
; When done with an HDF file, it should be closed:
HDF_SD_END, sd_id
```

Another example can be seen in the documentation for HDF_SD_ATTRSET.

Version History

Introduced: 4.0

See Also

HDF_CLOSE, HDF_OPEN, HDF_SD_ENDACCESS, HDF_SD_START

HDF_SD_ENDACCESS

The HDF_SD_ENDACCESS procedure closes an SD dataset interface. Failure to close the interface can result in the loss of any changed or added SD data. This routine should be called once for each call to HDF_SD_START or HDF_SD_CREATE. After all SD dataset interfaces are closed, the HDF file can safely be closed with HDF_SD_END.

Syntax

HDF_SD_ENDACCESS, *SD_ID*

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD_SELECT, or HDF_SD_CREATE.

Keywords

None.

Examples

```
; Open a new HDF file:
sd_id = HDF_SD_START('test.hdf', /CREATE)
; Access the HDF file:
sds_id_1 = HDF_SD_SELECT(sd_id,0)
; End access to any SD IDs:
HDF_SD_ENDACCESS, sds_id_1
; Close the HDF file:
HDF_SD_END, sd_id
```

Also see the example in HDF_SD_ATTRSET.

Version History

Introduced: 4.0

See Also

HDF_CLOSE, HDF_OPEN, HDF_SD_CREATE, HDF_SD_ENDACCESS, HDF_SD_START

HDF_SD_FILEINFO

The HDF_SD_FILEINFO procedure retrieves the number of datasets and global attributes in an HDF file.

Syntax

HDF_SD_FILEINFO, *SD_ID*, *Datasets*, *Attributes*

Arguments

SD_ID

An SD interface ID as returned by HDF_SD_START.

Datasets

A named variable in which the total number of SD-type objects (i.e., the number of datasets + the number of dimensions) in the file is returned.

Attributes

A named variable in which the number of global attributes in the file is returned.

Keywords

None.

Examples

```
; Start the SD interface:
sd_id = HDF_SD_START('demo.hdf', /CREATE)
; Set a global attribute:
HDF_SD_ATTRSET,sd_id, 'TITLE', 'MYTITLE'
; Set another one:
HDF_SD_ATTRSET,sd_id, 'TITLE2', 'MYTITLE2'
; Create a dataset:
sds_id = HDF_SD_CREATE(sd_id, 'var1', [10,3])
; Retrieve info about the dataset:
HDF_SD_FILEINFO, sd_id, datasets, attributes
; Print information about the returned variables:
HELP, datasets, attributes
; End SD access:
HDF_SD_ENDACCESS, sds_id
```

```
; Close the SD interface:
HDF_SD_END, sd_id
```

IDL Output

```
DATASETS LONG = 1
ATTRIBUTES LONG = 2
```

Version History

Introduced: 4.0

See Also

HDF_SD_ATTRFIND, HDF_SD_ATTRINFO, HDF_SD_START

HDF_SD_GETDATA

The HDF_SD_GETDATA procedure retrieves a hyperslab of values from an SD dataset. By default, the retrieved data is transposed from HDF's column order format into IDL's row order which is more efficient in IDL. To retrieve the dataset without this transposition, set the NOREVERSE keyword.

Syntax

HDF_SD_GETDATA, *SDS_ID*, *Data* [, COUNT=*vector*] [, /NOREVERSE] [, START=*vector*] [, STRIDE=*vector*]

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD _SELECT or HDF_SD_CREATE.

Data

A named variable in which the values are returned.

Keywords

COUNT

Set this keyword to a vector containing the counts, or number of items, to be read. The default is to read all available data.

NOREVERSE

Set the keyword to retrieve the data without transposing the data from column to row order.

START

Set this keyword to a vector containing the starting position for the read. The default start position is [0, 0, ..., 0].

STRIDE

Set this keyword to a vector containing the strides, or sampling intervals, between accessed values of the HDF variable. The default stride vector is that for a contiguous read: [0, 0, ..., 0].

Examples

For an example using this routine, see the documentation for HDF_GR_ATTRINFO

Version History

Introduced: 4.0

See Also

HDF_GR_ATTRINFO, HDF_SD_GETINFO

HDF_SD_GETINFO

The HDF_SD_GETINFO procedure retrieves information about an SD dataset.

Warning

Reading a label, unit, format, or coordinate system string that has more than 256 characters can have unpredictable results.

Syntax

HDF_SD_GETINFO, *SDS_ID* [, CALDATA=*variable*] [, COORDSYS=*variable*] [, DIMS=*variable*] [, FILL=*variable*] [, FORMAT=*variable*] [, HDF_TYPE=*variable*] [, LABEL=*variable*] [, NAME=*variable]* [, NATTS=*variable*] [, NDIMS=*variable*] [, /NOREVERSE] [, RANGE=*variable*] [, TYPE=*variable*] [, UNIT=*variable*]

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD _SELECT or HDF_SD_CREATE.

Keywords

CALDATA

Set this keyword to a named variable in which the calibration data associated with the SD dataset is returned. The data is returned in a structure of the form:

For more information about calibration data, see the documentation for HDF_SD_SETINFO.

COORDSYS

Set this keyword to a named variable in which the coordinate system description string is returned.

DIMS

Set this keyword to a named variable in which the dimensions of the SD dataset are returned. For efficiency, these dimensions are returned in reverse order from their HDF format unless the NOREVERSE keyword is also set.

FILL

Set this keyword to a named variable in which the fill value of the SD dataset is returned. Note that a fill value *must* be set in the SD dataset. If a fill value is not set, the value of the variable named by this keyword will be undefined, and IDL will issue a warning message.

FORMAT

Set this keyword to a named variable in which the format description string is returned. If the format description string is not present, this variable will contain an empty string.

HDF_TYPE

Set this keyword to a named variable in which the HDF type of the SD dataset is returned as a scalar string. Possible returned values are DFNT_NONE, DFNT_CHAR8, DFNT_FLOAT32, DFNT_FLOAT64, DFNT_INT8, DFNT_INT16, DFNT_INT32, DFNT_UINT8, DFNT_UINT16, and DFNT_UINT32.

LABEL

Set this keyword to a named variable in which the label description string is returned. If the label description string is not present, this variable will contain an empty string.

NAME

Set this keyword to a named variable in which the SD dataset name is returned. If the SD dataset name is not present, this variable will contain an empty string.

NATTS

Set this keyword to a named variable in which the number of “NetCDF-style” attributes for the SD dataset is returned.

NDIMS

Set this keyword to a named variable in which the number of dimensions in the dataset is returned.

NOREVERSE

Set this keyword in conjunction with DIMS to return the variable dimensions in non-reversed form. By default, IDL reverses data and dimensions from the HDF format to improve efficiency.

RANGE

Set this keyword to a named variable in which the maximum and minimum of the current SD dataset is returned as a two-element vector. Note that a range *must* be set in the SD dataset. If the range is not set, the value of the variable named by this keyword will be undefined, and IDL will issue a warning message.

TYPE

Set this keyword to a named variable in which the IDL type of the SD dataset is returned as a scalar string. Possible returned values are BYTE, INT, LONG, FLOAT, DOUBLE, STRING, or UNKNOWN.

UNIT

Set this keyword to a named variable in which the unit description string is returned. If the unit description string is not present, this variable will contain an empty string.

Examples

For an example using this routine, see the documentation for HDF_SD_SETINFO.

Version History

Introduced: 4.0

See Also

HDF_OPEN, HDF_SD_END, HDF_SD_SETINFO, HDF_SD_START

HDF_SD_IDTOREF

The HDF_SD_IDTOREF function converts a SD data set ID into a SD data set reference number. The reference number can be used to add the SD data set to a Vgroup through the HDF_VG interface. The tag number for an SD is 720.

Syntax

Result = HDF_SD_IDTOREF(*SDS_ID*)

Return Value

Returns the SD data set reference number.

Arguments

SDS_ID

A SDS_ID as returned from HDF_SD_CREATE or HDF_SD_SELECT.

Keywords

None.

Examples

```
; Create an SD data set and get the Reference number:
file_id = HDF_OPEN('demo.hdf', /ALL)
sd_id = HDF_SD_START('demo.hdf', /RDWR)
dim=[100]
sds_id = HDF_SD_CREATE(sd_id, 'demo_data', dim, /FLOAT)
ref = HDF_SD_IDTOREF(sds_id)
HDF_SD_ADDDATA, sds_id, FINDGEN(100)/10.45 + 2.98
HDF_SD_ENDACCESS, sds_id
HDF_SD_END, sd_id

; Use the Reference number to add the SD to a Vgroup:
SD_TAG = 720
vgID = HDF_VG_GETID(file_id,-1)
vg_handle = HDF_VG_ATTACH(file_id, vgID, /WRITE)
HDF_VG_SETINFO, vg_handle, name='data1', class='demo'
HDF_VG_ADDTR, vg_handle, SD_TAG, ref
```

```
; Use HDF_VG_INQTR to verify the SD was added correctly:
IF HDF_VG_INQTR(vg_handle, SD_TAG, ref) THEN $
   PRINT, 'SUCCESS' ELSE PRINT, 'Failure'
HDF_VG_DETACH, vg_handle
HDF_CLOSE, file_id
```

IDL Output

```
SUCCESS
```

Version History

Introduced: 4.0

HDF_SD_ISCOORDVAR

The HDF_SD_ISCOORDVAR function determines whether or not the specified dataset ID represents a NetCDF “coordinate” variable.

Syntax

Result = HDF_SD_ISCOORDVAR(*SDS_ID*)

Return Value

Returns True (1) if the supplied data set ID is a NetCDF coordinate variable. Otherwise, False (0) is returned.

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD _SELECT or HDF_SD_CREATE.

Keywords

None.

Version History

Introduced: 4.0

HDF_SD_NAMETOINDEX

The HDF_SD_NAMETOINDEX function returns an SD dataset index given its name and SD interface ID. An error message is printed if the dataset cannot be located. The returned index can be used by HDF_SD_SELECT to access an SD dataset.

Syntax

Result = HDF_SD_NAMETOINDEX(*SD_ID*, *SDS_Name*)

Return Value

Returns the specified SD dataset index number.

Arguments

SD_ID

An SD interface ID as returned by HDF_SD_START.

SDS_Name

A string containing the name of the SD dataset be located.

Keywords

None.

Examples

```
; Start the SD interface:
sd_id = HDF_SD_START('demo.hdf')
; Return the index of the 'variable_2' dataset:
index = HDF_SD_NAMETOINDEX(sd_id, 'variable_2')
; Access the dataset:
sds_id=HDF_SD_SELECT(sd_id,index)
; End access:
HDF_SD_ENDACCESS, sds_id
HDF_SD_END, sd_id
```

Version History

Introduced: 4.0

See Also

HDF_SD_REFTOINDEX, HDF_SD_SELECT, HDF_SD_START

HDF_SD_REFTOINDEX

The HDF_SD_REFTOINDEX function returns a scientific dataset's index given its reference number and SD interface ID.

Syntax

Result = HDF_SD_REFTOINDEX(*SD_ID*, *Refno*)

Return Value

Returns the index number associated with the specified SD dataset.

Arguments

SD_ID

An SD interface ID as returned by HDF_SD_START.

Refno

The SD reference number for the desired dataset.

Keywords

None.

Examples

```
; Initialize the SD interface:
sd_id = HDF_SDSTART('demo.hdf')
; Define the reference number for which we want to search:
refno = 66
; Return the index number:
index = HDF_SD_REFTOINDEX(sd_id, refno)
; Now the dataset can be accessed:
sds_id = HDF_SD_SELECT(sd_id, index)
; End access:
HDF_SD_ENDACCESS,SDS_ID
HDF_SD_END, sd_id
```

Version History

Introduced: 4.0

See Also

HDF_SD_IDTOREF, HDF_SD_NAMETOINDEX

HDF_SD_SELECT

The HDF_SD_SELECT function returns an SD dataset ID given the current SD interface ID, and the zero-based SD dataset index.

HDF_SD_FILEINFO can be used to determine the number of SD datasets in an HDF file, HDF_SD_REFTOINDEX can be used to find the index from its SD dataset ID, and HDF_SD_NAMETOINDEX can be used to find the index from its name.

Syntax

Result = HDF_SD_SELECT(*SD_ID*, *Number*)

Return Value

Returns the specified SD dataset's identifier.

Arguments

SD_ID

A SD interface ID as returned from HDF _SD_START.

Number

A zero-based SD dataset index.

Keywords

None.

Examples

```
; Open an HDF file:
sd_id = HDF_SD_START('test.hdf')
; Access the first SD in the HDF file:
sds_id_1=HDF_SD_SELECT(sd_id, 0)
; End access to any SD ids:
HDF_SD_ENDACCESS, sds_id_1
; Close the file:
HDF_SD_END, sd_id
```

Version History

Introduced: 4.0

See Also

HDF_SD_CREATE, HDF_SD_END, HDF_SD_ENDACCESS, HDF_SD_NAMETOINDEX, HDF_SD_REFTOINDEX, HDF_SD_SELECT, HDF_SD_START

HDF_SD_SETCOMPRESS

The HDF_SD_SETCOMPRESS procedure compresses an existing HDF SD dataset or sets the compression method of a newly created HDF SD dataset. Available compression methods are No Compression, run-length encoding (RLE), adaptive (skipping) huffman, and GZIP compression. All of these compression methods are lossless. When using skipping huffman compression, IDL automatically determines the correct skipping size. The EFFORT keyword determines the effort applied when using GZIP compression (i.e., when comptype is 4). In general, the default GZIP compression method is the best combination of speed and file size reduction.

Syntax

HDF_SD_SETCOMPRESS, *SDS_ID*, *comptype* [, EFFORT=*integer*{1 to 9}]

Arguments

SDS_ID

The HDF SD dataset id as returned by HDF_SD_CREATE or HDF_SD_SELECT.

comptype

The compression type to be applied to the HDF SD dataset. Allowable values are:

- 0 = NONE (no compression)
- 1 = RLE (run-length encoding)
- 3 = SKIPPING HUFFMAN
- 4 = GZIP

Note

All compression types are lossless.

Keywords

EFFORT

If the comptype is set to 4 (GZIP), then this keyword specifies the effort that GZIP expends in compressing the dataset. The EFFORT keyword is restricted to the range 1 (minimal compression, fastest) to 9 (most compressed, slowest). The default is EFFORT=5.

Examples

```
; Create an HDF SD file:
sd_id = HDF_SD_START('compress.hdf', /CREATE)
; Create an SDS dataset:
sds_id = HDF_SD_CREATE(sd_id, 'dataset1', [9,40], /LONG)
; Maximal GZIP compression:
HDF_SD_SETCOMPRESS,sds_id,4,EFFORT=9
; Write the data to be compressed:
HDF_SD_ADDDATA,sds_id,fix(dist(9,40))
; End access to the SDS:
HDF_SD_ENDACCESS, sds_id
; End access to the SD interface:
HDF_SD_END, sd_id
```

Note

Compression of HDF SD datasets is a new feature as of HDF 4.1r2 / IDL 5.2.1. Attempts to read HDF SD datasets not created with HDF 4.1r2 (IDL 5.1) or greater will give unpredictable results. Attempts to read HDF compressed SD datasets with IDL versions prior to IDL 5.1, or other HDF readers that use an HDF version prior to HDF 4.1r2, will fail.

Version History

Introduced: 5.2.1

HDF_SD_SETEXTFILE

The HDF_SD_SETEXTFILE procedure moves data values from a dataset into an external file. Only the data is moved—all other information remains in the original file. This routine can only be used with HDF version 3.3 (and later) files, not on older HDF files or NetCDF files. Data can only be moved once, and the user must keep track of the external file(s). The OFFSET keyword allows writing to an arbitrary location in the external file.

As shown in the example, when adding data to an external file SD, you *must* first use HDF_SD_ENDACCESS to sync the file, then reacquire the SDS ID with HDF_SD_SELECT before using HDF_SD_SETEXTFILE.

Syntax

HDF_SD_SETEXTFILE, *SDS_ID*, *Filename* [, OFFSET=*bytes*]

Arguments

sds_id

An SD dataset ID as returned by HDF_SD_SELECT.

Filename

The name of the external file to be written.

Keywords

OFFSET

Set this keyword to a number of bytes from the beginning of the external file at which data writing should begin. Exercise extreme caution when using this keyword with existing files.

Examples

```
; Create an HDF file:
sd_id = HDF_SD_START('ext_main.hdf', /CREATE)
; Add an SD:
sds_id = HDF_SD_CREATE(sd_id, 'float_findgen', [3,5], /FLOAT)
; Put some data into the SD:
HDF_SD_ADDDATA, sds_id, FINDGEN(3,5)
```

```
; Call HDF_SD_ENDACCESS to sync the file:
HDF_SD_ENDACCESS,sds_id
; Reacquire the SDS_ID:
sds_id = HDF_SD_SELECT(sd_id, 0)
; Move data to an external file named findgen.hdf:
HDF_SD_SETEXTFILE, sds_id, 'findgen.hdf'
; Retrieve data from the external file into the variable fout:
HDF_SD_GETDATA, sds_id, fout
; Print the contents of fout:
PRINT, fout
; Sync and close the files:
HDF_SD_ENDACCESS, sds_id
HDF_SD_END, sd_id
```

IDL Output

```
0.00000 1.00000 2.00000
3.00000 4.00000 5.00000
6.00000 7.00000 8.00000
9.00000 10.0000 11.0000
12.0000 13.0000 14.0000
```

Version History

Introduced: 4.0

HDF_SD_END, HDF_SD_ENDACCESS, HDF_SD_SELECT, HDF_SD_START

HDF_SD_SETINFO

The HDF_SD_SETINFO procedure sets information about an SD dataset.

Warning

Setting a label, unit, format, or coordinate system string that has more than 256 characters can have unpredictable results.

Syntax

HDF_SD_SETINFO, *SDS_ID* [, FILL=*value*] [, FORMAT=*string*] [, LABEL=*string*] [, RANGE=*[max, min]*] [, UNIT=*string*] [, COORDSYS=*string*] [, CALDATA=*structure*]

Arguments

SDS_ID

An SD dataset ID as returned by HDF_SD _SELECT or HDF_SD_CREATE.

Keywords

FILL

Set this keyword to the fill value of the SD dataset.

FORMAT

Set this keyword to a string to be used as the SD dataset format.

LABEL

Set this keyword to a string to be used as the SD dataset label.

RANGE

Set this keyword to a two dimensional array that contains the minimum and maximum values of the SD dataset.

UNIT

Set this keyword to a string to be used as the SD dataset units.

COORDSYS

Set this keyword to a string to be used as the SD dataset coordinate system.

CALDATA

Set this keyword to a structure that contains the calibration data. This structure must contain five tags as shown below. The first four tags are of double-precision floating-point type. The fifth tag should be a long integer that specifies the HDF number type. The structure should have the following form:

```
CALDATA={ Cal: 0.0D $          ;Calibration Factor
      Cal_Err: 0.0D $          ;Calibration Error
       Offset: 0.0D $          ;Uncalibrated Offset
       Offset_Err: 0.0D $      ;Uncalibrated Offset Error
       Num_Type: 0L }           ;Number Type of Uncalibrated Data
```

The relationship between HDF and IDL number types is illustrated by the following table:

HDF Number Type	IDL Data Type
0L	UNDEFINED
3L	STRING
21L	BYTE
22L	INTEGER
24L	LONG INTEGER
5L	FLOATING-POINT
6L	DOUBLE-PRECISION

Table D-10: HDF Number Types vs. IDL Data Types

The relationship between the calibrated data (CD) and the uncalibrated data (UD) is given by the equation:

```
CD = Cal * (UD - Offset)
```

Cal and Offset are the values of the Cal and Offset structure fields described above.

Examples

```
; Open an HDF file:
sd_id = HDF_SD_START('demo.hdf', /RDWR)
; Define a new dataset for the file:
sds_id = HDF_SD_CREATE(sd_id, 'variable1', [10, 20], /DOUBLE)
; Create a calibration data structure:
CAL={Cal:1.0D, Cal_Err:0.1D, Offset:2.5D, Offset_Err:0.1D, $
   Num_Type:6L}
; Set information about the dataset:
HDF_SD_SETINFO, sds_id, LABEL='label1', unit='unit1', $
   format='format1', coordsys='coord1', FILL=999.991, $
   RANGE=[99.99,-78], caldata=CAL
; Retrieve the information:
HDF_SD_GETINFO, sds_id, LABEL=l, UNIT=u, FORMAT=f, $
   COORDSYS=c, FILL=fill, RANGE=r, CALDATA=cd, $
   NDIMS=ndims, DIMS=dims, TYPE=ty
; Print information about the returned variables:
HELP, l, u, f, c, fill, r, cd, ndims, dims, ty
; Print the range:
PRINT, r
; Print the calibration data:
PRINT, cd
; Print the dimensions:
PRINT, dims
; Close the SD interface:
HDF_SD_ENDACCESS, sds_id
HDF_SD_END, sd_id
```

IDL Output

```
L STRING = 'label1'
U STRING = 'unit1'
F STRING = 'format1'
C STRING = 'coord1'
FILL DOUBLE = 999.99103
R DOUBLE = Array(2)
CD STRUCT = -> < Anonymous > Array(1)
NDIMS LONG = 2
DIMS LONG = Array(2)
TY STRING = 'DOUBLE'

HDF_SD_END, HDF_SD_ENDACCESS, HDF_SD_GETINFO, HDF_SD_START

HDF_SD_START

The HDF_SD_START function opens or creates an HDF file and initializes the SD interface.

Note that every file opened with HDF_SD_START should eventually be closed with a call to HDF_SD_END.

Syntax

Result = HDF_SD_START(*Filename* [, /READ | , /RDWR] [, /CREATE])

Return Value

The returned value of this function is the SD ID of the HDF file. If no keywords are present, the file is opened in read-only mode.

Arguments

Filename

A scalar string containing the name of the file to be opened or created. HDF_SD_START can open the following file types: XDR-based NetCDF files, “old-style” DFSD files, or “new-style” SD files. New files are created as “new-style” SD files.

Keywords

READ

Set this keyword to open the SD interface in read-only mode. If no keywords are specified, this is the default behavior.

RDWR

Set this keyword to open the SD interface in read and write mode.

CREATE

Set this keyword to create a new SD file.

Examples

```
; Open a new HDF file. The file is ready to be accessed:
sd_id = HDF_SD_START('test.hdf', /CREATE)
; When finished with the file, close it with a call to HDF_SD_END:
HDF_SD_END, sd_id
```

For a more complicated example, see the documentation for HDF_SD_ATTRSET.

Version History

Introduced: 4.0

HDF_UNPACKDATA

This procedure unpacks an array of byte data into a number of IDL variables. It is useful in deconstructing the output of multi-field HDF Vdata reading routines, such as those found in HDF-EOS, into a set of IDL variables. The packed data is assumed to be an array of bytes that is organized as a number of records. Each record consists of one or more data fields. A record is defined using the HDF_TYPE and HDF_ORDER keywords. These define the record layout in terms of HDF data types. The procedure walks through the input array and copies the values into output IDL arrays. There must be as many entries in the HDF_TYPE and HDF_ORDER keywords as there are data arguments.

Syntax

HDF_UNPACKDATA, *packeddata*, *data1* [, *data2* [, *data3* [, *data4* [, *data5* [, *data6* [, *data7* [, *data8*]]]]]]] [, HDF_ORDER=*array*] [, HDF_TYPE=*array*] [, NREC=*records*]

Arguments

packeddata

A BYTE array of packed data.

data1...data8

These arguments return IDL arrays of the types specified by HDF_TYPE with values for each record in the packed data. If HDF_ORDER is greater than one, the returned array will be 2D and the leading dimension will be of length HDF_ORDER. The one exception is string types, which will be returned as a 1D array of IDL strings. The fixed-length string field is returned as an IDL string up to the first zero value (if present). The trailing dimension will be equal to the minimum of the NREC keyword value or the number of complete records that fit in the packeddata array.

Keywords

HDF_ORDER

Set this keyword to an array with the same length as the number of data fields. The values in the array are equal to the number of elements in the return argument for each record. In the case of strings, this is the length (in characters) of the string to be read. A value of zero is interpreted as one element. The default for this keyword is an array of ones.

HDF_TYPE

Set this keyword to an array with the same length as the number of data fields. The value in the array is an HDF data type for each return argument. The returned IDL variables will have these types. The default for this keyword is an array of the value 5 (an HDF 32-bit float). See "IDL and HDF Data Types" on page 3245 for valid values.

NREC

Set this keyword to the number of records to read from packeddata. The default is to read as many complete records as exist in the packeddata array.

Examples

```
a = INDGEN(5)
b = FINDGEN(5)
c = ['This', 'is', 'a', 'string', 'array.']
HELP, a, b, c
hdftype = [ 22, 5, 4] ; HDF INT16, FLOAT32 and CHAR
order = [ 0, 0, 6] ;  2 + 4 + 6 = 12 bytes/record
data = HDF_PACKDATA( a, b, c, HDF_TYPE=hdftype, HDF_ORDER=order)
HELP, data ; a [12, 5] array (5 - 12byte records)
HDF_UNPACKDATA, data, d, e, f, HDF_TYPE=hdftype, HDF_ORDER=order
HELP, d, e, f ; recover the original arrays
```

HDF_PACKDATA, HDF_VD_READ, EOS_PT_READLEVEL

HDF_VD_ATTACH

The HDF_VD_ATTACH function accesses a VData with the given Id in an HDF file.

Syntax

Result = HDF_VD_ATTACH(*FileHandle*, *VDataId* [, /READ] [, /WRITE])

Return Value

If successful, a handle for that VData is returned, otherwise 0 is returned.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

VDataId

The VData reference number, usually obtained by HDF_VD_GETID or HDF_VD_LONE. Set this argument to -1 to create a new VData.

Keywords

READ

Set this keyword to open the VData for reading. This is the default.

WRITE

Set this keyword to open the VData for writing. If VDataID is set equal to -1, the file is opened for writing whether or not this keyword is set.

Version History

Introduced: 4.0

HDF_VD_ATTRFIND

The HDF_VD_ATTRFIND function returns an attribute's index number given the name of an attribute associated with the specified VData or VData/field pair.

Syntax

Result = HDF_VD_ATTRFIND(*VData*, *FieldID*, *Name*)

Return Value

Returns the specified attribute’s index number or –1 if the attribute cannot be located.

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

FieldID

A zero-based index specifying the field, or a string containing the name of the field within the VData to which the attribute is attached. Setting FieldID to –1 specifies that the attribute is attached to the VData itself.

Name

A string containing the name of the attribute whose index is to be returned.

Keywords

None.

Examples

For an example using this routine, see the documentation for HDF_VD_ATTRSET.

Version History

Introduced: 5.5

See Also

HDF_VD_ATTRINFO, HDF_VD_ATTRSET, HDF_VD_ISATTR, HDF_VD_NATTRS

HDF_VD_ATTRINFO

The HDF_VD_ATTRINFO procedure reads or retrieves information about a VData attribute or a VData field attribute from the currently attached HDF VData structure. If the attribute is not present, an error message is printed.

Syntax

HDF_VD_ATTRINFO, *VData*, *FieldID*, *AttrID* [, COUNT=*variable*] [, DATA=*variable*] [, HDF_TYPE=*variable*] [, NAME=*variable*] [, TYPE=*variable*]

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

FieldID

A zero-based index specifying the field, or a string containing the name of the field within the VData whose attribute is to be read. Setting FieldID to -1 specifies that the attribute to be read is attached to the VData itself.

AttrID

A zero-based integer index specifying the attribute to be read, or a string containing the name of that attribute.

Keywords

COUNT

Set this keyword to a named variable in which the number of data values (order of the attribute) is returned.

DATA

Set this keyword to a named variable in which the attribute data is returned.

HDF_TYPE

Set this keyword to a named variable in which the HDF data type of the attribute is returned as a scalar string.

NAME

Set this keyword to a named variable in which the name of the attribute is returned.

TYPE

Set this keyword to a named variable in which the IDL type of the attribute is returned as a scalar string.

Examples

For an example using this routine, see the documentation for HDF_VD_ATTRSET.

Version History

Introduced: 5.5

See Also

HDF_VD_ATTRFIND, HDF_VD_ATTRSET, HDF_VD_ISATTR, HDF_VD_NATTRS

HDF_VD_ATTRSET

The HDF_VD_ATTRSET procedure writes a VData attribute or a VData field attribute to the currently attached HDF VData structure. If no data type keyword is specified, the data type of the attribute value is used.

Syntax

HDF_VD_ATTRSET, *VData*, *FieldID*, *Attr_Name*, *Values* [, *Count*] [, /BYTE] [, /DFNT_CHAR8] [, /DFNT_FLOAT32] [, /DFNT_FLOAT64] [, /DFNT_INT8] [, /DFNT_INT16] [, /DFNT_INT32] [, /DFNT_UCHAR8] [, /DFNT_UINT8] [, /DFNT_UINT16] [, /DFNT_UINT32] [, /DOUBLE] [, /FLOAT] [, /INT] [, /LONG] [, /SHORT] [, /STRING] [, /UINT] [, /ULONG]

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Note

The VData structure must have been attached in write mode in order for attributes to be correctly associated with a VData or one of its fields. If the VData is not write accessible, HDF does not return an error; instead, the attribute information is written to the file but is not associated with the VData.

FieldID

A zero-based index specifying the field, or a string containing the name of the field within the VData whose attribute is to be set. If FieldID is set to -1, the attribute will be attached to the VData itself.

Attr_Name

A string containing the name of the attribute to be written.

Values

The attribute value(s) to be written.

Note

Attributes to be written as characters may not be a multi-dimensional array (e.g. if being converted from byte values) or an array of IDL strings.

Count

An optional integer argument specifying how many values are to be written. Count must be less than or equal to the number of elements in the Values argument. If not specified, the actual number of values present will be written.

Keywords

BYTE

Set this keyword to indicate that the attribute is composed of bytes. Data will be stored with the HDF DFNT_UINT8 data type. Setting this keyword is the same as setting the DFNT_UINT8 keyword.

DFNT_CHAR8

Set this keyword to create an attribute of HDF type DFNT_CHAR8. Setting this keyword is the same as setting the STRING keyword.

DFNT_FLOAT32

Set this keyword to create an attribute of HDF type DFNT_FLOAT32. Setting this keyword is the same as setting the FLOAT keyword.

DFNT_FLOAT64

Set this keyword to create an attribute of HDF type DFNT_FLOAT64. Setting this keyword is the same as setting the DOUBLE keyword.

DFNT_INT8

Set this keyword to create an attribute of HDF type DFNT_INT8.

DFNT_INT16

Set this keyword to create an attribute of HDF type DFNT_INT16. Setting this keyword is the same as setting either the INT keyword or the SHORT keyword.

DFNT_INT32

Set this keyword to create an attribute of HDF type DFNT_INT32. Setting this keyword is the same as setting the LONG keyword.

DFNT_UCHAR8

Set this keyword to create an attribute of HDF type DFNT_UCHAR8.

DFNT_UINT8

Set this keyword to create an attribute of HDF type DFNT_UINT8. Setting this keyword is the same as setting the BYTE keyword.

DFNT_UINT16

Set this keyword to create an attribute of HDF type DFNT_UINT16.

DFNT_UINT32

Set this keyword to create an attribute of HDF type DFNT_UINT32.

DOUBLE

Set this keyword to indicate that the attribute is composed of double-precision floating-point values. Data will be stored with the HDF type DFNT_FLOAT64. Setting this keyword is the same as setting the DFNT_FLOAT64 keyword.

FLOAT

Set this keyword to indicate that the attribute is composed of single-precision floating-point values. Data will be stored with the HDF type DFNT_FLOAT32 data type. Setting this keyword is the same as setting the DFNT_FLOAT32 keyword.

INT

Set this keyword to indicate that the attribute is composed of 16-bit integers. Data will be stored with the HDF type DFNT_INT16 data type. Setting this keyword is the same as setting either the SHORT keyword or the DFNT_INT16 keyword.

LONG

Set this keyword to indicate that the attribute is composed of longword integers. Data will be stored with the HDF type DFNT_INT32 data type. Setting this keyword is the same as setting the DFNT_INT32 keyword.

SHORT

Set this keyword to indicate that the attribute is composed of 16-bit integers. Data will be stored with the HDF type DFNT_INT16 data type. Setting this keyword is the same as setting either the INT keyword or the DFNT_INT16 keyword.

STRING

Set this keyword to indicate that the attribute is composed of strings. Data will be stored with the HDF type DFNT_CHAR8 data type. Setting this keyword is the same as setting the DFNT_CHAR8 keyword.

UINT

Set this keyword to indicate that the attribute is composed of unsigned 2-byte integers. Data will be stored with the HDF type DFNT_UINT16 data type. Setting this keyword is the same as setting the DFNT_UINT16 keyword.

ULONG

Set this keyword to indicate that the attribute is composed of unsigned longword integers. Data will be stored with the HDF type DFNT_UINT32 data type. Setting this keyword is the same as setting the DFNT_UINT32 keyword.

Examples

```
; Open an HDF file.
fid = HDF_OPEN(FILEPATH('vattr_example.hdf',$
   SUBDIRECTORY = ['examples', 'data']), /RDWR)

; Locate and attach an existing vdata.
vdref = HDF_VD_FIND(fid, 'MetObs')
vdid = HDF_VD_ATTACH(fid, vdref, /WRITE)

; Attach two attributes to the vdata.
HDF_VD_ATTRSET, vdid, -1, 'vdata_contents', $
   'Ground station meteorological observations.'
HDF_VD_ATTRSET, vdid, -1, 'num_stations', 10
```

```
; Attach an attribute to one of the fields in the vdata.
HDF_VD_ATTRSET, vdid, 'TempDP', 'field_contents', $
   'Dew point temperature in degrees Celsius.'

; Get the number of attributes associated with the vdata.

HDF_VD_DETACH

The HDF_VD_DETACH procedure is called when done accessing a VData in an HDF file. This routine must be called for every VData attached for writing before closing the HDF file to insure that VSET information is properly updated.

Syntax

HDF_VD_DETACH, *VData*

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Keywords

None.

Version History

Introduced: 4.0

HDF_VD_FDEFINE

The HDF_VD_FDEFINE procedure adds a new field specification for a VData in an HDF file. HDF_VD_FDEFINE can only be used for a new VData.

Syntax

HDF_VD_FDEFINE, *VData*, *Fieldname* [, /BYTE | , /DLONG, | , /DOUBLE | , /DULONG | , /FLOAT | , /INT | , /LONG | , /UINT, | , /ULONG] [, ORDER=*value*]

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Fieldname

A string containing the new field name.

Keywords

BYTE

Set this keyword to indicate that the field will contain 8-bit unsigned integer data.

DOUBLE

Set this keyword to indicate that the field will contain 64-bit floating point data.

FLOAT

Set this keyword to indicate that the field will contain 32-bit floating point data.

INT

Set this keyword to indicate that the field will contain 16-bit integer data.

LONG

Set this keyword to indicate that the field will contain 32-bit integer data.

ORDER

This keyword specifies the number of distinct components in the new field. Compound variables have an order greater than 1. The default order is 1.

Examples

```
HDF_VD_FDEFINE, vid, 'VEL', /DOUBLE, ORDER=3
```

Version History

Introduced: 4.0

HDF_VD_FEXIST

The HDF_VD_FEXIST function determines whether the specified fields exist in the given HDF file.

Syntax

Result = HDF_VD_FEXIST(*VData*, *Fieldnames*)

Return Value

Returns 1 (True) if all the specified fields exist.

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Fieldnames

A string containing a comma-separated list of fields to test. For example, 'VEL' or 'PZ,PY,PX'.

Keywords

None.

Version History

Introduced: 4.0

HDF_VD_FIND

The HDF_VD_FIND function returns the reference number of a VData with the specified name in an HDF file.

Syntax

Result = HDF_VD_FIND(*FileHandle*, *Name*)

Return Value

Returns the reference number of the named VData. A 0 is returned if an error occurs or a VData of the given name does not exist.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

Name

A string containing the name of the VData to be found.

Keywords

None.

Version History

Introduced: 4.0

HDF_VD_GET

The HDF_VD_GET procedure is a general VData inquiry routine. Set the various keywords to named variables to return information about a VData in an HDF file.

Syntax

HDF_VD_GET, *VData* [, CLASS=*variable*] [, COUNT=*variable*]
[, FIELDS=*variable*] [, INTERLACE=*variable*] [, NAME=*variable*]
[, NFIELDS=*variable*] [, REF=*variable*] [, SIZE=*variable*] [, TAG=*variable*]

Arguments

VData

A VData handle returned by HDF_VD_ATTACH.

Keywords

CLASS

Set this keyword to a named variable in which the class name of the VData is returned as a string.

COUNT

Set this keyword to a named variable in which a long, containing the number of records in the VData, is returned.

FIELDS

Set this keyword to a named variable in which a comma-separated string of fields in the VData is returned (e.g., 'PX,PY,PZ')

The maximum number of fields is 256. Each field can be up to 128 characters in length. The returned fields may or may not contain buffering whitespace depending on how the HDF file was created.

INTERLACE

Set this keyword to a named variable in which a string, containing either 'FULL_INTERLACE' or 'NO_INTERLACE', is returned.

NAME

Set this keyword to a named variable in which a string, containing the name of the VData, is returned.

NFIELDS

Set this keyword to a named variable in which a long, containing the number of fields in the VDATA, is returned. For example, the VData containing the fields “PX,PY,PZ”, has an NFIELDS of 3.

REF

Set this keyword to a named variable in which the reference number of the VData is returned.

SIZE

Set this keyword to a named variable in which a long, containing the local size of a record of VData, is returned.

TAG

Set this keyword to a named variable in which the tag number of the VData is returned.

Examples

```
HDF_VD_GET, vdat, CLASS=c, COUNT=co, FIELDS=f, NAME=n, SIZE=s
```

Version History

Introduced: 4.0

See Also

HDF_VD_GETINFO, HDF_VG_GETINFO

HDF_VD_GETID

The HDF_VD_GETID function returns the VData reference number for the next VData in an HDF file after the specified *VDataId*.

Set VDataId to -1 to return the first VData ID in the file.

Syntax

Result = HDF_VD_GETID(*FileHandle*, *VDataId*)

Return Value

Returns the next VData reference number.

Arguments

FileHandle

The HDF file handle returned by a previous call to HDF_OPEN.

VDataID

The VData reference number, generally obtained by HDF_VD_GETID or HDF_VD_LONE. Set this argument to -1 to return the first VData in the file.

Keywords

None.

Version History

Introduced: 4.0

HDF_VD_GETINFO

The HDF_VD_GETINFO procedure is a general VData inquiry routine. Set the various keywords to named variables to return information about each field of a VData in a HDF file.

Syntax

HDF_VD_GETINFO, *VData*, *Index* [, NAME=*variable*] [, ORDER=*variable*] [, SIZE=*variable*] [, TYPE=*variable*]

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Index

A zero-based index specifying which field or the name of the field within the VData to inquire about. For example:

```
HDF_VD_GETINFO, Vdat, 'VEL', ORDER=order
```

Keywords

NAME

Set this keyword to a named variable in which the name of the field is returned as a string.

ORDER

Set this keyword to a named variable in which the order of the field is returned.

SIZE

Set this keyword to a named variable in which the size of a data value for the specified field in the VData is returned.

TYPE

Set this keyword to a named variable in which the type of the field is returned. One of the following strings is returned: 'BYTE', 'INT', 'LONG', 'FLOAT', 'DOUBLE'.

Examples

```
HDF_VD_GET, Vdat, NFIELDS=n
FOR index=0,n-1 DO BEGIN
  HDF_VD_GETINFO, Vdat, index, NAME=n, TYPE=t, ORDER=o
  PRINT, index, ':', n, 'TYPE=', t, 'ORDER=', o
ENDFOR
```

Version History

Introduced: 4.0

HDF_VD_INSERT

The HDF_VD_INSERT procedure adds a VData or VGroup to the contents of a VGroup in an HDF file.

Syntax

HDF_VD_INSERT, *VGroup*, *VData(or Vgroup)*[, POSITION=*variable*]

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

VData

The VData (or VGroup) handle returned by HDF_VD_ATTACH (HDF_VG_ATTACH).

Keywords

None.

Version History

Introduced: 4.0

HDF_VD_ISATTR

The HDF_VD_ISATTR function determines whether or not a VData is storing an attribute. HDF stores attributes as VDatas, so this routine provides a means to test whether or not a particular VData contains an attribute.

Syntax

Result = HDF_VD_ISATTR(*VData*)

Return Value

Returns TRUE (1) if the VData is storing an attribute, FALSE (0) otherwise.

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Keywords

None.

Examples

For an example using this routine, see the documentation for HDF_VD_ATTRSET.

Version History

Introduced: 4.0

See Also

HDF_VD_ATTRFIND, HDF_VD_ATTRINFO, HDF_VD_ATTRSET, HDF_VD_NATTRS

HDF_VD_ISVD

The HDF_VD_ISVD function determines if the object associated with *Id* is a VData in an HDF file.

Syntax

Result = HDF_VD_ISVD(*VGroup*, *Id*)

Return Value

Returns True (1) if the object is VData, or False (0) otherwise.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Id

The VGroup reference number obtained by a previous call to HDF_VG_GETNEXT.

Keywords

None.

Examples

```
Vid = HDF_VG_GETNEXT(Vgrp, -1)
PRINT, HDF_VD_ISVD(VGrp, Vid)
```

Version History

Introduced: 4.0

HDF_VD_ISVG

The HDF_VD_ISVG function determines if the object associated with *Id* is a VGroup in an HDF file.

Syntax

Result = HDF_VG_ISVG(*VGroup*, *Id*)

Return Value

Returns True (1) if the object is a VGroup, or False (0) otherwise.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Id

The VGroup reference number obtained by a previous call to HDF_VG_GETNEXT.

Keywords

None.

Examples

```
Vid = HDF_VG_GETNEXT(Vgrp, -1)
PRINT, HDF_VD_ISVG(VGrp, Vid)
```

Version History

Introduced: 4.0

HDF_VD_LONE

The HDF_VD_LONE function returns an array containing all VDatas in an HDF file that are not contained in another VData.

Syntax

Result = HDF_VD_LONE(*FileHandle* [, MAXSIZE=*value*])

Return Value

Returns any lone VDatas within an array. If there are no lone VDatas, HDF_VD_LONE returns -1.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

Keywords

MAXSIZE

The maximum number of groups to be returned (the default is to return all known lone VDatas). For example, to return only the first 12 groups:

```
X = HDF_VD_LONE(fid, MAX=12)
```

Examples

```
X = HDF_VD_LONE(fid)
IF N_ELEMENTS(X) EQ 0 THEN $
PRINT, 'No Lone VDatas' ELSE PRINT, 'Lone VDatas:', X
```

Version History

Introduced: 4.0

HDF_VD_NATTRS

The HDF_VD_NATTRS function returns the number of attributes associated with the specified VData or VData/field pair.

Syntax

Result = HDF_ VD _NATTRS(*VData*, *FieldID*)

Return Value

Returns the number of attributes if successful. Otherwise, –1 is returned.

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

FieldID

A zero-based index specifying the field, or a string containing the name of the field, within the VData whose attributes are to be counted. Setting Index to –1 specifies that attributes attached to the VData itself are to be counted.

Keywords

None.

Examples

For an example using this routine, see the documentation for HDF_VD_ATTRSET.

Version History

Introduced: 5.5

See Also

HDF_VD_ATTRFIND, HDF_VD_ATTRINFO, HDF_VD_ATTRSET, HDF_VD_ISATTR

HDF_VD_READ

The HDF_VD_READ function reads data from a VData in an HDF file.

The default is to use FULL_INTERLACE and to read all fields in all records. The user can override the defaults with keywords. If multiple fields with different data types are read, all of the data is read into a byte array. The data must then be explicitly converted back into the correct type(s) using various IDL type conversion routines. For example:

```
nread = HDF_VD_READ(vdat, x, NREC=1, FIELDS=”FLT,LNG”)
floatvalue = FLOAT(x, 0)
longvalue = LONG(x, 4)
```

Syntax

Result = HDF_VD_READ(*VData*, *Data* [, FIELDS=*string*] [, /FULL_INTERLACE | , /NO_INTERLACE] [, NRECORDS=*records*])

Return Value

This function returns the number of records successfully read from the VData.

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Data

A named variable in which the data is returned.

Keywords

FIELDS

A string containing a comma-separated list of fields to be read. Normally HDF_VD_READ will read all fields in the VData.

FULL_INTERLACE

Set this keyword to use full interlace when reading (the default).

NO_INTERLACE

Set this keyword to use no interlace when reading.

NRECORDS

The number of records to read. By default, HDF_VD_READ reads all records from a VData.

Examples

Typical read:

```
NREC = HDF_VD_READ(Vdat, X)
```

Read one field:

```
NREC = HDF_VD_READ(Vdat, X, FIELDS='VEL')
```

Read a record:

```
NREC = HDF_VD_READ(Vdat, X, NRECORDS=1)
```

Version History

Introduced: 4.0

HDF_VD_SEEK

The HDF_VD_SEEK procedure moves the read pointer within the specified VData in an HDF file to a specific record number. Note that the record number is zero-based.

Syntax

HDF_VD_SEEK, *VData*, *Record*

Arguments

VData

A VData handle returned by HDF_VD_ATTACH.

Record

The zero-based record number to seek.

Keywords

None.

Version History

Introduced: 4.0

HDF_VD_SETINFO

The HDF_VD_SETINFO procedure specifies general information about a VData in an HDF file. Keywords can be used to establish the name, class, and interlace for the specified VData.

Syntax

HDF_VD_SETINFO, *VData* [, CLASS=*string*] [, /FULL_INTERLACE | , /NO_INTERLACE] [, NAME=*string*]

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Keywords

CLASS

A string that sets the class name for the VData.

FULL_INTERLACE

Set this keyword to store data in the file with full interlace (i.e., sequentially by record).

NAME

A string that sets the name of the VData.

NO_INTERLACE

Set this keyword to store data in the file with no interlace (i.e., sequentially by field).

Examples

```
HDF_VD_SETINFO, Vdat, NAME='My Favorite Data', /FULL
```

Version History

Introduced: 4.0

HDF_VD_WRITE

The HDF_VD_WRITE procedure stores data in a VData in an HDF file.

There are many restrictions on writing data to a VData. When writing multiple fields of varying types, only limited error checking is possible. When writing a series of fields all with the same type, data is converted to that type before writing. For example:

```
Vdat = HDF_VD_ATTACH(Fid, -1, /WRITE)
; Create a 10 integer vector:
Data = INDGEN(10)
; Data converted to FLOAT before write:
HDF_VD_WRITE, Vdat, 'PX', Data
```

It is possible to write less data than exists in the Data argument by using the NRECORDS keyword. For example, the following command writes 5 records, instead of the 10 implied by the size of the data (VEL is assumed to be of type FLOAT, order=3):

```
HDF_VD_WRITE, Vdat, 'VEL', FINDGEN(3,10),NREC=5
```

VEL now contains [[0.0, 1.0, 2.0], ..., [12.0, 13.0, 14.0]]

HDF_VD_WRITE will not allow a user to specify more records than exist. For example, the following command fails:

```
HDF_VD_WRITE, Vdat, 'VEL', [1,2,3], NREC=1000
```

Bugs

HDF vdatas can only be appended or overwritten if they are defined at creation with a file interlacing mode of FULL_INTERLACE. Records in a fully interlaced vdata are written record-by-record which allows them to be appended or overwritten. For further information, consult the "Writing to Multi-Field Vdatas" section in the *HDF User's Guide* published by the National Center for Supercomputing (available at http://hdf.ncsa.uiuc.edu/doc.html).

Restrictions

It is not possible to write IDL structures directly to a VData (because of possible internal padding depending upon fields/machine architecture, etc.). The user must put the data into a byte array before using HDF_VD_WRITE.

When writing a series of fields all with the same type, the low order dimension of *Data* must match the sum of the orders of the fields. For example:

```
HDF_VD_WRITE, Vdat, 'PX,PY', FLTARR(3,10)
```

fails. PX and PY are both order 1 (total 2) and the array's low order dimension is 3.

Syntax

HDF_VD_WRITE, *VData*, *Fields*, *Data*
[, /FULL_INTERLACE | , /NO_INTERLACE] [, NRECORDS=*records*]

Arguments

VData

The VData handle returned by a previous call to HDF_VD_ATTACH.

Fields

A string containing a comma-separated list of the fields to be written.

Data

The data to be written to the specified VData.

Keywords

FULL_INTERLACE

Set this keyword to use full interlace when writing (the default).

NO_INTERLACE

Set this keyword to use no interlace when writing.

NRECORDS

The number of records to written. By default, HDF_VD_WRITE writes all records from a VData.

Version History

Introduced: 4.0

HDF_VG_ADDTR

The HDF_VG_ADDTR procedure adds a tag and reference to the specified VGroup in an HDF file.

Syntax

HDF_VG_ADDTR, *VGroup*, *Tag*, *Ref*

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Tag

The tag to be written.

Ref

The reference number to be written.

Keywords

None.

Examples

See “HDF_SD_IDTOREF” on page 3412 for an example using this function.

Version History

Introduced: 4.0

See Also

HDF_VG_GETTR, HDF_VG_GETTRS, HDF_VG_INQTR, HDF_VG_INSERT

HDF_VG_ATTACH

The HDF_VG_ATTACH function attaches (opens) a VGroup in an HDF file for reading or writing.

If VGroupId is set to -1, a new VGroup is created. If neither the READ nor WRITE keywords are set, the VGroup is opened for reading.

Syntax

Result = HDF_VG_ATTACH(*FileHandle, VGroupId* [, /READ] [, /WRITE])

Return Value

If successful, a handle for the specified group is returned. If it fails, 0 is returned.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

VGroupId

The VGroup reference number, generally obtained by HDF_VG_GETID or HDF_VG_LONE.

Keywords

READ

Set this keyword to open the VGroup for reading.

WRITE

Set this keyword to open the VGroup for writing.

Examples

See “HDF_SD_IDTOREF” on page 3412 for an example using this function.

Version History

Introduced: 4.0

HDF_VG_DETACH

The HDF_VG_DETACH procedure should be called when you are finished accessing a VGroup in an HDF file. This routine must be called for every VGroup attached for writing before closing the HDF file in order to insure that VSET information is properly updated.

Syntax

HDF_VG_DETACH, *VGroup*

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Keywords

None.

Examples

See "HDF_SD_IDTOREF" on page 3412 for an example using this function.

Version History

Introduced: 4.0

HDF_VG_GETID

The HDF_VG_GETID function returns the VGroup ID for the next VGroup after the specified VGroupId in an HDF file. Use a VGroupId of -1 to get the first VGroup in the file.

Syntax

Result = HDF_VG_GETID(*FileHandle*, *VGroupId*)

Return Value

Returns the next VGroup ID.

Arguments

FileHandle

The HDF file handle returned from a previous call to HDF_OPEN.

VGroupID

The VGroup reference number, generally obtained by HDF_VG_GETID or HDF_VG_LONE.

Keywords

None.

Examples

See “HDF_SD_IDTOREF” on page 3412 for an example using this function.

Version History

Introduced: 4.0

HDF_VG_GETINFO

The HDF_VG_GETINFO procedure is a general VGroup inquiry routine. Set the various keywords to named variables to return information about different aspects of a VGroup in an HDF file.

Syntax

HDF_VG_GETINFO, *VGroup* [, CLASS=*variable*] [, NAME=*variable*] [, NENTRIES=*variable*] [, REF=*variable*] [, TAG=*variable*]

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Keywords

CLASS

Set this keyword to a named variable in which the class of the VGroup is returned as a string.

NAME

Set this keyword to a named variable in which the name of the VGroup is returned as a string.

NENTRIES

Set this keyword to a named variable in which the number of objects inside the VGroup is returned as a long integer.

REF

Set this keyword to a named variable in which the reference number of the specified Vgroup is returned.

TAG

Set this keyword to a named variable in which the tag number of the specified Vgroup is returned.

Examples

```
HDF_VG_GETINFO, Vgrp, CLASS=c, NAME=nm, NENTRIES=n
PRINT, c, nm, n
```

Version History

Introduced: 4.0

HDF_VG_GETNEXT

The HDF_VG_GETNEXT function returns the reference number of the next object inside a VGroup in an HDF file. If Id is -1, the first item in the VGroup is returned, otherwise Id should be set to a reference number previously returned by HDF_VG_GETNEXT.

Syntax

Result = HDF_VG_GETNEXT(*VGroup*, *Id*)

Return Value

Returns the reference number of the next object or returns -1 if there was an error or there are no more objects after the one specified by Id.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Id

A VGroup or VData reference number obtained by a previous call to HDF_VG_GETNEXT. Alternatively, this value can be set to -1 to return the first item in the VGroup.

Keywords

None.

Version History

Introduced: 4.0

HDF_VG_GETTR

The HDF_VG_GETTR procedure returns the tag/reference pair at the specified position within a VGroup in an HDF file.

Syntax

HDF_VG_GETTR, *VGroup*, *Index*, *Tags*, *Refs*

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Index

The position within *VGroup*.

Tags

A named variable in which the tag numbers are returned.

Refs

A named variable in which the reference numbers are returned.

Keywords

None.

Version History

Introduced: 4.0

HDF_VG_GETTRS

The HDF_VG_GETTRS procedure returns the tag/reference pairs of the HDF file objects belonging to the specified VGroup.

Syntax

HDF_VG_GETTRS, *VGroup*, *Tags*, *Refs* [, MAXSIZE=*value*]

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Tags

A named variable in which the tag numbers are returned.

Refs

A named variable in which the reference numbers are returned.

Keywords

MAXSIZE

The maximum number of tags and references to be returned. The default is to return all tags and references in VGroup.

Version History

Introduced: 4.0

HDF_VG_INQTR

The HDF_VG_INQTR function returns true if the specified tag and reference pair is linked to the specified VGroup in an HDF file.

Syntax

Result = HDF_VG_INQTR(*VGroup*, *Tag*, *Ref*)

Return Value

Returns true if the link exists.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Tag

The tag number.

Ref

The reference number.

Keywords

None.

Examples

See “HDF_SD_IDTOREF” on page 3412 for an example using this function.

Version History

Introduced: 4.0

HDF_VG_INSERT

The HDF_VG_INSERT procedure adds a VData or VGroup to the contents of a VGroup in an HDF file.

Syntax

HDF_VG_INSERT, *VGroup*, *VData(or Vgroup)*[, POSITION=*variable*]

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

VData

The VData (or VGroup) handle returned by HDF_VD_ATTACH (HDF_VG_ATTACH).

Keywords

None.

Version History

Introduced: 4.0

HDF_VG_ISVD

The HDF_VG_ISVD function returns true if the object associated with Id is a VData in an HDF file.

Syntax

Result = HDF_VG_ISVD(*VGroup*, *Id*)

Return Value

Returns true if the specified object is a VData.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Id

The VGroup or VData reference number obtained by a previous call to HDF_VG_GETNEXT.

Keywords

None.

Examples

```
Vid = HDF_VG_GETNEXT(Vgrp, -1)
PRINT, HDF_VG_ISVD(VGrp, Vid)
```

Version History

Introduced: 4.0

HDF_VG_ISVG

The HDF_VG_ISVG function returns true if the object associated the Id is a VGroup in an HDF file.

Syntax

Result = HDF_VG_ISVG(*VGroup*, *Id*)

Return Value

Returns true if the specified object is a VGroup.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Id

The VGroup or VData reference number obtained by a previous call to HDF_VG_GETNEXT.

Keywords

Examples

```
Vid = HDF_VG_GETNEXT(Vgrp, -1)
PRINT, HDF_VG_ISVG(VGrp, Vid)
```

Version History

Introduced: 4.0

HDF_VG_LONE

The HDF_VG_LONE function returns an array containing the IDs of all VGroups in an HDF file that are not contained in another VGroup.

Syntax

Result = HDF_VG_LONE(*FileHandle* [, MAXSIZE=*value*])

Return Value

Returns the IDs of lone VGroups or returns -1 if there are no lone VGroups,.

Arguments

FileHandle

The HDF file handle returned by a previous call to HDF_OPEN.

Keywords

MAXSIZE

The maximum number of groups to return (the default is to return all lone VGroups). For example, to return no more than 12 VGroups, use the command:

```
X = HDF_VG_LONE(fid, MAX=12)
```

Examples

```
X=HDF_VG_LONE(fid)
IF X(0) EQ-1 THEN $
   PRINT, "No Lone VGroups" ELSE PRINT, "Lone VGroups:", X
```

Version History

Introduced: 4.0

HDF_VG_NUMBER

The HDF_VG_NUMBER function returns the number of HDF file objects in the specified VGroup.

Syntax

Result = HDF_VG_NUMBER(*VGroup*)

Return Value

Returns the number of objects.

Arguments

VGroup

The VGroup handle returned by a previous call to HDF_VG_ATTACH.

Keywords

None.

Version History

Introduced: 4.0

HDF_VG_SETINFO

The HDF_VG_SETINFO procedure sets the name and class of a VGroup.

Syntax

HDF_VG_SETINFO, *VGroup* [, CLASS=*string*] [, NAME=*string*]

Arguments

VGroup

The VGroup handle as returned by HDF_VG _ATTACH.

Keywords

CLASSNAME

A string containing the class name for the VGroup.

NAME

A string containing the name for the VGroup.

Examples

```
fid = HDF_OPEN('demo.hdf',/RDWR) ; Open an HDF file:
vgid = HDF_VG_ATTACH(fid, -1, /WRITE) ; Add a new VGroup:
; Set the name and class for the VGroup:
HDF_VG_SETINFO, vgid, NAME='My Name', CLASS='My VGroup Class'
; Retrieve the name and class information from the file:
HDF_VG_GETINFO, vgid, NAME=outname, CLASS=outclass
; Print information about the returned variables:
HELP, outname, outclass
; End VGroup access:
HDF_VG_DETACH, vgid
; Close the HDF file:
HDF_CLOSE, fid
```

IDL Output

```
OUTNAME STRING = 'My Name'
OUTCLASS STRING = 'My VGroup Class'
```

Version History

Introduced: 4.0

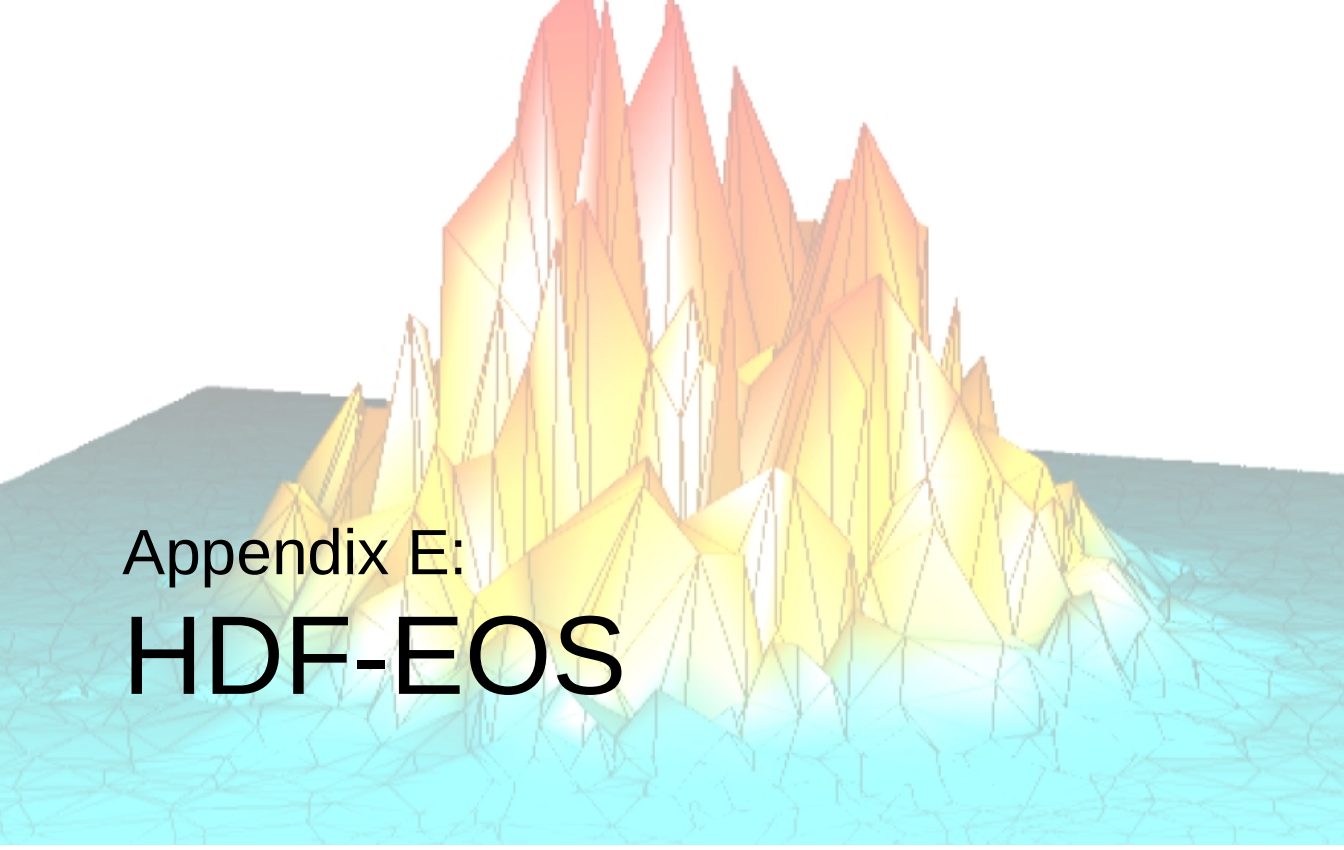
HDF_VG_GETINFO



Appendix E: HDF-EOS

The following topics are covered in this appendix:

Overview 3486
Feature Routines 3487
HDF-EOS Programming Model 3488
Alphabetic Listing of EOS Routines . . . 3490

Overview

HDF-EOS (Hierarchical Data Format-Earth Observing System) is an extension of NCSA (National Center for Supercomputing Applications) HDF and uses HDF calls as an underlying basis. This API contains functionality for creating, accessing and manipulating Grid, Point and Swath structures. IDL's HDF-EOS routines all begin with the prefix "EOS_". This version of IDL supports HDF-EOS 2.8.

Note

On the AIX platform, the HDF-EOS library supports version 2.4.

HDF-EOS is a product of NASA, information may be found at:

```
http://hdfeos.gsfc.nasa.gov
```

Feature Routines

HDF-EOS is an extension of NCSA (National Center for Supercomputing Applications) HDF and uses HDF calls as an underlying basis. This API contains functionality for creating, accessing and manipulating Grid, Point and Swath structures.

The Grid interface is designed to support data that has been stored in a rectilinear array based on a well-defined and explicitly supported projection.

Tips on writing a grid:

- Setting a compression method affects all subsequently defined fields
- Setting a tiling scheme affects all subsequently defined fields

The Point interface is designed to support data that has associated geolocation information, but is not organized in any well-defined spatial or temporal way.

Tips on writing a point:

- Every level in a point data set must be linked into the hierarchy
- Before two levels can be linked, a link field must exist

The Swath interface is tailored to support time-oriented data such as satellite swaths (which consist of a time-oriented series of scanlines), or profilers (which consist of a time-oriented series of profiles).

Tips on writing a swath:

- Define dimensions before using them to define fields of maps
- Setting a compression method affects all subsequently defined fields
- If a dimension map is not defined, a one-to-one mapping is assumed during subsetting.

HDF-EOS Programming Model

Writing

- open file
- create object
- define structure
- detach object
- attach object
- write data
- detach object
- close file

Reading

- open file
- attach object
- inquire object
- read data
- detach object
- close file

Note

When writing an HDF-EOS object, be sure to detach the object before attaching it for the first time. This will initialize the library for the new object. The object will not be written correctly if the above model is not followed.

Note on Array Ordering

In versions prior to version 5.5, IDL was inconsistent in its handling of array ordering between IDL and C-language routines in the HDF-EOS library. Beginning with IDL 5.5, all data arrays (either input or output) use standard IDL array ordering. Dimension size vectors and dimension name lists are also now in IDL order rather than in C-language order.

Programs written using versions of the IDL HDF-EOS routines prior to IDL version 5.5 may have been created to intentionally compensate for the previous behavior. When used with IDL 5.5 and later versions of the IDL HDF-EOS routines, these programs may generate incorrect results.

Affected routines include:

- EOS_SW_DEFDATAFIELD
- EOS_SW_DEFGEOFIELD
- EOS_SW_EXTRACTPERIOD
- EOS_SW_EXTRACTREGION
- EOS_SW_PERIODINFO
- EOS_SW_READFIELD
- EOS_SW_REGIONINFO
- EOS_SW_WRITEDATAMETA
- EOS_SW_WRITEFIELD
- EOS_SW_WRITEGEOMETA
- EOS_GD_DEFFIELD
- EOS_GD_DEFTILE
- EOS_GD_READFIELD
- EOS_GD_READTILE
- EOS_GD_REGIONINFO
- EOS_GD_TILEINFO
- EOS_GD_WRITEFIELD
- EOS_GD_WRITEFIELDMETA
- EOS_GD_WRITETILE

Note

For the EOS_GD_READFIELD, EOS_SW_READFIELD, EOS_GD_WRITEFIELD, and EOS_SW_WRITEFIELD routines, the START, STRIDE, and EDGE keywords should also be specified in the IDL dimension order.

Note

EOS_GD_INQDIMS and EOS_SW_INQDIMS return dimension size and name information without consideration of order.

Alphabetic Listing of EOS Routines

The remainder of this chapter is an alphabetical listing of HDF_EOS routines.

EOS_EH_CONVANG

This function converts angles between three units: decimal degrees, radians, and packed degrees-minutes-seconds. In the degrees-minutes-seconds unit, an angle is expressed as an integral number of degrees and minutes and a float point value of seconds packed as a single double as follows: DDDMMMSSS.SS.

Syntax

Result = EOS_EH_CONVANG(*inAngle*, *code*)

Return Value

Returns angle in desired units.

Arguments

inAngle

Input angle (float).

code

Conversion code (long). Allowable values are:

- 0 = Radians to Degrees
- 1 = Degrees to Radians
- 2 = DMS to Degrees
- 3 = Degrees to DMS
- 4 = Radians to DMS
- 5 = DMS to Radians

Keywords

None.

Examples

To convert 27.5 degrees to packed format:

```
inAng = 27.5
outAng = EOS_EH_CONVANG(inAng, 3)
```

outAng will contain the value 27030000.00.

Version History

Introduced: 5.2

EOS_EH_GETVERSION

The EOS_EH_GETVERSION function is used to retrieve the HDF-EOS version string of an HDF-EOS file, which is returned in the *version* argument. This designates the version of HDF-EOS that was used to create the file. This string is of the form “HDFEOS_Vmaj.min” where maj is the major version and min is the minor version.

Syntax

Result = EOS_EH_GETVERSION(*fid*, *version*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

fid

File id (long) returned by EOS_SW_OPEN, EOS_GD_OPEN, or EOS_PT_OPEN.

version

HDF-EOS version (string).

Keywords

None.

Examples

To get the HDF-EOS version (assumed to be 2.3) used to create the HDF-EOS file:

```
fid = EOS_SW_OPEN("Swathfile.hdf", /READ)
status = EOS_EH_GETVERSION(fid, version)
```

`version` will contain the string “HDFEOS_V2.3”.

Version History

Introduced: 5.2

EOS_EH_IDINFO

This function returns the HDF file IDs corresponding to the HDF-EOS file ID returned by EOS_SW_OPEN, EOS_GD_OPEN, or EOS_PT_OPEN. These IDs can then be used to create or access native HDF structures such as SDS arrays, Vdatas, or HDF attributes within an HDF-EOS file.

Syntax

Result = EOS_EH_IDINFO(*fid*, *HDFfid*, *sdInterfaceID*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

fid

File ID (long) returned by EOS_SW_OPEN, EOS_GD_OPEN, or EOS_PT_OPEN.

HDFfid

A named variable that will contain the HDF file ID (long) returned by Hopen.

sdInterfaceID

A named variable that will contain the SD interface ID (long) returned by SDstart.

Keywords

None.

Examples

To create a vdata within an existing HDF-EOS file:

```
fid = EOS_SW_OPEN("SwathFile.hdf", /RDWR)
status = EOS_EH_IDINFO(fid, hdffid, sdid)
```

Version History

Introduced: 5.2

EOS_EXISTS

The EOS_EXISTS function determines whether the current HDF-EOS extensions are supported on the current platform.

Syntax

Result = EOS_EXISTS( )

Return Value

Returns success (1) if the HDF-EOS extensions are supported, and fail (0) if not.

Arguments

None

Keywords

None

Examples

```
IF (NOT HDF_EOS_EXISTS) THEN PRINT,'HDF-EOS not available.'
```

Version History

Introduced: 5.2.1

EOS_GD_ATTACH

This function attaches to the grid using the gridname parameter as the identifier.

Syntax

Result = EOS_GD_ATTACH(*fid*, *gridname*)

Return Value

Returns the grid handle (gridID) if successful and FAIL(–1) otherwise.

Arguments

fid

Grid file id (long) returned by EOS_GD_OPEN.

gridname

Name of grid (string) to be attached.

Keywords

None.

Examples

In this example, we attach to the previously created grid, “ExampleGrid”, within the HDF file, GridFile.hdf, referred to by the handle, fid:

```
gridID = EOS_GD_ATTACH(fid, "ExampleGrid")
```

The grid can then be referenced by subsequent routines using the handle, gridID.

Version History

Introduced: 5.2

EOS_GD_ATTRINFO

This function returns number type and number of elements (count) of a grid attribute.

Syntax

Result = EOS_GD_ATTRINFO(*gridID*, *attrname*, *numbertype*, *count*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

attrname

Attribute name (string).

numbertype

A named variable that will contain the number type (long) of an attribute.

count

A named variable that will contain the number of total bytes in an attribute (long).

Keywords

None.

Examples

In this example, we return information about the ScalarFloat attribute:

```
status = EOS_GD_ATTRINFO(pointID, "ScalarFloat", nt, count)
```

Version History

Introduced: 5.2

EOS_GD_BLKSOMOFFSET

This function writes block SOM offset values. This is a special function for SOM MISR data.

Syntax

Result = EOS_GD_BLKSOMOFFSET(*gridID*, *offset*, *code*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

gridID

The grid ID (long) as returned from EOS_GD_ATTACH.

offset

A scalar or array of offset values.

code

The type of action performed (read (r), write (w)). This value must be set to either the string r or w. If the string value is not recognized, the *code* defaults to r.

Keywords

None.

Version History

Introduced: 5.3

EOS_GD_CLOSE

This function closes the HDF grid file.

Syntax

Result = EOS_GD_CLOSE(*fid*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

fid

Grid file id (long) returned by EOS_GD_OPEN.

Keywords

None.

Examples

```
status = EOS_GD_CLOSE(fid)
```

Version History

Introduced: 5.2

EOS_GD_COMPINFO

This function returns the compression code and compression parameters for a given field.

Syntax

Result = EOS_GD_COMPINFO(*gridID*, *fieldname*, *compcode*, *compparm*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

compcode

A named variable that will contain the HDF compression code (long).

compparm

A named variable that will contain the compression parameters (long array).

Keywords

None.

Examples

To retrieve the compression information about the Opacity field defined in the EOS_GD_DEFCOMP section:

```
status = EOS_GD_COMPINFO(gridID, "Opacity", compcode, compparm)
```

Version History

Introduced: 5.2

EOS_GD_DEFCOMP

EOS_GD_CREATE

This function creates a grid within the file. The grid is created as a Vgroup within the HDF file with the name gridname and class GRID. This function establishes the resolution of the grid, (i.e., the number of rows and columns), and its location within the complete global projection through the upleftpt and lowrightpt arrays. These arrays should be in meters for all GCTP projections other than the Geographic Projection, which should be in packed degree format (q.v. below). For GCTP projection information, see the *HDF-EOS User's Guide, Volume 2: Reference Guide* provided by NASA.

Syntax

Result = EOS_GD_CREATE(*fid*, *gridname*, *xdimsize*, *ydimsize*, *upleftpt*, *lowrightpt*)

Return Value

Returns the grid handle (gridID) and FAIL(–1) otherwise.

Arguments

fid

Grid file id (long) returned by EOS_GD_OPEN.

gridname

Name of grid (string) to be created.

xdimsize

Number of columns (long) in grid.

ydimsize

Number of rows (long) in grid.

upleftpt

Location (double, 2 element array) of upper left corner of the upper left pixel.

lowrightpt

Location (double, 2 element array) of lower right corner of the lower right pixel.

Keywords

None.

Examples

In this example, we create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude. We divide it into 120 bins along the x-axis and 200 bins along the y-axis.

```
uplft[0]=10584.50041d
uplft[1]=3322395.95445d
lowrgt[0]=813931.10959d
lowrgt[1]=214162.53278d
xdim=120
ydim=200
gridID = EOS_GD_CREATE(fid, "UTMGrid", xdim, ydim, uplft, lowrgt)
```

The grid structure is then referenced by subsequent routines using the handle, gridID.

The xdim and ydim values are referenced in the field definition routines by the reserved dimensions: XDim and YDim.

For the Polar Stereographic, Goode Homolosine and Lambert Azimuthal projections, we have established default values in the case of an entire hemisphere for the first projection, the entire globe for the second and the entire polar or equatorial projection for the third.

In the case of the Geographic projection (linear scale in both longitude latitude), the upleftpt and lowrightpt arrays contain the longitude and latitude of these points in packed degree format (DDDMMMSSS.SS).

- upleftpt- Array that contains the X-Y coordinates of the upper left corner of the upper left pixel of the grid. First and second elements of the array contain the X and Y coordinates respectively. The upper left X coordinate value should be the lowest X value of the grid. The upper left Y coordinate value should be the highest Y value of the grid.

- lowrightpt - Array that contains the X-Y coordinates of the lower right corner of the lower right pixel of the grid. First and second elements of the array contain the X and Y coordinates respectively. The lower right X coordinate value should be the highest X value of the grid. The lower right Y coordinate value should be the lowest Y value of the grid.

If the projection is geographic (i.e., projcode=0) then the X-Y coordinates should be specified in degrees/minutes/seconds (DDDMMMSSS.SS) format. The first element of the array holds the longitude and the second element holds the latitude. Latitudes are from –90 to +90 and longitudes are from –180 to +180 (west is negative).

For all other projection types the X-Y coordinates should be in meters in double precision. These coordinates have to be computed using the GCTP software with the same projection parameters that have been specified in the projparm array. For UTM projections use the same zone code and its sign (positive or negative) while computing both upper left and lower right corner X-Y coordinates irrespective of the hemisphere.

Version History

Introduced: 5.2

EOS_GD_DEFBOXREGION

This function defines a longitude-latitude box region for a grid. It returns a grid region ID which is used by the EOS_GD_EXTRACTREGION function to read all the entries of a data field within the region.

Syntax

Result = EOS_GD_DEFBOXREGION(*gridID*, *cornerlon*, *cornerlat*)

Return Value

Returns the grid region ID if successful and FAIL (–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

cornerlon

Longitude (double, 2 element array) in decimal degrees of box corners.

cornerlat

Latitude (double, 2 element array) in decimal degrees of box corners.

Keywords

None.

Examples

In this example, we define the region to be the first quadrant of the Northern hemisphere:

```
cornerlon[0] = 0.d
cornerlat[0] = 90.d
cornerlon[1] = 90.d
cornerlat[1] = 0.d
regionID = EOS_GD_DEFBOXREGION(EOS_GD_id, cornerlon, cornerlat)
```

Version History

Introduced: 5.2

EOS_GD_DEFCOMP

This function sets the HDF field compression for subsequent grid field definitions. The compression does not apply to one-dimensional fields. The compression schemes currently supported are: run length encoding (1), skipping Huffman (3), deflate (gzip) (4) and no compression (0, the default). Deflate compression requires a single integer compression parameter in the range of one to nine with higher values corresponding to greater compression.

Compressed fields are written using the standard EOS_GD_WRITEFIELD function, however, the entire field must be written in a single call. If this is not possible, the user should consider tiling. See EOS_GD_DEFTILE for further information. Any portion of a compressed field can then be accessed with the EOS_GD_READFIELD function. Compression takes precedence over merging so that multi-dimensional fields that are compressed are not merged. The user should refer to the HDF Reference Manual for a fuller explanation of compression schemes and parameters.

Syntax

Result = EOS_GD_DEFCOMP(*gridID*, *compcode* [, *compparm*])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

compcode

HDF compression code (long).

compparm

Compression parameters array. Allowable values are:

- 0 = None
- 1 = Run Length Encoding (RLE)
- 3 = Skipping Huffman
- 4 = Deflate (gzip)

Keywords

None.

Examples

Suppose we wish to compress the Pressure field using run length encoding, the Opacity field using deflate compression, the Spectra field with skipping Huffman compression, and use no compression for the Temperature field:

```
status = EOS_GD_DEFCOMP(gridID, 1)
status = EOS_GD_DEFFIELD(gridID, "Pressure", "YDim,XDim", 5)
compparm[0] = 5
status = EOS_GD_DEFCOMP(gridID, 4, compparm)
status = EOS_GD_DEFFIELD(gridID, "Opacity", "YDim,XDim", 5)
status = EOS_GD_DEFCOMP(gridID, 3)
status = EOS_GD_DEFFIELD(gridID, "Spectra", "Bands,YDim,XDim", 5)
status = EOS_GD_DEFCOMP(gridID, 0)
status = EOS_GD_DEFFIELD(gridID, "Temperature", "YDim,XDim", 5,$
   /MERGE)
```

Note that the MERGE keyword will be ignored in the Temperature field definition.

Version History

Introduced: 5.2

EOS_GD_DEFDIM

This function defines dimensions that are used by the field definition routines (described subsequently) to establish the size of the field.

Syntax

Result = EOS_GD_DEFDIM(*gridID*, *dimname*, *dim*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

dimname

Name of dimension to be defined (string).

dim

The size of the dimension (long).

Keywords

None.

Examples

In this example, we define a dimension, Band, with size 15:.

```
status = EOS_GD_DEFDIM(gridID, "Band", 15)
```

To specify an unlimited dimension that can be used to define an appendable array, the dimension value should be set to zero:

```
status = EOS_GD_DEFDIM(gridID, "Unlim", 0)
```

Version History

Introduced: 5.2

EOS_GD_DEFFIELD

This function defines data fields to be stored in the grid. The dimensions are entered as a string consisting of geolocation dimensions separated by commas. The API will attempt to merge into a single object those fields that share dimensions and in case of multidimensional fields, numbertype. If the MERGE keyword is not set, the API will not attempt to merge it with other fields. Fields using the unlimited dimension will not be merged. Because merging breaks the one-to-one correspondence between HDF-EOS fields and HDF SDS arrays, it should not be set if the user wishes to access the HDF-EOS fields directly using HDF.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_DEFFIELD(*gridID*, *fieldname*, *dimlist*, *numbertype* [, /MERGE])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Name of field (string) to be defined.

dimlist

The list of data dimensions (string) defining the field.

numbertype

The HDF data type (long) of the data stored in the field

Keywords

MERGE

If set, automerge will occur.

Examples

In this example, we define a grid field, Temperature with dimensions XDim and YDim (as established by the EOS_GD_CREATE routine) containing 4-byte floating point numbers and a field, Spectra, with dimensions XDim, YDim, and Bands:

```
status = EOS_GD_DEFFIELD(gridID, "Temperature", &
   "YDim,XDim", 5, /MERGE)
status = EOS_GD_DEFFIELD(gridID, "Spectra", "Bands,YDim,XDim", 5)
```

Version History

Introduced: 5.2

EOS_GD_DEFORIGIN

This function defines the origin of the grid data. This allows the user to select any corner of the grid as the origin.

Syntax

Result = EOS_GD_DEFORIGIN(*gridID*, *origincode*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

origincode

Location of the origin (long) of the grid data. The allowable values are:

- 0 = Upper left
- 1 = Upper right
- 2 = Lower left
- 3 = Lower right

Keywords

None.

Examples

In this Example we define the origin of the grid to be the Lower Right corner:

```
status = EOS_GD_DEFORIGIN(gridID, 3)
```

Version History

Introduced: 5.2

EOS_GD_DEFPIXREG

This function defines whether the pixel center or pixel corner (as defined by the EOS_GD_DEFORIGIN function) is used when requesting the location (longitude and latitude) of a given pixel.

Syntax

Result = EOS_GD_DEFPIXREG(*gridID*, *pixreg*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

pixreg

Pixel registration (long). The allowable values are:

- 0 = Center
- 1 = Corner

Keywords

None.

Examples

In this example, we define the pixel registration to be the corner of the pixel cell:

```
status = EOS_GD_DEFPIXREG(gridID, 1)
```

Version History

Introduced: 5.2

EOS_GD_DEFPROJ

This function defines the GCTP projection and projection parameters of the grid. For GCTP projection information, see the *HDF-EOS User's Guide, Volume 2: Reference Guide* provided by NASA.

Syntax

Result = EOS_GD_DEFPROJ(*gridID*, *projcode*, *zonecode*, *spherecode*, *projparm*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

projcode

GCTP projection code (long).

zonecode

GCTP zone code used by UTM projection (long).

spherecode

GCTP spheroid code (long).

projparm

GCTP projection parameter array.

Keywords

None.

Examples

Example 1

In this example, we define a Universal Transverse Mercator (UTM) grid bounded by 54 E - 60 E longitude and 20 N - 30 N latitude - UTM zonecode 40, using default spheroid (Clarke 1866), spherecode = 0:

```
spherecode = 0
zonecode = 40
status = EOS_GD_DEFPROJ(gridID, 1, zonecode, spherecode, 0)
```

Example 2

In this example, we define a Polar Stereographic projection of the Northern Hemisphere (True scale at 90 N, 0 Longitude below pole) using the International 1967 spheroid:

```
spherecode = 3
projparm = lonarr (13)
;Set Long below pole & true scale in DDDMMMSSS.SSS form
projparm[5] = 90000000.00
status = EOS_GD_DEFPROJ(gridID, 6, 0, spherecode, projparm)
```

Example 3

Finally, we define a Geographic projection. In this case, neither the zone code, sphere code, or the projection parameters are used:

```
status = EOS_GD_DEFPROJ(gridID, 0, 0, 0, 0)
```

Version History

Introduced: 5.2

EOS_GD_DEFTILE

This function defines the tiling dimensions for fields defined following this function call, analogous to the procedure for setting the field compression scheme using EOS_GD_DEFCOMP. The number of tile dimensions and subsequent field dimensions must be the same and the tile dimensions must be integral divisors of the corresponding field dimensions. A tile dimension set to 0 will be equivalent to 1.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_DEFTILE(*gridID*, *tilecode* [, *tilerank*, *tiledims*])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

tilecode

Tile code (long): 0 = notile, 1 = tile

tilerank

The number of tile dimensions (long) (optional).

tiledims

Tile dimensions (long) (optional).

Keywords

None.

Examples

We will define four fields in a grid, two 2-D fields of the same size with the same tiling, a three-dimensional field with a different tiling scheme, and a fourth with no tiling. We assume that XDim is 200 and YDim is 300.

```
tiledims[0] = 100
tiledims[1] = 200
status = EOS_GD_DEFTILE(gridID, 1, 2, tiledims)
status = EOS_GD_DEFFIELD(gridID, "Pressure", "YDim,XDim", 22)
status = EOS_GD_DEFFIELD(gridID, "Temperature", "YDim,XDim", 5)
tiledims[0] = 1
tiledims[1] = 150
tiledims[2] = 100
status = EOS_GD_DEFTILE(gridID, 1, 3, tiledims)
status = EOS_GD_DEFFIELD(gridID, "Spectra", "Bands,YDim,XDim", 5)
status = EOS_GD_DEFTILE(gridID, 0, 0)
status = EOS_GD_DEFFIELD(gridID, "Communities", "YDim,XDim", 24,
/MERGE)
```

Version History

Introduced: 5.2

EOS_GD_DEFVRTREGION

This function subsets on a monotonic field or contiguous elements of a dimension. Whereas the EOS_GD_DEFBOXREGION function subsets along the XDim and YDim dimensions, this function allows the user to subset along any other dimension. The region is specified by a set of minimum and maximum values and can represent either a dimension index (case 1) or field value range (case 2). In the second case, the field must be one-dimensional and the values must be monotonic (strictly increasing or decreasing) in order that the resulting dimension index range be contiguous. (For the current version of this routine, the second option is restricted to fields with number type: 22, 24, 5, 6)

This function may be called after EOS_GD_DEFBOXREGION to provide both geographic and “vertical” subsetting. In this case the user provides the id from the previous subset call. (This same id is then returned by the function.) This routine may also be called “stand-alone” by setting the input id to (–1).

This function may be called up to eight times with the same region ID. It this way a region can be subsetted along a number of dimensions.

The EOS_GD_REGIONINFO and EOS_GD_EXTRACTREGION functions work as before, however the field to be subsetted, (the field specified in the call to EOS_GD_REGIONINFO and EOS_GD_EXTRACTREGION) must contain the dimension used explicitly in the call to EOS_GD_DEFVRTREGION (case 1) or the dimension of the one-dimensional field (case 2).

Syntax

Result = EOS_GD_DEFVRTREGION(*gridID*, *regionID*, *vertObj*, *range*)

Return Value

Returns the grid region ID if successful and FAIL (–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

regionID

Region or period id (long) from previous subset call or –1 to start a new region.

vertObj

Dimension or field to subset (string).

range

Minimum and maximum range for subset (double) 2 element array.

Keywords

None.

Examples

Suppose we have a field called Pressure of dimension Height whose values increase from 100 to1000. If we desire all the elements with values between 500 and 800, we make the call:

```
range[0] = 500.d
range[1] = 800.d
regionID = EOS_GD_DEFVRTREGION(gridID, -1, "Pressure", range)
```

The routine determines the elements in the Height dimension which correspond to the values of the Pressure field between 500 and 800.

If we wish to specify the subset as elements 2 through 5 (0 - based) of the Height dimension, the call would be:

```
range[0] = 2.d
range[1] = 5.d
regionID = EOS_GD_DEFVRTREGION(gridID, -1, "DIM:Height", range)
```

The “DIM:” prefix tells the routine that the range corresponds to elements of a dimension rather than values of a field.

If a previous subset region or period was defined with id, subsetID, that we wish to refine further with the vertical subsetting defined above we make the call:

```
regionID = EOS_GD_DEFVRTREGION(gridID, subsetID, "Pressure", $
   range)
```

The return value, regionID, is set equal to subsetID. That is, the subset region is modified rather than a new one created.

In this example, any field to be subsetted must contain the Height dimension.

Version History

Introduced: 5.2

EOS_GD_DETACH

This function detaches from the grid interface. This routine should be run before exiting from the grid file for every grid opened by EOS_GD_CREATE or EOS_GD_ATTACH.

Syntax

Result = EOS_GD_DETACH(*gridID*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

Keywords

None.

Examples

In this example, we detach a grid structure:

```
status = EOS_GD_DETACH(gridID)
```

Version History

Introduced: 5.2

EOS_GD_DIMINFO

This function retrieves the size of the specified dimension.

Syntax

Result = EOS_GD_DIMINFO(*gridID*, *dimname*)

Return Value

Size of dimension. If FAIL(–1), could signify an improper grid id or dimension name.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

dimname

Dimension name (string)

Keywords

None.

Examples

In this example, we retrieve information about the dimension, “Bands”:

```
dimsize = EOS_GD_DIMINFO(gridID, "Bands")
```

Version History

Introduced: 5.2

EOS_GD_DUPREGION

This function copies the information stored in a current region or period to a new region or period and generates a new id. It is useful when the user wishes to further subset a region (period) in multiple ways.

Syntax

Result = EOS_GD_DUPREGION(*regionID*)

Return Value

Returns new region or period ID or FAIL (–1) if the region cannot be duplicated.

Arguments

regionID

Region or period id (long) returned by EOS_GD_DEFBOXREGION or EOS_GD_DEFVRTREGION.

Keywords

None.

Examples

In this example, we first subset a grid with EOS_GD_DEFBOXREGION, duplicate the region creating a new region ID, regionID2, and then perform two different vertical subsets of these (identical) geographic subset regions:

```
regionID = EOS_GD_DEFBOXREGION(gridID, cornerlon, cornerlat)
regionID2 = EOS_GD_DUPREGION(regionID)
regionID = EOS_GD_DEFVRTREGION(gridID, regionID, "Pressure",$
   rangePres)
regionID2 = EOS_GD_DEFVRTREGION(gridID, regionID2, $
   "Temperature", rangeTemp)
```

Version History

Introduced: 5.2

EOS_GD_EXTRACTREGION

This function reads data into the data buffer from a subsetted region as defined by EOS_GD_DEFBOXREGION.

Syntax

Result = EOS_GD_EXTRACTREGION(*gridID*, *regionID*, *fieldname*, *buffer*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

regionID

Region or period id (long) returned by EOS_GD_DEFBOXREGION.

fieldname

Field to subset (string).

buffer

A named variable that will contain the data Buffer.

Keywords

None.

Examples

In this example, we extract data from the “Temperature” field from the region defined in EOS_GD_DEFBOXREGION. The size of the subsetted region for the field is given by the EOS_GD_REGIONINFO routine.

```
status = EOS_GD_EXTRACTREGION(EOS_GD_id, regionID, $
   "Temperature", datbuf32)
```

Version History

Introduced: 5.2

EOS_GD_FIELDINFO

This function retrieves information on a specific data field.

Syntax

Result = EOS_GD_FIELDINFO(*gridID*, *fieldname*, *rank*, *dims*, *numbertype*, *dimlist*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) if the specified field does not exist.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

rank

A named variable that will contain the pointer to rank (long) of the field.

dims

A named variable that will contain an array (long) of the dimension sizes of the field.

numbertype

A named variable that will contain the HDF data type (long) of the field.

dimlist

A named variable that will contain the dimension list (string).

Keywords

None.

Examples

In this example, we retrieve information about the Spectra data fields:

```
status = EOS_GD_FIELDINFO(gridID, "Spectra", rank, dims,$
   numbertype, dimlist)
```

Version History

Introduced: 5.2

EOS_GD_GETFILLVALUE

This function retrieves the fill value for the specified field.

Syntax

Result = EOS_GD_GETFILLVALUE(*gridID*, *fieldname*, *fillvalue*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

fillvalue

A named variable that will contain the fill value.

Keywords

None.

Examples

In this example, we get the fill value for the “Temperature” field:

```
status = EOS_GD_GETFILLVALUE(gridID, "Temperature", tempfill)
```

Version History

Introduced: 5.2

EOS_GD_GETPIXELS

This function returns the pixel rows and columns for specified longitude/latitude pairs. This function converts longitude/latitude pairs into (0-based) pixel rows and columns. The origin is the upper left-hand corner of the grid. This routine is the pixel subsetting equivalent of EOS_GD_DEFBOXREGION.

Syntax

Result = EOS_GD_GETPIXELS(*gridID*, *nLonLat*, *lonVal*, *latVal*, *pixRow*, *pixCol*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

nLonLat

Number of longitude/latitude pairs (long).

lonVal

Longitude values in degrees (double, 1D array).

latVal

Latitude values in degrees (double, 1D array).

pixRow

A named variable that will contain the pixel Rows (long array).

pixCol

A named variable that will contain the pixel Columns (long array).

Keywords

None.

Examples

This example converts two pairs of longitude/latitude values to rows and columns. The rows and columns of the two pairs will be returned in the rowArr and colArr arrays:

```
lonArr[0] = 134.2d
latArr[0] = -20.8d
lonArr[1] = 15.8d
latArr[1] = 84.6d
status = EOS_GD_GETPIXELS(gridID, 2, lonArr, latArr, rowArr, $
   colArr)
```

Version History

Introduced: 5.2

EOS_GD_GETPIXVALUES

This function reads data from a data field for the specified pixels. It is the pixel subsetting equivalent of EOS_GD_EXTRACTREGION. All entries along the non-geographic dimensions (i.e., NOT XDim and YDim) are returned.

Syntax

Result = EOS_GD_GETPIXVALUES(*gridID, nPixels, pixCol, pixRow, fieldname, buffer*)

Return Value

Returns size of data buffer if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH

nPixels

Number of pixels (long).

pixCol

Pixel Columns (long array).

pixRow

Pixel Rows (long array).

fieldname

Field (string) from which to extract data values.

buffer

A named variable that will contain data values.

Keywords

None.

Examples

To read values from the Spectra field with dimensions, Bands, YDim, and XDim:

```
bufsiz = EOS_GD_GETPIXVALUES(gridID, 2, rowArr, colArr, $
   "Spectra", buffer)
```

Version History

Introduced: 5.2

EOS_GD_GRIDINFO

This function returns the number of rows, columns and the location, in meters, of the upper left and lower right corners of the grid image.

Syntax

Result = EOS_GD_GRIDINFO(*gridID*, *xdimsize*, *ydimsize*, *upleft*, *lowright*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

xdimsize

A named variable that will contain the number of columns in grid (long).

ydimsize

A named variable that will contain the number of rows in grid (long).

upleft

A named variable that will contain the location (double, 2 element array; in meters) of upper left corner.

lowright

A named variable that will contain the location (double, 2 element array; in meters) of lower right corner.

Keywords

None.

Examples

In this example, we retrieve information from a previously created grid with a call to EOS_GD_ATTACH:

```
status = EOS_GD_GRIDINFO(gridID, xdimsize, ydimsize, $
   upleft, lowrgt)
```

Version History

Introduced: 5.2

EOS_GD_INQATTRS

This function retrieves information about attributes defined in a grid. The attribute list is returned as a string with each attribute name separated by commas.

Note

See STRSPLIT to separate the attribute list.

Syntax

Result = EOS_GD_INQATTRS(*gridID*, *attrlist* [, LENGTH=*variable*])

Return Value

Number of attributes found or (–1) if failure.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

attrlist

A named variable that will contain the attribute list (string) with entries separated by commas.

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the attribute list as a long integer.

Examples

In this example, we retrieve information about the attributes defined in a grid structure:

```
nattr = EOS_GD_INQATTRS(gridID, attrlist)
```

Version History

Introduced: 5.2

EOS_GD_INQDIMS

This function retrieves information about dimensions defined in a grid. The dimension list is returned as a string with each dimension name separated by commas.

Note

See STRSPLIT to separate the dimension list.

Syntax

Result = EOS_GD_INQDIMS(*gridID*, *dimname*, *dims*)

Return Value

Number of dimension entries found. If FAIL(–1), could signify an improper grid id.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

dimname

A named variable that will contain the dimension list (string) with entries separated by commas.

dims

A named variable that will contain an array (long) of the size of each dimension.

Keywords

None.

Examples

To retrieve information about the dimensions, use the following statement:

```
ndim = EOS_GD_INQDIMS(gridID, dimname, dims)
```

Version History

Introduced: 5.2

EOS_GD_INQFIELDS

This function retrieves information about the data fields defined in grid. The field list is returned as a string with each data field separated by commas. The rank and numbertype arrays will have an entry for each field.

Note

See STRSPLIT to separate the field list.

Syntax

Result = EOS_GD_INQFIELDS(*gridID*, *fieldlist*, *rank*, *numbertype*)

Return Value

Number of data fields found. If FAIL(–1), could signify an improper grid id.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldlist

A named variable that will contain the listing of data fields (string) with entries separated by commas.

rank

A named variable that will contain the array (long) containing the rank of each data field.

numbertype

A named variable that will contain the array (long) containing the numbertype of each data field.

Keywords

None.

Examples

To retrieve information about the data fields, use the following statement:

```
nfld = EOS_GD_INQFIELDS(gridID, fieldlist, rank, numbertype)
```

Version History

Introduced: 5.2

EOS_GD_INQGRID

This function retrieves number and names of grids defined in HDF-EOS file. The grid list is returned as a string with each grid name separated by commas.

Note

See STRSPLIT to separate the grid list.

Syntax

Result = EOS_GD_INQGRID(*filename*, *gridlist* [, LENGTH=*variable*])

Return Value

Number of grids found or (–1) if failure.

Arguments

filename

HDF-EOS filename (string).

gridlist

A named variable that will contain the grid list (string) with entries separated by commas.

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the grid list as a long integer.

Examples

In this example, we retrieve information about the grids defined in an HDF-EOS file, HDFEOS.hdf:

```
ngrid = EOS_GD_INQGRID("HDFEOS.hdf", gridlist)
```

Version History

Introduced: 5.2

EOS_GD_INTERPOLATE

This function performs bilinear interpolation on a grid field. It assumes that the pixel data values are uniformly spaced which is strictly true only for an infinitesimally small region of the globe but is a good approximation for a sufficiently small region. The default position of the pixel value is pixel center, however if the pixel registration has been set to 1 (with the EOS_GD_DEFPIXREG function) then the value is located at one of the four corners specified by the EOS_GD_DEFORIGIN routine.

All entries along the non-geographic dimensions (i.e., NOT XDim and YDim) are interpolated and all interpolated values are returned as FLOAT64. The reference for the interpolation algorithm is Numerical Recipes in C (2nd ed). (Note for the current version of this routine, the number type of the field to be interpolated is restricted to 22, 24, 5, 6.)

Syntax

Result = EOS_GD_INTERPOLATE(*gridID*, *Interp*, *lonVal*, *latVal*, *fieldname*, *interpVal*)

Return Value

Returns size in bytes of interpolated data values if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH

nInterp

Number of interpolation points (long).

lonVal

Longitude of interpolation points (double array).

latVal

Latitude of interpolation points (double array).

fieldname

The field (string) from which to interpolate data values.

interpVal

A named variable that will contain the (double) interpolated data values.

Keywords

None.

Examples

To interpolate the Spectra field at two geographic data points:

```
lonVal[0] = 134.2d
latVal[0] = -20.8d
lonVal[1] = 15.8d
latVal[1] = 84.6d
bufsiz = EOS_GD_INTERPOLATE(gridID, 2, lonVal, latVal, $
   "Spectra", interpVal)
```

Version History

Introduced: 5.2

EOS_GD_NENTRIES

This function returns the number of entries and descriptive string buffer size for a specified entity.

Syntax

Result = EOS_GD_NENTRIES(*gridID*, *entrycode* [, LENGTH=*variable*])

Return Value

Number of entries or FAIL(–1) which could signify an improper grid id or entry code.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

entrycode

Entrycode (long). Allowable values are:

- 0 = Dimensions
- 4 = Datafields

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the string returned by the corresponding inquiry routine as a long integer.

Examples

In this example, we determine the number of data field entries:

```
ndims = EOS_GD_NENTRIES(gridID, 4)
```

Version History

Introduced: 5.2

EOS_GD_OPEN

This function creates a new file or opens an existing one.

Syntax

Result = EOS_GD_OPEN(*filename*, *access* [, /CREATE] [, /RDWR | , /READ])

Return Value

Returns the grid file id handle (fid) if successful and FAIL(–1) otherwise.

Arguments

filename

Complete path and filename (string) for the file to be opened.

Keywords

CREATE

If file exists, delete it, then open a new file for read/write.

RDWR

Open for read/write. If file does not exist, create it.

READ

Open for read only. If file does not exist, error. This is the default.

Examples

In this example, we create a new grid file named, GridFile.hdf. It returns the file handle, fid.

```
fid = EOS_GD_OPEN("GridFile.hdf", /CREATE)
```

Version History

Introduced: 5.2

See Also

EOS_GD_CLOSE

EOS_GD_ORIGININFO

This function retrieves the origin code.

Syntax

Result = EOS_GD_ORIGININFO(*gridID*, *origincode*)

Return Value

Returns 0 if successful, and –1 otherwise. A return value of –1 could signify an improper grid id or entry code.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

origincode

A named variable that will contain the origin code (long). See EOS_GD_DEFORIGIN for a list of origin codes and their meanings.

Keywords

None.

Version History

Introduced: 5.2

EOS_GD_PIXREGINFO

This function retrieves the pixel registration code.

Syntax

Result = EOS_GD_PIXREGINFO(*gridID, pixregcode*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

pixregcode

A named variable that will contain the pixel registration code (long).

Keywords

None.

Version History

Introduced: 5.2

EOS_GD_PROJINFO

This function retrieves the GCTP projection code, zone code, spheroid code and the projection parameters of the grid. For GCTP projection information, see the *HDF-EOS User's Guide, Volume 2: Reference Guide* provided by NASA.

Syntax

Result = EOS_GD_PROJINFO(*gridID*, *projcode*, *zonecode*, *spherecode*, *projparm*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

projcode

A named variable that will contain the GCTP projection code (long).

zonecode

A named variable that will contain the GCTP zone code used by UTM projection (long).

spherecode

A named variable that will contain the GCTP spheroid code (long).

projparm

A named variable that will contain the GCTP projection parameter array (double).

Keywords

None.

Version History

Introduced: 5.2

EOS_GD_QUERY

The EOS_GD_QUERY function returns information about a specified grid.

Syntax

Result = EOS_GD_QUERY(*Filename*, *GridName*, [*Info*])

Return Value

This function returns an integer value of 1 if the file is an HDF file with EOS GRID extensions, and 0 otherwise.

Arguments

Filename

A string containing the name of the file to query.

GridName

A string containing the name of the grid to query.

Info

Returns an anonymous structure containing information about the specified grid. The returned structure contains the following fields:

Field	IDL Data Type	Description
ATTRIBUTES	String array	Array of attribute names
DIMENSION_NAMES	String array	Names of dimensions
DIMENSION_SIZES	Long array	Sizes of dimensions
FIELD_NAMES	String array	Names of fields
FIELD_RANKS	Long array	Ranks (dimensions) of fields
FIELD_TYPES	Long array	IDL types of fields
GCTP_PROJECTION	Long	GCTP projection code

Table E-1: Fields of the Info Structure

Field	IDL Data Type	Description
GCTP_PROJECTION_PARM	Double array	GCTP projection parameters
GCTP_SPHEROID	Long	GCTP spheroid code
GCTP_ZONE	Long	GCTP zone code (for UTM projection)
IMAGE_LOWRIGHT	Double[2]	Location of lower right corner (meters)
IMAGE_UPLEFT	Double[2]	Location of upper left corner (meters)
IMAGE_X_DIM	Long	Number of columns in grid image
IMAGE_Y_DIM	Long	Number of rows in grid image
NUM_ATTRIBUTES	Long	Number of attributes
NUM_DIMS	Long	Number of dimensions
NUM_IDX_MAPS	Long	Number of indexed dimension mapping entries
NUM_MAPS	Long	Number of dimension mapping entries
NUM_FIELDS	Long	Number of fields
NUM_GEO_FIELDS	Long	Number of geolocation field entries
ORIGIN_CODE	Long	Origin code
PIX_REG_CODE	Long	Pixel registration code

Table E-1: Fields of the Info Structure (Continued)

Version History

Introduced: 5.3

EOS_GD_READATTR

This function reads attributes from the grid.

Syntax

Result = EOS_GD_READATTR(*gridID*, *attrname*, *datbuf*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

attrname

Attribute name (string).

datbuf

A named variable that will contain the attribute values.

Keywords

None.

Examples

In this example, we read a single precision (32 bit) floating point attribute with the name “ScalarFloat”:

```
status = EOS_GD_READATTR(gridID, "ScalarFloat", f32)
```

Version History

Introduced: 5.2

EOS_GD_READFIELD

This function reads data from the grid field. The values within start, stride, and edge arrays refer to the grid field (input) dimensions. The default values for start and stride are 0 and 1 respectively. The default value for edge is (dim - start) / stride where dim refers to the size of the dimension.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_READFIELD(*gridID*, *fieldname*, *buffer* [, EDGE=*array*] [, START=*array*] [, STRIDE=*array*])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Name of field (string) to read.

buffer

A named variable that will contain the data read from the field.

Keywords

EDGE

Array (long) specifying the number of values to read along each dimension.

START

Array (long) specifying the starting location within each dimension.

STRIDE

Array (long) specifying the number of values to skip along each dimension.

Examples

In this example, we read data from the 10th row (0-based) of the Temperature field:

```
start=[10,1]
edge=[1,120]
status = EOS_GD_READFIELD(gridID, "Temperature", row, $
   START = start, EDGE = edge)
```

Version History

Introduced: 5.2

EOS_GD_READTILE

This function reads a single tile of data from a field. If the data is to be read tile by tile, this routine is more efficient than EOS_GD_READFIELD. In all other cases, the later routine should be used. EOS_GD_READTILE does not work on non-tiled fields. Note that the coordinates are in terms of tiles, not data elements.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_READTILE(*gridID*, *fieldname*, *tilecoords*, *buffer*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

tilecoords

Array (long) of tile coordinates.

buffer

A named variable that will contain the tile.

Keywords

None.

Examples

In this example. we read one tile from the Temperature field (see EOS_GD_DEFTILE example) located at the second column of the first row of tiles:

```
tilecoords[0] = 0
tilecoords[1] = 1
status = EOS_GD_READTILE(gridid, "Temperature",$
   tilecoords,buffer)
```

Version History

Introduced: 5.2

EOS_GD_REGIONINFO

This function returns information about a subsetted region for a particular field. Because of differences in number type and geolocation mapping, a given region will give different values for the dimensions and size for various fields. The upleftpt and lowrightpt arrays can be used when creating a new grid from the subsetted region.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_REGIONINFO(*gridID*, *regionID*, *fieldname*, *ntype*, *rank*, *dims*, *size*, *upleftpt*, *lowrightpt*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

regionID

Region or period id (long) returned by EOS_GD_DEFBOXREGION.

fieldname

Field to subset (string).

ntype

A named variable that will contain the HDF data type of field (long).

rank

A named variable that will contain the rank of field (long).

dims

A named variable that will contain the dimensions of subset region (long).

size

A named variable that will contain the size in bytes of subset region (long).

upleftpt

A named variable that will contain the upper left point of subset region (double array).

lowrightpt

A named variable that will contain the lower right point of subset region (double array).

Keywords

None.

Examples

In this example, we retrieve information about the region defined in EOS_GD_DEFBOXREGION for the “Temperature” field:

```
status = EOS_GD_REGIONINFO(EOS_GD_id, regionID, $
   "Temperature", ntype,$ rank, dims, size, upleft,$ lowright)
```

Version History

Introduced: 5.2

EOS_GD_SETFILLVALUE

This function sets the fill value for the specified field. The fill value is placed in all elements of the field which have not been explicitly defined.

Syntax

Result = EOS_GD_SETFILLVALUE(*gridID*, *fieldname*, *fillvalue*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

fillvalue

The fill value to be used.

Keywords

None.

Examples

In this example, we set a fill value for the “Temperature” field:

```
tempfill = -999.0
status = EOS_GD_SETFILLVALUE(gridID, "Temperature", tempfill)
```

Version History

Introduced: 5.2

EOS_GD_SETTILECACHE

This function sets tile cache parameters.

Syntax

Result = EOS_GD_SETTILECACHE(*gridID*, *fieldname*, *maxcache*, *cachecode*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

maxcache

Maximum number of tiles (long) to cache in memory.

cachecode

Currently must be set to 0 (long).

Keywords

None.

Examples

In this example, we set maxcache to 10 tiles. The particular subsetting envisioned for the Spectra field (defined in the EOS_GD_DEFTILE example) would never cross more than 10 tiles along the field's fastest varying dimension, i.e., XDim.

```
status = EOS_GD_SETTILECACHE(gridID, "Spectra", 10, 0)
```

Version History

Introduced: 5.2

EOS_GD_TILEINFO

This function returns the tiling code, tiling rank, and tiling dimensions for a given field.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_TILEINFO(*gridID*, *fieldname*, *tilecode*, *tilerank*, *tiledims*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

tilecode

A named variable that will contain the tile code (long): 0 No Tile, 1 Tile.

tilerank

A named variable that will contain the number of tile dimensions (long).

tiledims

A named variable that will contain the tile dimensions (long).

Keywords

None.

Examples

To retrieve the tiling information about the Pressure field defined in the EOS_GD_DEFTILE section:

```
status = EOS_GD_COMPINFO(gridID, "Pressure", tilecode, $
   tilerank, tiledims)
```

Version History

Introduced: 5.2

EOS_GD_WRITEATTR

This function writes/updates attributes in the grid. If the attribute does not exist, it is created. If it does exist, then the value(s) is (are) updated.

Syntax

Result = EOS_GD_WRITEATTR(*gridID*, *attrname*, *datbuf* [, COUNT=*value*] [, HDF_TYPE=*value*])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

attrname

Attribute name (string).

datbuf

Attribute values. If HDF_TYPE is specified, the IDL variable is first converted to the type specified by the keyword before being written.

Keywords

COUNT

Number of values to store in attribute (long).

HDF_TYPE

HDF data type of attribute (long).

Examples

In this example. we write a single precision (32 bit) floating point number with the name “ScalarFloat” and the value 3.14:

```
f32 = 3.14
status = EOS_GD_WRITEATTR(gridid, "ScalarFloat", f32)
```

We can update this value by simply calling the function again with the new value:

```
f32 = 3.14159
status = EOS_GD_WRITEATTR(gridid, "ScalarFloat", f32)
```

Version History

Introduced: 5.2

EOS_GD_WRITEFIELD

This function writes data to the grid field. The values within start, stride, and edge arrays refer to the grid field (output) dimensions. The input data in the data buffer is read from contiguously. The default values for start and stride are 0 and 1 respectively. The default value for edge is (dim - start) / stride where dim refers to the size of the dimension. Note that the data buffer for a compressed field must be the size of the entire field as incremental writes are not supported by the underlying HDF routines.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_WRITEFIELD(*gridID*, *fieldname*, *data* [, EDGE=*array*] [, START=*array*] [, STRIDE=*array*])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Name of field (string) to write.

data

Values (long) to be written to the field.

Keywords

EDGE

Array (long) specifying the number of values to write along each dimension.

START

Array (long) specifying the starting location within each dimension (0-based).

STRIDE

Array (long) specifying the number of values to skip along each dimension.

Examples

In this example, we write data to the Temperature field:

```
; Define elements of temperature array:
temperature = indegen (200, 120)
status = EOS_GD_WRITEFIELD(gridID, "Temperature", temperature)

; Update Row 10 (0-based) in this field:
start=[0,10], edge=[2000,1]

; Define elements of newrow array:
status = EOS_GD_WRITEFIELD(gridID, "Temperature", $
   START=start, EDGE=edge, newrow)
```

Version History

Introduced: 5.2

EOS_GD_WRITEFIELDMETA

This function writes the field metadata for a grid field not defined by the Grid API.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_WRITEFIELDMETA(*gridID*, *fieldname*, *dimlist*, *numbertype*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Name of field (string) that metadata information is to be written.

dimlist

Dimension list of field (long).

numbertype

Number type of data in field (long).

Keywords

None.

Examples

```
status = EOS_GD_writefieldmeta(gridID, "ExternField", $
   "Ydim,Xdim", 5)
```

Version History

Introduced: 5.2

EOS_GD_WRITETILE

This function writes a single tile of data to a field. If the data to be written to a field can be arranged tile by tile, this routine is more efficient than EOS_GD_WRITEFIELD. In all other cases, the EOS_GD_WRITEFIELD routine should be used. EOS_GD_WRITETILE does not work on non-tiled fields. Note that the are coordinates in terms of tiles, not data elements.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_GD_WRITETILE(*gridID*, *fieldname*, *tilecoords*, *data*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

gridID

Grid id (long) returned by EOS_GD_CREATE or EOS_GD_ATTACH.

fieldname

Fieldname (string).

tilecoords

Array of tile coordinates (long).

data

Data to be written to tile.

Keywords

None.

Examples

In this example, we write one tile to the Temperature field (see the EOS_GD_DEFTILE example) at the second column of the first row of tiles:

```
tilecoords[0] = 0
tilecoords[1] = 1
status=EOS_GD_WRITETILE(gridID, "Temperature", tilecoords, data)
```

Version History

Introduced: 5.2

EOS_PT_ATTACH

This function attaches to the point using the pointname parameter as the identifier.

Syntax

Result = EOS_PT_ATTACH(*fid*, *pointname*)

Return Value

Returns the point handle (pointID) if successful and FAIL (–1) otherwise.Typical reasons for failure are an improper point file id or point name.

Arguments

fid

Point file id (long) returned by EOS_PT_OPEN.

pointname

Name of point (string) to be attached.

Keywords

None.

Examples

In this example, we attach to the previously created point, “ExamplePoint”, within the HDF file, PointFile.hdf, referred to by the handle, fid:

```
pointID = EOS_PT_ATTACH(fid, "ExamplePoint")
```

The point can then be referenced by subsequent routines using the handle, pointID.

Version History

Introduced: 5.2

See Also

EOS_PT_DETACH

EOS_PT_ATTRINFO

This function returns number type and number of elements (count) of a point attribute.

Syntax

Result = EOS_PT_ATTRINFO(*pointID*, *attrname*, *numbertype*, *count*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

attrname

Attribute name (string).

numbertype

A named variable that will contain the HDF type of the attribute value (long).

count

A named variable that will contain the number of total bytes in attribute (long).

Keywords

None.

Examples

In this example, we return information about the ScalarFloat attribute:

```
status = EOS_PT_ATTRINFO(pointID, "ScalarFloat", nt, count)
```

Version History

Introduced: 5.2

EOS_PT_BCKLINKINFO

This function returns the linkfield to the previous level.

Syntax

Result = EOS_PT_BCKLINKINFO(*pointID*, *level*, *linkfield*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Point level (0-based long).

linkfield

A named variable that will contain the link field (string).

Keywords

None.

Examples

In this example, we return the linkfield connecting the Observations level to the previous Desc-Loc level. (These levels are defined in the EOS_PT_DEFLEVEL routine.)

```
status = EOS_PT_BCKLINKINFO(pointID2, 1, linkfield)
```

Version History

Introduced: 5.2

EOS_PT_CLOSE

This function closes the HDF point file.

Syntax

Result = EOS_PT_CLOSE(*fid*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

fid

Point file id (long) returned by EOS_PT_OPEN.

Keywords

None.

Examples

```
status = EOS_PT_CLOSE(fid)
```

Version History

Introduced: 5.2

EOS_PT_CREATE

This function creates a new point structure. The point is created as a Vgroup within the HDF file with the name *pointname* and class POINT.

Syntax

Result = EOS_PT_CREATE(*fid*, *pointname*)

Return Value

Returns the point handle (pointID) if successful and FAIL (–1) otherwise.

Arguments

fid

Point file id (long) returned by EOS_PT_OPEN.

pointname

Name of point (string) to be created.

Keywords

None.

Examples

In this example, we create a new point structure, ExamplePoint, in the previously created file, PointFile.hdf:

```
pointID = EOS_PT_CREATE(fid, "ExamplePoint")
```

The point structure is then referenced by subsequent routines using the handle, pointID.

Version History

Introduced: 5.2

EOS_PT_DEFBOXREGION

This function defines an area of interest for a point. It returns a point region ID which is used by the EOS_PT_EXTRACTREGION routine to read the fields from a level for those records within the area of interest.The point structure must have a level with both a Longitude and Latitude (or Colatitude) field defined.

Syntax

Result = EOS_PT_DEFBOXREGION(*pointID*, *cornerlon*, *cornerlat*)

Return Value

Returns the point regionID if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

cornerlon

Longitude (double) in decimal degrees of box corners (2 element, 1-D array).

cornerlat

Latitude (double) in decimal degrees of box corners (2 element, 1-D array).

Keywords

None.

Examples

In this example, we define an area of interest with (opposite) corners at –145 degrees longitude, –15 degrees latitude and –135 degrees longitude, –8 degrees latitude:

```
cornerlon = dblarr (2)
cornerlat = dblarr (2)
cornerlon[0] = -145.
cornerlat[0] = -15.
cornerlon[1] = -135.
```

```
cornerlat[1] = -8.
regionID = EOS_PT_DEFBOXREGION(pointID, cornerlon, cornerlat)
```

Version History

Introduced: 5.2

EOS_PT_DEFLEVEL

This function defines a level within the point. A simple point consists of a single level. A point where there is common data for a number of records can be more efficiently stored with multiple levels. The order in which the levels are defined determines the (0-based) level index.

Syntax

Result = EOS_PT_DEFLEVEL(*pointID*, *levelname*, *fieldlist*, *fieldtype*, *fieldorder*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

levelname

Name of level (string) to be defined.

fieldlist

List of fields (string) in level.

fieldtype

Array (long) containing HDF data type of each field within level.

fieldorder

Array (long) containing order of each field within level.

Note

An order of 0 is considered the same as an order of 1.

Keywords

None.

Examples

Example 1 — Simple Point:

In this example, we define a simple single level point, with levelname, Sensor. The levelname should not contain any slashes (“/”). It consists of six fields, ID, Time, Longitude, Latitude, Temperature, and Mode defined in the field list. The fieldtype and fieldorder parameters are arrays consisting of the HDF number type codes and field orders, respectively. The Temperature is an array field of dimension 4 and the Mode field a character string of size 4. All other fields are scalars. Note that the order for numerical scalar variables can be either 0 or 1.

```
fieldtype = [22, 22, 5, 5, 5, 4]
fieldorder = [0,0,0,0,4,4]
fldlist = "ID,Time,Longitude,Latitude,Temperature,Mode"
status = EOS_PT_DEFLEVEL(pointID, "Sensor", fldlist, fieldtype,$
fieldorder)
```

Example 2 — Multi-Level Point:

In this example, we define a two-level point that describes data from a network of fixed buoys. The first level contains information about each buoy and includes the name (label) of the buoy, its (fixed) longitude and latitude, its deployment date, and an ID that is used to *link* it to the following level. (The link field is defined in the EOS_PT_DEFLINKAGE routine described later.) The entries within the ID field must be unique. The second level contains the actual measurements from the buoys (rainfall and temperature values) plus the observation time and the ID which relates a given measurement to a particular buoy entry in the previous level. There can be many records in this level with the same ID since there can be multiple measurements from a single buoy. It is advantageous, although not mandatory, to store all records for a particular buoy (ID) contiguously.

Level 0

```
fieldtype0 = [4, 6, 6, 5, 4]
fieldorder0 = [8,0,0,0,1]
fldlist0 =       "Label,Longitude,Latitude,DeployDate,ID"
status = EOS_PT_deflevel(pointID2, "Desc-Loc", $
   fldlist0, fieldtype0, fieldorder0)
```

Level 1

```
fieldtype1 = [6, 5, 5, 4]
fieldorder1 = [0,0,0,1]
fldlist1 = "Time,Rainfall,Temperature,ID"
status = EOS_PT_DEFLEVEL(pointID2, "Observations", $
   fldlist1, fieldtype1, fieldorder1)
```

Version History

Introduced: 5.2

EOS_PT_DEFLINKAGE

This function defines the linkfield between two levels. This field must be defined in both levels.

Syntax

Result = EOS_PT_DEFLINKAGE(*pointID*, *parent*, *child*, *linkfield*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

parent

Name (string) of parent level.

child

Name (string) of child level.

linkfield

Name (string) of common linkfield.

Keywords

None.

Examples

In this example, we define the ID field as the link between the two levels defined previously in the EOS_PT_DEFLEVEL function:

```
status = EOS_PT_DEFLINKAGE(pointID2, "Desc-Loc", $
   "Observations", "ID")
```

Version History

Introduced: 5.2

EOS_PT_DEFTIMEPERIOD

This function defines a time period for a point. It returns a point period ID which is used by the EOS_PT_EXTRACTPERIOD function to read the fields from a level for those records within the time period. The point structure must have a level with the Time field defined.

Syntax

Result = EOS_PT_DEFTIMEPERIOD(*pointID*, *starttime*, *stoptime*)

Return Value

Returns the point periodID if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

starttime

Start time (double) of period.

stoptime

Stop time (double) of period.

Keywords

None.

Examples

In this example, we define a time period with a start time of 35208757.6 and a stop time of 35984639.2:

```
starttime = 35208757.6d
stoptime = 35984639.2d
periodID = EOS_PT_DEFTIMEPERIOD(pointID, starttime, stoptime)
```

Version History

Introduced: 5.2

EOS_PT_DEFVRTREGION

This function allows the user to select those records within a point whose field values are within a given range. (For the current version of this routine, the field must have one of the following HDF data types: 22, 24, 5, 6) This function may be called after EOS_PT_DEFBOXREGION or EOS_PT_DEFTIMEPERIOD to provide both geographic or time and vertical subsetting. In this case the user provides the id from the previous subset call. (This same id is then returned by the function.) This routine may also be called stand-alone by setting the input id to (–1).

This function may be called up to eight times with the same region ID. In this way a region can be subsetted along a number of dimensions.

The EOS_PT_REGIONINFO and EOS_PT_EXTRACTREGION functions work as before, however, because there is no mapping performed between geolocation dimensions and data dimensions for the field to be subsetted, (the field specified in the call to EOS_PT_REGIONINFO and EOS_PT_EXTRACTREGION) must contain the dimension used explicitly in the call to EOS_PT_DEFVRTREGION (case 1) or the dimension of the one-dimensional field (case 2).

Syntax

Result = EOS_PT_DEFVRTREGION(*pointID*, *regionID*, *vertObj*, *range*)

Return Value

Returns the point region ID if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

regionID

Region or period id (long) returned from a previous subset call.

vertObj

String name of a dimension or field by which to subset.

range

Minimum and maximum range for the subset (double, 2 element, 1-D array).

Keywords

None.

Examples

Suppose we wish to find those records within a point whose Rainfall values fall between 1 and 2. We wish to search all the records within the point, so we set the input region ID to (–1):

```
range = [1.,2.]
regionID = EOS_PT_DEFVRTREGION(pointID, -1, "Rainfall", range)

; Now we subset further using the Temperature field:
range = [22.,24.]
regionID = EOS_PT_DEFVRTREGION(pointID, regionID, $
   "Temperature", range)
```

The subsetted region referred to by regionID will now contain those records whose Rainfall field are between 1 and 2 and whose Temperature field are between 22 and 24.

Version History

Introduced: 5.2

EOS_PT_DETACH

This function detaches from a point data set. This function should be run before exiting from the point file for every point opened by EOS_PT_CREATE or EOS_PT_ATTACH.

Syntax

Result = EOS_PT_DETACH(*pointID*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH

Keywords

None.

Examples

```
status = EOS_PT_DETACH(pointID)
```

Version History

Introduced: 5.2

EOS_PT_EXTRACTPERIOD

This function reads data from the designated level fields into the data buffer from the subsetted time period.

Syntax

Result = EOS_PT_EXTRACTPERIOD(*pointID*, *periodID*, *level*, *fieldlist*, *buffer*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long).

periodID

Period id (long) returned by EOS_PT_DEFTIMEPERIOD.

level

Point level (0-based long).

fieldlist

List of fields (string) to extract.

buffer

A named variable that will contain the data buffer. This buffer is in packed format. Use HDF_UNPACKDATA to convert it into variables.

Keywords

None.

Examples

In this example, we read data within the subsetted time period defined by EOS_PT_DEFTIMEPERIOD from the Time field:

```
periodID = EOS_PT_DEFTIMEPERIOD(pointID, 35208757.6d, $
   35984639.2d)
IF (periodID NE -1) THEN BEGIN
   status = EOS_PT_EXTRACTPERIOD(pointID, periodID, 1, $
      "Time", buffer)
   HDF_UNPACKDATA, buffer, dataTime, HDF_TYPE=[6]
ENDIF
```

Version History

Introduced: 5.2

EOS_PT_EXTRACTREGION

This function reads data from the designated level fields into the data buffer from the subsetted area of interest.

Syntax

Result = EOS_PT_EXTRACTREGION(*pointID*, *regionID*, *level*, *fieldlist*, *buffer*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long).

regionID

Period id (long) returned by EOS_PT_DEFBOXREGION.

level

Point level (0-based long).

fieldlist

List of fields (string) to extract.

buffer

A named variable that will contain the data buffer.

Keywords

None.

Examples

In this example, we read data within the subsetted area of interest defined by EOS_PT_DEFBOXREGION from the Longitude and Latitude fields:

```
regionID = EOS_PT_DEFBOXREGION(pointID, [-145.,-135.], [-15.,-8.])
IF (regionID NE -1) THEN BEGIN
   status = EOS_PT_EXTRACTREGION(pointID, regionID, 0, $
      "Longitude,Latitude", buffer)
   HDF_UNPACKDATA, buffer, dataLong,dataLat,HDF_TYPE=[6,6]
ENDIF
```

Version History

Introduced: 5.2

EOS_PT_FWDLINKINFO

This function returns the linkfield to the given level.

Syntax

Result = EOS_PT_FWDLINKINFO(*pointID*, *level*, *linkfield*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Point level (0-based long).

linkfield

A named variable that will contain the link field (string).

Keywords

None.

Examples

In this example, we return the linkfield connecting the Desc-Loc level to the following Observations level. (These levels are defined in the EOS_PT_DEFLEVEL function.):

```
status = EOS_PT_FWDLINKINFO(pointID2, 1, linkfield)
```

Version History

Introduced: 5.2

EOS_PT_GETLEVELNAME

This function returns the name of a level given the level number (0-based).

Syntax

Result = EOS_PT_GETLEVELNAME(*pointID*, *level*, *levelname*
[, LENGTH=*variable*])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Point level (0-based long).

levelname

A named variable that will contain the level name (string).

Keywords

LENGTH

Set this keyword to a named variable that will contain the string length of the level name.

Examples

In this example, we return the level name of the 0th level of the second point defined in the EOS_PT_DEFLEVEL section:

```
status = EOS_PT_GETLEVELNAME(pointID2, 0, levelname)
```

Version History

Introduced: 5.2

EOS_PT_GETRECNUMS

This function returns the record numbers in one level that are connected to a given set of records in a different level. The two levels need not be adjacent. The records in one level are related to those in another through the link field. These in turn are related to the next. In this way, each record in any level is related to others in all the levels of the point structure.

Syntax

Result = EOS_PT_GETRECNUMS(*pointID*, *inlevel*, *outlevel*, *inNrec*, *inRecs*, *outNrec*, *outRecs*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

inlevel

Level number (long) of input records (0-based).

outlevel

Level number (long) of output records (0-based).

inNrec

Number of records (long) in the inRecs array.

inRecs

Array (long) containing the input record numbers.

outNrec

A named variable that will contain the number of records (long) in the outRecs array.

outRecs

A named variable that will contain the array (long) of output record numbers.

Keywords

None.

Examples

In this example, we get the record numbers in the second level that are related to the first record in the first level:

```
nrec = 1
recs[0] = 0
inLevel = 0
outLevel = 1
status = EOS_PT_GETRECNUMS(pointID2, inLevel, outLevel, $
   nrec, recs, outNrec, outRecs)
```

Version History

Introduced: 5.2

EOS_PT_INQATTRS

This function retrieves information about the attributes defined in a point structure. The attribute list is returned as a string with each attribute name separated by a comma.

Note

See STRSPLIT to separate the attribute list.

Syntax

Result = EOS_PT_INQATTRS(*pointID*, *attrlist* [, LENGTH=*variable*])

Return Value

Number of attributes found or (–1) if failure.

Arguments

pointID

Point id (long).

attrlist

A named variable that will contain the attribute list (string) entries separated by commas.

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the attribute list, as a long integer.

Examples

```
nattr = EOS_PT_INQATTRS(pointID, attrlist)
```

Version History

Introduced: 5.2

EOS_PT_INQPOINT

This function retrieves the number and names of points defined in an HDF-EOS file. The point list is returned as a string with each point name separated by a comma.

Note

See STRSPLIT to separate the attribute list.

Syntax

Result = EOS_PT_INQPOINT*(filename, pointlist* [, LENGTH=*variable*])

Return Value

Returns number of points found or (–1) if failure.

Arguments

filename

HDF-EOS filename (string).

pointlist

A named variable that will contain the point list (string) entries separated by commas.

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the point list as a long integer.

Examples

In this example, we retrieve information about the points defined in an HDF-EOS file, HDFEOS.hdf:

```
npoint = EOS_PT_INQPOINT("HDFEOS.hdf", pointlist)
```

Version History

Introduced: 5.2

EOS_PT_LEVELINDX

This function returns the level index for a given level specified by name.

Syntax

Result = EOS_PT_LEVELINDX(*pointID*, *levelname*)

Return Value

Returns the level index if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

levelname

Level Name (string).

Keywords

None.

Examples

In this example, we return the level index of the Observations level in the multilevel point structure defined in EOS_PT_DEFLEVEL:

```
levindx = EOS_PT_LEVELINDEX(pointID2, "Observations")
```

Version History

Introduced: 5.2

EOS_PT_LEVELINFO

This function returns information about the fields in a given level. Typical reasons for failure are an improper point id or level number.

Syntax

Result = EOS_PT_LEVELINFO(*pointID*, *level*, *fieldlist*, *fldtype*, *fldorder*)

Return Value

Returns number of fields if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Point level (0-based long).

fieldlist

A named variable that will contain field names (string) in level.

fldtype

A named variable that will contain the number HDF data type (long) of each field.

fldorder

A named variable that will contain the order (long) of each field.

Keywords

None.

Examples

In this example, we return information about the Desc-Loc (1st) level defined previously:

```
nflds = EOS_PT_LEVELINFO(pointID2, 0, fldlist, fldtype, fldorder)
```

The last variable is useful only when information on an entire point is requested.

Version History

Introduced: 5.2

EOS_PT_NFIELDS

This function returns the number of fields in a level.

Syntax

Result = EOS_PT_NFIELDS(*pointID*, *level* [, LENGTH=*bytes*])

Return Value

Returns number of fields if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Level number (0-based long).

Keywords

LENGTH

Size (long) in bytes of fieldlist for level.

Examples

In this example, we retrieve the number of fields in the 2nd point defined previously:

```
nflds=EOS_PT_NFIELDS(pointID2,0)
```

Version History

Introduced: 5.2

EOS_PT_NLEVELS

This function returns the number of levels in a point.

Syntax

Result = EOS_PT_NLEVELS(*pointID*)

Return Value

Returns number of levels if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

Keywords

None.

Examples

In this example, we retrieve the number of levels in the 2nd point defined previously:

```
nlevels = EOS_PT_NLEVELS(pointID2)
```

Version History

Introduced: 5.2

EOS_PT_NRECS

This function returns the number of records in a given level.

Syntax

Result = EOS_PT_NRECS(*pointID*, *level*)

Return Value

Returns number of records in a given level if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Level number (0-based long).

Keywords

None.

Examples

In this example, we retrieve the number of records in the first level of the 2nd point defined previously:

```
nrecs = EOS_PT_NRECS(pointID2, 0)
```

Version History

Introduced: 5.2

EOS_PT_OPEN

This function creates a new file or opens an existing one.

Syntax

Result = EOS_PT_OPEN(*fieldname* [, /CREATE] [, /RDWR | , /READ])

Return Value

Returns the point file id handle (fid) if successful and FAIL (–1) otherwise.

Arguments

fieldname

Complete path and filename (string) for the file to be opened.

Keywords

CREATE

If file exists, delete it, then open a new file for read/write.

RDWR

Open for read/write. If file does not exist, create it.

READ

Open for read only. If file does not exist then error.

Examples

In this example, we create a new point file named, PointFile.hdf. It returns the file handle, fid.

```
fid = EOS_PT_OPEN("PointFile.hdf", /CREATE)
```

Version History

Introduced: 5.2

See Also

EOS_PT_CLOSE

EOS_PT_PERIODINFO

This function returns information about a subsetted time period for a particular fieldlist.

Syntax

Result = EOS_PT_PERIODINFO(*pointID*, *periodID*, *level*, *fieldlist*, *size*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long).

periodID

Period id (long) returned by EOS_PT_DEFTIMEPERIOD.

level

Point level (0-based long).

fieldlist

List of fields (string) to extract.

size

A named variable that will contain the size in bytes (long) of subset period.

Keywords

None.

Examples

In this example, we get the size of the subsetted time period defined in EOS_PT_DEFTIMEPERIOD for the Time field:

```
status = EOS_PT_PERIODINTO(pointID, periodID, 0, "Time", size)
```

Version History

Introduced: 5.2

EOS_PT_PERIODRECS

This function returns the record numbers within a subsetted time period for a particular level.

Syntax

Result = EOS_PT_PERIODRECS(*pointID*, *periodID*, *level*, *nrec*, *recs*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long).

periodID

Period id (long) returned by EOS_PT_DEFTIMEPERIOD.

level

Point level (0-based long).

nrec

A named variable that will contain the number of records (long) within time period in level.

recs

A named variable that will contain the record numbers (long) of subsetted records in level.

Keywords

None.

Examples

In this example, we get the number of records and record numbers within the subsetted area of interest defined in EOS_PT_DEFTIMEPERIOD for the 0th level:

```
status = EOS_PT_PERIODRECS(pointID, periodID, 0, nrec, recs)
```

Version History

Introduced: 5.2

EOS_PT_QUERY

The EOS_PT_QUERY function returns information about a specified point.

Syntax

Result = EOS_PT_QUERY(*Filename*, *PointName*, [*Info*])

Return Value

This function returns an integer value of 1 if the file is an HDF file with EOS POINT extensions, and 0 otherwise.

Arguments

Filename

A string containing the name of the file to query.

PointName

A string containing the name of the point to query.

Info

Returns an anonymous structure containing information about the specified point. The returned structure contains the following fields:

Field	IDL Data Type	Description
ATTRIBUTES	String array	Array of attribute names
NUM_ATTRIBUTES	Long	Number of attributes
NUM_LEVELS	Long	Number of levels

Table E-2: Fields of the Info Structure

Keywords

None.

Version History

Introduced: 5.3

EOS_PT_READATTR

This function reads attributes.

Syntax

Result = EOS_PT_READATTR(*pointID*, *attrname*, *datbuf*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

attrname

Attribute name (string).

datbuf

A named variable that will contain the buffer allocated to hold attribute values.

Keywords

None.

Examples

In this example, we read a single precision (32 bit) floating point attribute with the name “ScalarFloat”:

```
status = EOS_PT_READATTR(pointID, "ScalarFloat", f32)
```

Version History

Introduced: 5.2

EOS_PT_READLEVEL

This function reads data from the specified fields and records of a single level in a point.

Syntax

Result = EOS_PT_READLEVEL(*pointID*, *level*, *fieldlist*, *nrec*, *recs*, *buffer*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Level to read (0-based long).

fieldlist

List of fields (string) to read.

nrec

Number of records (long) to read.

recs

Record number of records to read (0-based long).

buffer

A named variable that will contain the buffer to store data. This buffer is in packed format. Use HDF_UNPACKDATA to convert it into IDL variables.

Keywords

None.

Examples

In this example, we read records 0, 2, and 3 from the Temperature and Mode fields in the first level of the point referred to by point ID, pointID. Temperature is a 32-bit float field and Mode is a 4 character field (HDF types 5 and 4 respectively):

```
recs = [ 0, 2, 3 ]
status = EOS_PT_READLEVEL( pointID, 0, "Temperature,Mode", $
   3, recs, buffer)
IF (status EQ 0) THEN BEGIN
   HDF_UNPACKDATA, buffer, dataTemperature, dataMode, $
      HDF_TYPE=[5,4], HDF_ORDER = [4,4]
ENDIF
```

Version History

Introduced: 5.2

EOS_PT_REGIONINFO

This function returns information about a subsetted area of interest for a particular fieldlist.

Syntax

Result = EOS_PT_REGIONINFO(*pointID*, *regionID*, *level*, *fieldlist*, *size*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long).

regionID

Region id (long) returned by EOS_PT_DEFBOXREGION.

level

Point level (0-based long).

fieldlist

List of fields (sting) to extract.

size

A named variable that will contain the size in bytes (long) of subset period.

Keywords

None.

Examples

In this example, we get the size of the subsetted area of interest defined in EOS_PT_DEFBOXREGION from the Longitude and Latitude fields:

```
status = EOS_PT_REGIONINFO(pointID, regionID, 0, "Longitude, $
   Latitude",size)
```

Version History

Introduced: 5.2

EOS_PT_REGIONRECS

This function returns the record numbers within a subsetted geographic region for a particular level.

Syntax

Result = EOS_PT_REGIONRECS(*pointID*, *regionID*, *level*, *nrec*, *recs*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long).

regionID

Region id (long) returned by EOS_PT_DEFBOXREGION.

level

Point level (0-based long).

nrec

A named variable that will contain the number of records (long) within geographic region in level.

recs

A named variable that will contain the record numbers (long) of subsetted records in level.

Keywords

None.

Examples

In this example, we get the number of records and record numbers within the subsetted area of interest defined in EOS_PT_DEFBOXREGION for the 0th level:

```
status = EOS_PT_REGIONRECS(pointID, regionID, 0, nrec, recs)
```

Version History

Introduced: 5.2

EOS_PT_SIZEOF

This function returns information about specified fields in a point regardless of level.

Syntax

Result = EOS_PT_SIZEOF(*pointID*, *fieldlist*, *fldlevel*)

Return Value

Returns size in bytes of specified fields and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

fieldlist

Field names (string).

fldlevel

A named variable that will contain the level number (long) of each field.

Keywords

None.

Examples

In this example, we return the size in bytes of the Label and Rainfall fields in the 2nd point defined in the EOS_PT_DEFLEVEL function:

```
size = EOS_PT_SIZEOF(pointID2, "Label,Rainfall", fldlevel)
```

Version History

Introduced: 5.2

EOS_PT_UPDATELEVEL

This function updates the specified fields and records of a single level.

Syntax

Result = EOS_PT_UPDATELEVEL(*pointID*, *level*, *field*, *list*, *nrec*, *recs*, *data*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Level to update (0-based long).

fieldlist

List of fields (string) to update.

nrec

Number of records (long) to update.

recs

Record number of records to update (0-based long).

data

Values to be written to the fields. Data values are not converted to the internal HDF type automatically. Use HDF_PACKDATA if conversion is necessary or the data fields specify multiple types.

Keywords

None.

Examples

In this example, we update records 0, 2, and 3 in the Temperature and Mode fields in the second level in the point referred to by the point ID pointID. Temperature is a 4 value 32-bit float field and Mode is a 4 character field (HDF types 5 and 4 respectively):

```
recs = [ 0, 2, 3]
dataTemperature = [ [20, 21, 22, 23], [30, 31, 32, 33], $
   [40, 41, 42, 43]]]
dataMode = ['P', 'I', 'A']
buffer = HDF_PACKDATA(dataTemperature, dataMode, $
   HDF_TYPE = [5, 4], HDF_ORDER = [4, 4])
status = EOS_PT_UPDATELEVEL( pointID, 1, "Temperature,Mode", $
   3, recs, buffer)
```

Version History

Introduced: 5.2

EOS_PT_WRITEATTR

This function writes/updates an attribute in a point. If the attribute does not exist, it is created. If it does exist, then the value(s) is (are) updated.

Syntax

Result = EOS_PT_WRITEATTR(*pointID*, *attrname*, *datbuf* [, COUNT=*value*] [, HDF_TYPE=*value*])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

attrname

Attribute name (string).

datbuf

Attribute values.

Keywords

COUNT

Number of values (long) to store in attribute.

HDF_TYPE

Number type (long) of attribute.

Examples

In this example, we write a single precision (32 bit) floating point number with the name “ScalarFloat” and the value 3.14:

```
f32 = 3.14f
status = EOS_PT_WRITEATTR(pointid, "ScalarFloat", f32)
```

We can update this value by simply calling the function again with the new value:

```
f32 = 3.14159
status = EOS_PT_WRITEATTR(pointid, "ScalarFloat", f32)
```

Version History

Introduced: 5.2

EOS_PT_WRITELEVEL

This function writes (appends) full records to a level. The data in each record must be packed. Refer to the section on Vdatas in the HDF documentation. The input data buffer must be sufficient to fill the number of records designated.

Syntax

Result = EOS_PT_WRITELEVEL(*pointID*, *level*, *nrec*, *data*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

pointID

Point id (long) returned by EOS_PT_CREATE or EOS_PT_ATTACH.

level

Level to write (0-based long).

nrec

Number of records (long) to write.

data

Values to be written to the field. Data values are not converted to the internal HDF type automatically. Use HDF_PACKDATA if conversion is necessary or the data fields specify multiple types.

Examples

In this example, we write 5 records to the first level in the point referred to by the point id, pointID1:

```
status = EOS_PT_WRITELEVEL(pointID1, 0, 5, datbuf)
```

Version History

Introduced: 5.2

EOS_QUERY

The EOS_QUERY function returns information about the makeup of an HDF-EOS file.

Syntax

Result = EOS_QUERY(*Filename*, [*Info*])

Return Value

This function returns integer value of 1 if the file is an HDF file with EOS extensions, and 0 otherwise.

Arguments

Filename

A scalar string containing the name of the file to query.

Info

Returns an anonymous structure containing information about the contents of the file. The returned structure contains the following fields:

Field	IDL Data Type	Description
GRID_NAMES	String array	Names of grids
NUM_GRIDS	Long	Number of grids in file
NUM_POINTS	Long	Number of points in file
NUM_SWATHS	Long	Number of swaths in file
POINT_NAMES	String array	Names of points
SWATH_NAMES	String array	Names of swaths

Table E-3: Fields of the Info Structure

Version History

Introduced: 5.3

EOS_SW_ATTACH

This function attaches to the swath using the swathname parameter as the identifier.

Syntax

Result = EOS_SW_ATTACH(*fid*, *swathname*)

Return Value

Returns the swath handle (swathID) if successful and FAIL (–1) otherwise.

Arguments

fid

Swath file id (long) returned by EOS_SW_OPEN.

swathname

Name of swath (string) to be attached.

Keywords

None.

Examples

In this example, we attach to the previously created swath, “ExampleSwath”, within the HDF file, SwathFile.hdf, referred to by the handle, fid:

```
swathID = EOS_SW_ATTACH(fid, "ExampleSwath")
```

The swath can then be referenced by subsequent routines using the handle, swathID.

Version History

Introduced: 5.2

See Also

EOS_SW_DETACH

EOS_SW_ATTRINFO

This function returns the number type and number of elements (count) of a swath attribute.

Syntax

Result = EOS_SW_ATTRINFO(*swathID*, *attrname*, *numbertype*, *count*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

attrname

Attribute name (string).

numbertype

A named variable that will contain the HDF data type (long) of attribute.

count

A named variable that will contain the number of total bytes (long) in attribute.

Keywords

None.

Examples

In this example, we return information about the ScalarFloat attribute:

```
status = EOS_SW_ATTRINFO(pointID, "ScalarFloat", nt, count)
```

Version History

Introduced: 5.2

EOS_SW_CLOSE

This function closes the HDF swath file.

Syntax

Result = EOS_SW_CLOSE(*fid*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

fid

Swath file id (long) returned by EOS_SW_OPEN.

Keywords

None.

Examples

```
status = EOS_SW_CLOSE(fid)
```

Version History

Introduced: 5.2

EOS_SW_COMPINFO

This function returns the compression code and compression parameters for a given field.

Syntax

Result = EOS_SW_COMPINFO(*swathID*, *fieldname*, *compcode*, *compparm*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Fieldname (string).

compcode

A named variable that will contain the HDF compression code (long).

compparm

A named variable that will contain the compression parameters (long).

Keywords

None.

Examples

To retrieve the compression information about the Opacity field defined in the EOS_SW_DEFCOMP section:

```
status = EOS_SW_COMPINFO(swathID, "Opacity", compcode, compparm)
```

Version History

Introduced: 5.2

EOS_SW_CREATE

This function creates a swath within the file. The swath is created as a Vgroup within the HDF file with the name *swathname* and class EOS_SWATH.

Syntax

Result = EOS_SW_CREATE(*fid*, *swathname*)

Return Value

Returns the swath handle (swathID) if successful and FAIL (–1) otherwise.

Arguments

fid

Swath file id (long) returned by EOS_SW_OPEN.

swathname

Name of swath (string) to be created.

Keywords

None.

Examples

In this example, we create a new swath structure, “ExampleSwath”, in the previously created file, SwathFile.hdf.

```
swathID = EOS_SW_CREATE(fid, "ExampleSwath")
```

The swath structure is referenced by subsequent routines using the handle, swathID.

Version History

Introduced: 5.2

EOS_SW_DEFBOXREGION

This function defines a longitude-latitude box region for a swath. It returns a swath region ID that is used by the EOS_SW_EXTRACTREGION function to read all the entries of a data field within the region. A cross track is within a region if its midpoint is within the longitude-latitude box (0), or either of its endpoints is within the longitude-latitude box (1), or any point of the cross track is within the longitude-latitude box (2), depending on the inclusion mode designated by the user. All elements within an included cross track are considered to be within the region even though a particular element of the cross track might be outside the region. The swath structure must have both Longitude and Latitude (or Colatitude) fields defined.

Syntax

Result = EOS_SW_DEFBOXREGION(*swathID*, *cornerlon*, *cornerlat*, *mode*)

Return Value

Returns the swath region ID if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

cornerlon

Longitude in decimal degrees (double) of box corners (double, 2 element, 1-D array).

cornerlat

Latitude in decimal degrees (double) of box corners (double, 2 element, 1-D array).

mode

Cross Track inclusion mode (long). Allowable values are:

- 0 = Midpoint
- 1 = Endpoint
- 2 = Anypoint

Keywords

None.

Examples

In this example, we define a region bounded by 3 degrees longitude, 5 degrees latitude and 7 degrees longitude, 12 degrees latitude. We will consider a cross track to be within the region if its midpoint is within the region:

```
cornerlon[0] = 3.d
cornerlat[0] = 5.d
cornerlon[1] = 7.d
cornerlat[1] = 12.d
regionID = EOS_SW_DEFBOXREGION(swathID, cornerlon, cornerlat, 0)
```

Version History

Introduced: 5.2

EOS_SW_DEFCOMP

This function sets the HDF field compression for subsequent swath field definitions. The compression does not apply to one-dimensional fields. The compression schemes currently supported are: run length encoding (1), skipping Huffman (3), deflate (gzip) (4) and no compression (0, the default). Deflate compression requires a single integer compression parameter in the range of one to nine with higher values corresponding to greater compression. Compressed fields are written using the standard EOS_SW_WRITEFIELD function, however, the entire field must be written in a single call. Any portion of a compressed field can then be accessed with the EOS_SW_READFIELD function. Compression takes precedence over merging so that multi-dimensional fields that are compressed are not merged. The user should refer to the HDF Reference Manual for a fuller explanation of the compression schemes and parameters.

Syntax

Result = EOS_SW_DEFCOMP(*swathID*, *compcode*, [, *compparm*])

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

compcode

HDF compression code (long).

compparm

Compression parameters (long array) if applicable. Allowable values are:

- 0 = None
- 1 = Run Length Encoding (RLE)
- 3 = Skipping Huffman
- 4 = Deflate (gzip)

Keywords

None.

Examples

Suppose we wish to compress the Pressure using run length encoding, the Opacity field using deflate compression, the Spectra field with skipping Huffman compression, and use no compression for the Temperature field:

```
status = EOS_SW_DEFCOMP(swathID, 1)
status = EOS_SW_DEFDATAFIELD(swathID, "Pressure", $
   "Track,Xtrack", 5)
compparm[0] = 5
status = EOS_SW_DEFCOMP(swathID, 4, compparm)
status = EOS_SW_DEFDATAFIELD(swathID, "Opacity", $
   "Track,Xtrack", 5)
status = EOS_SW_DEFCOMP(swathID, 3)
status = EOS_SW_DEFDATAFIELD(swathID, "Spectra", $
   "Bands,Track,Xtrack", 5)
status = EOS_SW_DEFCOMP(swathID, 0)
status = EOS_SW_DEFDATAFIELD(swathID, $
   "Temperature", "Track,Xtrack", 5, /MERGE)
```

Note that the MERGE keyword will be ignored in the Temperature field definition.

Version History

Introduced: 5.2

EOS_SW_DEFDATAFIELD

This function defines data fields to be stored in the swath. The dimensions are entered as a string consisting of data dimensions separated by commas. The API will attempt to merge into a single object those fields that share dimensions and in case of multidimensional fields, numbertype. If the merge keyword is not set, the API will not attempt to merge it with other fields. Because merging breaks the one-to-one correspondence between HDF-EOS fields and HDF SDS arrays, it should not be set if the user wishes to access the HDF-EOS field directly using HDF routines. To assure that the fields defined by EOS_SW_DEFDATAFIELD are properly established in the file, the swath should be detached (and then reattached) before writing to any fields.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_DEFDATAFIELD(*swathID*, *fieldname*, *dimlist*, *numbertype* [, /MERGE])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Name of field (string) to be defined.

dimlist

The list of data dimensions (string) defining the field.

numbertype

The HDF data type (long) of the data stored in the field.

Keywords

MERGE

If set, automatic merging will occur. By default, fields are not merged.

Examples

In this example, we define a three dimensional data field named Spectra with dimensions Bands, DataTrack, and DataXtrack:

```
status = EOS_SW_DEFDATAFIELD(swathID, "Spectra", $
   "Bands,DataTrack,DataXtrack", 5, /MERGE)
```

Version History

Introduced: 5.2

EOS_SW_DEFDIM

This function defines dimensions that are used by the field definition functions (described subsequently) to establish the size of the field.

Syntax

Result = EOS_SW_DEFDIM(*swathID*, *fieldname*, *dim*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long).

fieldname

Name of dimension (string) to be defined.

dim

The size (long) of the dimension.

Keywords

None.

Examples

In this example, we define a track geolocation dimension, GeoTrack, of size 2000, a cross track dimension, GeoXtrack, of size 1000 and two corresponding data dimensions with twice the resolution of the geolocation dimensions:

```
status = EOS_SW_DEFDIM(swathID, "GeoTrack", 2000)
status = EOS_SW_DEFDIM(swathID, "GeoXtrack", 1000)
status = EOS_SW_DEFDIM(swathID, "DataTrack", 4000)
status = EOS_SW_DEFDIM(swathID, "DataXtrack", 2000)
status = EOS_SW_DEFDIM(swathID, "Bands", 5)
```

To specify an unlimited dimension that can be used to define an appendable array, the dimension value should be set to zero:

```
status = EOS_SW_DEFDIM(swathID, "Unlim", 0)
```

Version History

Introduced: 5.2

EOS_SW_DEFDIMMAP

This function defines monotonic mapping between the geolocation and data dimensions. Typically the geolocation and data dimensions are of different size (resolution). This function establishes the relation between the two where the offset gives the index of the data element (0-based) corresponding to the first geolocation element and the increment gives the number of data elements to skip for each geolocation element. If the geolocation dimension begins “before” the data dimension, then the offset is negative. Similarly, if the geolocation dimension has higher resolution than the data dimension, then the increment is negative. A typical reason for failure is an incorrect geolocation or data dimension name.

Syntax

Result = EOS_SW_DEFDIMMAP(*swathID*, *geodim*, *datadim*, *offset*, *increment*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

geodim

Geolocation dimension name (string).

datadim

Data dimension name (string).

offset

The offset (long) of the geolocation dimension with respect to the data dimension.

increment

The increment (long) of the geolocation dimension with respect to the data dimension.

Keywords

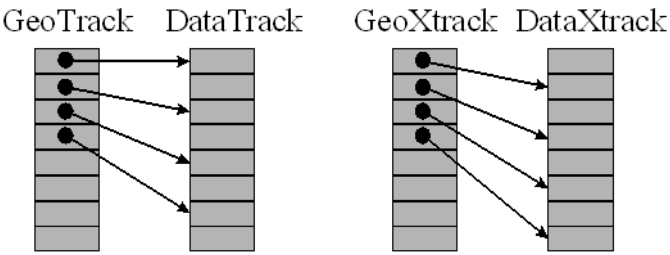
None.

Examples

In this example, we establish the following:

- The first element of the GeoTrack dimension corresponds to the first element of the DataTrack dimension and the data dimension has twice the resolution of the geolocation dimension.
- The first element of the GeoXtrack dimension corresponds to the second element of the DataTrack dimension and the data dimension has twice the resolution of the geolocation dimension.

```
   status=EOS_SW_DEFDIMMAP(swathID, "GeoTrack",  "DataTrack", 0, 2)
status=EOS_SW_DEFDIMMAP(swathID, "GeoXtrack", "DataXtrack", 1, 2)
```



Version History

Introduced: 5.2

EOS_SW_DEFGEOFIELD

This function defines geolocation fields to be stored in the swath. The dimensions are entered as a string consisting of geolocation dimensions separated by commas. The API will attempt to merge into a single object those fields that share dimensions and in case of multidimensional fields, numbertype. If the merge keyword is not set, the API will not attempt to merge it with other fields. Fields using the unlimited dimension will not be merged. Because merging breaks the one-to-one correspondence between HDF-EOS fields and HDF SDS arrays, it should not be set if the user wishes to access the HDF field directly using HDF routines. To assure that the fields defined by EOS_SW_DEFGEOFIELD are properly established in the file, the swath should be detached (and then reattached) before writing to any fields.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_DEFGEOFIELD(*swathID*, *fieldname*, *dimlist*, *numbertype* [, /MERGE])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Name of field (string) to be defined.

dimlist

The list of geolocation dimensions (sting) defining the field.

numbertype

The HDF data type (long) of the data stored in the field.

Keywords

MERGE

If set, automatic merging will occur. By default, fields are not merged.

Examples

In this example, we define the geolocation fields, Longitude and Latitude with dimensions GeoTrack and GeoXtrack and containing 4 byte floating point numbers. We allow these fields to be merged into a single object:

```
status = EOS_SW_DEFGEOFIELD(swathID, "Longitude",$
   "GeoTrack,GeoXtrack", 5, /MERGE
status = EOS_SW_DEFGEOFIELD(swathID, "Latitude", $
   "GeoTrack,GeoXtrack", 5, /MERGE
```

Version History

Introduced: 5.2

EOS_SW_DEFIDXMAP

If there does not exist a regular (linear) mapping between a geolocation and data dimension, then the mapping must be made explicit. Each element of the index array, whose dimension is given by the geolocation size, contains the element number (0-based) of the corresponding data dimension.

Syntax

Result = EOS_SW_DEFIDXMAP(*swathID*, *geodim*, *datadim*, *index*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

geodim

Geolocation dimension name (string).

datadim

Data dimension name (string).

index

The array (long) containing the indices of the data dimension to which each geolocation element corresponds.

Keywords

None.

Examples

In this example, we consider the (simple) case of a geolocation dimension IdxGeo of size 5 and a data dimension IdxData of size 8. In this case, the 0th element of IdxGeo will correspond to the 0th element of IdxData, the 1st element of IdxGeo to the 2nd element of IdxData, etc.:

```
index = [0,2,3,6,7]
status = EOS_SW_DEFIDXMAP(swathID, "IdxGeo", "IdxData", index)
```

Version History

Introduced: 5.2

EOS_SW_DEFTIMEPERIOD

This function defines a time period for a swath. It returns a swath period ID which is used by the EOS_SW_EXTRACTPERIOD function to read all the entries of a data field within the time period. A cross track is within a time period if its midpoint is within the time period box (0), or either of its endpoints is within the time period box (1), or any point of the cross track is within the time period box (2), depending on the inclusion mode designated by the user. All elements within an included cross track are considered to be within the time period even though a particular element of the cross track might be outside the time period. The swath structure must have the Time field defined.

Syntax

Result = EOS_SW_DEFTIMEPERIOD(*swathID, starttime , stoptime, mode*)

Return Value

Returns the swath period ID if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

starttime

Start time (double) of period.

stoptime

Stop time (double) of period.

mode

Cross Track inclusion mode (long). Allowable values are:

- 0 = Midpoint
- 1 = Endpoint
- 2 = Anypoint

Keywords

None.

Examples

In this example, we define a time period with a start time of 35232487.2 and a stop time of 36609898.1.We will consider a cross track to be within the time period if either one of the time values at the endpoints of a cross track are within the time period:

```
starttime = 35232487.2d
stoptime = 36609898.1d
periodID = EOS_SW_DEFTIMEPERIOD(swathID, starttime, stoptime, 1)
```

Version History

Introduced: 5.2

EOS_SW_DEFVRTREGION

Whereas the EOS_SW_DEFBOXREGION and EOS_SW_DEFTIMEPERIOD functions perform subsetting along the “Track” dimension, this function allows the user to subset along any dimension. The region is specified by a set of minimum and maximum values and can represent either a dimension index (case 1) or field value range (case 2). In the second case, the field must be one-dimensional and the values must be monotonic (strictly increasing or decreasing) in order that the resulting dimension index range be contiguous. (For the current version of this function, the second option is restricted to fields with one of the following HDF data types: 22, 24, 5, 6.)

This function may be called after EOS_SW_DEFBOXREGION or EOS_SW_DEFTIMEPERIOD to provide both geographic or time and “vertical” subsetting. In this case the user provides the id from the previous subset call. (This same id is then returned by the function.) This function may also be called “stand-alone” by setting the input id to (–1).

This function may be called up to eight times with the same region ID. It this way a region can be subsetted along a number of dimensions.

The EOS_SW_REGIONINFO and EOS_SW_EXTRACTREGION functions work as before, however, because there is no mapping performed between geolocation dimensions and data dimensions the field to be subsetted, (the field specified in the call to EOS_SW_REGIONINFO and EOS_SW_EXTRACTREGION) must contain the dimension used explicitly in the call to EOS_SW_DEFVRTREGION (case 1) or the dimension of the one-dimensional field (case 2).

Syntax

Result = EOS_SW_DEFVRTREGION(*swathID*, *regionID*, *vertObj*, *range*)

Return Value

Returns the swath region ID if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

regionID

Region or period id (long) from previous subset call, or –1 to create a new region within the entire dataset.

vertObj

Dimension or field (string) to subset by.

range

Minimum and maximum range (double) for subset.

Keywords

None.

Examples

Suppose we have a field called Pressure of dimension Height whose values increase from 100 to1000, and we desire all the elements with values between 500 and 800:

```
range[0] = 500.d
range[1] = 800.d
regionID = EOS_SW_DEFVRTREGION(swathID, -1, "Pressure", range)
```

The function determines the elements in the Height dimension that correspond to the values of the Pressure field between 500 and 800.

If we wish to specify the subset as elements 2 through 5 (0 - based) of the Height dimension, the call would be:

```
range[0] = 2.d
range[1] = 5.d
regionID = EOS_SW_DEFVRTREGION(swathID, -1, "DIM:Height", range)
```

The “DIM:” prefix tells the routine that the range corresponds to elements of a dimension rather than values of a field. In this example, any field to be subsetted must contain the Height dimension.

If a previous subset region or period was defined with an id of subsetID that we wish to refine further with the vertical subsetting defined above, we make the call:

```
regionID = EOS_SW_DEFVRTREGION(swathID, subsetID, $
   "Pressure", range)
```

The return value, regionID, is set equal to subsetID. That is, the subset region is modified rather than a new one created. We can further refine the subset region with another call to the function:

```
freq[0] = 1540.3d
freq[1] = 1652.8d
regionID = EOS_SW_DEFVRTREGION(swathID, regionID, $
   "FreqRange", freq)
```

Version History

Introduced: 5.2

EOS_SW_DETACH

This function detaches from the swath interface. It should be run before exiting from the swath file for every swath opened by EOS_SW_CREATE or EOS_SW_ATTACH.

Syntax

Result = EOS_SW_DETACH(*swathID*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

Keywords

None.

Examples

```
status = EOS_SW_DETACH(swathID)
```

Version History

Introduced: 5.2

EOS_SW_DIMINFO

This function retrieves the size of the specified dimension.

Syntax

Result = EOS_SW_DIMINFO(*swathID*, *dimname*)

Return Value

Size of dimension or FAIL (–1) if the swath ID or dimension name are invalid.

Arguments

swathID

Swath id (long).

dimname

Dimension name (string).

Keywords

None.

Examples

In this example, we retrieve information about the dimension, “GeoTrack”:

```
dimsize = EOS_SW_DIMINFO(swathID, "GeoTrack")
```

Version History

Introduced: 5.2

EOS_SW_DUPREGION

This function copies the information stored in a current region or period to a new region or period and generates a new id. It is useful when the user wishes to further subset a region (period) in multiple ways.

Syntax

Result = EOS_SW_DUPREGION(*regionID*)

Return Value

Returns new region or period ID or FAIL (–1) on error.

Arguments

regionID

Region or period id (long) returned by EOS_SW_DEFBOXREGION, EOS_SW_DEFTIMEPERIOD, or EOS_SW_DEFVRTREGION.

Keywords

None.

Examples

In this example, we first subset a swath with EOS_SW_DEFBOXREGION, duplicate the region creating a new region ID, regionID2, and then perform two different vertical subsets of these (identical) geographic subset regions:

```
regionID = EOS_SW_DEFBOXREGION(swathID, cornerlon, $
   cornerlat, 0)
regionID2 = EOS_SW_DUPREGION(regionID)
regionID = EOS_SW_DEFVRTREGION(swathID, regionID, $
   "Pressure", rangePres)
regionID2 = EOS_SW_DEFVRTREGION(swathID, regionID2, $
   "Temperature", rangeTemp)
```

Version History

Introduced: 5.2

EOS_SW_EXTRACTPERIOD

This function reads data into the data buffer from the subsetted time period. Only complete crosstracks are extracted. If the external_mode flag is set to (1) then the geolocation fields and the data field can be in different swaths. If set to (0), then these fields must be in the same swath structure.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_EXTRACTPERIOD(*swathID*, *periodID*, *fieldname*, *external_mode*, *buffer*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long).

periodID

Period id (long) returned by EOS_SW_DEFTIMEPERIOD.

fieldname

Field to subset (string).

external_mode

External geolocation mode (long).

buffer

A named variable that will contain the period data.

Keywords

None.

Examples

In this example, we read data within the subsetted time period defined in EOS_SW_DEFTIMEPERIOD from the Spectra field. Both the geolocation fields and the Spectra data field are in the same swath.

```
status = EOS_SW_EXTRACTPERIOD(EOS_SW_id, periodID, 0,"Spectra", $
  datbuf)
```

Version History

Introduced: 5.2

EOS_SW_EXTRACTREGION

This function reads data into the data buffer from the subsetted region. Only complete crosstracks are extracted. If the external_mode flag is set to (1) then the geolocation fields and the data field can be in different swaths. If set to (0), then these fields must be in the same swath structure.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_EXTRACTREGION(*swathID*, *regionID*, *fieldname*, *external_mode*, *buffer*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

regionID

Region id (long) returned by EOS_SW_DEFBOXREGION.

fieldname

Field to subset (string).

external_mode

External geolocation mode (long).

buffer

A named variable that will contain the data buffer.

Keywords

None.

Examples

In this example, we read data within the subsetted region defined in EOS_SW_DEFBOXREGION from the Spectra field. Both the geolocation fields and the Spectra data field are in the same swath.

```
status = EOS_SW_EXTRACTREGION(EOS_SW_id, regionID, 0, "Spectra",$
   datbuf)
```

Version History

Introduced: 5.2

EOS_SW_FIELDINFO

This function retrieves information on a specific data field.

Syntax

Result = EOS_SW_FIELDINFO(*swathID*, *fieldname*, *rank*, *dims*, *numbertype*, *dimlist*)

Return Value

Returns SUCCEED(0) if successful and FAIL(–1) if the specified field does not exist.

Arguments

swathID

Swath id (long).

fieldname

Fieldname (string).

rank

A named variable that will contain the rank of field (long).

dims

A named variable that will contain the array of length “rank” (long) containing the dimension sizes of the field. If one of the dimensions in the field is appendable, then the current value for that dimension will be returned in the dims array.

numbertype

A named variable that will contain HDF data type of the field.

dimlist

A named variable that will contain the list of dimensions (string) in field.

Keywords

None.

Examples

In this example, we retrieve information about the Spectra data fields:

```
status = EOS_SW_FIELDINFO(swathID, "Spectra", rank, dims, $
   numbertype, dimlist)
```

Version History

Introduced: 5.2

EOS_SW_GETFILLVALUE

This function retrieves the fill value for the specified field.

Syntax

Result = EOS_SW_GETFILLVALUE(*swathID*, *fieldname*, *fillvalue*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Fieldname (string).

fillvalue

A named variable that will contain the fill value.

Keywords

None.

Examples

In this example, we get the fill value for the “Temperature” field:

```
status = EOS_SW_GETFILLVALUE(swathID, "Temperature", tempfill)
```

Version History

Introduced: 5.2

EOS_SW_IDXMAPINFO

This function retrieves the size of the indexed array and the array of indexed elements of the specified geolocation mapping.

Syntax

Result = EOS_SW_IDXMAPINFO(*swathID*, *geodim*, *datadim*, *index*)

Return Value

Returns size of indexed array if successful and FAIL (–1) if the specified mapping does not exist.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

geodim

Geolocation dimension name (string).

datadim

Data dimension name (string).

index

A named variable that will contain an array (long) of indices of the data dimension to which each geolocation element corresponds.

Keywords

None.

Examples

In this example, we retrieve information about the indexed mapping between the “IdxGeo” and “IdxData” dimensions:

```
idxsz = EOS_SW_IDXMAPINFO(swathID, "IdxGeo", "IdxData", index)
```

Version History

Introduced: 5.2

EOS_SW_INQATTRS

This function retrieves information about attributes defined in swath. The attribute list is returned as a string with each attribute name separated by commas.

Note

See STRSPLIT to separate the attribute list.

Syntax

Result = EOS_SW_INQATTRS(*swathID*, *attrlist* [, LENGTH=*variable*])

Return Value

Number of attributes found or (–1) if failure.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

attrlist

A named variable that will contain the attribute list (string) with entries separated by commas.

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the attribute list as a long integer.

Examples

```
nattr = EOS_SW_INQATTRS(swathID, attrlist)
```

Version History

Introduced: 5.2

EOS_SW_INQDATAFIELDS

This function retrieves information about all of the data fields defined in swath. The field list is returned as a string with each data field separated by commas. The rank and numbertype arrays will have an entry for each field.

Note

See STRSPLIT to separate the field list.

Syntax

Result = EOS_SW_INQDATAFIELDS(*swathID*, *fieldlist*, *rank*, *numbertype*)

Return Value

Returns number of data fields found. If –1, could signify improper swath id.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldlist

A named variable that will contain the listing of data fields (string) with entries separated by commas.

rank

A named variable that will contain an array (long) of rank of each data field.

numbertype

A named variable that will contain an array (long) of numbertype of each data field.

Keywords

None.

Examples

```
nflds = EOS_SW_INQDATAFIELDS(swathID, fieldlist, rank, numbertype)
```

Version History

Introduced: 5.2

EOS_SW_INQDIMS

This function retrieves information about all of the dimensions defined in swath. The dimension list is returned as a string with each dimension name separated by commas.

Note

See STRSPLIT to separate the dimension list.

Syntax

Result = EOS_SW_INQDIMS(*swathID*, *dimname*, *dim*)

Return Value

Returns number of dimension entries found. If –1, could signify an improper swath id.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

dimname

A named variable that will contain the dimension list (string) with entries separated by commas.

dims

A named variable that will contain an array (long) of size of each dimension.

Keywords

None.

Examples

```
ndims = EOS_SW_INQDIMS(swathID, dimname, dims)
```

Version History

Introduced: 5.2

EOS_SW_INQGEOFIELDS

This function retrieves information about all of the geolocation fields defined in swath. The field list is returned as a string with each geolocation field separated by commas. The rank and numbertype arrays will have an entry for each field.

Note

See STRSPLIT to separate the field list.

Syntax

Result = EOS_SW_INQGEOFIELDS(*swathID*, *fieldlist*, *rank*, *numbertype*)

Return Value

Returns number of geolocation fields found. If –1, could signify an improper swath id.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldlist

A named variable that will contain the listing of geolocation fields (string) with entries separated by commas.

rank

A named variable that will contain an array (long) of the rank of each geolocation field.

numbertype

A named variable that will contain an array (long) of the numbertype of each geolocation field.

Keywords

None.

Examples

```
nflds = EOS_SW_INQGEOFIELDS(swathID, fieldlist, rank, numbertype)
```

Version History

Introduced: 5.2

EOS_SW_INQIDXMAPS

This function retrieves information about all of the indexed geolocation/data mappings defined in swath. The dimension mapping list is returned as a string with each mapping separated by commas. The two dimensions in each mapping are separated by a slash (/).

Note

See STRSPLIT to separate the mapping list.

Syntax

Result = EOS_SW_INQIDXMAPS(*swathID*, *idxmap*, *idxsizes*)

Return Value

Number of indexed mapping relations found. If –1, could signify an improper swath id.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

idxmap

A named variable that will contain the indexed Dimension mapping list (string) with entries separated by commas.

idxsizes

A named variable that will contain an array (long) of the sizes of the corresponding index arrays.

Keywords

None.

Examples

```
nidxmaps = EOS_SW_INQIDXMAPS(swathID, idxmap, idxsizes)
```

Version History

Introduced: 5.2

EOS_SW_INQMAPS

This function retrieves information about all of the (non-indexed) geolocation relations defined in swath. The dimension mapping list is returned as a string with each mapping separated by commas. The two dimensions in each mapping are separated by a slash (/).

Note

See STRSPLIT to separate the mapping list.

Syntax

Result = EOS_SW_INQMAPS(*swathID*, *dimmap*, *offset*, *increment*)

Return Value

Number of geolocation relation entries found. If –1, could signify an improper swath id.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

dimmap

A named variable that will contain the dimension mapping list (string) with entries separated by commas.

offset

A named variable that will contain an array (long) of the offset of each geolocation relation.

increment

A named variable that contain an array (long) of the increment of each geolocation relation.

Keywords

None.

Examples

```
nmaps = EOS_SW_INQMAPS(swathID, dimmap, offset, increment)
```

Version History

Introduced: 5.2

EOS_SW_INQSWATH

This function retrieves number and names of swaths defined in the HDF-EOS file. The swath list is returned as a string with each swath name separated by commas.

Note

See STRSPLIT to separate the swath list.

Syntax

Result = EOS_SW_INQSWATH(*filename*, *swathlist* [, LENGTH =*value*])

Return Value

Number of swaths found or (–1) if failure.

Arguments

filename

HDF-EOS filename (string).

swathlist

Swath list (string) with entries separated by commas.

Keywords

LENGTH

String length (long) of swath list.

Examples

In this example, we retrieve information about the swaths defined in an HDF-EOS file, HDFEOS.hdf:

```
nswath = EOS_SW_INQSWATH("HDFEOS.hdf", swathlist)
```

Version History

Introduced: 5.2

EOS_SW_MAPINFO

This function retrieves the offset and increment of the specified geolocation mapping.

Syntax

Result = EOS_SW_MAPINFO(*swathID*, *geodim*, *datadim*, *offset*, *increment*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) if the specified mapping does not exist.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

geodim

Geolocation dimension name (string).

datadim

Data dimension name (string).

offset

A named variable that will contain the mapping offset (long).

increment

A named variable that will contain the mapping increment (long).

Keywords

None.

Examples

In this example, we retrieve information about the mapping between the GeoTrack and DataTrack dimensions:

```
status = EOS_SW_MAPINFO(swathID, "GeoTrack", "DataTrack", $
   offset, increment)
```

Version History

Introduced: 5.2

EOS_SW_NENTRIES

This function returns number of entries and descriptive string buffer size for a specified entity. This function can be called before an inquiry routine in order to determine the sizes of the output arrays and descriptive strings.

Syntax

Result = EOS_SW_NENTRIES(*swathID*, *entrycode* [, LENGTH=*variable*])

Return Value

Number of entries or FAIL (–1) in the case of an improper swath id or entry code.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_EOS_SW_ATTACH.

entrycode

Entrycode (long). Allowable values are:

- 0 = Dimensions
- 1 = Dimension Mappings
- 2 = Indexed Dimension Mappings
- 3 = Geolocation Fields
- 4 = Data Fields

Keywords

LENGTH

Set this keyword to a named variable that will contain the length of the string that would be returned by the corresponding inquiry routine, as a long integer.

Examples

In this example, we determine the number of dimension mapping entries.

```
nmaps = EOS_SW_NENTRIES(swathID, 2)
```

Version History

Introduced: 5.2

EOS_SW_OPEN

This function creates a new file or opens an existing file.

Syntax

Result = EOS_SW_OPEN(*filename* [, /CREATE] [, /RDWR | , /READ])

Return Value

Returns the swath file id handle (fid) if successful and FAIL (–1) otherwise.

Arguments

filename

Complete path and filename for the file to be opened (string).

Keywords

CREATE

If file exists, delete it, then open a new file for read/write.

RDWR

Open for read/write, If file does not exist, create it.

READ

Open for read only. If file does not exist, error. This is the default.

Examples

In this example, we create a new swath file named, SwathFile.hdf. It returns the file handle, fid:

```
fid = EOS_SW_OPEN("SwathFile.hdf", /CREATE)
```

Version History

Introduced: 5.2

EOS_SW_PERIODINFO

This function returns information about a subsetted time period for a particular field. Because of differences in number type and geolocation mapping, a given time period will give different values for the dimensions and size for various fields.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_PERIODINFO(*swathID*, *periodID*, *fieldname*, *ntype*, *rank*, *dims*, *size*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

periodID

Period id (long) returned by EOS_SW_DEFTIMEPERIOD.

fieldname

Field to subset (string).

ntype

A named variable that will contain the number type of field (long).

rank

A named variable that will contain the rank of field (long).

dims

A named variable that will contain the dimensions of subset period (long).

size

A named variable that will contain the size in bytes of subset period (long).

Keywords

None.

Examples

In this example, we retrieve information about the time period defined in EOS_SW_DEFTIMEPERIOD for the Spectra field:

```
; Get size in bytes of time period for "Spectra" field
status = EOS_SW_PERIODINFO(EOS_SW_id, periodID, $
   "Spectra", ntype, rank, dims, size)
```

Version History

Introduced: 5.2

EOS_SW_QUERY

The EOS_SW_QUERY function returns information about a specified swath.

Syntax

Result=EOS_SW_QUERY(*Filename*, *SwathName*, [*Info*])

Return Value

This function returns an integer value of 1 if the file is an HDF file with EOS SWATH extensions, and 0 otherwise.

Arguments

Filename

A string containing the name of the file to be queried.

SwathName

A string containing the name of the swath to be queried.

Info

Returns an anonymous structure containing information about the specified swath. The returned structure contains the following fields:

Field	IDL data type	Description
ATTRIBUTES	String array	Array of attribute names
DIMENSION_NAMES	String array	Names of dimensions
DIMENSION_SIZES	Long array	Sizes of dimensions
FIELD_NAMES	String array	Names of fields
FIELD_RANKS	Long array	Ranks (dimensions) of fields
FIELD_TYPES	Long array	IDL types of fields

Table E-4: Fields of the Info Structure

Field	IDL data type	Description
GEO_FIELD_NAMES	String array	Names of geolocation fields
GEO_FIELD_RANKS	Long array	Ranks (dimensions) of geolocation fields
GEO_FIELD_TYPES	Long array	IDL types of geolocation fields
IDX_MAP_NAMES	String array	Names of index maps
IDX_MAP_SIZES	Long array	Sizes of index map arrays
NUM_ATTRIBUTES	Long	Number of attributes
NUM_DIMS	Long	Number of dimensions
NUM_FIELDS	Long	Number of fields
NUM_GEO_FIELDS	Long	Number of geolocation fields
NUM_IDX_MAPS	Long	Number of indexed dimension mapping entries
NUM_MAPS	Long	Number of mapping entries
MAP_INCREMENTS	Long array	Increment of each geolocation relation
MAP_NAMES	String array	Names of maps
MAP_OFFSETS	Long array	Offset of each geolocation relation

Table E-4: Fields of the Info Structure (Continued)

Keywords

None.

Version History

Introduced: 5.3

EOS_SW_READATTR

This function reads attributes from a swath field.

Syntax

Result = EOS_SW_READATTR(*swathID*, *attrname*, *datbuf*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

attrname

Attribute name (string).

datbuf

A named variable that will contain the attribute values.

Keywords

None.

Examples

In this example, we read a single precision (32-bit) floating-point attribute with the name “ScalarFloat”:

```
status = EOS_SW_READATTR(swathID, "ScalarFloat", f32)
```

Version History

Introduced: 5.2

EOS_SW_READFIELD

This function reads data from a swath field. The values within start, stride, and edge arrays refer to the swath field (input) dimensions. The default values for start and stride are 0 and 1 respectively if these keywords are not set. The default value for edge is (dim – start) / stride where dim refers to the IDL variable dimension.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_READFIELD(*swathID*, *fieldname*, *buffer* [, EDGE=*array*] [, START=*array*] [, STRIDE=*array*])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Name of field to read (string).

buffer

A named variable that will contain the data read from the field.

Keywords

EDGE

Array (long) specifying the number of values to read along each dimension.

START

Array (long) specifying the starting location within each dimension.

STRIDE

Array (long) specifying the number of values to skip along each dimension.

Examples

In this example, we read data from the 10th track (0-based) of the Longitude field:

```
start=[10,1]
edge=[1,1000]
status = EOS_SW_READFIELD(swathID, "Longitude", track, $
   START = start, EDGE = edge)
```

Version History

Introduced: 5.2

EOS_SW_REGIONINFO

This function returns information about a subsetted region for a particular field. Because of differences in number type and geolocation mapping, a given region will give different values for the dimensions and size for various fields.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_REGIONINFO(*swathID*, *regionID*, *fieldname*, *ntype*, *rank*, *dims*, *size*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

regionID

Region id (long) returned by EOS_SW_DEFBOXREGION.

fieldname

Field to subset (string).

ntype

A named variable that will contain the number type of field (long).

rank

A named variable that will contain the rank of field (long).

dims

A named variable that will contain the dimensions of subset region (long).

size

A named variable that will contain the size in bytes of subset region (long).

Keywords

None.

Examples

In this example, we retrieve information about the region defined in EOS_SW_DEFBOXREGION for the Spectra field:

```
status = EOS_SW_REGIONINFO(EOS_SW_id, regionID, "Spectra", $
   ntype, rank, dims, size)
```

Version History

Introduced: 5.2

EOS_SW_SETFILLVALUE

This function sets the fill value for the specified field. The fill value is placed in all elements of the field that have not been explicitly defined.

Syntax

Result = EOS_SW_SETFILLVALUE(*swathID*, *fieldname*, *fillvalue*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW__ATTACH.

fieldname

Fieldname (string).

fillvalue

The fill value to be used.

Keywords

None.

Examples

In this example, we set a fill value for the “Temperature” field:

```
tempfill = -999.0
status = EOS_SW_SETFILLVALUE(swathID, "Temperature", tempfill)
```

Version History

Introduced: 5.2

EOS_SW_WRITEATTR

This function writes/updates attributes in a swath. If the attribute does not exist, it is created. If it does exist, then the value is updated.

Syntax

Result = EOS_SW_WRITEATTR(*swathID*, *attrname*, *datbuf* [, COUNT=*value*] [, HDF_TYPE=*value*])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

attrname

Attribute name (string).

datbuf

Attribute values (long). If HDF_TYPE is specified, the attribute values are first converted to the type specified by HDF_TYPE before being stored.

Keywords

COUNT

Number of values to store in attribute (long).

HDF_TYPE

HDF data type of the attribute.

Examples

In this example, we write a single precision (32 bit) floating point number with the name “ScalarFloat” and the value 3.14:

```
f32 = 3.14
status = EOS_SW_WRITEATTR(swathid, "ScalarFloat", f32)
```

We can update this value by simply calling the function again with the new value:

```
f32 = 3.14159
status = EOS_SW_WRITEATTR(swathid, "ScalarFloat", f32)
```

Version History

Introduced: 5.2

EOS_SW_WRITEDATAMETA

This function writes field metadata for an existing data field. This is useful when the data field was defined without using the swath API. Note that any entries in the dimension list must be defined through the EOS_SW_DEFDIM function before this function is called.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_WRITEDATAMETA(*swathID*, *fieldname*, *dimlist*, *numbertype*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Name of field (string).

dimlist

The list of data dimensions defining the field (string).

numbertype

The number type of the data stored in the field (long).

Keywords

None.

Examples

In this example, we write the metadata for the “Band_1” data field used in the swath:

```
status = EOS_SW_WRITEDATAMETA(swathID, "Band_1", $
   "GeoTrack,GeoXtrack",5)
```

Version History

Introduced: 5.2

EOS_SW_WRITEFIELD

This function writes data to a swath field. The values within start, stride, and edge arrays refer to the swath field (output) dimensions. The default values for start and stride are 0 and 1 respectively and are used if keywords are not set. The default value for edge is (dim – start) / stride where dim refers to the size of the dimension. Note that the data buffer for a compressed field must be the size of the entire field as incremental writes are not supported by the underlying HDF routines.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_WRITEFIELD(*swathID*, *fieldname*, *data* [, EDGE=*array*] [, START=*array*] [, STRIDE=*array*])

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Name of field to write (string).

data

Values to be written to the field.

Keywords

EDGE

Array (long) specifying the number of values to write along each dimension.

START

Array (long) specifying the starting location within each dimension (0-based).

STRIDE

Array (long) specifying the number of values to skip along each dimension.

Examples

In this example, we write data to the Longitude field:

```
; Define elements of longitude array:
longitude = indgen(2000, 1000)
status = EOS_SW_WRITEFIELD(swathID,"Longitude", longitude)
; We now update Track 10 (0 - based) in this field:
newtrack = intarr (1000)
start=[10,0]
edge =[1,1000]
; Define elements of newtrack array:
status = EOS_SW_WRITEFIELD(swathID, "Longitude",newtrack, $
   START = start, EDGE = edge)
```

Version History

Introduced: 5.2

EOS_SW_WRITEGEOMETA

This function writes field metadata for an existing geolocation field. This is useful when the data field was defined without using the swath API. Note that any entries in the dimension list must be defined through the EOS_SW_DEFDIM function before this function is called.

Note

Array ordering of variables used or returned by this routine changed in IDL 5.5. Programs written for versions of this routine prior to IDL 5.5 may need to be modified to work correctly with the current version. See "Note on Array Ordering" on page 3489 for details.

Syntax

Result = EOS_SW_WRITEGEOMETA(*swathID*, *fieldname*, *dimlist*, *numbertype*)

Return Value

Returns SUCCEED (0) if successful and FAIL (–1) otherwise.

Arguments

swathID

Swath id (long) returned by EOS_SW_CREATE or EOS_SW_ATTACH.

fieldname

Name of field (string).

dimlist

The list of geolocation dimensions (string) defining the field.

numbertype

The number type of the data (long) stored in the field.

Keywords

None.

Examples

In this example, we write the metadata for the “Latitude” geolocation field used in the swath:

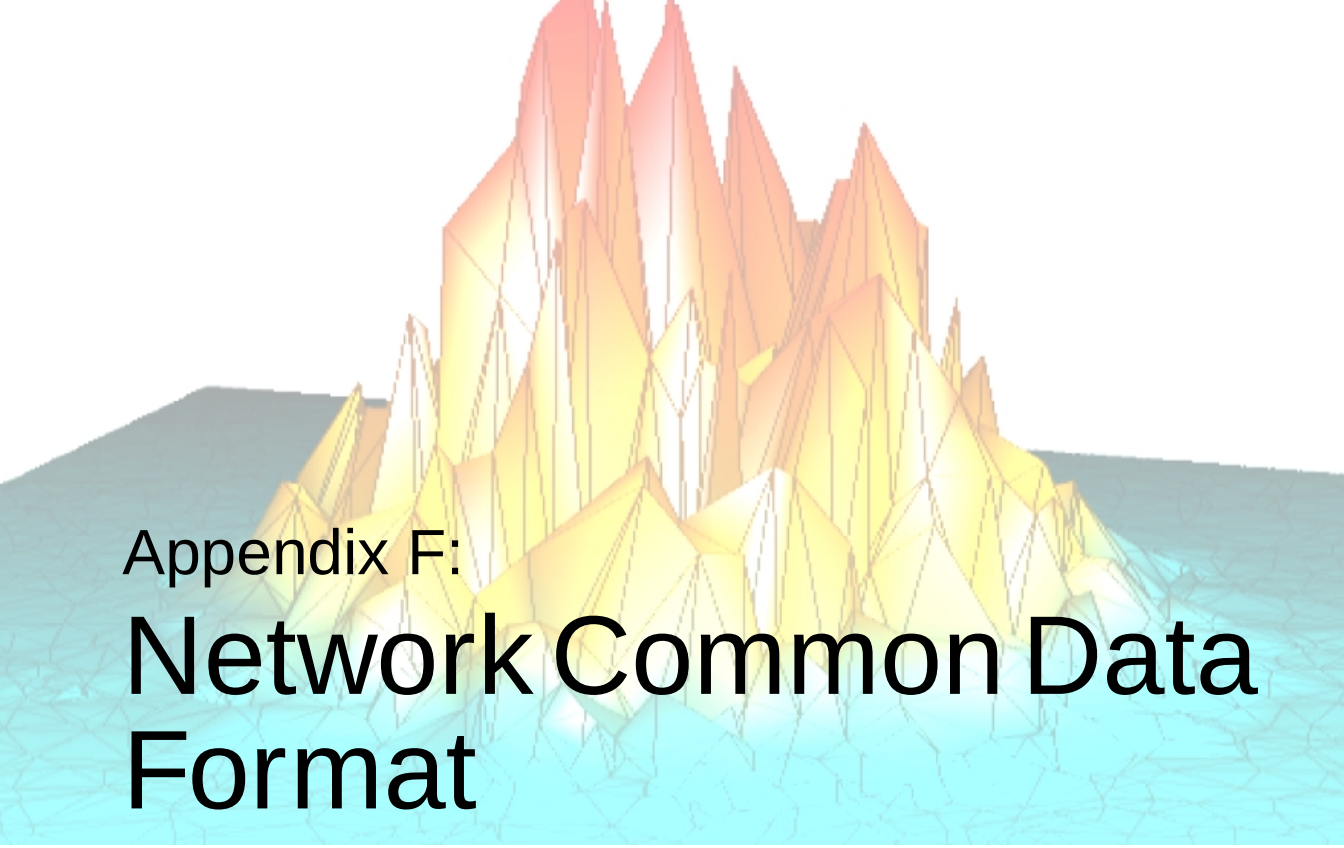
```
status = EOS_SW_WRITEGEOMETA(swathID, $
   "Latitude", "GeoTrack,GeoXtrack", 5)
```

Version History

Introduced: 5.2

Keywords

None.



Appendix F: Network Common Data Format

The following topics are covered in this appendix:

Overview 3710
NetCDF Data Modes 3711
Attributes, Dimensions, and Variables . . 3712
Creating NetCDF Files 3713
Type Conversion 3716
Specifying Attributes and Variables 3716
String Data in NetCDF Files 3717
Alphabetical Listing of NCDF Routines 3718

Overview

The network Common Data Format (netCDF) is a self-describing scientific data access interface and library developed at the Unidata Program Center in Boulder, Colorado. The netCDF interface and library use XDR (eXternal Data Representation) to make the data format machine-independent. This version of IDL supports netCDF 2.4. IDL's NetCDF routines all begin with the prefix "NCDF_".

More information about netCDF can be found on Unidata's netCDF World Wide Web home page which can be found at:

```
http://www.unidata.ucar.edu/packages/netcdf/
```

Further information and the original netCDF documentation can be obtained from Unidata at the following addresses:

UCAR Unidata Program Center
P.O. Box 3000
Boulder, Colorado, USA 80307
(303) 497-8644
e-mail: support@unidata.ucar.edu

NetCDF Data Modes

There are two modes associated with accessing a netCDF file: *define* mode and *data* mode. In define mode, dimensions, variables, and new attributes can be created but variable data cannot be read or written. In data mode, data can be read or written and attributes can be changed, but new dimensions, variables, and attributes cannot be created.

IDL's NCDF_CONTROL routine can be used control the mode of a netCDF file. The only time it is not necessary to set the mode with NCDF_CONTROL is when using the NCDF_CREATE procedure to create a new file. NCDF_CREATE places the new netCDF file into define mode automatically.

Attributes, Dimensions, and Variables

The three basic components of a netCDF file are described below.

Attributes

Attributes can contain auxiliary information about an entire netCDF file (*global* attributes) or about a single netCDF variable. Every attribute has a name, data type, and length associated with it. It is common to repeat attribute names for each variable. For example, every variable in a netCDF file might have an attribute named “Units”. Note however, that variables cannot have multiple attributes with the same names.

Dimensions

Dimensions are named integers that are used to specify the size (or *dimensionality*) of one or more variables. Each dimension must have a unique name, but a variable and dimension can share a name. Each netCDF file is allowed to have one boundless (or *unlimited*) dimension. Most often the unlimited dimension is used as a temporal variable, allowing data to be appended to an existing netCDF file. An example of this use is shown later.

Variables

Variables are multidimensional arrays of values of the same data type. Each variable has a size, type, and name associated with it. Variables can also have *attributes* that describe them.

Creating NetCDF Files

The following IDL commands should be used to create a new netCDF file:

- NCDF_CREATE: Call this procedure to begin creating a new file. The new file is put into *define* mode.
- NCDF_DIMDEF: Create dimensions for the file.
- NCDF_VARDEF: Define the variables to be used in the file.
- NCDF_ATTPUT: Optionally, use attributes to describe the data.
- NCDF_CONTROL, /ENDEF: Call NCDF_CONTROL and set the ENDEF keyword to leave *define* mode and enter *data* mode.
- NCDF_VARPUT: Write the appropriate data to the netCDF file.
- NCDF_CLOSE: Close the file.

Reading NetCDF Files

The following commands should be used to read data from a netCDF file:

- NCDF_OPEN: Open an existing netCDF file.
- NCDF_INQUIRE: Call this function to find the format of the netCDF file.
- NCDF_DIMINQ: Retrieve the names and sizes of dimensions in the file.
- NCDF_VARINQ: Retrieve the names, types, and sizes of variables in the file.
- NCDF_ATTNAME: Optionally, retrieve attribute names.
- NCDF_ATTINQ: Optionally, retrieve the types and lengths of attributes.
- NCDF_ATTGET: Optionally, retrieve the attributes.
- NCDF_VARGET: Read the data from the variables.
- NCDF_CLOSE: Close the file.

If the structure of the netCDF file is already known, the inquiry routines do not need to be called—only NCDF_OPEN, NCDF_ATTGET, NCDF_VARGET, and NCDF_CLOSE would be needed.

NetCDF Examples

Two example files that demonstrate the use of the netCDF routines can be found in the `examples/data_access/sdf` subdirectory of the IDL distribution. The file `ncdf_cat.pro` prints a summary of basic information about a netCDF file. The file `ncdf_rdwr.pro` creates a new netCDF file and then reads the information back from that file.

A Complete Example with Unlimited Dimensions

The following example shows how to create a netCDF file, populate it with data, read data from the file, and make a simple plot from the data.The resulting graphic is shown below.

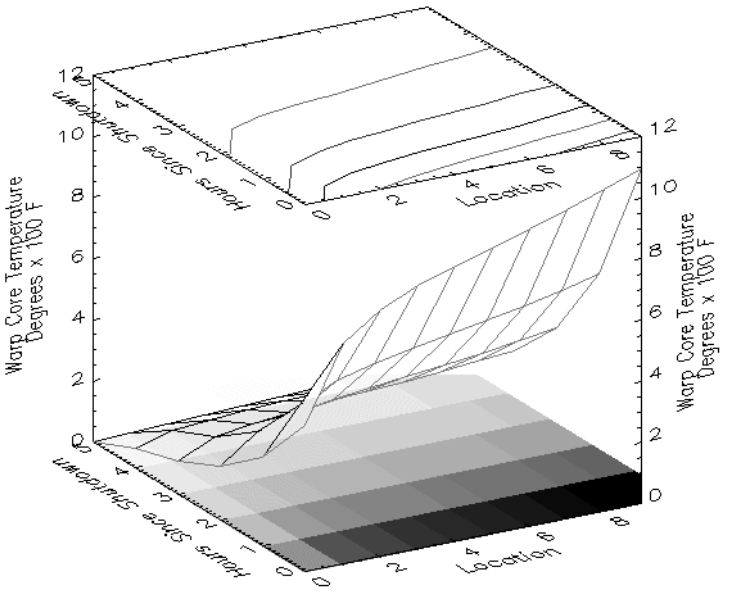


Figure F-1: SHOW3 result of unlimited dimensions example

```
; Create a new NetCDF file with the filename inquire.nc:
id = NCDF_CREATE('inquire.nc', /CLOBBER)
; Fill the file with default values:
NCDF_CONTROL, id, /FILL
; We'll create some time-dependent data, so here is an
; array of hours from 0 to 5:
hours = INDGEN(5)
; Create a 5 by 10 array to hold floating-point data:
data = FLTARR(5,10)
; Generate some values.
FOR i=0,9 DO $
   data(*,i) = (i+0.5) * EXP(-hours/2.) / SIN((i+1)/30.*!PI)
xid = NCDF_DIMDEF(id, 'x', 10)    ; Make dimensions.
zid = NCDF_DIMDEF(id, 'z', /UNLIMITED)
; Define variables:
hid = NCDF_VARDEF(id, 'Hour', [zid], /SHORT)
vid = NCDF_VARDEF(id, 'Temperature', [xid,zid], /FLOAT)
NCDF_ATTPUT, id, vid, 'units', 'Degrees x 100 F'
NCDF_ATTPUT, id, vid, 'long_name', 'Warp Core Temperature'
NCDF_ATTPUT, id, hid, 'long_name', 'Hours Since Shutdown'
NCDF_ATTPUT, id, /GLOBAL, 'Title', 'Really important data'
; Put file in data mode:
NCDF_CONTROL, id, /ENDEF
; Input data:
NCDF_VARPUT, id, hid, hours
FOR i=0,4 DO NCDF_VARPUT, id, vid, $
; Oops! We forgot the 6th hour! This is not a problem, however,
; as you can dynamically expand a netCDF file if the unlimited
; dimension is used.
   REFORM(data(i,*)), OFFSET=[0,i]
; Add the hour and data:
NCDF_VARPUT, id, hid, 6, OFFSET=[5]
; Add the temperature:
NCDF_VARPUT, id, vid, FINDGEN(10)*EXP(-6./2), OFFSET=[0,5]
; Read the data back out:
NCDF_VARGET, id, vid, output_data
NCDF_ATTGET, id, vid, 'long_name', ztitle
NCDF_ATTGET, id, hid, 'long_name', ytitle
NCDF_ATTGET, id, vid, 'units', subtitle
!P.CHARSIZE = 2.5
!X.TITLE = 'Location'
!Y.TITLE = STRING(ytitle) ; Convert from bytes to strings.
!Z.TITLE = STRING(ztitle) + '!C' + STRING(subtitle)
NCDF_CLOSE, id ; Close the NetCDF file.
SHOW3, output_data ; Display the data.
```

Type Conversion

Values are converted to the appropriate type before being written to a netCDF file. For example, in the commands below, IDL converts the string “12” to a floating-point 12.0 before writing it:

```
varid=NCDF_VARDEF(fileid, 'VarName', [d0,d1,d2+d3], /FLOAT)
NCDF_VARPUT, fileid, 'VarName', '12'
```

Specifying Attributes and Variables

Variables and attributes can be referred to either by name or by their ID numbers in most netCDF routines. For example, given the NCDF_VARDEF command shown below, the two NCDF_VARPUT commands shown after it are equivalent:

```
varid = NCDF_VARDEF(fileid, 'VarName', [d0,d1,d2+d3], /FLOAT)
; Reference by variable name:
NCDF_VARPUT, fileid, 'VarName', '12'
; Reference by variable ID:
NCDF_VARPUT, fileid, varid,'12'
```

String Data in NetCDF Files

Strings are stored as arrays of ASCII bytes in netCDF files. To read string data from netCDF files, use the STRING function to convert bytes back into characters. When writing an IDL string array to a variable, an extra dimension (the maximum string length) must be added to the variable definition. Both of these situations are illustrated by the following example:

```
; Make a test string:
string_in = REPLICATE('Test String',10,10)
; Make one element longer than the others:
string_in(0,0) = 'Long Test String'
HELP, string_in
; Create a new netCDF file:
ncdfid = NCDF_CREATE('string.nc', /CLOBBER)
; Define first dimension:
xid = NCDF_DIMDEF(ncdfid, 'height', 10)
; Define second dimension:
yid = NCDF_DIMDEF(ncdfid, 'width', 10)
; Find the length of the longest string and use that as the
; third dimension:
zid = NCDF_DIMDEF(ncdfid, 'length', MAX(STRLEN(string_in)))
; Define the variable with dimensions zid, yid, xid:
id = NCDF_VARDEF(ncdfid, 'strings', [zid,yid,xid], /CHAR)
; Put the file into define mode:
NCDF_CONTROL, ncdfid, /ENDEF
; Write the string variable. The array will be stored as bytes
; in the file:
NCDF_VARPUT, ncdfid, id, string_in
; Read the byte array back out:
NCDF_VARGET, ncdfid, id, byte_out
NCDF_CLOSE, ncdfid ; Close the file.
HELP, byte_out
; IDL reports that BYTE_OUT is a (16, 10, 10) BYTE array.
PRINT, STRING(byte_out(*,0,0))
; Taking the STRING of the first "row" of byte_out returns the
; first element of our original array, "Long Test String".
; Convert the entire byte array back into strings:
string_new = STRING(byte_out)
; The new string array has the same dimensions and values as
; our original string, string_in.
HELP, string_new
; This statement compares the two arrays and prints "Success!" if
; they are equal, and they are:
IF TOTAL(string_in NE string_new) EQ 0 THEN PRINT, 'Success!'
```

Alphabetical Listing of NCDF Routines

The remainder of this chapter is an alphabetical listing of NCDF routines.

NCDF_ATTCOPY

The NCDF_ATTCOPY function copies an attribute from one netCDF file to another. Note that *Incdf* and *Outcdf* can be the same netCDF ID.

Syntax

Result = NCDF_ATTCOPY(*Incdf* [, *Invar* | , /IN_GLOBAL] , *Name*, *Outcdf* [, *Outvar*] [, /OUT_GLOBAL])

Return Value

NCDF_ATTCOPY returns the attribute number of the copied attribute in the new file, or -1 if the copy was not successful.

Arguments

Incdf

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Invar

The netCDF variable ID to be read, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the IN_GLOBAL keyword is set, this argument must be omitted.

Name

A scalar string containing the name of the attribute to be copied.

Outcdf

The netCDF ID of a netCDF file opened for writing, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Outvar

The netCDF variable ID to be written, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the OUT_GLOBAL keyword is set, this argument must be omitted.

Keywords

IN_GLOBAL

Set this keyword to read a global attribute.

OUT_GLOBAL

Set this keyword to create a global attribute.

Examples

See example from “NCDF_ATTINQ” on page 3725.

Version History

Introduced: Pre 4.0

NCDF_ATTDEL

The NCDF_ATTDEL procedure deletes an attribute from a netCDF file.

Syntax

NCDF_ATTDEL, *Cdfid* [, *Varid* | , /GLOBAL] , *Name*

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable.

Name

A scalar string containing the name of the attribute to be deleted.

Keywords

GLOBAL

Set this keyword to delete a global variable.

Examples

```
; Open file test.nc for writing:
id = NCDF_OPEN('test.nc', /WRITE)
; Delete global attribute TITLE from the file:
NCDF_ATTDEL, id, 'TITLE', /GLOBAL
NCDF_CLOSE, id ; Close the file.
```

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTNAME, NCDF_ATTPUT

NCDF_ATTGET

The NCDF_ATTGET procedure retrieves the value of an attribute from a netCDF file.

Syntax

NCDF_ATTGET, *Cdfid* [, *Varid* | , /GLOBAL] , *Name*, *Value*

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the GLOBAL keyword is used, this argument must be omitted.

Name

A scalar string containing the attribute name.

Value

A named variable in which the attribute's value is returned. NCDF_ATTGET sets *Value*'s size and data type appropriately.

Keywords

GLOBAL

Set this keyword to retrieve the value of a global attribute.

Examples

For an example using this routine, see the documentation for NCDF_ATTINQ.

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTINQ, NCDF_ATTNAME, NCDF_ATTPUT

NCDF_ATTINQ

The NCDF_ATTINQ function returns a structure that contains information about a netCDF attribute. This structure, described below, has the form:

```
{ DATATYPE:'', LENGTH:0L }
```

Syntax

Result = NCDF_ATTINQ(*Cdfid* [, *Varid* | , /GLOBAL] , *Name*)

Return Value

The structure returned by this function contains the following tags:

Tag	Description
DataType	A string describing the data type of the variable. The string will be one of the following: BYTE, CHAR, INT, LONG, FLOAT, or DOUBLE.
Length	The number of values stored in the attribute. If the attribute is a string, the number of values indicates one more character than the string length to include the terminating null character. This is the NetCDF convention, as demonstrated in the following example.

Table 0-2: NCDF_ATTINQ Structure Tags

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the GLOBAL keyword is set, this argument must be omitted.

Name

A scalar string containing the name of the attribute for which information is to be returned.

Keywords

GLOBAL

Set this keyword to inquire about a global variable. If this keyword is set, the *Varid* argument must be omitted.

Examples

```
id = NCDF_CREATE('test.nc', /CLOBBER ; Open a new netCDF file.
id2 = NCDF_CREATE('test2.nc', /CLOBBER ; Open a second file.
; Create two global attributes TITLE and DATE:
NCDF_ATTPUT, id, /GLOBAL, 'TITLE', 'MY TITLE'
NCDF_ATTPUT, id, /GLOBAL, 'DAY', 'July 1,1996'
; Suppose we wanted to use DATE instead of DAY. We could use
; ATTRENAME to rename the attribute:
NCDF_ATTRENAME, id, 'DAY', 'DATE', /GLOBAL
; Next, copy both attributes into a duplicate file:
result = NCDF_ATTCOPY(id, 'TITLE', id2, /IN_GLOBAL, /OUT_GLOBAL)
result2 = NCDF_ATTCOPY(id, 'DATE', id2, /IN_GLOBAL, /OUT_GLOBAL)
; Put the file into data mode:
NCDF_CONTROL, id, /ENDEF
; Get the second attribute’s name:
name = NCDF_ATTNAME(id, /GLOBAL, 1)
; Retrieve the date:
NCDF_ATTGET, id, /GLOBAL, name, date
; Get info about the attribute:
result = NCDF_ATTINQ(id, /GLOBAL, name)
HELP, name, date, result, /STRUCTURE
PRINT, date
PRINT, STRING(date)
NCDF_DELETE, id ; Close the netCDF files.
NCDF_DELETE, id2
```

IDL Output

```
NAME            STRING    = 'DATE'
DATE            BYTE      = Array(12)
** Structure <400dac30>, 2 tags, length=12, refs=1:
   DATATYPE        STRING    'BYTE'
   LENGTH          LONG                12
```

Note the length includes the NCDF standard NULL terminator

```
74 117 108 121  32  49  44  49  57  57  54   0

July 1,1996
```

Version History

Introduced: 4.0

See Also

NCDF_ATTDEL, NCDF_ATTGET, NCDF_ATTNAME, NCDF_ATTPUT

NCDF_ATTNAME

The NCDF_ATTNAME function returns the name of an attribute in a netCDF file given its ID.

Syntax

Result = NCDF_ATTNAME(*Cdfid* [, *Varid* | , /GLOBAL] , *Attnum*)

Return Value

Returns the specified attribute's name or the NULL string ("") if there is no such attribute.

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the GLOBAL keyword is set, this argument must be omitted.

Attnum

An expression containing the number of the desired attribute. The attributes for each variable are numbered from 0 to the number-of-attributes minus 1. Note that the number of attributes can be found using NCDF_VARINQ or NCDF_INQUIRE (to find the number of global variables).

Keywords

GLOBAL

Set this keyword to return the name of one of the global attributes.

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTINQ

NCDF_ATTPUT

The NCDF_ATTPUT procedure creates an attribute in a netCDF file. If the attribute is new, or if the space required to store the attribute is greater than before, the netCDF file must be in *define* mode.

Syntax

NCDF_ATTPUT, *Cdfid* [, *Varid* | , /GLOBAL] , *Name* , *Value* [, LENGTH=*value*] [, /BYTE | , /CHAR | , /DOUBLE | , /FLOAT | , /LONG | , /SHORT]

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the GLOBAL keyword is set, this argument must be omitted.

Name

A scalar string containing the attribute name.

Value

An expression containing the data to be written. Although this procedure checks that there are a sufficient number of bytes of data, the data type is not checked or altered.

Keywords

GLOBAL

Set this keyword to create a global attribute.

LENGTH

Use this keyword to override the default length (the whole value). Set this keyword to a value less than or equal to the number of elements in *Value*. For example:

```
ATTR_ID = NCDF_ATTPUT(CDFID, VARID, 'Attr1', $
 INDGEN(10), LENGTH=5
```

writes Attr1 as [0,1,2,3,4].

The following keywords specify a non-default data type for the variable. By default, NCDF_ATTPUT chooses one based upon the type of data. If a data type flag is specified, the data supplied in *Value* is converted to that data type before being written to the file. Only one of these keywords can be used in a single call to NCDF_ATTPUT.

BYTE

Set this keyword to indicate that the data is composed of bytes.

CHAR

Set this keyword to indicate that the data is composed of bytes (assumed to be ASCII).

DOUBLE

Set this keyword to indicate that the data is composed of 8-byte floating point numbers (doubles).

FLOAT

Set this keyword to indicate that the data is composed of 4-byte floating point numbers (floats).

LONG

Set this keyword to indicate that the data is composed of 4-byte integers (longs).

SHORT

Set this keyword to indicate that the data is composed of 2-byte integers.

Examples

```
NCDF_ATTPUT, cdfid, /GLOBAL, "Title", "My Favorite Data File"
NCDF_ATTPUT, cdfid, "data", "scale_factor", 12.5D"
```

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTINQ

NCDF_ATTRENAME

The NCDF_ATTRENAME procedure renames an attribute in a netCDF file.

Syntax

NCDF_ATTRENAME, *Cdfid* [, *Varid* | , /GLOBAL] *Oldname*, *Newname*

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable. If the GLOBAL keyword is set, this argument must be omitted.

OldName

A scalar string containing the attribute's current name.

NewName

A scalar string containing the attribute's new name.

Keywords

GLOBAL

Set this keyword to rename a global attribute.

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTINQ

NCDF_CLOSE

The NCDF_CLOSE procedure closes an open netCDF file. If a writable netCDF file is not closed before exiting IDL, the disk copy of the netCDF file may not reflect recent data changes or new definitions.

Syntax

NCDF_CLOSE, *Cdfid*

Arguments

Cdfid

The netCDF ID of the file to be closed, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTINQ

NCDF_CONTROL

The NCDF_CONTROL procedure performs miscellaneous netCDF operations.

Different options are controlled by keywords. Only one keyword can be specified in any call to NCDF_CONTROL, unless the OLDFILL keyword is specified.

Syntax

NCDF_CONTROL, *Cdfid* [, /ABORT] [, /ENDEF] [, /FILL | , /NOFILL] [, /NOVERBOSE | , /VERBOSE] [, OLDFILL=*variable*] [, /REDEF] [, /SYNC]

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Keywords

ABORT

Set this keyword to close a netCDF file that is not in define mode. If the file is being created and is still in define mode, the file is deleted. If define mode was entered by a call to NCDF_CONTROL with the REDEF keyword, the netCDF file is restored to its state before definition mode was entered, and the file is closed.

ENDEF

Set this keyword to take an open netCDF file out of define mode (and into data mode).

FILL

Set this keyword so that data in the netCDF file is pre-filled with default fill values. The default values (which cannot be changed) are:

Data Type	Fill Value
BYTE	0
CHAR	0
SHORT	-32767
LONG	-2147483647
FLOAT	9.96921E+36
DOUBLE	9.96921E+36

Table F-1: Default Fill Values for netCDF Files

NOFILL

Set this keyword so that data in the netCDF file is not pre-filled. This option saves time when it is certain that variable values will be written before a read is attempted.

NOVERBOSE

Set this keyword to suppress the printing of netCDF error messages. *Cdfid* is required but not used.

OLDFILL

This keyword specifies a named variable in which the previous fill value is returned. This keyword can only be used in combination with the FILL or NOFILL keywords. For example:

```
NCDF_CONTROL, id, FILL=1, OLDFILL=previous_fill
```

REDEF

Set this keyword to put an open netCDF file into define mode.

SYNC

Set this keyword to update the disk copy of a netCDF file that is open for writing. The netCDF file must be in data mode. A netCDF file in define mode will be updated only when NCDF_CONTROL is called with the ENDEF keyword.

VERBOSE

Set this keyword to cause netCDF error messages to be printed. *Cdfid* is required but not used. For example:

```
NCDF_CONTROL, 0, /VERBOSE
```

is a valid command even if 0 is not a valid NetCDF file ID.

Examples

See the examples under NCDF_ATTINQ and NCDF_VARPUT.

Version History

Introduced: Pre 4.0

See Also

NCDF_CLOSE, NCDF_CREATE, NCDF_OPEN

NCDF_CREATE

The NCDF_CREATE function creates a new netCDF file.

Syntax

Result = NCDF_CREATE(*Filename* [, /CLOBBER | , /NOCLOBBER])

Return Value

If successful, the netCDF ID for the file is returned. The newly-created netCDF file is automatically placed into define mode. If you do not have write permission to create the specified Filename, NCDF_CREATE returns an error message instead of a netCDF file ID.

Arguments

Filename

A scalar string containing the name of the file to be created

Keywords

CLOBBER

Set this keyword to erase the existing file (if the file already exists) before creating the new version.

NOCLOBBER

Set this keyword to create a new netCDF file only if the specified file does not already exist. This is the default.

Examples

```
; Open a new NetCDF File and destroy test.nc if it already exists:
id = NCDF_CREATE('test.nc',/CLOBBER)

id2 = NCDF_CREATE('test.nc', /NOCLOBBER)
```

This attempt to create a new version of the file `test.nc` produces the following error because the NOCLOBBER keyword was set:

```
nccreate: filename "test.nc": File exists
% NCDF_CREATE: Operation failed
% Execution halted at $MAIN$   (NCDF_CREATE).
```

Version History

Introduced: Pre 4.0

See Also

NCDF_CLOSE, NCDF_CONTROL, NCDF_OPEN

NCDF_DIMDEF

The NCDF_DIMDEF function defines a dimension in a netCDF file given its name and size.

Syntax

Result = NCDF_DIMDEF(*Cdfid*, *DimName*, *Size* [, /UNLIMITED])

Return Value

If successful, the dimension ID is returned.

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

DimName

A scalar string containing the name of the dimension being defined.

Size

The size of the dimension. *Size* can be any scalar expression. If the UNLIMITED keyword is used, the *Size* parameter should be omitted.

Keywords

UNLIMITED

Set this keyword to create a dimension of unlimited size. Note that only one dimension in a netCDF file can be unlimited.

Examples

See NCDF_VARPUT.

Version History

Introduced: Pre 4.0

NCDF_DIMID

The NCDF_DIMID function returns the ID of a netCDF dimension, given the name of the dimension.

Syntax

Result = NCDF_DIMID(*Cdfid*, *DimName*)

Return Value

Return the dimension ID or -1 if the dimension does not exist.

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

DimName

A scalar string containing the dimension name.

Keywords

None.

Examples

See NCDF_VARPUT.

Version History

Introduced: Pre 4.0

NCDF_DIMINQ

The NCDF_DIMINQ procedure retrieves the name and size of a dimension in a netCDF file, given its ID. The size for the unlimited dimension, if any, is the maximum value used so far in writing data for that dimension.

Syntax

NCDF_DIMINQ, *Cdfid*, *Dimid*, *Name*, *Size*

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Dimid

The netCDF dimension ID, returned from a previous call to NCDF_DIMID or NCDF_DIMDEF, or an indexed number from 0 to NDIMS-1 that indexes the desired dimension. The first dimension has a DIMID of 0, the second dimension has a DIMID of 1, and so on.

Name

A named variable in which the dimension name is returned (a scalar string).

Size

A named variable in which the size of the dimension is returned (a scalar longword integer)

Keywords

None.

Examples

See NCDF_VARPUT.

Version History

Introduced: Pre 4.0

NCDF_DIMRENAME

The NCDF_DIMRENAME procedure renames an existing dimension in a netCDF file which has been opened for writing. If the new name is longer than the old name, the netCDF file must be in define mode. You cannot rename one dimension to have the same name as another dimension.

Syntax

NCDF_DIMRENAME, *Cdfid*, *Dimid*, *NewName*

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Dimid

The netCDF dimension ID, returned from a previous call to NCDF_DIMID or NCDF_DIMDEF, or the name of the dimension.

NewName

A scalar string containing the new name for the dimension.

Keywords

None.

Examples

See NCDF_VARPUT.

Version History

Introduced: Pre 4.0

NCDF_EXISTS

The NCDF_EXISTS function returns true if the Network Common Data Format (netCDF) scientific data format library is supported on the current IDL platform.

This routine is written in the IDL language. Its source code can be found in the file `ncdf_exists.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = NCDF_EXISTS( )

Return Value

Returns true if the library is supported.

Arguments

None.

Keywords

None.

Examples

The following IDL command prints an error message if the NetCDF library is not available:

```
IF NCDF_EXISTS() EQ 0 THEN PRINT, 'NCDF not supported.'
```

Version History

Introduced: Pre 4.0

NCDF_INQUIRE

The NCDF_INQUIRE function returns a structure that contains information about an open netCDF file. This structure of the form:

```
{ NDIMS:0L, NVARS:0L, NGATTS:0L, RECDIM:0L }
```

The structure tags are described below.

Syntax

Result = NCDF_INQUIRE(*Cdfid*)

Return Value

The returned structure contains the following tags:

Tag	Description
Ndims	The number of dimensions defined for this netCDF file.
Nvars	The number of variables defined for this netCDF file.
Ngatts	The number of global attributes defined for this netCDF file.
RecDim	The ID of the unlimited dimension, if there is one, for this netCDF file. If there is no unlimited dimension, RecDim is set to -1.

Table 0-3: NCDF_INQUIRE Structure Tags

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Keywords

None.

Examples

See NCDF_VARDEF.

Version History

Introduced: Pre 4.0

NCDF_OPEN

The NCDF_OPEN function opens an existing netCDF file.

Syntax

Result = NCDF_OPEN(*Filename* [, /NOWRITE | , /WRITE])

Return Value

If successful, the netCDF ID for the file is returned.

Arguments

Filename

A scalar string containing the name of the file to be opened.

Keywords

NOWRITE

Set this keyword to open an existing netCDF file as read only. This is the default.

WRITE

Set this keyword to open an existing netCDF file for both writing and reading.

Version History

Introduced: Pre 4.0

See Also

NCDF_ATTINQ

NCDF_VARDEF

The NCDF_VARDEF function adds a new variable to an open netCDF file in define mode.

Syntax

Result = NCDF_VARDEF(*Cdfid*, *Name* [, *Dim*] [, /BYTE | , /CHAR | , /DOUBLE | , /FLOAT | , /LONG | , /SHORT])

Return Value

If successful, the variable ID is returned. If a new variable cannot be defined, NCDF_VARDEF returns -1.

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Name

A scalar string containing the variable name.

Dim

An optional vector containing the dimension IDs corresponding to the variable dimensions. If the ID of the unlimited dimension is included, it must be the rightmost element in the array. If *Dim* is omitted, the variable is assumed to be a scalar.

Keywords

The following keywords specify the data type for the variable. Only one of these keywords can be used. If no data type keyword is specified, FLOAT is used by default.

BYTE

Set this keyword to indicate that the data is composed of bytes.

CHAR

Set this keyword to indicate that the data is composed of bytes (assumed to be ASCII).

DOUBLE

Set this keyword to indicate that the data is composed of double-precision floating-point numbers.

FLOAT

Set this keyword to indicate that the data is composed of floating-point numbers.

LONG

Set this keyword to indicate that the data is composed of longword integers.

SHORT

Set this keyword to indicate that the data is composed of 2-byte integers.

Examples

```
id = NCDF_CREATE('test.nc', /CLOBBER) ; Create the netCDF file.
NCDF_ATTPUT, id, 'TITLE', 'Incredibly Important Data', /GLOBAL
NCDF_ATTPUT, id, 'GALAXY', 'Milky Way', /GLOBAL
NCDF_ATTPUT, id, 'PLANET', 'Earth', /GLOBAL
xid = NCDF_DIMDEF(id, 'x', 100) ; Define the X dimension.
yid = NCDF_DIMDEF(id, 'y', 200) ; Define the Y dimension.
zid = NCDF_DIMDEF(id, 'z', /UNLIMITED) ; Define the Z dimension.
vid0 = NCDF_VARDEF(id, 'image0', [yid, xid], /FLOAT)
vid1 = NCDF_VARDEF(id, 'image1', [yid, xid], /FLOAT)
; Rename image0 to dist_image:

Version History

Introduced: Pre 4.0

NCDF_VARGET

The NCDF_VARGET procedure retrieves a hyperslab of values from a netCDF variable. The netCDF file must be in *data* mode to use this procedure.

Syntax

NCDF_VARGET, *Cdfid*, *Varid*, *Value* [, COUNT=*vector*] [, OFFSET=*vector*] [, STRIDE=*vector*]

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable.

Value

A named variable in which the values are returned. NCDF_VARGET sets *Value*'s size and data type as appropriate.

Keywords

COUNT

An optional vector containing the counts to be used in reading *Value*. COUNT is a 1-based vector with an element for each dimension of the data to be written.The default matches the size of the variable so that all data is written out.

OFFSET

An optional vector containing the starting position for the read. The default start position is [0, 0, ...].

STRIDE

An optional vector containing the strides, or sampling intervals, between accessed values of the netCDF variable. The default stride vector is that for a contiguous read, [1, 1, ...].

Examples

Suppose that a 230 by 230 image is saved in the netCDF file `dave.nc`. The following commands extract both the full image and a 70x70 sub-image starting at [80,20] sampling every other X pixel and every third Y pixel:

```
; A variable that contains the offset for the sub-image:
offset = [80, 20]
; The dimensions of the sub-image:
count = [70, 70]
; Create a variable to be used as a value for the STRIDE keyword.
; Every other X element and every third Y element will be sampled:
stride = [2, 3]
; Open the NetCDF file:
id = NCDF_OPEN('dave.nc')
; Get the variable ID for the image:
image = NCDF_VARID(id, 'image')
; Get the full image:
NCDF_VARGET, id, image, fullimage
; Extract the sub-sampled image:
NCDF_VARGET, id, image, subimage, $
   COUNT=count, STRIDE=stride, OFFSET=offset
; Close the NetCDF file:
NCDF_CLOSE, id
```

Version History

Introduced: Pre 4.0

See Also

NCDF_VARGET1, NCDF_VARID, NCDF_VARINQ, NCDF_VARPUT

NCDF_VARGET1

The NCDF_VARGET1 procedure retrieves one element from a netCDF variable. The netCDF file must be in *data* mode to use this procedure.

Syntax

NCDF_VARGET1, *Cdfid*, *Varid*, *Value* [, OFFSET=*vector*]

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable.

Value

A named variable in which the value of the variable is returned. NCDF_VARGET1 sets *Value*'s size and data type as appropriate.

Keywords

OFFSET

A vector containing the starting position of the read. The default starting position is [0, 0, ...].

Examples

Suppose that the file `dave.nc` contains an image saved with the netCDF variable name “dave”. The following commands extract the value of a single pixel from the image:

```
; The location of the single element (pixel) whose value we will
; retrieve:
offset = [180,190]
; Open the netCDF file:
id = NCDF_OPEN('dave.nc')
; Get the variable ID for variable "dave":
varid = NCDF_VARID(id, 'dave')
; Extract the element and return the value in the variable
; single_pixel:
NCDF_VARGET1, id, varid, single_pixel, OFFSET=offset
; Close the netCDF file:
NCDF_CLOSE, id
```

Version History

Introduced: Pre 4.0

See Also

NCDF_VARGET, NCDF_VARID, NCDF_VARINQ, NCDF_VARPUT

NCDF_VARID

The NCDF_VARID function returns the ID of a netCDF variable.

Syntax

Result = NCDF_VARID(*Cdfid*, *Name*)

Return Value

This function returns the variable IDL or returns -1 if the variable does not exist.

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Name

A scalar string containing the variable name.

Keywords

None.

Examples

See NCDF_VARDEF.

Version History

Introduced: Pre 4.0

NCDF_VARINQ

The NCDF_VARINQ function returns a structure that contains information about a netCDF variable, given its ID. This structure has the form:

```
{ NAME:"", DATATYPE:"", NDIMS:0L, NATTS:0L, DIM:LONARR(NDIMS) }
```

This structure is described below.

Syntax

Result = NCDF_VARINQ(*Cdfid*, *Varid*)

Return Value

The returned structure contains the following tags:

Tag	Description
Name	The name of the variable.
DataType	A string describing the data type of the variable. The string will be one of the following: 'BYTE', 'CHAR', 'INT', 'LONG', 'FLOAT', or 'DOUBLE'.
Ndims	The number of dimensions.
Natts	The number of attributes assigned to this variable.
Dim	A vector of the dimension IDs for the variable dimensions.

Table 0-4: NCDF_VARINQ Structure Tags

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable.

Examples

See NCDF_VARDEF.

Version History

Introduced: Pre 4.0

NCDF_VARPUT

The NCDF_VARPUT procedure writes a hyperslab of values to a netCDF variable. The netCDF file must be in *data* mode to use this procedure.

Syntax

NCDF_VARPUT, *Cdfid, Varid, Value* [, COUNT=*vector*] [, OFFSET=*vector*] [, STRIDE=*vector*]

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable.

Value

Data values to be written to the netCDF file. If the data type of *Value* does not match that of the netCDF variable, it is converted to the correct data type before writing. *Value* must have a dimensionality less than or equal to that of the variable being written.

Keywords

COUNT

An optional vector containing the counts to be used in writing *Value*. COUNT is a 1-based vector with an element for each dimension of the data to be written. Note that counts do not have to match the dimensions of *Value*. The default count vector is the dimensionality of *Value*.

OFFSET

An optional vector containing the starting position to write. The default start position is [0, 0, ...].

STRIDE

An optional vector containing the strides, or writing intervals, between written values of the netCDF variable. The default stride vector is that for a contiguous write, [1, 1, ...].

Examples

Suppose that you wish to create a 100x100 byte (0 & 1) checker board:

```
; Create offsets for even and odd rows:
offset_even = [0,0] & offset_odd = [1,1]
; Create count and stride values:
count = [50,50] & stride = [2,2]
; Make the "black" spaces of the checker board:
black = BYTARR(50,50) > 1B
; Create the netCDF file:
id = NCDF_CREATE('checker.nc', /CLOBBER)
; Fill the file with BYTE zeros:
NCDF_CONTROL, id, /FILL
; Define the X dimension:
xid = NCDF_DIMDEF(id, 'x', 100)
; Define the Y dimension:
yid = NCDF_DIMDEF(id, 'y', 100)
; Define the Z dimension, UNLIMITED:
zid = NCDF_DIMDEF(id, 'yy', /UNLIMITED)
; Define a variable with the name "board":
vid = NCDF_VARDEF(id, 'board', [yid, xid], /BYTE)
; Rename 'yy' to 'z' as the zid dimension name:
NCDF_DIMRENAME, id, zid, 'z'
; Put the file into data mode:
NCDF_CONTROL, id, /ENDEF
; Use NCDF_DIMID and NCDF_DIMINQ to verify the name and size
; of the zid dimension:
check_id = NCDF_DIMID(id,'z')
NCDF_DIMINQ, id, check_id, dim_name, dim_size
HELP, check_id, dim_name, dim_size
```

IDL prints:

```
CHECK_ID     LONG            =   2
DIM_NAME     STRING          = 'z'
DIM_SIZE     LONG            =   0
```

Note that the DIM_SIZE is 0 because no records have been written yet for this dimension.

```
NCDF_VARPUT, id, vid, black, $
   COUNT=count, STRIDE=stride, OFFSET=offset_even
NCDF_VARPUT, id, vid, black, $
   COUNT=count, STRIDE=stride, OFFSET=offset_odd
; Get the full image:
NCDF_VARGET, id, vid, output
; Create a window for displaying the image:
WINDOW, XSIZE=100, YSIZE=100
; Display the image:
TVSCL, output
; Make stride larger than possible:
stride = [2,3]
; As an experiment, attempt to write to an array larger than
; the one we previously allocated with NCDF_VARDEF:
NCDF_VARPUT, id, vid, black, $
   COUNT=count, STRIDE=stride, OFFSET=offset_odd
```

IDL prints:

```
% NCDF_VARPUT: Requested write is larger than the available data
area.
```

You will need to change the OFFSET/COUNT/STRIDE, or redefine the variable dimensions. You attempted to access 150 elements in a 100 array.

```
NCDF_CLOSE, id ; Close the netCDF file.
```

Version History

Introduced: Pre 4.0

NCDF_VARGET, NCDF_VARGET1, NCDF_VARID, NCDF_VARINQ

NCDF_VARRENAME

The NCDF_VARRENAME procedure renames a netCDF variable.

Syntax

NCDF_VARRENAME, *Cdfid*, *Varid*, *Name*

Arguments

Cdfid

The netCDF ID, returned from a previous call to NCDF_OPEN or NCDF_CREATE.

Varid

The netCDF variable ID, returned from a previous call to NCDF_VARDEF or NCDF_VARID, or the name of the variable.

Name

A scalar string containing the new name for the variable.

Keywords

None.

Examples

See NCDF_VARDEF.

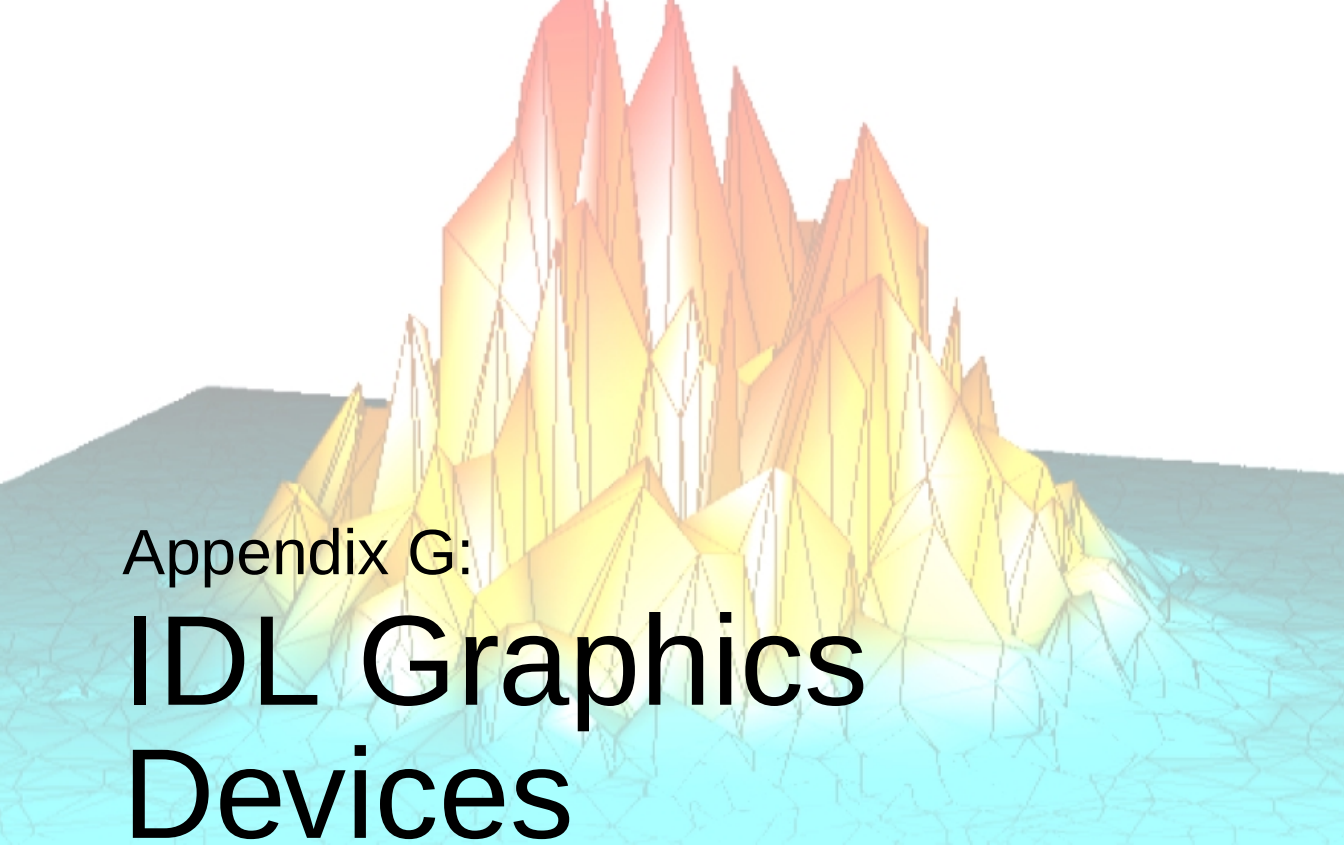
Introduced: Pre 4.0



Appendix G: IDL Graphics Devices

The following topics are covered in this appendix:

Supported Devices 3764
Keywords Accepted by the IDL Devices 3766
Window Systems 3806
Printing Graphics Output Files 3809
The CGM Device 3812
The HP-GL Device 3814
The Metafile Display Device 3816
The Null Display Device 3818
The PCL Device 3819
The Printer Device 3821
The PostScript Device 3822
The Regis Terminal Device 3834
The Tektronix Device 3835
The Microsoft Windows Device 3837
The X Windows Device 3838
The Z-Buffer Device 3847

Supported Devices

IDL Direct Graphics support graphic output to the devices listed below:

Device Name	Description
CGM	Computer Graphics Metafile
HP	Hewlett-Packard Graphics Language (HP-GL)
METAFILE	Windows Metafile Format (WMF)
NULL	No graphics output
PCL	Hewlett-Packard Printer Control Language (PCL)
PRINTER	System printer
PS	PostScript
REGIS	Regis graphics protocol (DEC systems only)
TEK	Tektronix compatible terminal
WIN	Microsoft Windows
X	X Window System
Z	Z-buffer pseudo device

Table G-1: IDL Graphics Output Devices

Each of these devices is described in a section of this chapter. The SET_PLOT procedure can be used to select the graphic device to which IDL directs its output. IDL Object Graphics does not rely on the concept of a current graphics device; see *Using IDL* for details about IDL Object Graphics.

The DEVICE procedure controls the graphic device-specific functions. An attempt has been made to isolate all device-specific functions in this procedure. DEVICE controls the graphics device currently selected by SET_PLOT. When using DEVICE, it is important to make sure that the current graphics device is the one you intend to use. This is because most of the devices have different keywords—you will most likely get a "`Keyword ... ... not allowed in call to: Device`" error if you call DEVICE when the wrong device is selected.

Obsolete Graphics Devices and Device Keywords

The following graphics devices are obsolete:

- LJ
- MAC

For information on obsolete graphics devices, See Appendix O, “Obsolete Features”.

The following graphics device keywords are obsolete:

- DEPTH
- FONT

For information on obsolete keywords, See Appendix O, “Obsolete Features”.

Keywords Accepted by the IDL Devices

The following table indicates which keywords are accepted by the DEVICE procedure. The NULL device is not listed as it accepts no keywords. Details of the various keywords can be found on the page indicated in the table.

Note

Most keywords to the DEVICE procedure are sticky — that is, once you set them, they remain in effect until you explicitly change them again, or end your IDL session. The exceptions are keywords used to return a value from the system (GET_FONTNAMES, for example) and those that perform a one-time-only operation (CLOSE_FILE, for example).

Table G-2: Keywords accepted by the IDL devices (Continued)

Keywords accepted by the DEVICE command are described below. A list of devices that accept the keyword is included in parentheses below the keyword name.

AVANTGARDE

(PS)

Set this keyword to select the ITC Avant Garde PostScript font.

AVERAGE_LINES

(REGIS)

Controls the method of writing images to the VT240. If this keyword is set, (default setting), even and odd pairs of image lines are averaged and written to a single line. If clear, each image line is written to the screen. See the discussion below. This keyword has no effect when using a VT300 series terminal.

BINARY

(CGM)

Set this keyword to set the encoding type for the CGM output file to binary.

BITS_PER_PIXEL

(PS)

IDL is capable of producing PostScript images with 1, 2, 4, or 8 bits per pixel. Using more bits per pixel gives higher resolution at the cost of generating larger files. BITS_PER_PIXEL is used to specify the number of bits to use. If you do not specify a value for BITS_PER_PIXEL, a default value of 4 is used.

It should be noted that many laser printers, including the original Apple Laserwriter are capable of only 32 different shades of gray (which can be represented by 5 bits). Thus, specifying 8 bits per pixel does not give 256 apparent shades of grey as might be expected, only 32, at a cost of sending twice the number of bits to the printer. Often, 4 bits (16 levels of gray) will give acceptable results with a large savings in file size.

BKMAN

(PS)

Set this keyword to select the ITC Bookman PostScript font.

BOLD

(PS)

Set this keyword to specify that the bold version of the current PostScript font should be used.

BOOK

(PS)

Set this keyword to specify that the book version of the current PostScript font should be used.

BYPASS_TRANSLATION

(WIN, X)

Set this keyword to bypass the translation tables, allowing direct specification of color indices. See "Color Translation" on page 3843 Pixel values read via the TVRD function are not translated if this keyword is set, and the result contains the byte value of the actual pixel values present in the display.

By default, the translation tables are used with shared and static color tables. When using displays with private color tables, the translation tables are bypassed.

This keyword is accepted by the WIN device (for compatibility with the X device), but has no effect when set.

CLOSE

(Z)

Set this keyword to deallocate the memory used by the Z-buffer. The Z-buffer device is reinitialized if subsequent graphics operations are directed to the device.

CLOSE_DOCUMENT

(PRINTER)

Set this keyword to have IDL send any buffered output to the currently selected printer. This keyword is applicable only when the printer device is selected. See "The Printer Device" on page 3821 for details.

CLOSE_FILE

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Set this keyword to have IDL output any buffered commands and close the current graphics file.

Caution: If you close the output file and then cause IDL to produce more output (e.g., by executing a new PLOT command), IDL will open the file again, causing the contents of the recently closed file to be lost. To avoid this, use the FILENAME keyword to specify a different file name or use SET_PLOT to disable the graphics driver, or be sure to print the closed output file before creating more output.

See the discussion of printing output files in "Printing Graphics Output Files" on page 3809

COLOR

(PCL, PS)

Set this keyword to enable color PCL or PostScript output. See "The PCL Device" on page 3819 or "The PostScript Device" on page 3822.

COLORS

(CGM, TEK)

This keyword specifies the maximum number of colors and the size of the color table used for output. The value of the system variable fields !D.N_COLORS and !D.TABLE_SIZE are set to this value and !P.COLOR is set to one less than this value.

For Tektronix Terminals Only

This keyword sets the number of colors supported by a 4100 series terminal. For example, if your terminal has 4-bit planes, the number of colors is $2^4 = 16$:

```
DEVICE, COLORS = 16
```

Valid values of this parameter are: 2, 4, 8, 16, or 64; other values will cause problems. Some Tektronix terminals will not operate properly if this parameter does not exactly match the number of colors available in the terminal hardware.

This parameter sets the field !D.N_COLORS, which affects the loading of color tables, the scaling used by the TVSCL procedure, and the number of bits output by the TV procedure to the terminal. It also changes the default color, !P.COLOR to the number of colors minus one.

COPY

(WIN, X)

Use this keyword to copy a rectangular area of pixels from one region of a window to another. COPY should be set a six or seven element array: $[X_s, Y_s, N_x, N_y, X_d, Y_d, W]$, where: (X_s, Y_s) is the lower left corner of the source rectangle, (N_x, N_y) are the number of columns and rows in the rectangle, and (X_d, Y_d) is the coordinate of the destination rectangle. Optionally, W is the index of the window *from which the pixels should be copied to the current* window. If it is not supplied, the current window is used as both the source and destination.

COURIER

(PS)

Set this keyword to select the Courier PostScript font.

CURSOR_CROSSHAIR

(WIN, X)

Set this keyword to selects the crosshair cursor type. This is the IDL default.

CURSOR_IMAGE

(WIN, X)

Specifies the cursor pattern. The value of this keyword must be a 16-line by 16-column bitmap, contained in a 16-element short integer vector. The offset from the upper left pixel to the point that is considered the hot spot can be provided via the CURSOR_XY keyword.

CURSOR_MASK

(WIN, X)

When the CURSOR_IMAGE keyword is used to specify a cursor bitmap, the CURSOR_MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the CURSOR_IMAGE that should be seen and bits that are not set are masked out.

By default, the CURSOR_IMAGE bitmap is used for both the image and the mask. This can cause the cursor to be invisible on a black background (because only black pixels are allowed to be displayed).

CURSOR_ORIGINAL

(WIN, X)

Set this keyword to select the window system’s default cursor. Under X Windows, it is the cursor in use by the root window when IDL starts. For the Microsoft Windows device, it is the arrow pointer.

CURSOR_STANDARD

(WIN, X)

This keyword can be used to change the cursor appearance in IDL graphics windows.

For X Windows

This keyword selects one of the predefined cursors provided by the X Window system. The available cursors shapes are defined in the file `cursorfont.h` in the directory `/usr/include/X11`. In order to use one of these cursors, you select the number of the cursor and provide it as the value of the CURSOR_STANDARD keyword. For example, the file gives the value of XC_CROSS as being 30. In order to make that the current cursor, use the statement:

```
DEVICE, CURSOR_STANDARD=30
```

For Microsoft Windows

The table below shows the values for CURSOR_STANDARD that result in different cursor shapes. For example, to change the cursor to an “I-beam” when the cursor is in an IDL graphics window, use the command:

```
DEVICE, CURSOR_STANDARD = 32513
```

Value	Cursor Shape
32512	Arrow
32513	I-Beam
32514	Hourglass
32515	Black Crosshair
32516	Up Arrow
32640	Size (Windows NT only)
32641	Icon (Windows NT only)
32642	Size NW-SE
32643	Size NE-SW
32644	Size E-W
32645	Size N-S

Table G-3: Values for the WIN device CURSOR_STANDARD Keyword

CURSOR_XY

(WIN, X)

A two element integer vector giving the (X, Y) pixel offset of the cursor hot spot, the point which is considered to be the mouse position, from the lower left corner of the cursor image. This parameter is only applicable if CURSOR_IMAGE is provided. The cursor image is displayed top-down—the first row is displayed at the top.

DECOMPOSED

(WIN, X)

This keyword is used to control the way in which graphics color index values are interpreted when using displays with decomposed color (TrueColor or DirectColor visuals). This keyword has no effect with other types of visuals.

Set this keyword to 1 to cause color indices to be interpreted as 3, 8-bit color indices where the least-significant 8 bits contain the red value, the next 8 bits contain the green value, and the most-significant 8 bits contain the blue value. This is the way IDL has always interpreted pixels when using visual classes with decomposed color.

Set this keyword to 0 to cause the least-significant 8 bits of the color index value to be interpreted as a PseudoColor index. This setting allows users with DirectColor and TrueColor displays to use IDL programs written for standard, PseudoColor displays without modification.

In older versions of IDL, color index values higher than !D.N_COLORS-1 were clipped to !D.N_COLORS-1 in the higher level graphics routines. In some cases, this clipping caused the exclusive-OR graphics mode to malfunction with raster displays. This clipping has been removed. Programs that incorrectly specified color indices higher than !D.N_COLORS-1 will now probably exhibit different behavior.

DEMI

(PS)

Set this keyword to specify that the demi version of the current PostScript font should be used.

DIRECT_COLOR

(X)

Set this keyword to select the DirectColor visual. The value of the keyword represents the number of bits per pixel. This keyword has effect only if no windows

have been created. Visual classes are discussed in more detail in “X Windows Visuals” on page 3838.

EJECT

(HP)

In order to perform an erase operation on a plotter, it is necessary to remove the current sheet of paper and load a fresh sheet. The ability of various plotters to do this varies, so the EJECT keyword allows you to specify what should be done. The following table describes the possible values.

Value	Meaning
0	Do nothing. Note that this is likely to cause one page to plot over the previous one, so you should limit yourself to one page of output per file. This is the default.
1	Use the sheet feeder to load the next page.
2	Put the plotter off-line at the beginning of each page after the first.

Table G-4: Values for the HP-GL Eject Keyword

Many HP-GL plotters lack a sheet feeder, and require the user to load the next page manually. Therefore, the default action is for IDL to not issue any page eject instructions. In this case, you must restrict yourself to generating only a single plot at a time. If your plotter has a sheet feeder, you will want to issue the command:

```
DEVICE, /EJECT
```

to tell IDL that it should use the sheet feeder instead of placing the plotter off-line.

If your plotter does not have a sheet feeder, but it does understand the HP-GL NR command, use the command:

```
DEVICE, EJECT=2
```

to place the plotter off-line at the start of every plot except the first one. This causes the plotter to wait between plots for the user to replace the paper. When the user puts the plotter back on-line, the graphics commands for the new page are executed by the plotter. Consult the programming manual for your plotter to determine if this instruction is provided.

ENCAPSULATED

(PS)

Set this keyword to create an encapsulated PostScript file, suitable for importing into another document (e.g., a LaTeX or FrameMaker document).

Note

You must explicitly set this keyword to zero to create “regular” PostScript output after creating encapsulated output. (That is, like most keyword settings to the DEVICE procedure, the setting “sticks” until you change it, or until you quit IDL.)

Normally, IDL assumes that its PostScript-generated output will be sent directly to a printer. It therefore includes PostScript commands to position the plot on the page and to eject the page from the printer. These commands are undesirable if the output is going to be inserted into the middle of another PostScript document. If ENCAPSULATED is present and non-zero, IDL does not generate these commands.

IDL follows the standard PostScript convention for encapsulated files. It assumes the standard PostScript scaling is in effect (72 points per inch), In addition, it declares the size, or *bounding box* of the plotting region at the top of the output file. This size is determined when the output file is opened (when the first graphics command is given), by multiplying the size of the plotting region (as specified with the XSIZE and YSIZE keywords) by the current scale factor (as specified by the SCALE_FACTOR keyword).

Changing the size of the plotting region or scale factor once graphics have been output will not be reflected in the declared bounding box, and will confuse programs that attempt to import the resulting graphics. Therefore, when generating encapsulated PostScript, do not change the plot region size or scaling factor once any graphics commands have been issued. If you need to change these parameters, use the FILENAME keyword to start a new file.

ENCODING

(CGM)

Set this keyword to set the CGM encoding type for the output file. Valid values are:

Value	Description
1	Binary encoding - the default.

Table G-5: CGM Encoding Values

Value	Description
2	Text encoding.
3	NCAR binary encoding.

Table G-5: CGM Encoding Values

The encoding type can only be changed when no CGM file is open.

FILENAME

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Normally, all generated output is sent to a file named `idl.xxx`, where `xxx` is the lowercase name of the device shown in the table under "Supported Devices" on page 3764. The FILENAME keyword can be used to change these defaults. If FILENAME is specified:

1. If the file is already open (as happens if plotting commands have been directed to the file since the call to SET_PLOT), then the file is completed and closed as if CLOSE_FILE had been specified.
2. The specified file is opened for subsequent graphics output.

HP-GL Only

Under UNIX, if you wish to send HP-GL output directly to a plotter without generating an intermediate file, you should specify the device special file for the plotter as the argument to FILENAME. For example, if your plotter is connected to a serial input/output port known on your system as `/dev/ttya`, you would issue the command:

```
DEVICE, FILENAME='/dev/ttya'
```

All subsequent HP-GL output is sent directly to the plotter connected to serial port `/dev/ttya`.

FLOYD

(PCL, X)

Set this keyword to select the Floyd-Steinberg method of dithering. This algorithm distributes the error, due to displaying intermediate shades in either black or white, to surrounding pixels. This method generally gives the most pleasing results but requires the most computer time.

FONT_INDEX

(PS)

An integer representing the font index to be mapped to the current PostScript font.

Normally the font specification keywords (AVANTGARDE, etc.) take effect immediately to change the current font. The FONT_INDEX keyword alters this behavior. The current font is not changed. Instead, the specified font is mapped to the specified font index. This mapping can then be used within text strings to change the font in the middle of the string. See “Using PostScript Fonts” on page 3823

FONT_SIZE

(PS)

The default height used for displayed text. FONT_SIZE is given in points (a common typesetting unit of measure). The default size is 12 point text.

GET_CURRENT_FONT

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the name of the current font is returned as a scalar string. A null string is returned if the Windows font is the default font. If the current device is PRINTER or METAFILE, the current font is returned.

GET_DECOMPOSED

(WIN, X)

Set this keyword to a named variable in which is returned the current state of the decomposed flag in the current direct graphics device.

GET_FONTNAMES

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which a string array containing the names of available fonts is returned. If no fonts are found, a null scalar string is returned. This keyword must be used in conjunction with the SET_FONT keyword. Set the SET_FONT keyword to a scalar string containing the name of the desired font or to a wildcard. For example, the following command will return in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

GET_FONTNUM

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the number of fonts available to your installation is returned. This keyword must be used in conjunction with the SET_FONT keyword. Set the SET_FONT keyword to a scalar string containing the name of the desired font or a wildcard. For example, the following command will return in the variable `numfonts` the number of available fonts:

```
DEVICE, GET_FONTNUM=numfonts, SET_FONT='*'
```

GET_GRAPHICS_FUNCTION

(WIN, X, Z)

Set this keyword to a named variable that returns the value of the current graphics function (which is set with the SET_GRAPHICS_FUNCTION keyword). This can be used to remember the current graphics function, change it temporarily, and then restore it. See “SET_GRAPHICS_FUNCTION” on page 3797 keyword for an example.

GET_PAGE_SIZE

(PRINTER)

Set this keyword to a named variable in which to return a two-element vector that contains the width and height of the page size in pixels.

GET_SCREEN_SIZE

(WIN, X)

Set this keyword to a named variable in which to return a two-word array that contains the width and height of the server’s screen, in pixels.

GET_VISUAL_DEPTH

(WIN, X)

Set this keyword to a named variable into which a long integer is returned containing the depth of the visual associated with this device. Under X, if the X server is not connected when you call the DEVICE procedure with this keyword set, a new connection is made.

GET_VISUAL_NAME

(WIN, X)

Set this keyword equal to a named variable in which a string containing the name of the current visual class IDL is using is returned. Possible return values are:

- StaticGray (X only)
- GrayScale (X only)
- StaticColor (X only)
- PseudoColor
- TrueColor
- DirectColor (X only)

Under X, if no connection to the X server has been established when the DEVICE procedure is called with this keyword set, a new connection is made.

GET_WINDOW_POSITION

(WIN, X)

Set this keyword to a named variable that returns a two-element array containing the (X,Y) position of the lower left corner of the current window on the screen. The origin is also in the lower left corner of the screen.

GET_WRITE_MASK

(WIN, X)

Specifies the name of a variable to receive the current value of the write mask.

GIN_CHARS

(TEK)

The number of characters IDL is to read when accepting a GIN (Graphics INput) report. The default is 5. If your terminal is configured to send a carriage return at the end of each GIN report, set this parameter to 6. If the number of GIN characters is too large, the IDL CURSOR procedure will not respond until two or more keys are struck. If it is too small, the extra characters sent by the terminal will appear as input to the next IDL prompt.

GLYPH_CACHE

(METAFILE, PRINTER, PS, WIN, Z)

Set this keyword to a scalar specifying the maximum number of glyphs to cache at any given time. The first time a glyph from a TrueType font is used, it is tessellated into triangles. These triangles are cached so that the tessellation step is not repeated for each use of that glyph. If the glyph cache fills, the least used glyph will be released before a new glyph is generated and cached. The default is 256.

HELVETICA

(PS)

Set this keyword to select the Helvetica PostScript font.

INCHES

(HP, METAFILE, PCL, PRINTER, PS)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if INCHES is present and non-zero, they are taken to be in inches instead.

INDEX_COLOR

(METAFILE, PRINTER)

Set this keyword to place the printer or MetaFile device in index color mode. This is the default. This keyword is applicable only when the printer or MetaFile device is selected.

ISOLATIN1

(PS)

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters.

ITALIC

(PS)

Set this keyword to specify that the italic version of the current PostScript font should be used.

LANDSCAPE

(HP, PCL, PRINTER, PS)

IDL normally generates plots with portrait orientation (the abscissa is along the short dimension of the page). If the LANDSCAPE keyword is set, landscape orientation (abscissa along the long dimension of the page) is used instead. Note that explicitly setting LANDSCAPE=0 is the same as setting the PORTRAIT keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to landscape layout is started.

Note

The ability to set a printer to landscape mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

LANGUAGE_LEVEL

(PS)

Set this keyword to indicate the language level of the PostScript output that is to be generated by the device. Valid values include 1 (the default) and 2 (required for some features, such as filled patterns for polygons).

LIGHT

(PS)

Set this keyword to specify that the light version of the current PostScript font should be used.

MEDIUM

(PS)

Set this keyword to specify that the medium version of the current PostScript font should be used.

NARROW

(PS)

Set this keyword to specify that the narrow version of the current PostScript font should be used.

NCAR

(CGM)

Set this keyword to set the encoding type for the CGM output file to NCAR binary.

The NCAR Binary Encoding

The NCAR binary encoding is used exclusively by the NCAR graphics package. Version 3.01 of NCAR View (`ctrans`, `ictrans`, and `cgm2ncgm`) does not correctly handle the following graphic elements:

- Cell arrays (raster images) with an odd number of pixels in the X dimension. Solution: specify an even number of pixels for the X dimension or make the image one column wider and fill with zeros.
- Raster images drawn in top down order. Solution: invert the image prior to using TV or TVSCL and do not use the /ORDER keyword. For example:

```
TV, image
; Draw image top to bottom:
TV, ROTATE(image, 7)
```

OBLIQUE

(PS)

Set this keyword to specify that the oblique version of the current PostScript font should be used.

OPTIMIZE

(PCL)

It is desirable, though not always possible, to compress the size of the PCL output file. Such optimization reduces the size of the output file, and improves I/O speed to the printer. There are three levels of optimization:

Value	Description
0	No optimization is performed. This is the default because it will work with any PCL device. However, users of devices which can support optimization should use one of the other optimization levels.

Table G-6: PCL Optimization Values

Value	Description
1	Optimization is performed using PCL optimization primitives. This gives the best output compression and printing speed. Unfortunately, not all PCL devices support it. On those that can't, the result will be garbage printed on the page. Consult the programmers manual for your printer to determine if it supports the required escape sequences. The required sequences are: `<ESC>*b0M` (select full graphics mode), `<ESC>*b1M` (select compacted graphics mode 1), and `<ESC>*b2M` (select compacted graphics mode 2). The HP LaserJet II does not support this optimization level. The DeskJet PLUS does.
2	IDL attempts to optimize the output by explicitly moving the left margin and then outputting non-blank sections of the page. This is primarily intended for use with the LaserJet II, which does not support optimization level 1. Note: This optimization can be very slow on some devices (such as the DeskJet PLUS). On such devices, it is best to avoid this optimization level.

Table G-6: PCL Optimization Values (Continued)

ORDERED

(PCL, X)

Set this keyword to select the ordered dither method. This introduces a pseudo-random error into the display by using a 4 by 4 "dither" matrix, yielding 16 apparent intensities. This is the default method.

OUTPUT

(HP, PS)

Specifies a scalar string that is sent directly to the graphics output file without any processing, allowing the user to send arbitrary commands to the file. Since IDL does not examine the string, it is the user's responsibility to ensure that the string is correct for the target device.

PALATINO

(PS)

Set this keyword to select the Palatino PostScript font.

PIXELS

(PCL)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if the PIXELS keyword is set, they are taken to be in pixels instead. Note that the selected resolution will determine how large a region is actually written on the page.

PLOT_TO

(REGIS, TEK)

Directs the Tektronix graphic output that would normally go to the user's terminal to the specified I/O unit. The logical unit specified should be open with write access to a device or file. Graphic output may be saved in files for later playback, redirected to other terminals, or to devices that can accept Textronix graphic commands.

Do not use the interactive graphics cursor when graphic output is not directed to your terminal.

To direct the graphic data to both the terminal and the file, set the unit to the negative of the actual unit number. Alternatively, you can use the TTY keyword, described below.

If the specified unit number is zero then Tektronix output to the file is stopped.

PLOTTER_ON_OFF

(HP)

There are some configurations in which a HP-GL plotter is connected between the computer and a terminal. In this mode (known as eavesdrop mode), the plotter ignores everything it is sent and passes it through to the terminal—the plotter is logically off. This state continues until an escape sequence is sent that turns the plotter logically on. At this point the plotter interprets and executes all input as HP-GL commands. Another escape sequence is sent at the end of the HP-GL commands to return the plotter to the logically off state.

Most configurations do not use eavesdrop mode, and the plotter is always logically on. However, if you are using this style of connection, you must use PLOTTER_ON_OFF to instruct IDL to generate the necessary on/off commands. If present and non-zero, PLOTTER_ON_OFF causes each output page to be bracketed by device control commands that turn the plotter logically on and off. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

POLYFILL

(HP)

Some plotters (e.g., HP7550A) can perform polygon filling in hardware, while others (e.g., HP7475) cannot. IDL therefore assumes that the plotter cannot, and generates all polygon operations in software using line drawing. Specifying a non-zero value for the POLYFILL keyword causes IDL to use the hardware polygon filling. Setting it to zero reverts to software filling.

Different implementations of HP-GL plotters may have different limits for the number of vertices that can be specified for a polygon region before the plotter runs out of internal memory. Since this limit can vary, the HP-GL driver cannot check for calls to POLYFILL that specify too many points. Therefore, it is possible for the user to produce HP-GL output that causes an error when sent to the plotter. To avoid this situation, minimize the number of points used. On the HP7550A, the limit is about 127 points. If you do generate output that exceeds the limit imposed by your plotter, you will have to break that polygon filling operation into multiple smaller operations.

PORTRAIT

(HP, PCL, PRINTER, PS)

Set the PORTRAIT keyword to generate plots using portrait orientation. Portrait orientation is the default. Note that explicitly setting PORTRAIT=0 is the same as setting the LANDSCAPE keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to portrait layout is started.

Note

The ability to set a printer to portrait mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

PRE_DEPTH

(PS)

Set this keyword to a value indicating the bit depth to be used for the preview in the PostScript file. Valid values are 1 (for black and white preview) and 8 (for 8-bit grayscale preview). This keyword applies only if the PREVIEW keyword is nonzero. The default depth is 8.

PRE_XSIZE

(PS)

Set this keyword to the width to be used for the preview in the PostScript file. PRE_XSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, "A Note About Preview Dimensions".

PRE_YSIZE

(PS)

Set this keyword to the height to be used for the preview in the PostScript file. PRE_YSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, "A Note About Preview Dimensions".

PREVIEW

(PS)

Set this keyword to 1 to add a platform-independent preview to the PostScript output file in encapsulated PostScript interchange format (EPSI). EPSI is an ASCII format. Set this keyword to 2 to write the EPS file in EPSF format, including an on-screen preview that is supported by many Windows applications, e.g. MSWord. The default (0) is to not include a preview.

Note

EPSF is not an ASCII format and cannot be sent directly to a Postscript printer, unlike the EPSI format. It must be imported into an application for printing.

A Note About Preview Dimensions

Different applications may utilize the information within a PostScript file in different ways when displaying a screen preview. Some applications will ignore the preview contents entirely, and simply use the primary PostScript contents to generate a screen preview. Other applications will use the preview data and its corresponding dimensions for screen display. Still others will use the preview data and stretch it to the dimensions of the primary PostScript contents. It is therefore recommended that the target application (into which the encapsulated PostScript file is to be loaded) be

considered when selecting an appropriate XSIZE, YSIZE, PRE_XSIZE, and PRE_YSIZE.

PRINT_FILE

(WIN)

Set this keyword to the name of a file (e.g., PostScript or PCL) to be sent to the currently-selected Windows printer. IDL performs no type checking on this file before sending it to the printer. Therefore, if you have a PostScript printer selected and you send a file that contains no valid PostScript information, you'll simply get text output.

To send the file `myfile.ps` to the currently-selected Windows printer, enter:

```
DEVICE, PRINT_FILE='myfile.ps'
```

PSEUDO_COLOR

(X)

If this keyword is present, the PseudoColor visual is used. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3838.

RESET_STRING

(TEK)

The string used to place the terminal back into the normal interactive mode after drawing graphics. Use this parameter, in conjunction with the SET_STRING keyword, to control the mode switching of your terminal.

For example, the GraphON 200 series terminals require the string `<ESC>2` to activate the alphanumeric window after drawing graphics. The call to set this is:

```
DEVICE, RESET = string(27b) + '2'
```

If the 4100 series mode switch is set, using the keyword TEK4100, the default mode resetting string is `<ESC>%!1`, which selects the ANSI code mode.

RESOLUTION

(PCL)

PCL Only

The resolution at which the PCL printer will work. PCL supports resolutions of 75, 100, 150, and 300 dots per inch. The default is 300 dpi. Lower resolution gives smaller output files, while higher resolution gives superior quality.

RETAIN

(WIN, X)

Use this keyword to specify the default method used for backing store when creating new windows. This is the method used when the RETAIN keyword is not specified with the WINDOW procedure. Backing store is discussed in more detail under "Backing Store" on page 3806, along with the possible values for this keyword. If RETAIN is not used to specify the default method, method 1 (server-supplied backing store) is used.

Microsoft Windows Only

The initial value of this parameter can be set by selecting File-Preferences from the menu bar. See "Backing Store" on page 3806.

A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See "Unexpected Results Using TVRD with X Windows" on page 1971.

SCALE_FACTOR

(PRINTER, PS)

Specifies a scale factor applied to the entire plot. The default value is 1.0, allowing output to appear at its normal size. SCALE_FACTOR is used to magnify or shrink the resulting output.

The SCALE_FACTOR keyword behaves slightly differently in the context of the PRINTER device than it does in the context of the PS device.

When the current device is PRINTER, the SCALE_FACTOR keyword is designed to emulate a scalable resolution setting on the printer. For example, if you have a 300 x 300 pixel image—stored in the variable *image*—the following IDL commands will print *image* in a 0.5 inch square on a 600 dpi printer:

```
SET_PLOT, 'printer'
TV, image
```

Setting SCALE_FACTOR to 2 will scale the image to a 1 inch square on the same 600 dpi printer:

```
SET_PLOT, 'printer'
DEVICE, SCALE_FACTOR=2
TV, image
```

The output of IDL's Direct Graphics routines (CONTOUR, PLOT, SURFACE, etc.) is automatically scaled to fill the available drawing area. As a result, the following IDL commands will produce two identical copies of the same output on any printer:

```
SET_PLOT, 'printer'
PLOT, data
DEVICE, SCALE_FACTOR=2
PLOT, data
```

SCHOOLBOOK

(PS)

Set this keyword to select the New Century Schoolbook PostScript font.

SET_CHARACTER_SIZE

(CGM, HP, METAFILE, PCL, PRINTER, PS, REGIS, TEK, WIN, X, Z)

Set this keyword equal to a two-element vector to specify the font size and line spacing (leading) of vector and TrueType fonts, and the line spacing of device fonts. The way that the value of this vector determines character size is not completely intuitive.

The vector specified to the SET_CHARACTER_SIZE keyword sets the values of the X_CH_SIZE and Y_CH_SIZE fields in the !D System Variable structure. These values describe the size of the rectangle that contains the "average" character in the current font. (It is not important what the "average" character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the "average" character is determined by the *width* of the rectangle. The aspect ratio of the "average" character remains fixed;

the character is scaled so that its width fits in the specified rectangle. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines (baseline to baseline) is determined explicitly by the height of the rectangle.

For device fonts, the character size is fixed. When the device font system is in use, the first element of the vector specified to SET_CHARACTER_SIZE is silently ignored, and only the line-spacing value is used.

Note

Changing between font systems (and sometimes changing from one font to another within the same font system) can also change the !D structure, so do not assume that the character size you have set is preserved when you change fonts.

SET_COLORMAP

(PCL)

Set this keyword to a 14,739 ($= 3 \cdot 17^3$) element byte vector containing the RGB-to-printer color translation table for a color PCL printer. The default table is for an HP Deskjet 500C printer.

The translation table is divided into red, green, and blue planes of 4913 ($=17^3$) elements each. For a given RGB triple, the offset into each plane is calculated as follows:

```
Offset = (Red/16)*289 + (Green/16)*17 + (Blue/16)
```

Thus, if the RGB triple is [16,32,160], the offset into each plane is 333. The printer will use the value at element 332 of the translation table as the red value, the value at element 5245 (=4913+332) as the green value, and the value at element 10158 (=9826+332) as the blue value.

The following example shows how to scale an existing colortable for use by a PCL printer.

```
; Set the plot window to the X device:
SET_PLOT, 'X'
; Create a window:
WINDOW,0,XS=300,YS=300
; Load a color table:
LOADCT,13
; Read color table values into variables:
TVLCT,r,g,b,/GET
; Re-size color table variables:
r2=CONGRID(r,4913)
g2=CONGRID(g,4913)
```

```
b2=CONGRID(b,4913)
; Create 14,739-element color map:
colormap=[r2,g2,b2]
; Change to the PCL device:
SET_PLOT, 'PCL'
; Set file name, resolution, color, and color map:
DEVICE, FILE = 'pcl.pcl', RESOLUTION = 300, $
    /COLOR, SET_COLORMAP = colormap
; Display an image:
TVSCL,DIST(900)
; Close the device:
DEVICE,/CLOSE
```

Note

The color table used need not be one of IDL's predefined tables.

SET_COLORS

(Z)

Sets the number of pixel values, !D.N_COLORS and !D.TABLE_SIZE. This value is used by a number of IDL routines to determine the scaling of pixel data and the default drawing index. Allowable values range from 2 to 256, and the default value is 256. Use this parameter to make the Z-buffer device compatible with devices with fewer than 256 colors indices.

SET_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to a scalar string specifying the name of the font used when a hardware or TrueType font is selected. Note that hardware fonts cannot be rotated, scaled, or projected, and that the "!" commands for formatting may not work. When generating three-dimensional plots, it is best to use the vector-drawn or TrueType characters. Note that for the PS device, only one hardware font (other than the predefined fonts set via the fontname keywords, such as /AVANTEGARDE) may be loaded at a time.

Note on the FONT Keyword

The SET_FONT keyword was introduced with IDL version 5.1 and replaces the FONT and USER_FONT keywords used in previous versions.

Using TrueType Fonts

For TrueType fonts, the specified font name must exactly match one of the names in the first column of the `ttfont.map` file in the `resource/fonts/tt` directory or

(on Windows platforms) the name of an installed font. See “About TrueType Fonts” on page 3935 for details on the `ttfont.map` file and for a listing of TrueType fonts distributed with IDL. Note that you must include the TT_FONT keyword to indicate that the font specified is a TrueType font. For example, the following sets the font to the font to the TrueType font Helvetica Bold Italic:

```
DEVICE, SET_FONT='Helvetica-BoldItalic'
```

Note

You can append additional TrueType fonts to the `ttfont.map` file if desired; on Windows platforms, additional fonts can also be added via the normal font installation procedures for your system. Research Systems cannot guarantee that TrueType fonts you add will be satisfactorily tessellated or displayed. See “About TrueType Fonts” on page 3935 for details.

Using Hardware Fonts

Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. X Windows users can use the `xlsfonts` command to list available X Windows fonts.

On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

Microsoft Windows

The SET_FONT keyword should be set to a string with the following form:

```
DEVICE, SET_FONT='font*modifier1*modifier2*...modifiern'
```

where the asterisk (*) acts as a delimiter between the font’s name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE

- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = 'GARAMOND*ITALIC*24'
PLOT, FINDGEN(10), TITLE = 'IDL Plot'
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

SET_GRAPHICS_FUNCTION

(WIN, X, Z)

Most window systems allow applications to specify the graphics function. This is a logical function which specifies how the source pixel values generated by a graphics operation are combined with the pixel values already present on the screen. The complete list of possible values is given in the following table:

Logical Function	Code	Definition
GXclear	0	0
GXand	1	source AND destination
GXandReverse	2	source AND (NOT destination)
GXcopy	3	source
GXandInverted	4	(NOT source) AND destination
GXnoop	5	destination
GXxor	6	source XOR destination
GXor	7	source OR destination

Table G-7: Graphic Function Codes

Logical Function	Code	Definition
GXnor	8	(NOT source) AND (NOT destination)
GXequiv	9	(NOT source) XOR destination
GXinvert	10	(NOT destination)
GXorReverse	11	source OR (NOT destination)
GXcopyInverted	12	(NOT source)
GXorInverted	13	(NOT source) OR destination
GXnand	14	(NOT source) OR (NOT destination)
GXset	15	1

Table G-7: Graphic Function Codes (Continued)

The default graphics function is GXcopy, which causes new pixels to completely overwrite any previous pixels. Not all functions are available on all window systems.

For example, the following code segment inverts the bottom bit in the rectangle defined by its diagonal corners (x_0, y_0) and (x_1, y_1):

```
; Set graphics function to exclusive or (GXor), and save the
; old function:
DEVICE, GET_GRAPHICS_FUNCTION = oldg, SET_GRAPHICS_FUNCTION = 6
; Use POLYFILL to select the area to be inverted. The source
; pixel value is 1:
POLYFILL, [[x0,y0], [x0,y1], [x1,y1], [x1,y0]], $
   /DEVICE, COLOR=1
; Restore the previous graphics function:
DEVICE, SET_GRAPHICS_FUNCTION=oldg
```

SET_RESOLUTION

(Z)

Set this keyword to a two-element vector that specifies the width and height of the Z-buffers. The default size is 640 by 480. If this size is not the same as the existing buffers, the current buffers are destroyed and the device is reinitialized.

SET_STRING

(TEK)

The string used to place the terminal into the graphics mode from the normal interactive terminal mode. If the 4100 series mode switch is set, using the keyword TEK4100, the default graphic mode setting string is `<ESC>%!0`, which selects the Tektronix code mode.

SET_TRANSLATION

(X)

This keyword can be used to allow multiple, simultaneous IDL sessions to use the same colors from a shared colormap. Use this keyword before the X connection is established (i.e., before a window is created), IDL will use the shared color map without allocating any additional colors, and will not load a grayscale ramp as is usually done when the X server starts up. The following example shows two cooperating IDL processes sharing the same colormap:

Execute the following commands in the first IDL session:

```
WINDOW, GET_X_ID = a
DEVICE, TRANSLATION = t
OPENW, 1, 'junk.dat'
WRITEU, 1, a, !D.N_COLORS, t[0:!D.N_COLORS-1]
CLOSE, 1
LOADCT, 3
```

Execute the following commands in the second IDL session:

```
OPENR, 1, 'junk.dat'
a=0L
n=0L
READU,1, a, n
t = BYTARR(n)
READU, 1, t
CLOSE, 1
DEVICE, SET_TRANSLATION = t
WINDOW, COLORS=n, SET_X_ID=a
TV, DIST(256)
```

SET_WRITE_MASK

(X, Z)

Sets the write mask to the specified value. For an *n*-bit system, the write mask can range from 0 to 2^n-1.

STATIC_COLOR

(X)

Use this keyword to select the X Windows StaticColor visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3838.

STATIC_GRAY

(X)

Use this keyword to select the X Windows StaticGray visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3838.

SYMBOL

(PS)

Set this keyword to select the Symbol PostScript font.

TEK4014

(TEK)

Set this keyword to specify that coordinates are to be output with full 12-bit resolution. If this keyword is not present or is zero, 10-bit coordinates are output. Normally, IDL sends 10-bit coordinates. 12-bit coordinates are compatible with most terminals, even those without the full resolution, but require more characters to send.

Note

The 4014 and the 4100 modes can be used together. The coordinate system IDL uses for the Tektronix is 0 to 4095 in the X direction and 0 to 3120 in the Y direction, even when not in the 4014 mode. In the 10-bit case the internal coordinates are divided by 4 prior to output.

TEK4100

(TEK)

Set this keyword to indicate that the terminal is a 4100 or 4200 series terminal. The use of color, ANSI and Tektronix mode switching, hardware line styles, and pixel

output with the TV procedure is supported with these terminals. Also, text is output differently.

TEXT

(CGM)

Set this keyword to set the encoding type for the CGM output file to text.

THRESHOLD

(PCL, X)

Set this keyword to select the threshold algorithm—the simplest dithering method. The value of this keyword is the threshold to be used. This algorithm simply compares each pixel against the given threshold, usually 128. If the pixel equals or exceeds the threshold the display pixel is set to white, otherwise it is black.

TIMES

(PS)

Set this keyword to select the Times-Roman PostScript font.

TRANSLATION

(WIN, X)

As discussed in “Shared Colormaps” on page 3841, using the shared colormap (normally recommended) causes IDL to translate between IDL color indices (which always start with zero and are contiguous) and the pixel values actually present in the display. The TRANSLATION keyword specifies the name of a variable to receive the translation vector. To read the translation table, use the command:

```
DEVICE, TRANSLATION=TRANSARR
```

where TRANSARR is a named variable into which the translation array is stored. The result is a 256-element byte vector. Element zero of the vector contains the pixel value allocated for the first color in the IDL colormap, and so forth.

Microsoft Windows Only

This keyword is accepted by the WIN device, for compatibility with the X Windows driver, but simply returns a 256-element vector where each element has the value of its subscript (0 to 255).

TRUE_COLOR

(METAFILE, PRINTER, X)

Use this keyword to select TrueColor visuals. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3838. If the current device is PRINTER or METAFILE, the printer is placed in RGB or TrueColor mode if the value of the TRUE_COLOR keyword is greater than zero (the number of bits per pixel specified is ignored.)

TT_FONT

(METAFILE, PRINTER, WIN, X, Z)

Set this keyword to indicate that the font set via the SET_FONT keyword (either to set the fontname or to retrieve fontnames in conjunction with the GET_FONTNAMES or GET_FONTNUM keywords) should be treated as a TrueType font.

TTY

(REGIS, TEK)

Set this keyword to specify that output should be sent to the terminal at the same time that it is being sent to a file due to the FILENAME or PLOT_TO keywords. A zero value causes output to go only to the file. If no output file is in use, this keyword has no effect.

USER_FONT

(PS)

This keyword is now obsolete and has been replaced by the SET_FONT keyword. Code that uses the USER_FONT keyword will continue to function as before, but we suggest that all new code use SET_FONT.

VT240, VT241

(REGIS)

Set this keyword to configure the REGIS device for VT240 series terminals.

VT340, VT341

(REGIS)

Set this keyword to configure the REGIS device for VT340 series terminals.

WINDOW_STATE

(WIN, X)

Set this keyword to a named variable that returns an array containing one element for each possible window. Array element *i* contains a 1 if window *i* is open, otherwise it contains a 0.

XOFFSET

(HP, PCL, PRINTER, PS)

Specifies the X position, on the page, of the lower left corner of output generated by IDL. XOFFSET is specified in centimeters, unless INCHES is specified. See "Positioning Graphics Output" on page 3810.

PostScript Only

SCALE does not affect the value of XOFFSET.

XON_XOFF

(HP)

If present and non-zero, XON_XOFF causes each output page to start with device control commands that instruct the plotter to obey xon/xoff (^S/^Q) style flow control. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

Such handshaking is the default. To turn it off, use the command

```
DEVICE, XON_XOFF=0
```

Often, it is not necessary to tell the plotter to obey flow control because the printing facilities on the system handle such details for you, but it is usually harmless.

XSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the width of output generated by IDL. XSIZE is specified in centimeters, unless INCHES is specified.

PostScript Only

SCALE modifies the value of XSIZE. Hence, the following statement:

```
DEVICE,/INCHES,XSIZE=7.0,SCALE_FACTOR=0.5
```

results in a real width of 3.5 inches.

Also see "A Note About Preview Dimensions" on page 3790.

YOFFSET

(HP, PCL, PRINTER, PS)

Specifies the Y position, on the page, of the lower left corner of output generated by IDL. YOFFSET is specified in centimeters, unless INCHES is specified. See "Positioning Graphics Output" on page 3810.

Note

The corner of the page from which the Y offset is measured (lower or upper left) differs on various devices. Read the device specific information in the following sections to determine how this is handled for your device.

PostScript Only

SCALE does not affect the value of YOFFSET.

YSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the height of output generated by IDL. YSIZE is specified in centimeters, unless INCHES is specified.

PostScript Only

SCALE modifies the value of YSIZE. Hence, the following statement:

```
DEVICE,/INCHES,YSIZE=5.0,SCALE_FACTOR=0.5
```

results in a real width of 2.5 inches.

Also see "A Note About Preview Dimensions" on page 3790.

ZAPFCHANCERY

(PS)

Set this keyword to select the ITC Zapf Chancery PostScript font.

ZAPFDINGBATS

(PS)

Set this keyword to select the ITC Zapf Dingbats PostScript font.

Z_BUFFERING

(Z)

This keyword enables and disables the Z-buffering. If this keyword is specified with a zero value, the driver operates as a standard 2-D device, the Z-buffering is disabled, and the Z-buffer (if any) is deallocated. Setting this keyword to one (the default value), enables the Z-buffering.

To disable Z-buffering enter:

```
DEVICE, Z_BUFFERING = 0
```

Window Systems

The different window systems supported by IDL have many features in common. This section describes those features. See the individual descriptions of each system later in this chapter for additional information about each one.

IDL utilizes the window system by creating and using one or more largely independent windows, each of which can be used for the display of graphics and/or images. One color map table is shared among all these windows. Multiple windows can be active simultaneously. Windows are referenced using their index which is a non-negative integer.

“Dithering” or halftoning techniques are used to display images with multiple shades of gray on monochrome displays—displays that can only display white or black. This topic is discussed in “Image Display On Monochrome Devices” on page 3808.

Graphic and image output is always directed to the current window. When a window system is selected as the current IDL graphics device, the index number of the current window is found in the !D.WINDOW system variable. This variable contains -1 if no window is open or selected. The WSET procedure is used to change the current window. WSHOW hides, displays, and iconifies windows. WDELETE deletes a window.

The WINDOW procedure creates a new window with a given index. If a window already exists with the same index, it is first deleted. The size, position, title, and number of colors, may also be specified. If you access the display before creating the first window, IDL automatically creates a window with an index number of 0 and with the default attributes.

Backing Store

One of the features that distinguishes various window systems is how they handle the issue of backing store. When part of a window that was previously not visible is exposed, there are two basic approaches that a window system can take. Some keep track of the current contents of all windows and automatically repair any damage to their visible regions (retained windows). This saved information is known as the backing store. Others simply report the damage to the program that created the

window and leave repairing the visible region to the program (non-retained windows).

Value	Description
0	No backing store.
1	Request the server or window system to perform backing store.
2	Make IDL perform backing store.

Table G-8: Allowed Values for the RETAIN Keyword

There are convincing arguments for and against both approaches. It is generally more convenient for IDL if the window system handles this problem automatically, but this often comes at a performance penalty. The actual cost of retained windows varies between systems and depends partially on the application.

The X Window system does not by default keep track of window contents. Therefore, when a window on the display is obscured by another window, the contents of its obscured portion is lost. Re-exposing the window causes the X server to fill the missing data with the default background color for that window, and request the application to redraw the missing data. Applications can request a backing store for their windows, but servers are not required to provide it. Many X servers do not provide backing store, and even those that do cannot necessarily provide it for all requesting windows. Therefore, requesting backing store from the server might help, but there is no certainty.

The IDL window system drivers allow you to control the issue of backing store using the RETAIN keyword to the DEVICE and WINDOW procedures. Using it with DEVICE allows you to set the default action for all windows, while using it with WINDOW lets you override the default for the new window. The possible values for this keyword are summarized under "Backing Store" on page 3806, and are described below:

- Setting the RETAIN keyword to 0 specifies that no backing store is kept. In this case, exposing a previously obscured window leaves the missing portion of the window blank. Although this behavior can be inconvenient, it usually has the highest performance because there is no need to keep a copy of the window contents.
- Setting the RETAIN keyword to 1 causes IDL to request that a backing store be maintained. If the window system decides to accept the request, it will automatically repair the missing portions when the window is exposed. X

Windows may or may not provide backing store when requested, depending on the capabilities of the server and the resources available to it.

- Setting the RETAIN keyword to 2 specifies that IDL should keep a backing store for the window itself, and repair any window damage when the window system requests it. This option exists for X Windows. In this case, a pixmap (off-screen display memory) the same size as the window is created at the same time the window is created, and all graphics operations sent to the window are also sent to the pixmap. When the server requests IDL to repair freshly exposed windows, this pixmap is used to fill in the missing contents. Pixmaps are a precious resource in the X server, so backing pixmaps should only be requested for windows with contents that must absolutely be preserved.

If the type of backing store to use is not explicitly specified using the RETAIN keyword, IDL assumes option 1 and requests the window system to keep a backing store.

A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See “Unexpected Results Using TVRD with X Windows” on page 1971.

Image Display On Monochrome Devices

Images are automatically dithered when sent to some monochrome devices. Dithering is a technique which increases the number of apparent brightness levels at the expense of spatial resolution. Images with 256 gray levels are displayed on a display with only two colors, black and white, using halftoning techniques. PostScript handles dithering directly. IDL supports dithering for other devices if their DEVICE procedures accept the FLOYD, ORDERED, or THRESHOLD keywords.

Printing Graphics Output Files

For printer and plotter devices (e.g., PCL, PostScript, and HP-GL), IDL creates a file containing output commands. This file can be sent to the printer via the normal methods provided by the local operating system. When attempting to output the file before exiting IDL, the user must be sure that the graphics output file is complete. For example, the following IDL commands (executed under UNIX) will not produce the desired result:

```
SET_PLOT,'PS'
PLOT,x,y
SPAWN,'lpr idl.ps'
```

These commands fail because the attempt to print the file is premature—the file is still open within IDL and is not yet complete.

The following lines of code are an IDL procedure called OUTPUT_PLOT which closes the current graphics file and sends it to the printer. This routine assumes that the graphics output file is named `idl.xxx`, where `xxx` represents the name of the graphics driver. For example, PostScript output file is assumed to be `idl.ps`. It also assumes that the graphics output to be printed is from the current graphics device, as selected with SET_PLOT.

```
; Close the current graphics file, and print it. If the
; New_file parameter is present, rename the file to the given
; name so it won't be overwritten:
Pro OUTPUT_PLOT, New_file
; Close current graphics file:
DEVICE,/CLOSE
; Build the default output file name by using the idl name for
; the current device (!D.NAME):
file = 'idl.' + STRLOWCASE(!D.NAME)
; Build shell commands to send file to the printer.
; You will probably have to change this command in accordance
; with local usage:
cmd = 'lpr ' + file
; Concatenate rename command if new file specified:
IF N_ELEMENTS(New_file) GT 0 THEN $
   cmd = cmd + '; mv' + file + ' ' + New_file
; Issue shell commands to print/rename file:
SPAWN, cmd
END
```

The call to DEVICE causes IDL to finish the file and close it, which makes it available for printing.

Setting Up The Printer

In order for IDL generated output files to work properly with printers and plotters, it is necessary for the device to be configured properly. This usually involves configuring both the device hardware and the operating system printing software. When setting up your system, keep the following points in mind:

- The device and computer must use some form of flow control to prevent the computer from sending data faster than the printing device can handle it. The most common form of flow control is known as XON/XOFF, and involves the sending of Control-S (off) and Control-Q (on) characters from the device to the printer to manage the flow of data.

  Many printers have a large buffer into which they store incoming data they haven't yet processed. This reduces the need to invoke flow control. When testing your configuration to ensure flow control is actually enabled, you must be sure to print a document long enough to fill any such buffer, or flow control may never occur, giving a false impression that the setup is correct. A common source of problems stem from attempting to print long IDL generated output files without proper flow control.

- Some devices (such as PCL) require an eight-bit data path, while others (such as PostScript) do not. For devices that do, it is important to ensure that the printer port and system printing software provide such a connection.

  If you are having problems printing on a PostScript printer, the `ehandler.ps` file in the `resource/fonts/ps` subdirectory of the IDL distribution can help you to debug your problem. Sending this file to your PostScript Printer causes it to print any subsequent errors it encounters on a sheet of paper and eject it. The effect of this file lasts until the printer is reset.

Setting Up Printers Under UNIX

Printers are configured in the `/etc/printcap` file. This file describes to the system which printers are connected to it, the characteristics of each printer, and how the printer port should be configured. Managing the printcap file is usually discussed in the system management documentation supplied with the system by the manufacturer.

Positioning Graphics Output

The difference between the XOFFSET and YOFFSET keywords to the DEVICE procedure, and the higher level plot positioning keywords and system variables (discussed in Appendix H, "Graphics Keywords" and Chapter 17, "Direct Graphics

Plotting" in the *Using IDL* manual) can lead to confusion. A common misunderstanding is to attempt to use the DEVICE procedure "offset" and "size" keywords multiple times in an attempt to produce multiple plots on a single output page.

The DEVICE keywords are intended to specify the size and position of the entire output area on the page, not to move the plotting region for multiple plots. The driver does not monitor their values continuously, but only when initializing a new page or ejecting the current one.

The proper way to produce multiple plots is to use the high level positioning abilities. The !P.MULTI, !P.POSITION, and !P.REGION system variables can be used to position individual plots on the page. The plotting routines also accept the POSITION, MARGIN and REGION keywords.

Image Background Color

Graphical output that is displayed with a black background on a monitor frequently look better if the background is changed to white when printed on white paper. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

The CGM Device

Device Keywords Accepted by the CGM Device:

BINARY, CLOSE_FILE, COLORS, ENCODING, FILENAME, NCAR, SET_CHARACTER_SIZE, TEXT

The CGM, Computer Graphics Metafile, standard describes a device independent file format used for the exchange of graphic information. The IDL CGM driver produces CGM files encoded in one of three methods: *Text*, *Binary* or *NCAR Binary*. To direct graphics output to a CGM file, issue the command:

```
SET_PLOT,'CGM'
```

This causes IDL to use the CGM driver for producing graphical output. Once the CGM driver is selected, the DEVICE procedure controls its actions, as described below. Typing `HELP, /DEVICE` displays the current state of the CGM driver. The CGM driver defaults to the binary encoding using 256 colors.

Abilities and Limitations

This section describes details specific to IDL's CGM implementation:

- IDL uses the CGM default integer encoding for graphic primitives. Coordinate values range from 0 to 32767. It is advisable to use the values stored in !D.X_SIZE and !D.Y_SIZE instead of assuming a fixed coordinate range.
- Color information is output with a resolution of 8 bits (color indices and intensity values range from 0 to 255).
- The definition of background color in the CGM standard is somewhat ambiguous. According to the standard, color index 0 and the background color are the same. Because background color is specified in the metafile as a color value (RGB triple), not an index, it is possible to have the background color not correspond with the color value of index 0.
- The CGM BACKGROUND_COLOUR attribute is explicitly set by IDL only during an erase operation: changing the value of the color map at index 0 does not cause IDL to generate a BACKGROUND_COLOUR attribute until the next ERASE occurs. An ERASE command sets the background color to the value in the color map at index 0. The command `ERASE, INDEX` (where INDEX is not 0) generates the message "`Value of background color is out of allowed range.`" For consistent results, modify the color table before any graphics are output.

- The CGM standard uses scalable (variable size) pixels for raster images. By default, the TV and TVSCL procedures output images, regardless of size, using the entire graphics output area. To output an image smaller than the graphics output area, specify the XSIZE and YSIZE keywords with the TV and TVSCL procedures. For example:

```
; Select the CGM driver:
SET_PLOT, 'CGM'
; Create a 64 x 64 element array:
X = DIST(64)
; Display the image (fills entire screen):
TVSCL, X
; Now display 4 images on the screen:
ERASE
XS = !D.X_SIZE / 2 ; Size of each image, X dimension
YS = !D.Y_SIZE / 2 ; Size of each image, Y dimension
TVSCL, X, 0, XSIZE=XS, YSIZE=YS ; Upper left
TVSCL, X, 1, XSIZE=XS, YSIZE=YS ; Upper right
TVSCL, X, 2, XSIZE=XS, YSIZE=YS ; Lower left
TVSCL, X, 3, XSIZE=XS, YSIZE=YS ; Lower right
```

The HP-GL Device

Device Keywords Accepted by the HP-GL Device:

CLOSE_FILE, EJECT, FILENAME, INCHES, LANDSCAPE, OUTPUT, PLOTTER_ON_OFF, POLYFILL, PORTRAIT, SET_CHARACTER_SIZE, XOFFSET, XON_XOFF, XSIZE, YOFFSET, YSIZE

HP-GL (Hewlett-Packard Graphics Language) is a plotter control language used to produce graphics on a wide family of pen plotters. To use HP-GL as the current graphics device, issue the IDL command:

```
SET_PLOT,'HP'
```

This causes IDL to use HP-GL for producing graphical output. Once the HP-GL driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings for the HP-GL driver are shown in the following table. Use the statement:

```
HELP, /DEVICE
```

to view the current state of the HP-GL driver.

Feature	Value
File	idl.hp
Orientation	Portrait
Erase	No action
Polygon filling	Software
Turn plotter logically on/off	No
Specify xon/xoff flow control	Yes
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.

Table G-9: Default HP-GL Driver Settings

Abilities And Limitations

IDL is able to produce a wide variety of graphical output using HP-GL. The following is a list of what is and is not supported:

- All types of vector graphics can be generated, including line plots, contours, surfaces, etc.
- HP-GL plotters can draw lines in different colors selected from the pen carousel. It should be noted that color tables are not used with HP-GL. Instead, each color index refers directly to one of the pens in the carousel.
- Some HP-GL plotters can do polygon filling in hardware. Others can rely on the software polygon filling provided by IDL.
- It is possible to generate graphics using the hardware generated text characters, although such characters do not give much improvement over the standard vector fonts. To use hardware characters, set the !P.FONT system variable to zero, or set the FONT keyword to the plotting routines to zero.
- Since HP-GL is designed to drive pen plotters, it does not support the output of raster images. Therefore, TV and TVSCL do not work with HP-GL.
- Since pen plotters are not interactive devices, they cannot support such operations as cursors and windows.

HP-GL Linestyles

The LINESTYLE graphics keyword allows specifying any of 6 linestyles. HP-GL does not support all of these linestyles, and styles 3 and 4 differ from the definition in Appendix H, “Graphics Keywords”. The following table summarizes the differences:

Index	Normal Line Style	HP-GL Line Style
0	Solid	same
1	Dotted	same
2	Dashed	same
3	Dash Dot	Relative size of dash and dot are different.
4	Dash Dot Dot Dot	Dash Dot Dot
5	Long Dashes	same

Table G-10: Linestyles for the HP-GL Device

The Metafile Display Device

Device Keywords Accepted by the Null Device:

CLOSE_FILE, FILENAME, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GLYPH_CACHE, INCHES, INDEX_COLOR, SET_CHARACTER_SIZE, SET_FONT, TRUE_COLOR, TT_FONT, XSIZE, YSIZE

The Windows Metafile Format (WMF) is used by Windows to store vector graphics in order to exchange graphics information between applications. This format is only available on the Windows platforms. To direct graphics to a file in the WMF format, use the SET_PLOT procedure:

```
SET_PLOT, 'METAFILE'
```

This causes IDL to use the Metafile driver for producing graphical output. Once the Metafile driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions. The default settings are given in the following table:

Feature	Value
File	idl.emf
Mode	N/A
Horizontal offset	N/A
Vertical offset	N/A
Width	7 in.
Height	5 in.
Resolution	Screen

Table G-11: Default Metafile Driver Settings

For example, the following will create a WMF file for a simple plot:

```
;Create X and Y Axis data
x=findgen(10)
y=findgen(10)

;Save current device name
mydevice=!D.NAME
```

```
;Set the device to Metafile
SET_PLOT, 'METAFILE'

;Name the file to be created
DEVICE, FILE='test.emf'

;Create the plot
PLOT, x, y

;Close the device which creates the Metafile
DEVICE, /CLOSE

;Set the device back to the original
SET_PLOT, mydevice
```

The Null Display Device

Device Keywords Accepted by the Null Device:

No keywords are accepted by the DEVICE procedure when the NULL device is selected.

To suppress graphics output entirely, use the null device:

```
SET_PLOT, 'NULL'
```

The PCL Device

Device Keywords Accepted by the PCL Device:

CLOSE_FILE, COLOR, FILENAME, FLOYD, INCHES, LANDSCAPE, OPTIMIZE, ORDERED, PIXELS, PORTRAIT, RESOLUTION, SET_CHARACTER_SIZE, SET_COLORMAP, THRESHOLD, XOFFSET, XSIZE, YOFFSET, YSIZE

PCL (Printer Control Language) is used by Hewlett-Packard laser and ink jet printers to produce graphics output. To direct graphics output to a PCL file, issue the command:

```
SET_PLOT,'PCL'
```

This causes IDL to use the PCL driver for producing graphical output. Once the PCL driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings for the PCL driver are listed in the following table:

Feature	Value
File	idl.pcl
Mode	Portrait
Optimization level	0 (None)
Dither method	Floyd-Steinberg
Resolution	300 dpi
Horizontal offset	1/2 in.
Vertical offset	1 in.
Width	7 in.
Height	5 in.

Table G-12: Default PCL Driver Settings

The PCL device draws into a memory buffer of the specified size (or the default size, if the XSIZE and YSIZE keywords to DEVICE are not specified). Anything drawn outside this buffer will be silently discarded.

Note

Unlike monitors where white is the most visible color, PCL writes black on white paper. Setting the output color index to 0, the default when PCL output is selected, writes in black. A color index of 255 writes white which is invisible on white paper.

Color tables are not used with PCL unless the color mode has been enabled using the COLOR keyword to the DEVICE procedure. For images, color dithering produces realistic color image output even though PCL printers only produce eight output colors. In most cases, simply choosing an appropriate color table (using LOADCT or XLOADCT), or creating a color table from an image (via TVLCT) will work fine. If you need finer control over the colors used, see the SET_COLORMAP keyword for additional information. For vector graphics, only eight colors are supported—no line dithering is implemented. Any RGB component that is not zero is treated as 255. The correct RGB definitions for each color are shown in the following table. Use the `HELP, /DEVICE` command to view the current options for PCL output.

Color	Red Value	Green Value	Blue Value
Red	255	0	0
Green	0	255	0
Blue	0	0	255
Cyan	0	255	255
Magenta	255	0	255
Yellow	255	255	0
Black	0	0	0
White	255	255	255

Table G-13: PCL RGB Color Definitions

The Printer Device

Device Keywords Accepted by the PRINTER Device:

CLOSE_DOCUMENT, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_PAGE_SIZE, INDEX_COLOR, PORTRAIT, SCALE_FACTOR, SET_CHARACTER_SIZE, TRUE_COLOR, XOFFSET, XSIZE, YOFFSET, YSIZE

The PRINTER device allows IDL Direct Graphics to be output to a system printer. To direct graphics output to a printer, issue the command:

```
SET_PLOT, 'printer'
```

This causes IDL to use a printer driver to produce graphical output. By default, the default system printer is used for output. Use the DIALOG_PRINTERSETUP function to define the printing parameters for the printer device. Use the DIALOG_PRINTJOB function to control the print job itself.

Note that the printer device is an IDL Direct Graphics device. Like other Direct Graphics devices, you must change to the new device and then issue the IDL commands that send output to that device. With the printer device, you must use the CLOSE_DOCUMENT keyword to the DEVICE routine to actually initiate the print job and make something come out of your printer.

The PostScript Device

Device Keywords Accepted by the PS Device:

AVANTGARDE, BITS_PER_PIXEL, BKMAN, BOLD, BOOK, CLOSE_FILE, COLOR, COURIER, DEMI, ENCAPSULATED, FILENAME, FONT_INDEX, FONT_SIZE, HELVETICA, INCHES, ISOLATIN1, ITALIC, LANDSCAPE, LIGHT, MEDIUM, NARROW, OBLIQUE, OUTPUT, PALATINO, PORTRAIT, PRE_DEPTH, PRE_XSIZE, PRE_YSIZE, PREVIEW, SCALE_FACTOR, SCHOOLBOOK, SET_CHARACTER_SIZE, SET_FONT, SYMBOL, TIMES, TT_FONT, XOFFSET, XSIZE, YOFFSET, YSIZE, ZAPFCHANCERY, ZAPFDINGBATS

PostScript is a programming language designed to convey a description of a page containing text and graphics. Many laser printers and high-resolution, high-quality photo typesetters support PostScript. Color output or direct color separations can be produced with color PostScript. To direct graphics output to a PostScript file, issue the command:

```
SET_PLOT, 'PS'
```

This causes IDL to use the PostScript driver for producing graphical output. Once the PostScript driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings are given in the following table:

Feature	Value
File	idl.ps
Mode	Portrait, non-encapsulated, no color
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.
Scale factor	1.0
Font size	12 points

Table G-14: Default PostScript Driver Settings

Feature	Value
Font	Helvetica
# Bits / Image Pixel	4

Table G-14: Default PostScript Driver Settings (Continued)

Note

Unlike monitors where white is the most visible color, PostScript writes black on white paper. Setting the output color index to 0, the default when PostScript output is selected, writes black. A color index of 255 writes white which is invisible on white paper. Color tables are not used with PostScript unless the color mode has been enabled using the DEVICE procedure. See "Color Images" on page 3824

To obtain adequate resolution, the device coordinate system used for PostScript output is expressed in units of 0.001 centimeter (i.e., 1000 pixels/cm).

Use the `HELP, /DEVICE` call to view the current font, file, and other options set for PostScript output.

Using PostScript Fonts

Information necessary for rendering a set of 35 standard PostScript fonts are included with IDL. (The standard 35 fonts are the fonts found on the Apple Laserwriter II PostScript printer; the same fonts are found on almost any PostScript printer made in the time since the LaserWriter II appeared.) Use of PostScript fonts is discussed in detail in "About Device Fonts" on page 3940.

Color PostScript

If you have a color PostScript device you can enable the use of color with the statement:

```
DEVICE, /COLOR
```

Enabling color also enables the color tables. Text and graphic color indices are translated to RGB by dividing the red, green and blue color table values by 255. As with most display devices, color indices range from 0 to 255. Zero is normally black and white is normally represented by an index of 255. For example, to create and load a color table with four elements, black, red, green and blue:

```
TVLCT, [0,255,0,0], [0,0,255,0], [0,0,0,255]
```

Drawing text or graphics with a color index of 0 results in black, 1 in red, 2 in green, and 3 in blue.

Color Images

As with black and white PostScript, images may be output with 1, 2, 4, or 8 bits, yielding 1, 2, 16, or 256 possible colors. In addition, images are either pseudo-color or TrueColor. A pseudo-color image is a two dimensional image, each pixel of which is used to index the color table, thereby obtaining an RGB value for each possible pixel value. Pseudo-color images are similar to those displayed using the workstation monitor.

Note

In the case of pseudo-color images of fewer than 8 bits, the number of columns in the image should be an exact multiple of the number of pixels per byte (i.e., when displaying 4 bit images the number of columns should be even, and 2 bit images should have a column size that is a multiple of 4). If the image column size is not an exact multiple, extra pixels with a value of 255 are output at the end of each row. This causes no problems if the color white is loaded into the last color table entry, otherwise a stripe of the last (index number 255) color is drawn to the right of the image.

TrueColor Images

A TrueColor image consists of an array with three dimensions, one of which has a size of three, containing the three color components. It may be considered as three two dimensional images, one each for the red, green and blue components. For example a TrueColor *n* by *m* element image can be ordered in three ways: pixel interleaved (3, *n*, *m*), row interleaved (*n*, 3, *m*), or image interleaved (*n*, *m*, 3). By convention the first color is always red, the second green, and the last is blue.

TrueColor images are also routed through the color tables. The red color table array contains the intensity translation table for the red image, and so forth. Assuming that the color tables have been loaded with the vectors *R*, *G*, and *B*, a pixel with a color value of (*r*, *g*, *b*) is displayed with a color of (R_r, G_g, B_b). As with other devices, a color table value of 255 represents maximum intensity, while 0 indicates an absence of the color. To pass the RGB pixel values without change, load the red, green and blue color tables with a ramp with a slope of 1.0:

```
TVLCT, INDGEN(256), INDGEN(256), INDGEN(256)
```

or with the LOADCT procedure:

```
; Load standard black/white table:
```

```
LOADCT, 0
```

Use the TRUE keyword to the TV and TVSCL procedures to indicate that the image is a TrueColor image and to specify the dimension over which color is interleaved. A value of 1 specifies pixel interleaving, 2 is row interleaving, and 3 is image interleaving. The following example writes a 24-bit image, interleaved over the third dimension, to a PostScript file:

```
SET_PLOT, 'PS'
;Set the PostScript device to *8* bits per color, not 24:
DEVICE, FILE='24bit.ps', /COLOR, BITS=8
TV, [[[r]], [[g]], [[b]]], TRUE=3
DEVICE, /CLOSE
; Return plotting to X windows:
SET_PLOT, 'X'
```

Note

Currently, the PostScript device does not support TrueColor plots. Only TrueColor images are supported.

Image Background Color

Images that are displayed with a black background on a monitor frequently look better if the background is changed to white when displayed with PostScript. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

PostScript Positioning

Using the XOFFSET and YOFFSET Keywords

Often, IDL users are confused by the use of the XOFFSET and YOFFSET keywords to the PostScript DEVICE routine. These keywords control the position of IDL plots on the page. XOFFSET specifies the “X” position of the lower left corner of the output generated by IDL. This offset is always taken relative to the lower left-hand corner of the page when viewed in portrait orientation. YOFFSET specifies the “Y” position of the lower left corner of the output generated by IDL. This offset is also taken relative to the lower left-hand corner of the page when viewed in portrait orientation.

The following figure shows how the XOFFSET and YOFFSET keywords are interpreted by the PostScript device in the Portrait (left) and Landscape (right) modes. Note that the landscape plot uses the same origin for determining the effect of

the XOFFSET and YOFFSET keywords, but that the output is rotated 270 degrees clockwise.

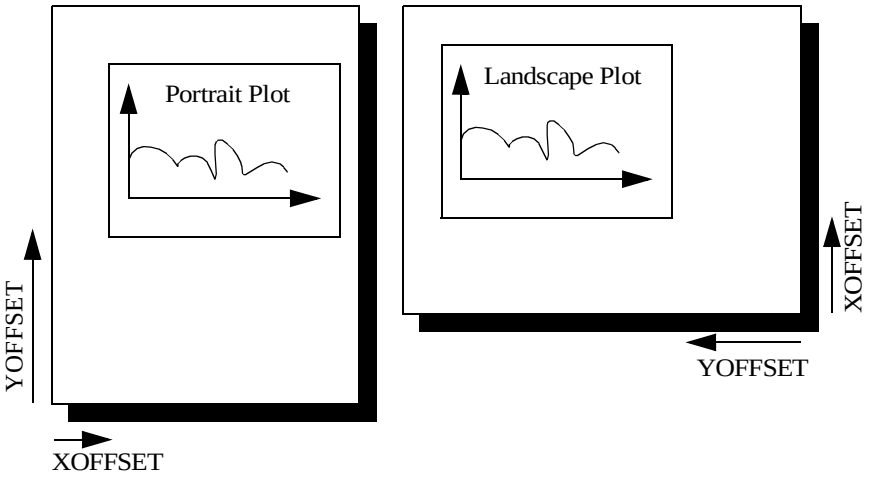

Figure G-1: Interpretation of the XOFFSET and YOFFSET Keywords

The page on the left shows an IDL plot printed in “portrait” orientation. Note that the X and Y offsets work just as we expect them to—increasing the XOFFSET moves the plot to the right and increasing the YOFFSET moves the plot up the page. The page on the right shows an IDL plot printed in “landscape” orientation. Here, the X and Y offsets are still taken relative to the same points even though the orientation of the plot has changed. This happens because IDL moves the origin of the plot *before* rotating the PostScript coordinate system 270 degrees clockwise for the landscape plot.

Note

The XOFFSET and YOFFSET keywords have no effect when you generate ENCAPSULATED PostScript output.

Encapsulated PostScript Output

Another form of PostScript output is Encapsulated PostScript. This is the format used to import PostScript files into page layout and desktop publishing programs. An Encapsulated PostScript (EPS) file is similar to a regular PostScript file except that it contains only one page of PostScript output contained in a “bounding box” that is used to tell other programs about the size and aspect ratio of the encapsulated image.

Most of the time, output from IDL to an EPS file is properly scaled into the EPS bounding box because commands such as PLOT take full advantage of the plotting area made available to them. Sometimes, however, the default bounding box is inappropriate for the image being displayed.

As an example, suppose you have an image that is narrow and tall that, when TV'ed to an IDL window, fills only a small portion of the plotting window. Similarly, when output to an EPS file, this image will only fill a small portion of the bounding box. When the resulting EPS file is brought into a desktop publishing program, it becomes very hard to properly scale the image since the aspect ratio of the bounding box bears no relation to the aspect ratio of the image itself.

To solve this problem, use the XSIZE and YSIZE keywords to the DEVICE procedure to make the bounding box just large enough to contain the image. Since IDL uses a resolution of 1000 dots per centimeter with the PostScript device, the correct XSIZE and YSIZE (in centimeters) can be computed as:

- XSIZE = Width of image in pixels/1000.0 pixels per cm
- YSIZE = Height of image in pixels/1000.0 pixels per cm

The following IDL procedure demonstrates this technique. This procedure reads an X Windows Dump file and writes it back out as a properly-sized, 8-bit-color Encapsulated PostScript file:

```
PRO XWDTOEPS, filename
; Read the XWD file. Pixel intensity information is stored
; in the variable 'array'. Values to reconstruct the color
; table are stored in 'r', 'g', and 'b':
array = READ_XWD(filename, r, g, b)
; Reconstruct the color table:
TVLCT, r,g,b
; Display the image in an IDL window:
TV, array
; Find the size of the picture. The width of the picture
; (in pixels) is stored in s[1]. The height of the picture
; is stored in s[2]:
s = SIZE(array)
; Take the 'xwd' (for X Windows Dump) extension off of
; the old filename and replace it with 'eps':
fl = STRLEN(filename)
filename = STRMID(filename, 0, fl-4)
filename = filename + '.eps'
PRINT, 'Making file: ', filename
PRINT, s
; Set the plotting device to PostScript:
SET_PLOT, 'ps'
; Use the DEVICE procedure to make the output encapsulated,
```

```
; 8 bits, color, and only as wide and high as it needs to
; be to contain the XWD image:
DEVICE, /ENCAPSUL, BITS_PER_PIXEL=8, /COLOR, $
   FILENAME=filename, XSIZE=S[1]/1000., $
   YSIZE=S[2]/1000.
; Write the image to the file:
TV, array
; Close the file:
DEVICE, /CLOSE
; Return plotting to X Windows:
SET_PLOT, 'x'
END
```

Multiple Plots on the Same Page

To put multiple plots on the same PostScript page, use the !P.MULTI system variable (described in more detail in “!P System Variable” on page 3899). !P.MULTI is a 5-element integer array that controls the number of rows and columns of plots to make on a page or in a graphics window.

The first element of !P.MULTI is a counter that reports how many plots remain on the page. The second element of !P.MULTI is the number of columns per page. The third element is the number of rows per page.

For example, the following lines of code create a PostScript file, `multi.ps`, with 6 different plots arranged as 2 columns and 3 rows:

```
; Set plotting to PostScript:
SET_PLOT, 'PS'
; Set the filename:
DEVICE, FILENAME='multi.ps'
; Make IDL’s plotting area hold 2 columns and 3 rows of plots:
!P.MULTI = [0, 2, 3]
; Create a simple dataset:
A = FINDGEN(10)
; Make 6 different plots:
PLOT, A
PLOT, SIN(A)
PLOT, COS(A)
PLOT, TAN(A)
PLOT, TANH(A)
PLOT, SINH(A)
; Close the file:
DEVICE, /CLOSE
; Return plotting to Windows:
SET_PLOT, 'win'
; Reset plotting to 1 plot per page:
!P.MULTI = 0
```

The resulting file produces a set of plots as shown in the following figure:

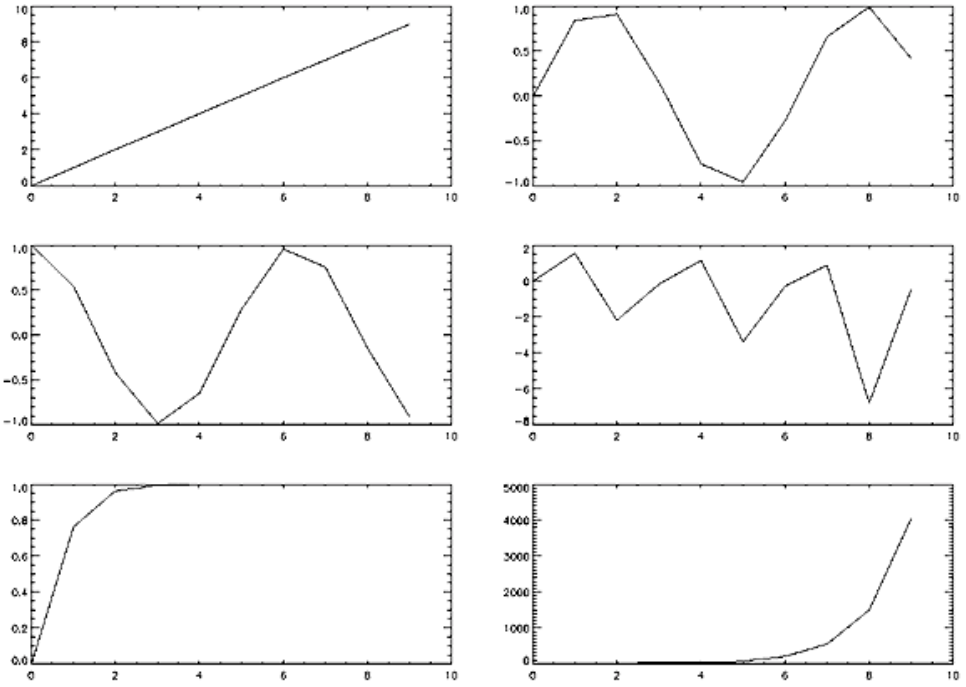

Figure G-2: Multiple plots on a single page produced by setting the !P.MULTI system variable.

Importing IDL Plots into Other Documents

This section shows how to generate IDL PostScript graphics so that they can be inserted into other documents. It also provides several examples of how the PostScript graphics device is used. Simply omit the ENCAPSULATED keyword from the calls to DEVICE if you wish to produce plots that can be printed directly. The following figure is an encapsulated PostScript file suitable for inclusion in other documents. The figure was produced with the following IDL statements. Note the use of the ENCAPSULATED keyword in the call to DEVICE:

```
; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic1.ps'
x = FINDGEN(200)
```

```
    ; Plot the sine wave:
    PLOT, 10000 * SIN(x/5) / EXP(x/100), $
        LINESTYLE = 2, TITLE = 'IDL PostScript Plot', $
        XTITLE = 'Point Number', YTITLE='Y Axis Title', $
        FONT = 0
    ; Add the cosine:
    OPLOT, 10000 * COS(x/5) / EXP(x/100), LINESTYLE = 4
    ; Annotate the plot:
    XYOUTS, 100, -6000, 'Sine', FONT = 0
    OPLOT, [120, 180], [-6000, -6000], LINESTYLE = 2
    XYOUTS, 100, -8000, 'Cosine', FONT = 0

OPLOT, [120, 180], [-8000, -8000], LINESTYLE = 4
```

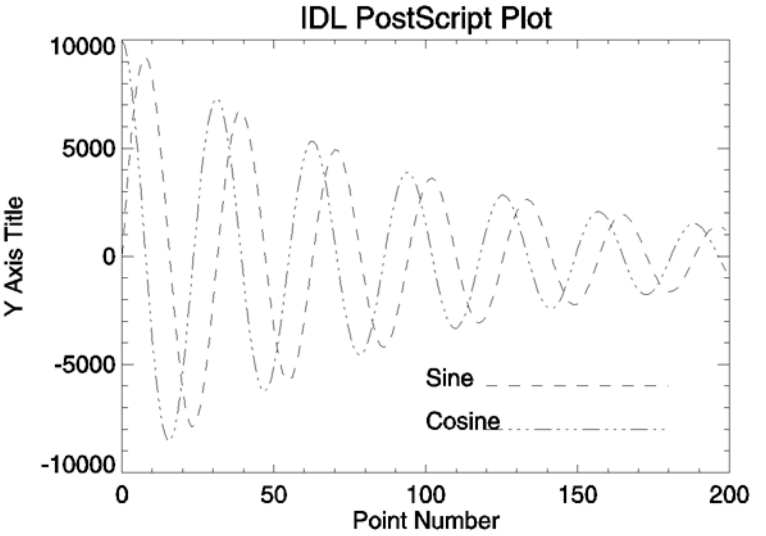

Figure G-3: Sample PostScript plot using Helvetica font.

The following figure is a more complicated plot. It demonstrates some of the three-dimensional plotting capabilities of IDL. It was produced with the following IDL statements:

```
    ; Select the PostScript driver:
    SET_PLOT, 'PS'
    ; Note use of ENCAPSULATED keyword:
    DEVICE, /ENCAPSULATED, FILENAME = 'pic2.ps'
    ; Access the data:
    OPENR, 1, FILEPATH('abnorm.dat', SUBDIR=['examples', 'data'])
    aa = ASSOC(1, BYTARR(64, 64))
```

```
   ; Get a smoothed version:
   a = SMOOTH(aa[0], 3)
   ; Generate the surface:
   SURFACE, a, /SAVE, ZAXIS = 1, XSTYLE = 1, YSTYLE = 1
   ; Add the contour:
   CONTOUR, a, /T3D, /NOERASE, ZVALUE = 1, $
      XSTYLE = 1, YSTYLE = 1, C_LINESTYLE = [0,1,2], $
      TITLE = 'IDL PostScript Plot'

CLOSE, 1
```

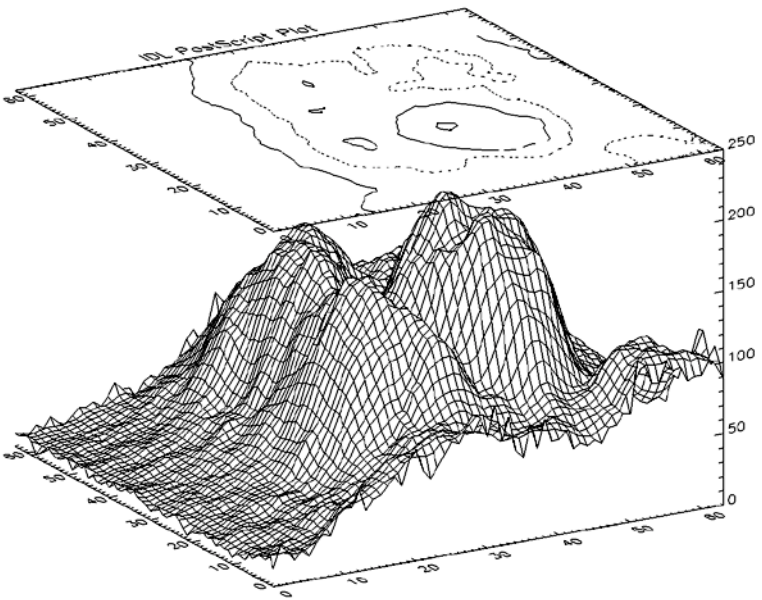

Figure G-4: Three-Dimensional Plot with Vector-Drawn Characters

The following figure illustrates polygon filling. It was produced with the following IDL statements:

```
   SET_PLOT, 'PS'
   DEVICE, /ENCAPSULATED, FILENAME = 'pic3.ps'
   x = FINDGEN(200)
   ; Upper sine wave:
   a = 10000 * sin(x / 5) / exp(x / 100)
   PLOT, a, /NODATA, TITLE = 'IDL PostScript Plot', $
      XTITLE='Point Number', YTITLE='Y Axis Title', $
      FONT = 0
```

```
    ; Vector of X vertices for polygon filling. Note that the
    ; ROTATE(V,2) function call returns the vector V in reverse order:
    C = [X, ROTATE(X, 2)]
    ; Vector of Y vertices for polygon filling:
    D = [A, ROTATE(A-2000, 2)]
    ; Fill the region using an intensity of about 75% white:
POLYFILL, C, D, COLOR=192
```

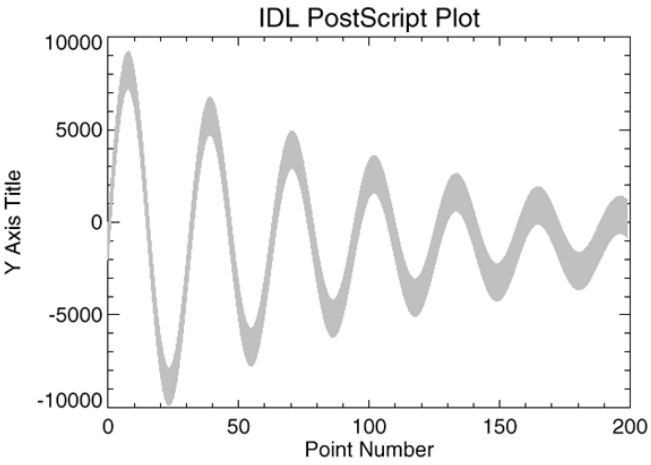

Figure G-5: Polygon Filling Example

The following figure illustrates IDL PostScript images. In this case, the same image is reproduced four times. In each case, a different number of bits are used per image pixel. It was produced with the following IDL statements:

```
SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic4.ps'
; Open image file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
; Variable to hold image:
a = BYTARR(192, 192, /NOZERO)
; Input the image:
READU, 1, a
; Done with the file:
CLOSE, 1
; Add a color table ramp to the bottom of the image:
A[0,0] = BYTSCL(INDGEN(192))#REPLICATE(1,16)
; Output the image four times:
FOR i = 0,3 DO BEGIN
   ; Use 1, 2, 4, and 8 bits per pixel:
```

```
      DEVICE, BITS_PER_PIXEL=2^i
      ; Output using TV with position numbers 0, 1, 2, and 3:
      TV, a, i, XSIZE=2.5, YSIZE=2.5, /INCHES

ENDFOR
```

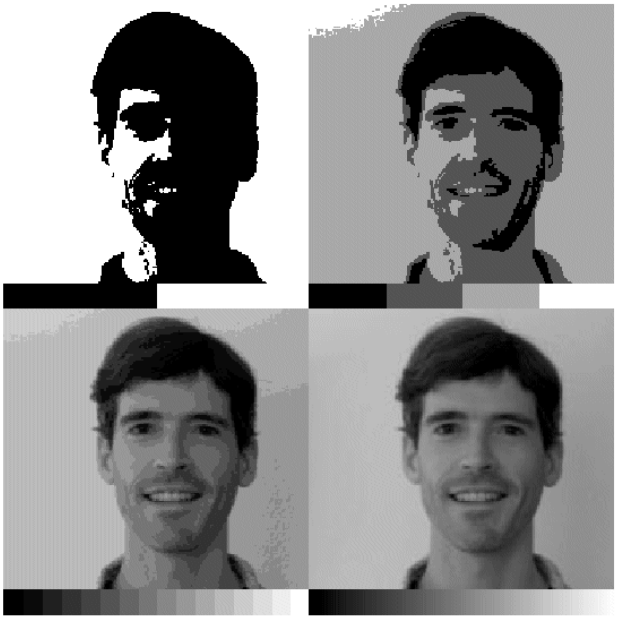

Figure G-6: 1, 2, 4, and 8-bit PostScript Images

The Regis Terminal Device

Device Keywords Accepted by the REGIS Device:

AVERAGE_LINES, CLOSE_FILE, FILENAME, PLOTTER_ON_OFF, SET_CHARACTER_SIZE, TTY, VT240, VT241, VT340, VT341

IDL provides Regis graphics output for the DEC VT240, VT330, and VT340 series of terminals. To output graphics to such terminals, issue the IDL command:

```
SET_PLOT, 'REGIS'
```

This causes IDL to use the Regis driver for producing graphical output.

Defaults for Regis Devices

The default setting for Regis output is: VT340, 16 colors, 4 bits per pixel.

Regis Limitations

- Four colors are available with VT240 and VT241 terminals, sixteen colors are available with the VT330 and VT340.
- Thick lines are emulated by filling polygons. There may be a difference in linestyle appearance between thick and normal lines.
- Image output is slow and is of poor quality, especially on the VT240 series. The VT240 is only able to write pixels on even numbered screen lines. IDL offers two methods of writing images to the 240:
  - Even and odd pairs of rows are averaged and written to the screen. An *n*, *m* image will occupy *n* columns and *m* screen rows. If this method is selected, graphics and image coordinates coincide. This method is the default (`AVERAGE_LINES = 1`). Routines that rely on a uniform graphics and image coordinate system, such as SHADE_SURF, work only in this mode.
  - Each line of the image is written to the screen, displaying every image pixel. An *n*, *m* image occupies 2*m* lines on the screen. (`AVERAGE_LINES = 0`). Graphics and image coordinates coincide only at the lower left corner of the image.
- Pixel values cannot be read back from the terminal, rendering the TVRD function inoperable.

The Tektronix Device

Device Keywords Accepted by the REGIS Device:

CLOSE_FILE, COLORS, FILENAME, GIN_CHARS, PLOT_TO, RESET_STRING, SET_CHARACTER_SIZE, SET_STRING, TEK4014, TEK4100, TTY

The Tektronix 4000 (4010, 4014, etc.), 4100 and 4200 series of graphics terminals (and the multitude of terminals and microcomputers that emulate them) are among the most common graphics devices available. To use IDL graphics with such terminals, issue the command:

```
SET_PLOT,'TEK'
```

This causes IDL to use the Tektronix driver for producing graphical output. Once the Tektronix driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, and to configure IDL for the specific features of your terminal. If you never call the DEVICE procedure, IDL assumes a plain vanilla Tektronix 4000 series compatible terminal. The 4200 series is upwardly compatible with the 4100 series; all references to the 4100 series also include the 4200 series. To set up IDL for use with a 4100 series compatible terminal with *n* colors, enter the following commands:

```
SET_PLOT, 'TEK'
DEVICE, /TEK4100, COLORS = n
```

The number of colors should be set to 2B where B is the number of bit planes in your terminal. If you use a Tektronix compatible terminal that requires calling the DEVICE procedure for configuration, you should probably create and use a start-up procedure the calls the DEVICE procedure, as described in Chapter 2. Because of the tremendous variation among the requirements and abilities of these terminals, it is crucial that you configure IDL properly for your terminal. In particular, the mode switching character sequences, set by the keyword parameters SET_STRING and RESET_STRING must be set correctly.

The DEVICE Procedure For Tektronix Terminals

The default setting for Tektronix output is: 10-bit coordinates, 4000 series terminals, and no use of color. The DEVICE keywords can be used to modify these defaults.

Tektronix Limitations

- The line drawing procedures work with all models. Line style and color capabilities vary greatly among terminal models and/or emulation programs.

- Color and the display of images (albeit very slowly and frequently of a poor quality because of the small number of colors) is usable only with 4100 series terminals. Hardware polygon fill and thick lines do not work with the 4000 series.
- The image coordinate system does not match the graphics coordinate system. The graphics coordinates range from 0 to 3071 in Y, and from 0 to 4095 in X. Image coordinates vary according to terminal model. A typical range is from 0 to 479 in Y, and 0 to 639 in X. Because of this, the SHADE_SURF procedure does not work with Tektronix terminals.

Warning

Not all 4100 series terminals are capable of displaying images—the Tektronix pixel operations option is required. Many terminal emulators do not emulate this option. The Tektronix commands used to output images are: RU, begin pixel operations, RS, set pixel viewport, and RP, raster write. If your terminal or emulator does not accept these commands, you will not be able to display images.

- The Tektronix graphics protocol does not allow the specification of line thickness. Lines with a thickness more than 1.0 are drawn using polygon filling in the case of 4100 series terminals. With 4000 series terminals, thick lines are emulated by drawing multiple thin lines. This scheme will produce artifacts on some Tektronix emulating devices because of differing resolutions, normal line thicknesses and inexact coordinate conversions.

Tektronix Device Limitations

Usage of Tektronix and Tektronix-compatible terminals with IDL has the following limitations:

- Image coordinates do not match the coordinates used by the rest of the graphic procedures. This is because no two models of Tektronix terminals are compatible. The graphics procedures utilize the default coordinate system of 1024 by 780, or 4096 by 3120 in the 12-bit mode. The size of the pixel memory and coordinate system vary widely between models. The *Position* parameter of the TV and TVSCL procedures does not work.
- The cursor can not be positioned from the computer meaning that the TVCRS procedure cannot be used with the Tektronix driver.
- Pixel values may not be read back from the terminal, rendering the TVRD function inoperable.

The Microsoft Windows Device

Device Keywords Accepted by the WIN Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR, CURSOR_ORIGINAL, CURSOR_STANDARD, DECOMPOSED, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE, GET_WINDOW_POSITION, PRINT_FILE, RETAIN, SET_CHARACTER_SIZE, SET_FONT, SET_GRAPHICS_FUNCTION, TRANSLATION, WINDOW_STATE

The Microsoft Windows version of IDL uses the “WIN” device by default. This device is similar to the X Windows device described below. The “WIN” device is only available in IDL for Windows.

To set plotting to the Microsoft Windows device, use the command:

```
SET_PLOT, 'WIN'
```

The X Windows Device

Device Keywords Accepted by the X Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR, CURSOR_IMAGE, CURSOR_MASK, CURSOR_ORIGINAL, CURSOR_STANDARD, CURSOR_XY, DECOMPOSED, DIRECT_COLOR, FLOYD, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE, GET_VISUAL_NAME, GET_WINDOW_POSITION, GET_WRITE_MASK, ORDERED, PSEUDO_COLOR, RETAIN, SET_CHARACTER_SIZE, SET_FONT, SET_GRAPHICS_FUNCTION, SET_TRANSLATION, SET_WRITE_MASK, STATIC_COLOR, STATIC_GRAY, THRESHOLD, TRUE_COLOR, TTY, WINDOW_STATE

X Windows is a network-based windowing system developed by MIT's project Athena. IDL uses the X System (often referred to simply as "X"), to provide an environment in which the user can create one or more independent windows, each of which can be used for the display of graphics and/or images.

In the X system, there are two basic cooperating processes: *clients* and *servers*. A server consists of a display, keyboard, and pointer (such as a mouse) as well as the software that controls them. Client processes (such as IDL) display graphics and text on the screen of a server by sending X protocol requests across the network to the server. Although in the most common case, the server and client reside on the same machine, this network based design allows much more elaborate configurations.

To use X Windows as the current graphics device, issue the IDL command:

```
SET_PLOT, 'X'
```

This causes IDL to use the X Window System for producing graphical output. Once the X driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the X Windows driver.

X Windows Visuals

Visuals specify how the hardware deals with color. The X Window server (your display) may provide colors or only gray scale (black and white), or both. The color

tables may be changeable from within IDL (read-write), or may be fixed (read-only). The value of each pixel value may be mapped to any color (Un-decomposed Colormap), or certain bits of each pixel are dedicated to the red, green, and blue primary colors (Decomposed Colormap).

There are six X Windows visual classes—read-write and read-only visuals for three types of displays: Gray Scale, Pseudo Color, and Decomposed Color. The names of the visuals are shown in the following table:

Visual Name	Writable	Description
StaticGray	no	Gray scale
GrayScale	yes	Gray scale
StaticColor	no	Undecomposed color
PseudoColor	yes	Undecomposed color
TrueColor	no	Decomposed color
DirectColor	yes	Decomposed color

Table G-15: X Windows Visual Classes

IDL supports all six types of visuals, although not at all possible depths. UNIX X Window System users can use the command `xdpyinfo` to determine which visuals are supported by their systems.

Each X Window server has a default visual class. Many servers may provide multiple visual classes. For example, a server with display hardware that supports an 8-bit-deep, un-decomposed, writable color map (PseudoColor), may also easily provide StaticColor, StaticGray, and GrayScale visuals.

You can select the visual used by IDL using the DEVICE procedure before a window is created, or by including the resource `idl.gr_visual` in your X defaults file, as explained in "Setting the X Window Defaults" on page 3846.

How IDL Selects a Visual Class

When opening the display, IDL asks the display for the following visuals, in order, until a supported visual class is found:

1. DirectColor, 24-bit
2. TrueColor, 24-bit
3. TrueColor, 16-bin (on Linux platforms only)

4. PseudoColor, 8-bit, then 4-bit
5. StaticColor, 8-bit, then 4-bit
6. GrayScale, any depth
7. StaticGray, any depth

You can override this behavior by using the DEVICE routine to specify the desired visual class and depth before you create a window. For example, if you are using a display that supports both the DirectColor, 24-bit-deep visual, and an 8-bit-deep PseudoColor visual, IDL will select the 24-bit-deep DirectColor visual. To instead use PseudoColor, issue the following command before creating a window:

```
DEVICE, PSEUDO_COLOR = 8
```

The colormap/visual class combination is chosen when IDL first connects with the X Window server. Note that if you connect with the X server by creating a window or using the DEVICE keyword to the HELP procedure, the visual class will be set; it then cannot be changed until IDL is restarted. If you wish to use a visual class other than the default, be sure to set it with a call to the DEVICE procedure *before* creating windows or otherwise connecting with the X Window server.

Windows are created in two ways:

1. Using the WINDOW procedure. WINDOW allows you to explicitly control many aspects of how the window is created.
2. If no windows exist and a graphics operation requiring a window is executed, IDL implicitly creates window 0 with the default characteristics.

Once the visual class is selected, all subsequently-created windows share the same class and colormap. The number of simultaneous colors available is stored in the system variable !D.N_COLORS. The visual class and number of colors, once initialized, cannot be changed without first exiting IDL.

How IDL Obtains a Colormap

IDL chooses the type of colormap in the following manner:

- By default, the shared colormap is used whenever possible (i.e., whenever IDL is using the default visual for the system). All available colors from the shared colormap are allocated for use by IDL. This is what happens when no window currently exists and a graphics operation causes IDL to implicitly create one.
- If the number of colors to use is explicitly specified using the COLORS keyword with the WINDOW procedure, IDL attempts to allocate the number of colors specified from the shared colormap using the default visual of the

screen. If there aren't enough colors available, a private colormap with that number of colors is used instead.

- Specifying a negative value for the COLORS keyword to the WINDOW procedure causes IDL to attempt to use the shared colormap, allocating all but the specified number of colors. For example:

```
WINDOW, COLORS = -8
```

  allocates all but 8 of the currently available colors. This allows other applications that might need their own colors to run in tandem with IDL.

- If a visual type and depth is specified, via the DEVICE procedure, which does not match the default visual of the screen, a new, private, colormap is created.

Using Color Under X

Colormaps define the mapping from color index to screen color. Two attributes of colormaps are important to the IDL user: they may be *private* or *shared*; and they may be *static* or *writable*. These different types of colormaps are described below.

Shared Colormaps

The window manager creates a colormap when it is started. This is known as the default colormap, and can be shared by most applications using the display. When each application requires a colormap entry (i.e., a mapping from a color index to a color), it allocates one from this shared table. Advantages and disadvantages of shared colormaps include:

- Using the shared colormap ensures that all applications share the available colors without conflict. A given application will not change a color that is allocated to a different application. In the case of IDL it means that IDL can change the colors it has allocated without changing the colors in use by the window manager or other applications.
- The window system interface routines must translate between the actual and allocated pixel values, significantly slowing the transfer of images.
- The shared colormap might not have enough colors available to perform the desired operations with IDL.
- The number of available colors in the shared colormap depends on the window manager in use and the demands of other applications. Thus, the number of available colors can vary.

- The allocated colors in a shared colormap do not generally start at zero and they are not necessarily contiguous. This makes it difficult to use the write mask for certain operations.

Private Colormaps

An application can create its own private color map. Most hardware can only display a single colormap at a time, so these private colormaps are called virtual color maps, and only one at a time is actually in use and visible. When the window manager gives the color focus to a window with a private colormap, the X window system loads its virtual colormap into the hardware colormap.

- Every color index supported by the hardware is available to IDL, improving the quality of images.
- Allocated colors always start at zero and are contiguous. This simplifies using the write mask.
- No translation between internal pixel values and the values required by the server is required, making the transfer of images more efficient.
- When the IDL colormap is loaded, other applications are displayed using the wrong colors. Furthermore, colors from the shared colormap are usually allocated from the lower end of the map first. These are the colors allocated by the window manager for such things as window borders, the color of text, and so forth. Since most IDL colormaps have very dark colors in the lower entries, the end effect with the IDL colormap loaded is that the non-IDL portions of the screen go blank.

Static Colormaps

As mentioned above, the contents of static colormaps are determined outside of IDL and cannot be changed. When using a static colormap, the TVLCT procedure simulates writable colormaps by finding the closest RGB color entry in the colormap to the requested color. The colormap translation table is then set to map IDL color indices to those of the closest colors in the colormap.

The colors present in the colormap may, and probably will, *not* match the requested colors exactly. For example, with a typical static color map, loading the IDL standard color table number 0, which consists of 256 intensities of gray, results in only 8 or 16 distinct intensities.

With static colormaps, loading a new color table does not affect the appearance of previously written objects. The internal translation tables are modified, which only affects objects that are subsequently written.

Color Translation

As mentioned above, colors from the shared colormap do not necessarily start from index zero, and are not necessarily contiguous. IDL preserves the illusion of a zero based contiguous colormap by maintaining a translation table between user color indices, which range from 0 to !D.TABLE_SIZE, and the actual pixel values allocated from the X server. Normally, the user need not be concerned with this translation table, but it is available using the statement:

```
DEVICE, TRANSLATION=T
```

This statement stores the current translation table, a 256 element byte vector, in the variable T. Element zero of the vector contains the value pixel allocated for the zeroth color in the IDL colormap, and so forth. In the case of a private colormap, each element of the translation vector contains it's own index value, because private colormaps start at zero and are contiguous.

The translation table may be bypassed, allowing direct access to the display's color indices, by setting the BYPASS_TRANSLATION keyword in the DEVICE procedure.

```
DEVICE, /BYPASS_TRANSLATION
```

Translation can be reestablished by setting the keyword to zero:

```
DEVICE, BYPASS_TRANSLATION=0
```

When a private or static (read-only) color table is initialized, the bypass flag is cleared. It is set when initializing a shared color table.

Using Pixmaps

X Windows can direct graphics to *windows* or *pixmaps*. Windows are the usual windows that appear on the screen and contain graphics. Pixmaps are invisible graphics memory contained in the server. Drawing to a window produces a viewable result, while drawing to a pixmap simply updates the pixmap memory.

Pixmaps are useful because it is possible to write graphics to a pixmap and then copy the contents of the pixmap to a window where it can be viewed. Furthermore, this copy operation is very fast because it happens entirely within the server. Provided enough pixmap memory is available, this technique works very well for animating a series of images by placing the images into pixmap memory and then sequentially copying them to a visible window.

To create a pixmap, use the PIXMAP keyword with the WINDOW procedure. For example, to create a square pixmap with 128 pixels per side as IDL window 1, use the command:

```
WINDOW, 1, /PIXMAP, XSIZE=128, YSIZE=128
```

Once they are created, pixmaps are treated just like normal windows, although some operations (WSHOW for instance) don't do anything useful when applied to a pixmap.

The following procedure shows how animation can be done using pixmap memory. It uses a series of 15 heart images taken from the file `abnorm.dat`. This file is supplied with all IDL distributions in the `examples/data` subdirectory of the main IDL directory. It creates a pixmap and writes the heart images to it. It then uses the COPY keyword of the DEVICE procedure to copy the images to a visible window. Pressing any key causes the display process to halt:

```
; Animate heart series:
PRO animate_heart
; Open the file containing the images:
OPENR, u, FILEPATH('abnorm.dat', SUBDIR = ['examples','data']), $
   /GET_LUN
; Associate a file variable with the file. Each heart image
; is 64x64 pixels:
frame = ASSOC(u, BYTARR(64,64))
; Window pixwin is a pixmap which is 4 images tall and 4
; images wide. The images will be placed in this pixmap:
WINDOW, pixwin, /PIXMAP, XSIZE = 512, YSIZE = 512, /FREE
; Write each image to the pixmap. SMOOTH is used to improve
; the appearance of each image and REBIN is used to
; enlarge/shrink each image to the final display size:
FOR i=0, 15-1 DO TV, REBIN(SMOOTH(frame[i],3), 128, 128),i
; Close the image file and free the file unit:
FREE_LUN, u
; Window win is a visible window. It will be used to display
; the animated heart cycle:
WINDOW, win, XSIZE = 128, YSIZE=128, TITLE='Heart', /FREE
; Current frame number:
i = 0L
; Display frames until any key is pressed:
WHILE GET_KBRD(0) EQ '' DO BEGIN
; Compute x and y locations of pixmap image's lower left corner:
   x = (i mod 4) * 128 & y = 384 - (i/4) * 128
; Copy the next image from the pixmap to the visible window:
DEVICE, COPY = [x, y, 128, 128, 0, 0, pixwin]
; Keep track of total frame count:
i = (i + 1) MOD 15
ENDWHILE
END
```

Animation sequences with more and/or larger images can be made. See the documentation for the XANIMATE procedure, which is a more generalized embodiment of the above procedure.

Note

Some X Windows servers will refuse to create a pixmap that is larger than the physical screen in either dimension.

How Color is Interpreted for a TrueColor Visual

How a color (such as !P.COLOR) is interpreted by IDL (when a TrueColor visual is being utilized) depends in part upon the decomposed setting for the device.

To retrieve the decomposed setting:

```
DEVICE, GET_DECOMPOSED = currentDecomposed
```

To set the decomposed setting:

```
DEVICE, DECOMPOSED = newDecomposed
```

If the decomposed value is zero, colors (like !P.COLOR) are interpreted as indices into IDL's color table. A color should be in the range from 0 to !D.TABLE_SIZE - 1. The IDL color table contains a red, green, and blue component at a given index; each of these components is in the range of 0 up to 255.

Note

IDL’s color table does not map directly to a hardware color table for a TrueColor visual. If IDL’s color table is modified, for example using the LOADCT or TVLCT routines, then the new color table will only take effect for graphics that are drawn after it has been modified.

If the decomposed value is non-zero, colors (like !P.COLOR) are interpreted as a combination of red, green, and blue settings. The least significant 8 bits contain the red component, the next 8 bits contain the green component, and the most significant 8 bits contain the blue component.

In either case, the most significant bits of each of the resulting red, green, and blue components are utilized. The number of bits utilized per component depends upon the red, green, and blue masks for the visual. On UNIX systems, a new field (Bits Per RGB) has been added to the output from HELP, /DEVICE. This Bits Per RGB field indicates the amount of bits utilized for each component.

Tip

The UNIX command `xdpyinfo` also provides information about each of the visuals.

Setting the X Window Defaults

You can set the initial default value of the following parameters by setting resources in the file `.Xdefaults` file in your home directory as follows:

Resource Name	Description
idl.colors	The number of colors used by IDL.
idl.gr_depth	The depth, in bits, of the visual used by IDL.
idl.retain	The default setting for the *`retain`* parameter: 0=none, 1= by server, 2=by IDL.
idl.gr_visual	The type of visual: StaticGray, GrayScale, StaticColor, PseudoColor, TrueColor, or DirectColor.

Table G-16: IDL/ X Window Defaults

For example, to set the default visual to PseudoColor, and to allocate 100 colors, insert the following lines in your defaults file:

```
idl.gr_visual: PseudoColor
idl.colors: 100
```

The Z-Buffer Device

Device Keywords Accepted by the Z Device:

CLOSE, GET_GRAPHICS_FUNCTION, GET_WRITE_MASK, SET_CHARACTER_SIZE, SET_COLORS, SET_FONT, SET_GRAPHICS_FUNCTION, SET_RESOLUTION, Z_BUFFERING

The IDL Z-buffer device is a pseudo device that draws 2-D or 3-D graphics in a buffer contained in memory. This driver implements the classic Z buffer algorithm for hidden surface removal. Although primarily used for 3-D graphics, the Z-buffer driver can be used to create 2-D objects in a frame buffer in memory. The resolution of this device can be set by the user.

All of the IDL plotting and graphics routines work with the Z-buffer device driver. In addition, the POLYFILL procedure has a few keyword parameters, allowing Gouraud shading and warping images over 3-D polygons, that are only effective when used with the Z-buffer.

When used for 3-D graphics, two buffers are present: an 8-bit-deep frame buffer that contains the picture; and a 16-bit-deep Z-buffer of the same resolution, containing the z-value of the visible surface of each pixel. The Z-buffer is initialized to the depth at the back of the viewing volume. When objects are drawn, the z-value of each pixel is compared with the value at the same location in the Z-buffer, and if the z-value is greater (closer to the viewer), the new pixel is written in the frame buffer and the Z-buffer is updated with the new z-value.

The Z-buffer device is a “pseudo device” in that drawing commands update buffers in memory rather than sending commands to a physical device or file. The TVRD function reads the contents of either buffer to an IDL array. This array may then be further processed, written to a file, or output to a raster-based graphics output device.

The Z-buffer driver can be used for 2-D graphics by disabling the depth computations.

To use the Z-buffer as the current graphics device, issue the IDL command:

```
SET_PLOT, 'Z'
```

Once the Z-buffer driver is enabled the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the Z-buffer driver and the amount of memory used for the buffers.

Reading and Writing Buffers

The contents of both buffers are directly accessed by the TV and TVRD routines. The frame buffer that contains the picture is 8 bits deep and is accessed as channel 0. The Z depth buffer contains 16 bit integers and is accessed as channel 1. Always use `CHANNEL=1` and set the keyword WORDS when reading or writing the depth buffer.

The normal procedure is to set the graphics device to “Z”, draw the objects, read the frame buffer, and then select another graphics device and write the image. For example, to create an image with the Z-buffer driver and then display it on an X-Window display:

```
; Select Z-buffer device:
SET_PLOT,'Z'
; Write objects to the frame buffer using normal graphics
; routines, e.g. PLOT, SURFACE, POLYFILL
... ... ...
; Read back the entire frame buffer:
a=TVRD()
; Select X Windows:
SET_PLOT,'X'
; Display the contents of the frame buffer:
TV, a
```

To read the depth values in the Z-buffer, use the command:

```
a = TVRD(CHANNEL=1, /WORDS)
```

To write the depth values, use the command:

```
TV, a, /WORDS, CHANNEL=1
```

The TV, TVSCL, and TVRD routines write or read pixels directly to a rectangular area of the designated buffer without affecting the other buffer.

Z-Axis Scaling

The values in the depth buffer are short integers, scaled from -32765 to +32765, corresponding to normalized Z-coordinate values of 0.0 to 1.0.

Polyfill Procedure

The following POLYFILL keywords are active only with the Z-buffer device: IMAGE_COORDINATES, IMAGE_INTERPOLATE, and TRANSPARENT. These

parameters allow images, specified via the PATTERN keyword, to be warped over 2-D and 3-D polygons.

The IMAGE_COORDINATES keyword contains a 2 by *N* array containing the image space coordinates that correspond to each of the *N* vertices of the polygon. The IMAGE_INTERPOLATE keyword indicates that bilinear interpolation is to be used, rather than the default nearest neighbor sampling. Pixels less than the value of TRANSPARENT are not drawn, simulating transparency. For Gouraud shading of polygons, the COLOR keyword can contain an array specifying the color index for each polygon vertex.

Examples Using the Z-Buffer

This example forms a Bessel function, draws its shaded surface and overlays its contour, using the Z-buffer as shown in the following figure.The final output is directed to PostScript.

```
; Select the Z-buffer:
SET_PLOT, 'Z'
n = 50 ; Size of array for Bessel
; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)
; Draw the surface, label axes in black, background in white:
SHADE_SURF, a, /SAVE, COLOR=1, BACKGROUND=255
nlev = 8 ; Number of contour levels
; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
   LEVELS=FINDGEN(nlev)*1.5/nlev-.5, COLOR=1
; Read image:
b=TVRD()
; Select PostScript output:
SET_PLOT, 'PS'
; Output the image:
TV, b
; Close the new PostScript file:
DEVICE, /CLOSE
```

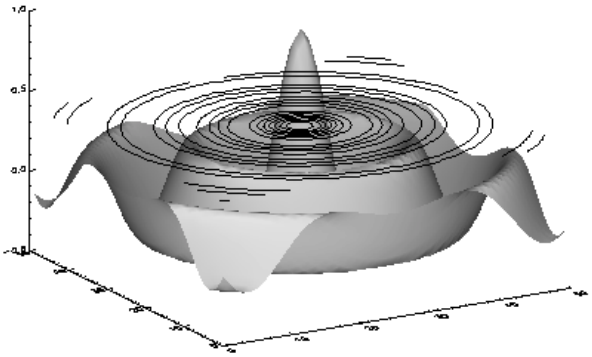

Figure G-7: Combined Shaded Surface and Contour Plot

The following example warps an image to a cube as shown in the figure below. The lower two quadrants of the image are warped to the front two faces of the cube. The upper-right quadrant is warped to the top face of the cube. The image is held in the array a, with dimensions nx by ny. The image is then output to PostScript as in the previous example.

```
; Select the Z-buffer:
SET_PLOT, 'Z'
; Make a white background for final output to PostScript:
ERASE, 255
; Establish 3-D scaling as (0,1) cube:
SCALE3, XRANGE=[0,1], YRANGE=[0,1], ZRANGE=[0,1]
; Define vertices of cube. Vertices 0-3 are bottom, 4-7 are top:
verts = [[0,0,0], [1,0,0], [1,1,0], [0,1,0], $
   [0,0,1], [1,0,1], [1,1,1], [0,1,1]]
; Fill lower left face:
POLYFILL, verts[*, [3,0,4,7]], /T3D, PATTERN=a, $
   IMAGE_COORD=[[0,0], [nx/2,0], [nx/2,ny/2], [0,ny/2]]
; Fill lower right face:
POLYFILL, verts[*, [0,1,5,4]], /T3D, PATTERN=a, $
   IMAGE_COORD=[[nx/2,0], [nx-1,0], $
   [nx-1,ny/2], [nx/2,ny/2]]
; Fill top face:
POLYFILL, verts[*, [4,5,6,7]], /T3D, PATTERN=a, $
   IMAGE_COORD = [[nx/2,ny/2], [nx-1,ny/2], $
   [nx-1,ny-1], [nx/2,ny-1]]
; Draw edges of cube in black:
PLOTS, verts[*, [0,4]], /T3D, COLOR=0
```

```
   ; Edges of top face:
PLOTS, verts[*, [4,5,6,7,4]], /T3D, COLOR=0
```

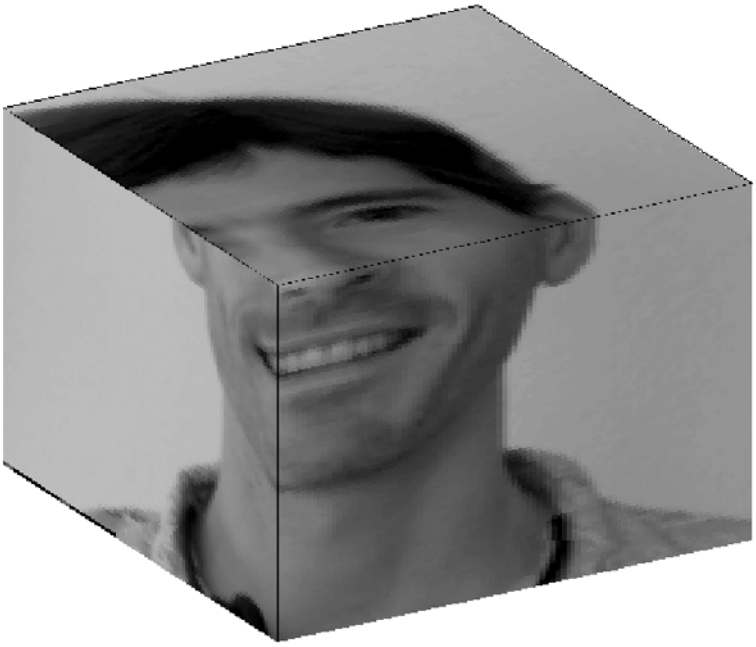

Figure G-8: Image Warped to a Cube Using the Z-Buffer

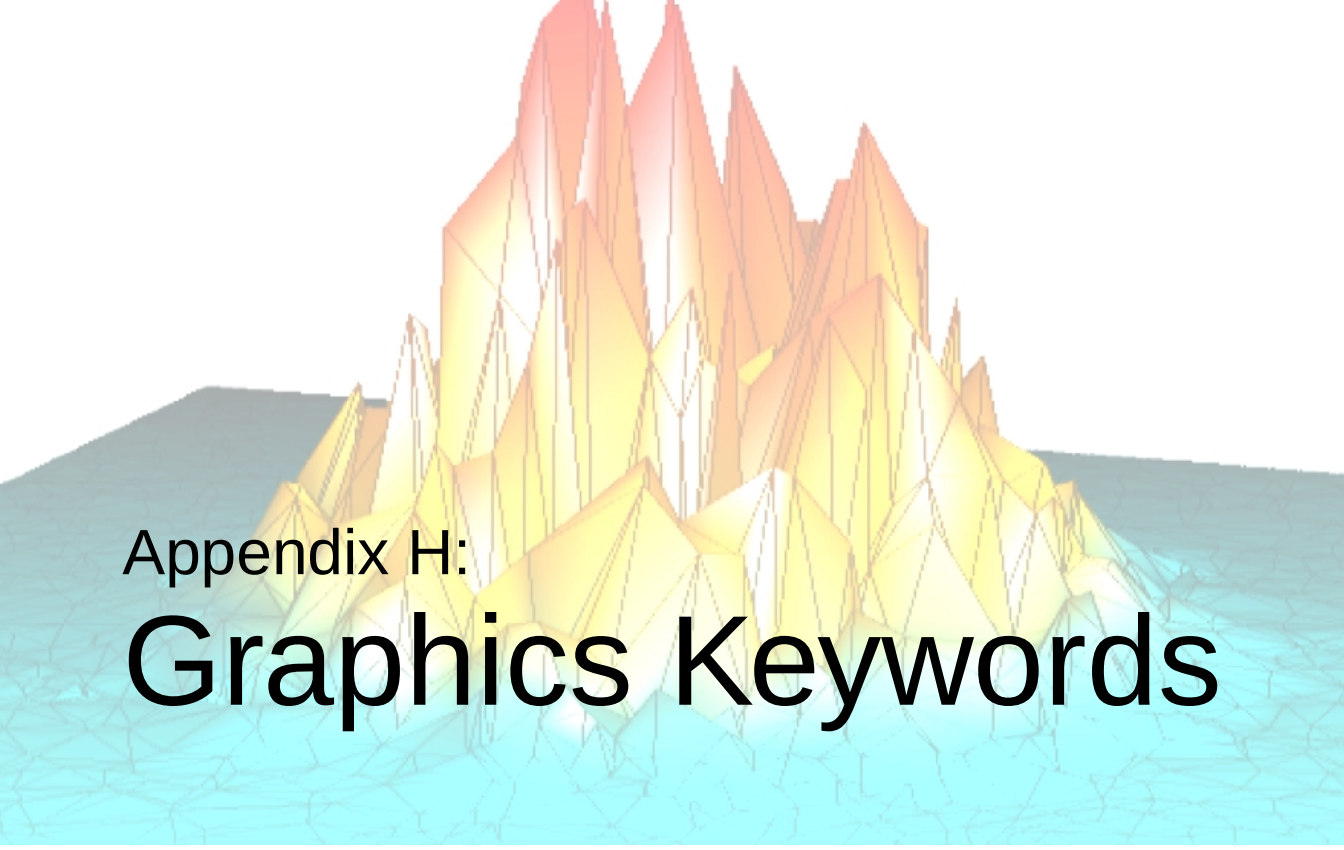


Appendix H: Graphics Keywords

The IDL Direct Graphics routines, CURSOR, ERASE, PLOTS, POLYFILL, TV (and TVSCL), TVCRS, TVRD, and XYOUTS, and the plotting procedures, AXIS, CONTOUR, PLOT, OPLOT, SHADE_SURF, and SURFACE, accept a number of common keywords. Therefore, instead of describing each keyword along with the description of each routine, this section contains a brief summary of each graphics keyword. Routine-specific keywords are documented in the description of the routine.

The graphics keywords are described below. The name of each keyword is followed by a list of routines that accept that keyword. Keywords that have a direct correspondence to fields in a system variable (usually !P) are also indicated.

The keywords that control the plot axes are prefixed with the character ‘X’, ‘Y’, or ‘Z’ depending on the axis in question. These keywords correspond to fields in the axis system variables: !X, !Y, and !Z, and are described in more detail in “Graphics System Variables” on page 3895 The axis keywords are shown in the form [XYZ]NAME. For example, [XYZ]CHARSIZE refers to the three keywords XCHARSIZE, YCHARSIZE, and ZCHARSIZE, which control the size of the characters annotating the three axes.

The system variable fields that control this are !X.CHARSIZE, !Y.CHARSIZE, and !Z.CHARSIZE.

The following graphics keywords are discussed in this appendix:

BACKGROUND	ORIENTATION	[XYZ]STYLE
CHANNEL	POSITION	[XYZ]THICK
CHARSIZE	PSYM	[XYZ]TICK_GET
CHARTHICK	SUBTITLE	[XYZ]TICKFORMAT
CLIP	SYMSIZE	[XYZ]TICKINTERVAL
COLOR	T3D	[XYZ]TICKLAYOUT
DATA	THICK	[XYZ]TICKLEN
DEVICE	TICKLEN	[XYZ]TICKNAME
FONT	TITLE	[XYZ]TICKS
LINESTYLE	[XYZ]CHARSIZE	[XYZ]TICKUNITS
NOCLIP	[XYZ]GRIDSTYLE	[XYZ]TICKV
NODATA	[XYZ]MARGIN	[XYZ]TITLE
NOERASE	[XYZ]MINOR	Z
NORMAL	[XYZ]RANGE	ZVALUE

BACKGROUND

Accepted by: CONTOUR, PLOT, SURFACE.

System variable equivalent: !P.BACKGROUND.

The background color index to which all pixels are set when erasing the screen or page. The default is 0 (black). Not all devices support erasing the background to a specified color index.

For example, to produce a black plot with a white background on a color display:

```
PLOT, Y, BACKGROUND = 255, COLOR = 0
```

CHANNEL

Accepted by: ERASE, TV, TVRD. System variable equivalent: !P.CHANNEL.

This keyword specifies the memory channel for the operation. This parameter is ignored on display systems that have only one memory channel. When using a "decomposed" display system, the red channel is 1, the green channel is 2, and the blue channel is 3. Channel 0 indicates all channels. If omitted, !P.CHANNEL contains the default channel value.

Note

CONTOUR, PLOT, SHADE_SURF, and SURFACE also accept the CHANNEL keyword, but simply pass it to ERASE.

CHARSIZE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.CHARSIZE.

The overall character size for the annotation when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. A CHARSIZE of 1.0 is normal. The size of the annotation on the axes may be set, relative to CHARSIZE, with *x*CHARSIZE, where *x* is X, Y, or Z. The main title is written with a character size of 1.25 times this parameter.

CHARTHICK

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.CHARTHICK.

An integer value specifying the line thickness of the vector drawn font characters.This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

CLIP

Accepted by: CONTOUR, DRAW_ROI, OPLOT, PLOT, PLOTS, POLYFILL, SURFACE, XYOUTS. System variable equivalent: !P.CLIP.

The coordinates of a rectangle used to clip the graphics output. The rectangle is specified as a vector of the form $[X_0, Y_0, X_1, Y_1]$, giving coordinates of the lower left and upper right corners, respectively. The default clipping rectangle is the plot window, the area enclosed within the axes of the most recent plot. Coordinates are specified in data units unless an overriding coordinate unit specification keyword is present (i.e., NORMAL or DEVICE). If the clipping is provided in data or

normalized units, the actual clipping rectangle is computed by converting those values to device units. The clipping itself always occurs in device space.

Note

The default is not to clip the output of PLOTS and XYOUTS. To enable clipping include the keyword parameter NOCLIP = 0. With PLOTS, POLYFILL, and XYOUTS, this keyword controls the clipping of vectors and vector-drawn text.

For example, to draw a vector using normalized coordinates with its contents clipped within a rectangle covering the upper left quadrant of the display:

```
PLOTS, X, Y, CLIP=[0.,.5,.5,1.0], /NORM, NOCLIP=0
```

COLOR

Accepted by: AXIS, CONTOUR, DRAW_ROI, ERASE, OPLOT, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.COLOR.

The color index of the data, text, line, or solid polygon fill to be drawn. If this keyword is omitted, !P.COLOR specifies the color index.

When used with the PLOTS, POLYFILL, or XYOUTS procedure, this keyword parameter can be set to a vector to specify multiple color indices.

Gouraud shading of polygons is performed with the Z-buffer graphics output device and POLYFILL procedure when COLOR contains an array of color indices, one for each vertex.

DATA

Accepted by: AXIS, CONTOUR, CURSOR, DRAW_ROI, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the data coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

DEVICE

AXIS, CONTOUR, CURSOR, DRAW_ROI, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the device coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

For example, the following code displays an image contained in the variable A and then draws a contour plot of pixels [100:499, 100:399] over the correct section of the image:

```
;Display the image.
TV,A

;Draw the contour plot, specify the coordinates of the plot, in
;device coordinates, do not erase, set the X and Y axis styles to
;EXACT.
CONTOUR, A[100:499, 100:399], $
    POS = [100,100, 499,399], /DEVICE, $
   /NOERASE, XSTYLE=1, YSTYLE=1
```

Note that in the above example, the keyword specification `/DEVICE` is equivalent to `DEVICE = 1`.

FONT

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.FONT.

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to selects the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See Appendix N, “Fonts” for a complete description of IDL’s font systems.

LINESTYLE

Accepted by: DRAW_ROI, OPLOT, PLOT, PLOTS, SURFACE. System variable equivalent: !P.LINESTYLE.

This keyword indicates the line style used to draw lines; it indicates the line style of the lines used to connect the data points. This keyword should be set to the appropriate index for the desired linestyle as described in the following table.

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table H-1: IDL Linestyles

NOCLIP

Accepted by: CONTOUR, DRAW_ROI, OPLOT, PLOT, PLOTS, POLYFILL, SURFACE, XYOUTS. System variable equivalent: !P.NOCLIP.

Set this keyword to suppress clipping of the plot. The clipping rectangle is contained in !P.CLIP. By default, the plot is clipped within the plotting window.

Note

The default value is clipping-disabled for PLOTS, POLYFILL, and XYOUTS. For all other routines, the default is to enable clipping.

With PLOTS, POLYFILL, and XYOUTS, this keyword controls the clipping of vectors and vector-drawn text. The default is to disable clipping, so to enable clipping include the parameter NOCLIP = 0. To explicitly disable clipping set this parameter to one.

NODATA

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE.

If this keyword is set, only the axes, titles, and annotation are drawn. No data points are plotted.

For example, to draw an empty set of axes between some given values:

```
PLOT, [XMIN, XMAX],[YMIN, YMAX], /NODATA
```

NOERASE

Accepted by: AXIS, CONTOUR, PLOT, SURFACE. System variable equivalent: !P.NOERASE.

Specifies that the screen or page is not to be erased. By default, the screen is erased, or a new page is begun, before a plot is produced.

NORMAL

Accepted by: AXIS, CONTOUR, CURSOR, DRAW_ROI, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the normalized coordinate system, and range from 0.0 to 1.0. The default coordinate system is DATA if no other coordinate-system specifications are present.

ORIENTATION

Accepted by: DRAW_ROI, POLYFILL, XYOUTS.

Specifies the counterclockwise angle in degrees from horizontal of the text baseline and the lines used to fill polygons.When used with the POLYFILL procedure, this keyword forces the “linestyle” type of fill, rather than solid or patterned fill.

POSITION

Accepted by: CONTOUR, MAP_SET, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.POSITION.

Allows direct specification of the plot window. POSITION is a 4-element vector giving, in order, the coordinates $[(X_0, Y_0), (X_1, Y_1)]$, of the lower left and upper right corners of the data window. Coordinates are expressed in normalized units ranging from 0.0 to 1.0, unless the DEVICE keyword is present, in which case they are in actual device units. The value of POSITION is never specified in data units, even if the DATA keyword is present.

When setting the position of the window, be sure to allow space for the annotation, which resides outside the window. IDL outputs the message “% Warning: Plot truncated.” if the plot region is larger than the screen or page size. The plot region is the rectangle enclosing the plot window and the annotation.

When plotting in three dimensions, the POSITION keyword is a 6-element vector with the first four elements describing, as above, the XY position, and with the last two elements giving the minimum and maximum Z coordinates. The Z specification is always in normalized coordinate units.

When making more than one plot per page it is more convenient to set !P.MULTI than to manipulate the position of the plot directly with the POSITION keyword.

For example, the following statement produces a contour plot with data plotted in only the upper left quarter of the screen:

```
CONTOUR, Z, POS=[0., 0.5, 0.5, 1.0]
```

Because no space on the left or top edges was allowed for the axes or their annotation, the above described warning message results.

PSYM

Accepted by: DRAW_ROI, OPLOT, PLOT, PLOTS. System variable equivalent: !P.PSYM.

The symbol used to mark each data point. Normally, PSYM is 0, data points are connected by lines, and no symbols are drawn to mark the points. Set this keyword, or the system variable !P.PSYM, to the symbol index as shown in the table below to mark data points with symbols. The keyword SYMSIZE is used to set the size of the symbols.

PSYM Value	Plotting Symbol
1	Plus sign (+)
2	Asterisk (*)
3	Period (.)
4	Diamond
5	Triangle
6	Square
7	X
8	User-defined. See USERSYM procedure.

Table H-2: Values for the PSYM Keyword

PSYM Value	Plotting Symbol
9	Undefined
10	Histogram mode. Horizontal and vertical lines connect the plotted points, as opposed to the normal method of connecting points with straight lines.

Table H-2: Values for the PSYM Keyword

Negative values of PSYM cause the symbol designated by PSYM to be plotted at each point with solid lines connecting the symbols. For example, a value of -5 plots triangles at each data point and connects the points with lines.

The following IDL code plots an array using points, and then overplots the smoothed array, connecting the points with lines:

```
;Plot using points.
PLOT, A, PSYM=3

;Overplot smoothed data.
OPLOT, SMOOTH(A,7)
```

SUBTITLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.SUBTITLE.

A text string to be used as a subtitle for the plot. Subtitles appear below the X axis.

SYMSIZE

Accepted by: DRAW_ROI, OPLOT, PLOT, PLOTS.

Specifies the size of the symbols drawn when PSYM is set. The default size of 1.0 produces symbols approximately the same size as a character.

T3D

Accepted by: AXIS, CONTOUR, DRAW_ROI, MAP_SET, OPLOT, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS. System variable equivalent: !P.T3D.

Set this keyword to indicate that the generalized transformation matrix in !P.T is to be used. If not present, the user-supplied coordinates are simply scaled to screen coordinates. See the examples in the description of the SAVE keyword.

Note

Since T3D uses the transformation matrix in !P.T, it is important that !P.T contain a valid transformation matrix. This can be achieved in several ways:

- Use the SAVE keyword to save the transformation matrix from an earlier graphics operation.
- Establish a transformation matrix using the T3D, SURFR, or, SCALE3 procedures.
- Set the value of !P.T directly.

THICK

Accepted by: AXIS, DRAW_ROI, OPLOT, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE. System variable equivalent: !P.THICK.

Indicates the line thickness. THICK overrides the setting of !P.THICK.

TICKLEN

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.TICKLEN.

Controls the length of the axis tick marks, expressed as a fraction of the window size. The default value is 0.02. TICKLEN of 1.0 produces a grid, while a negative TICKLEN makes tick marks that extend outside the window, rather than inwards.

For example, to produce outward-going tick marks of the normal length:

```
PLOT, X, Y, TICKLEN = -0.02
```

To provide a new default tick length, set !P.TICKLEN.

TITLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.TITLE.

Produces a main title centered above the plot window. The text size of this main title is larger than the other text by a factor of 1.25. For example:

```
PLOT, X, Y, TITLE = 'Final Results'
```

[XYZ]CHARSIZE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalents: ![XYZ].CHARSIZE.

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor set by !P.CHARSIZE or the keyword CHARSIZE.

[XYZ]GRIDSTYLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINESTYLE for a list of linestyles.

[XYZ]MARGIN

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].MARGIN.

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. Default margins are 10 and 3 for the X axis, and 4 and 2 for the Y axis. The ZMARGIN keyword is present for consistency and is currently ignored.

[XYZ]MINOR

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].MINOR.

The number of minor tick mark intervals.

[XYZ]RANGE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].RANGE.

The desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. IDL will frequently round this range. This override can be defeated using the [XYZ]STYLE keywords.

[XYZ]STYLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].STYLE.

This keyword allows specification of axis options such as rounding of tick values and selection of a box axis. Each option is described in the following table:

Value	Description
1	Force exact axis range.
2	Extend axis range.
4	Suppress entire axis
8	Suppress box style axis (i.e., draw axis on only one side of plot)
16	Inhibit setting the Y axis minimum value to 0 (Y axis only)

Table H-3: Values for the [XYZ]STYLE Keyword

Note that this keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the XAXIS keyword to `1+8`, or 9.

[XYZ]THICK

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].THICK.

This keyword controls the thickness of the lines forming the axis and tick marks. A value of 1.0 is the default.

[XYZ]TICK_GET

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE.

A named variable in which to return the values of the tick marks for the designated axis. The result is a double precision floating-point array with the same number of elements as ticks.

For example, to retrieve in the variable V the values of the tick marks selected by IDL for the Y axis:

```
PLOT, X, Y, YTICK_GET = V
```

[XYZ]TICKFORMAT

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKFORMAT.

Set this keyword to a string or a vector of strings. If a vector is provided, each string corresponds to a level of the axis. The [XYZ]TICKUNITS keyword determines the number of levels for an axis.

Each string is one of the following:

A format code:

If the string begins with an open parenthesis, it is treated as a standard format string. See "Format Codes" in Chapter 10 of the *Building IDL Applications* manual for more information on format codes.

Example 1: Display the X axis tick values using a format of F6.2 (six characters, with 2 places after the decimal point):

```
PLOT, X, Y, XTICKFORMAT='(F6.2)'
```

Example 2: Display the Y tick values using the "dollars and cents" format $*dddd.dd*:

```
PLOT, X, Y, YTICKFORMAT='("$", F7.2)'
```

The string 'LABEL_DATE' :

Set [XYZ]TICKFORMAT to the string 'LABEL_DATE' to create axes with date labels. The formatting of the labels is specified by first calling LABEL_DATE with the DATE_FORMAT keyword. See LABEL_DATE for more information.

Example: Use the LABEL_DATE function as the callback function to display the X tick values in a date/time format:

```
dummy = LABEL_DATE(DATE_FORMAT='%M %Z')
mytimes = TIMEGEN(12, UNITS='MONTHS', START=JULDAY(1,1,2000))
y = FINDGEN(12)
PLOT, mytimes, y, XTICKUNITS='Time', XTICKFORMAT='LABEL_DATE'
```

The name of a user-defined function:

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [XYZ]TICKUNITS is specified:

If [XYZ]TICKUNITS is *not* specified, the callback function is called with three parameters, *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis.
- *Index* is the tick mark index (indices start at 0).
- *Value* is the data value at the tick mark (a double-precision floating point value).

Note

Value is a double-precision floating-point value that represents the Julian date. The Julian date follows the astronomical convention, where Julian date 0.0d corresponds to 1 Jan 4713 B.C.E. at 12 pm.

If [XYZ]TICKUNITS is specified, the callback function is called with four parameters, *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled (level indices start at 0).

Example 1: Use a callback function to display the Y tick values as a percentage of a fixed value. Note that because we don't specify [XYZ]TICKUNITS, we do not include the *Level* parameter in our function definition:

```
FUNCTION YTICKS, axis, index, value
   fixvalue = 389.0d
   pvalue = (value/fixvalue) * 100.0d
   RETURN, STRING(pvalue, FORMAT='(D5.2,"%")')
END

PRO use_callback

   Y = FINDGEN(10)
   PLOT, Y, YTICKFORMAT='YTICKS'

END
```

Example 2: Create a two-level X axis. Display the X tick values in a customized date/time format that shows the number of days open for business for each month on one level, and marks leap years with an asterisk on another level:

```
FUNCTION XTICKS, axis, index, value, level

   CASE level OF
     0: BEGIN ; months
          ; Number of days open for business in given month:
```

```
            CALDAT, value, month
            open = [18,19,23,20,22,22,19,10,20,21,22,14]
            nbdays = open[month]
            ; Return a string containing the month name plus
            ; the number of business days in parentheses:
            RETURN, STRING(value, nbdays, $
               FORMAT='(C(CMoA), "(", I2, ")")')
         END
      1: BEGIN ; years
            ; Generate a string for the year.
            yrStr = STRING(value, FORMAT='(C(CYI))')
            ; Determine if a leap year.  If so,
            ; append an asterisk to the string.
            CALDAT, value, mo, da, yr
            IF (yr MOD 4 EQ 0) THEN BEGIN
               IF (yr MOD 100 EQ 0) THEN $
                  isLeap = (yr MOD 400) EQ 0 $
               ELSE $
                  IsLeap = 1b
            ENDIF ELSE $
            isLeap = 0b
            IF (isLeap NE 0b) THEN $
               yrStr = yrStr + '*'
               RETURN, yrStr
            END
      ENDCASE

END

PRO plot_sales

   myDates = TIMEGEN(12, UNITS='Months', START=JULDAY(1,1,2000))
   sales = [180,190,230,200,220,220,190,100,200,210,220,140]
   PLOT, myDates, sales, XTICKUNITS=['Months', 'Years'], $
      XTICKFORMAT='XTICKS', XTITLE = 'Date (* = Leap Year)', $
      YTITLE='Sales (units)', POSITION = [0.2, 0.2, 0.9, 0.9]

END
```

[XYZ]TICKINTERVAL

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE

variable equivalent: ![XYZ].TICKINTERVAL

Set this keyword to a scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis range

([XYZ]RANGE) and the number of major tick intervals ([XYZ]TICKS). This keyword takes precedence over [XYZ]TICKS.

For example, if TICKUNITS=[“Seconds”, “Hours”, “Days”], and XTICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

[XYZ]TICKLAYOUT

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKLAYOUT.

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKLEN.

This keyword controls the lengths of tick marks (expressed in normal coordinates) for the individual axes. This keyword, if nonzero, overrides the global tick length specified in !P.TICKLEN, and/or the TICKLEN keyword parameter, which is expressed in terms of the window size.

[XYZ]TICKNAME

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKNAME.

A string array of up to 30 elements that controls the annotation of each tick mark.

[XYZ]TICKS

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKS.

The number of major tick *intervals* to draw for the axis. If this keyword is omitted, IDL selects from three to six tick intervals. Setting this field to *n*, where $n > 1$, produces exactly *n* tick intervals, and *n*+1 tick marks. Setting this field equal to 1 suppresses tick marks.

[XYZ]TICKUNITS

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKUNITS.

Set this keyword to a string or a vector of strings indicating the units to be used for axis tick labeling. If a vector of strings is provided, the axis will be drawn in multiple levels, where each string represents one level in the specified units.

Note

When creating multiple-level axes, you may need to adjust the plot positioning using the POSITION or [XYZ]MARGIN keywords in order to ensure that axis labels and titles are visible in the plot window.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- 'Numeric'
- 'Years'
- 'Months'
- 'Days'
- 'Hours'

- 'Minutes'
- 'Seconds'
- 'Time' - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- ''- Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the 'Numeric' unit. This is the default setting.

If any of the time units are utilized, the tick values are interpreted as Julian date/time values.

Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

[XYZ]TICKV

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKV.

The data values for each tick mark, an array of up to 60 elements.

Note

To specify the number of ticks and their values exactly, set [XYZ]TICKS=*N(where N > 1)* and [XYZ]TICKV=*Values*, where *Values* has *N*+1 elements.

[XYZ]TITLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TITLE.

A string that contains a title for the specified axis.

Z

Accepted by: PLOTS, POLYFILL, TV, TVCRS, XYOUTS.

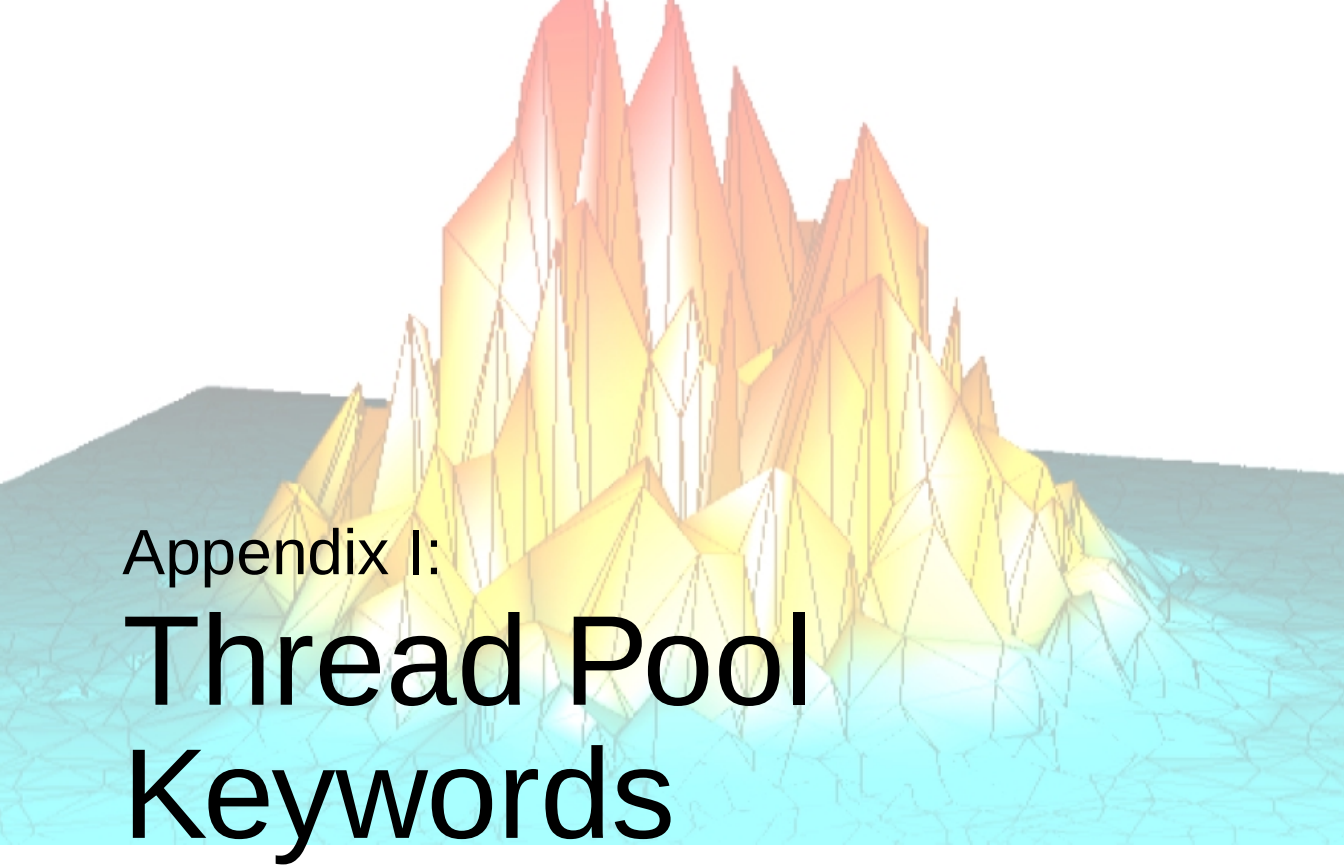
Provides the Z coordinate if a Z parameter is not present in the call. This is of use only if the three-dimensional transformation is in effect (i.e., the T3D keyword is set).

ZVALUE

Accepted by: AXIS, CONTOUR, MAP_SET, OPLOT, PLOT, SHADE_SURF, SURFACE.

Sets the Z coordinate, in normalized coordinates in the range of 0 to 1, of the axis and data output from PLOT, OPLOT, and CONTOUR.

This keyword has effect only if !P.T3D is set and the three-dimensional to two-dimensional transformation is stored in !P.T. If ZVALUE is not specified, CONTOUR will output each contour at its Z coordinate, and the axes and title at a Z coordinate of 0.0.



Appendix I: Thread Pool Keywords

Many of the system routines documented in this manual make use of the IDL thread pool. The thread pool is discussed in detail in Chapter 15, “Multithreading in IDL” in the *Building IDL Applications* manual. System-wide use of the thread pool can be controlled with the CPU procedure, and the current system settings are visible via the !CPU system variable.

All system routines that use the thread pool accept the following keywords, which can be used to modify the default behavior for the duration of a single call. This allows you to modify the settings for a particular computation without affecting the global default settings of the IDL session.

Thread Pool Keywords

TPOOL_MAX_ELTS

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number you specify, IDL will not use the thread pool for the computation. Setting this value to 0 removes any limit on the maximum number of elements, and any computation with at least TPOOL_MIN_ELTS will use the thread pool.

This keyword overrides the default value, given by !CPU.TPOOL_MAX_ELTS. See "Possible Drawbacks to the Use of the IDL Thread Pool" in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a maximum number of elements.

TPOOL_MIN_ELTS

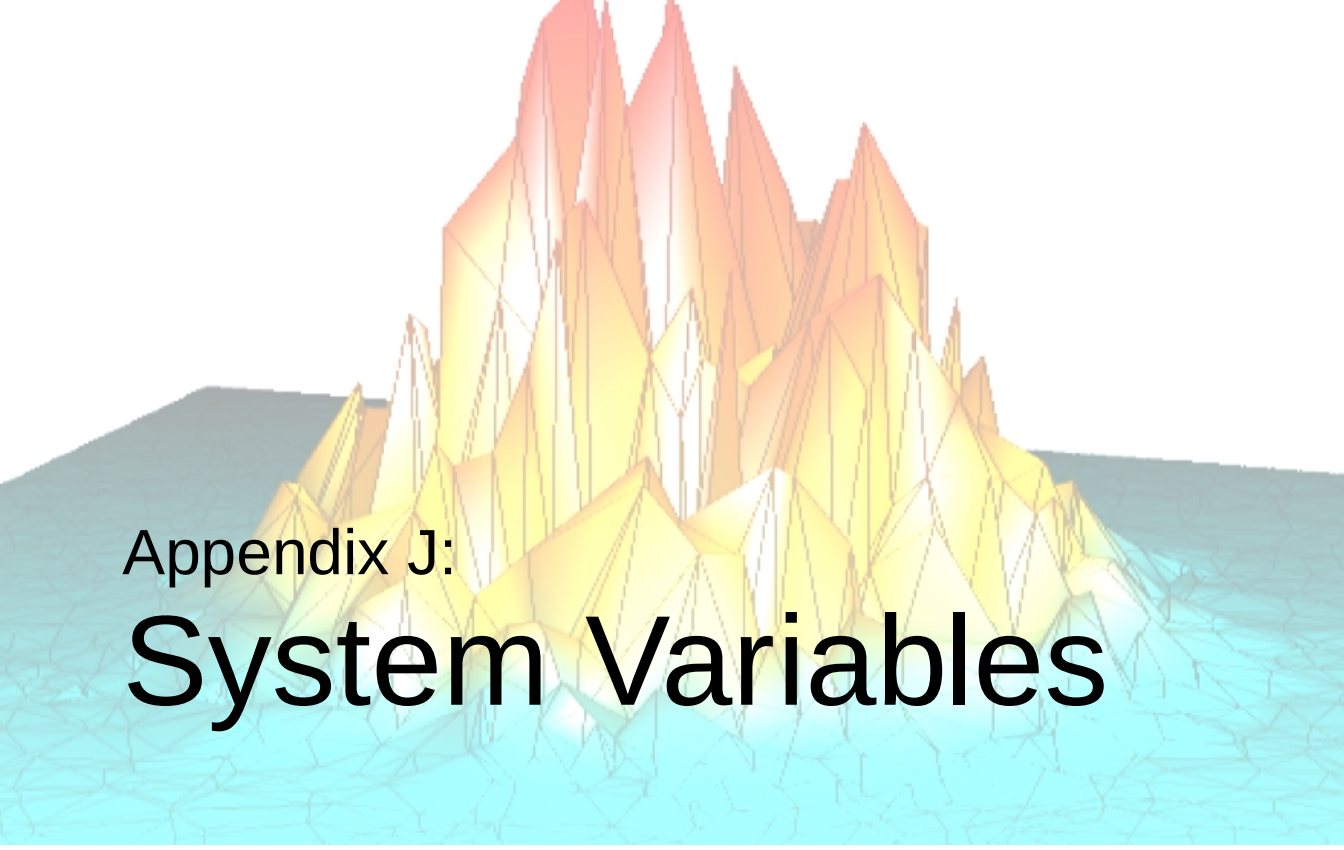
Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number you specify, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

This keyword overrides the default value, given by !CPU.TPOOL_MIN_ELTS. See "Possible Drawbacks to the Use of the IDL Thread Pool" in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a minimum number of elements.

TPOOL_NOTHREAD

Set this keyword to explicitly prevent IDL from using the thread pool for the current computation. If this keyword is set, IDL will use the non-threaded implementation of the routine even if the current settings of the !CPU system variable would allow use of the threaded implementation.

This keyword overrides the default value, given by !CPU.TPOOL_NTHREADS. See "Possible Drawbacks to the Use of the IDL Thread Pool" in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to disable use of the thread pool entirely.



Appendix J:
System Variables

The following topics are included in this appendix:

What Are System Variables? 3876
Constant System Variables 3877
Error Handling System Variables 3879
IDL Environment System Variables 3884
Graphics System Variables 3895

What Are System Variables?

System variables are a special class of predefined variables available to all program units. Their names always begin with the exclamation mark character (!). System variables are used to set the options for plotting, to set various internal modes, to return error status, etc.

System variables have a predefined type and structure that cannot be changed. When an expression is stored into a system variable, it is converted to the variable type, if necessary and possible. Certain system variables are *read only*, and their values cannot be changed. The user can define new system variables with the DEFSYSV procedure.

Constant System Variables

The following system variables contain pre-defined constants or values for use by IDL routines. System variables can be used just like other variables. For example, the command:

```
PRINT, ACOS(A) * !RADEG
```

converts a result expressed in radians to one expressed in degrees.

!DPI

A read-only variable containing the double-precision value of pi (π).

!DTOR

A read-only variable containing the floating-point value used to convert degrees to radians (π/180 ≅ 0.01745).

!MAP

An array variable containing the information needed to effect coordinate conversions between points of latitude and longitude and map coordinates. The values in this array are established by the MAP_SET procedure; the user should not change them directly.

!PI

A read-only variable containing the single-precision value of pi (π).

!RADEG

A read-only variable containing the floating-point value used to convert radians to degrees (180/π ≅ 57.2958).

!VALUES

A read-only variable containing the IEEE single- and double-precision floating-point values *Infinity* and *NaN* (Not A Number). !VALUES is a structure variable with the following fields:

```
** Structure !VALUES, 4 tags, length=24:
   F_INFINITY      FLOAT          Infinity
   F_NAN           FLOAT               NaN
   D_INFINITY      DOUBLE         Infinity
   D_NAN           DOUBLE              NaN
```

where *Infinity* is the value Infinity and *NaN* is the value Not A Number. For more information on these special floating-point values, see "Special Floating-Point Values" in Chapter 19 of the *Building IDL Applications* manual.

Error Handling System Variables

The following system variables are either set by IDL when an error condition occurs or used by IDL when displaying information about errors.

!ERR

This system variable is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !ERR system variable will continue to function as before, but all new code should use !ERROR_STATE.CODE.

!ERROR_STATE

A structure variable which contains the status of the last error message. !ERROR_STATE includes the following fields:

```
** Structure !ERROR_STATE, 8 tags, length=112, data length=108:
   NAME            STRING    'IDL_M_SUCCESS'
   BLOCK           STRING    'IDL_MBLK_CORE'
   CODE            LONG                 0
   SYS_CODE        LONG      Array[2]
   SYS_CODE_TYPE   STRING    ''
   MSG             STRING    ''
   SYS_MSG         STRING    ''
   MSG_PREFIX      STRING    '% '
```

- NAME: A read-only string variable containing the error name of the IDL-generated component of the last error message.
- BLOCK: A read-only string variable containing the name of the message block for the last error message's IDL-generated component.

  Note

  See the *External Development Guide* for more information about blocks.

- CODE: A long-integer variable containing the error code of the last error's IDL-generated component.
- SYS_CODE: A long-integer variable containing the error code of the last error's operating system-generated component, if it exists.

  For historical reasons, SYS_CODE is a two-element longword array. The first element of the array (that is, SYS_CODE[0]) contains the OS-defined error code. The second element of the array is not used, and always contains zero.

Either !ERROR_STATE.SYS_CODE or !ERROR_STATE.SYS_CODE[0] will return the relevant error code.

- SYS_CODE_TYPE: A string describing the type of system code contained in SYS_CODE. A null string in this field indicates that there is no system code corresponding to the current error. The possible non-NULL values are:

Value	Meaning
errno	Unix/Posix system error
win32	Microsoft Windows Win32 system error
winsock	Microsoft Windows sockets library error

Table J-1: SYS_COD_TYPE Values

- MSG: A read-only string variable containing the text of the last IDL-generated error message.
- SYS_MSG: A read-only string variable containing the text of the last error's operating system-generated component, if it exists.
- MSG_PREFIX: A string variable containing the prefix string used for error messages.

This system variable replaces !ERROR, !ERR_STRING, !MSG_PREFIX, !SYSERR_STRING, and !SYSERROR, and includes two new fields: error name and block name. For a more detailed explanation of !ERROR_STATE, see "Error Handling" in Chapter 19 of the *Building IDL Applications* manual.

!ERROR

This system variable is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !ERROR system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.CODE.

!ERR_STRING

This system variable is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !ERR_STRING system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.MSG.

!EXCEPT

An integer variable that controls when IDL checks for invalid mathematical computations (exceptions), such as division by zero. The three allowed values are:

Value	Description
0	Never report exceptions.
1	Report exceptions when the interpreter is returning to an interactive prompt (the default).
2	Report exceptions at the end of each IDL statement. Note that this slows IDL by roughly 5% compared to setting !EXCEPT=1.

Table J-2: EXCEPT Values

For more information on invalid mathematical computations and error reporting, see "Math Errors" in Chapter 19 of the *Building IDL Applications* manual.

The value of !EXCEPT is used by the CHECK_MATH function to determine when to return errors. See "CHECK_MATH" on page 215 for details.

Note

In versions of IDL up to and including IDL 4.0.1, the default exception handling was functionally identical to setting !EXCEPT=2.

!MOUSE

A structure variable that contains the status from the last cursor read operation. !MOUSE has the following fields:

```
** Structure !MOUSE, 4 tags, length=16:
   X               LONG               511
   Y               LONG               252
   BUTTON          LONG                 4
   TIME            LONG        1428829775
```

- X and Y: Contain the location (in device coordinates) of the cursor when the mouse button was pressed.
- BUTTON: Contains
  - 1 (one) if the left mouse button was pressed,

- 2 (two) if the middle mouse button was pressed
- 4 (four) if the right mouse button was pressed.

- TIME: Contains the number of milliseconds since a base time.

See "CURSOR" on page 329 for details on reading the cursor position.

!MSG_PREFIX

This keyword is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !MSG_PREFIX system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.MSG_PREFIX.

!SYSERROR

This keyword is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !SYSERROR system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.SYS_CODE.

!SYSERR_STRING

*This keyword is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !*SYSERR_STRING *system variable will continue to function as before, but we suggest that all new code use !ERROR_*STATE.SYS_MSG*.*

!WARN

A structure variable that causes IDL to print warnings to the console or command log when obsolete IDL features are found at compile time. !WARN has the following fields:

```
** Structure !WARN, 3 tags, length=3:
   OBS_ROUTINES         BYTE         0
   OBS_SYSVARS          BYTE         0
   PARENS               BYTE         0
```

Setting each of the three fields to 1 (one) generates a warning for a different type of obsolete code. If the OBS_ROUTINES field is set equal to one, IDL generates warnings when it encounters references to obsolete internal or library routines. If the OBS_SYSVARS field is set equal to one, IDL generates warnings when it encounters references to obsolete system variables. If the PARENS field is set equal to one, IDL generates warnings when it encounters a use of parentheses to specify an index into an array.

No warnings are generated when the fields of the !WARN structure are set equal to zero (the default).

IDL Environment System Variables

The following system variables contain information about IDL's configuration.

!CPU

IDL can use multiple system processors to perform some computations in parallel. See Chapter 15, "Multithreading in IDL" in the *Building IDL Applications* manual for additional information.

The !CPU system variable supplies information about the state of the system processor, and of IDL's use of it. !CPU is readonly, and cannot be modified directly. Use the CPU procedure to modify values contained in !CPU.

The !CPU structure is defined as follows:

```
{ !CPU, HW_VECTOR:0L, VECTOR_ENABLE:0L, HW_NCPU:0L,
  TPOOL_NTHREADS:0L, TPOOL_MIN_ELTS:0L, TPOOL_MAX_ELTS:0L }
```

The meaning of the fields of !CPU are given in the following table.!

Field	Meaning
HW_VECTOR	True (1) if the system supports a vector unit (e.g. Macintosh Altivec/Velocity Engine). False (0) otherwise. **Note -** This value is currently always 0 (False) on platforms other than Macintosh.
VECTOR_ENABLE	True (1) if IDL will use a vector unit, if such a unit is available on the current system, and False (0) otherwise. **Note -** This value is currently always 0 (False) on platforms other than Macintosh.
HW_NCPU	The number of CPUs contained in the system on which IDL is currently running.

Table J-3: Meaning of !CPU fields

Field	Meaning
TPOOL_NTHREADS	The number of threads that IDL will use in thread pool computations. The default is to use HW_NCPU threads, so that each thread will have the potential to run in parallel with the others. For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to using fewer CPUs.
TPOOL_MIN_ELTS	The number of elements in a computation that are necessary before IDL will use the thread pool to perform the work. For fewer than TPOOL_MIN_ELTS, the main IDL thread will simply perform the work without using the thread pool. It is important not to use the thread pool for small tasks because the overhead of threading will not be offset by the overhead incurred by operation of the pool, and the overall computation will go slower than if threading is not used.
TPOOL_MAX_ELTS	The maximum number of elements in a computation for which IDL will use the thread pool. If this value is 0 (zero) (the default), then no limit is imposed and any computation with at least TPOOL_MIN_ELTS is a candidate for the thread pool. If your computation is too large for the physical memory available on the system, the virtual memory system of the operating system will begin paging. Under such conditions, the performance of the thread pool can be worse than that of a single threaded computation because the threads end up fighting each other for access to memory. TPOOL_MAX_ELTS can be used to prevent this.

Table J-3: Meaning of !CPU fields (Continued)

!DIR

A string variable containing the path to the main IDL directory.

!DLM_PATH

Significant portions of IDL's built in functionality are packaged in the form of Dynamically Loadable Modules (DLMs). DLMs correspond to UNIX sharable libraries or Windows DLLs, depending on the operating system in use. At startup, IDL searches for DLM definition files (which end in the `.dlm` suffix) and makes note of the routines supplied by each DLM. If such are routine is called, IDL loads the DLM that supplies it into memory. To see a list of the DLMs that IDL knows about, use `HELP, /DLM` (see "HELP" on page 774 for more information).

!DLM_PATH is initialized from the environment variable IDL_DLM_PATH at startup. This initialization is similar to that performed for IDL_PATH, (see "!PATH" on page 3891), including recursive path expansion denoted with a leading "+" but *not* including any use of IDLDE preferences settings. See "Environment Variables Used by IDL" in Chapter 1 of the *Using IDL* manual for details on setting the IDL_DLM_PATH environment variable.

If the IDL_DLM_PATH environment variable is not defined, IDL supplies a default that contains the directory in the IDL distribution where the DLMs supplied by Research Systems reside. Once !DLM_PATH is expanded, IDL uses it as the list of places to look for DLM definition files.

Since all DLM searching happens once at startup time, it would be meaningless to change the value of !DLM_PATH afterwards. For this reason, it is a read-only system variable and cannot be assigned to. The value of !DLM_PATH is useful because it shows you where IDL looked for DLMs when it started.

Using Path Definition Tokens to Load a DLM Path

Note that using the `<IDL_BIN_DIRNAME>` token in the IDL_DLM_PATH environment variable can be useful for distributing packages of DLMs with support for multiple operating system and hardware combinations. This token is described in "The Path Definition String" under EXPAND_PATH.

For example, assume that you have your DLMs installed in `/usr/local/mydlm`, with support for each platform in a subdirectory using the same naming convention that IDL uses for the platform dependant subdirectories underneath the bin directory of the IDL distribution. The following line, which might be located in a file executed by a UNIX shell when you log in (`.cshrc`, `.login`), will add the location of the proper DLM for your current system to IDL's !DLM_PATH at startup:

```
% setenv IDL_DLM_PATH
"/usr/local/mydlm/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

(all on a single line). Setting the Windows environment variable IDL_DLM_PATH to a similar string would produce the same result on a Windows system.

Similarly, the `<IDL_VERSION_DIRNAME>` token can be useful for distributing packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms. This token is described in "The Path Definition String" under EXPAND_PATH.

For example, assume that you have your DLMs installed in `/usr/local/mydlm`. Within the `mydlm` subdirectory would be a directory for each supported version of IDL. Within each of those subdirectories would be a subdirectory for each operating system and hardware combination supported by that version of IDL. The following line, which might be located in a file executed by your shell when you log in (`.cshrc`, `.login`) will add the location of the proper DLM for your current system to IDL's !DLM_PATH at startup:

```
% setenv IDL_DLM_PATH
"/usr/local/mydlm/<IDL_VERSION_DIRNAME>/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

(all on a single line). Setting the Windows environment variable IDL_DLM_PATH to a similar string would produce the same result on a Windows system.

!EDIT_INPUT

An integer variable indicating whether keyboard line editing is enabled (when set to a non-zero value) or disabled (when set to zero). By default, !EDIT_INPUT is set equal to one, and line editing is enabled.

By default, IDL saves the last 20 command lines. You can change the number of command lines saved in the recall buffer by setting !EDIT_INPUT equal to the number of lines you would like to save. In order for the change to take effect, IDL must be able to process the assignment statement before providing a command prompt. This means that you must put the assignment statement in the IDL startup file. (See "Startup Files" in Chapter 1 of the *Using IDL* manual for more information on startup files.)

!HELP_PATH

A string variable listing the directories IDL will search for online help files. On UNIX systems, help files must be Adobe Portable Document Format (`.pdf`) files or HTML (`.html` or `.htm`) files. On Windows systems, help files can be HTML Help (`.chm`), Windows Help (`.hlp`), Portable Document Format (`.pdf`), or HTML (`.html` or `.htm`) files.

!HELP_PATH is initialized from the environment variable IDL_HELP_PATH at startup. This initialization is similar to that performed for IDL_PATH (see "!PATH" on page 3891), including recursive path expansion denoted with a leading "+" but *not* including any use of IDLDE preferences settings. See "Environment Variables Used by IDL" in Chapter 1 of the *Using IDL* manual for details on setting the IDL_HELP_PATH environment variable

If the IDL_HELP_PATH environment variable is not defined, IDL supplies a default that contains the directory in the IDL distribution where the help files supplied by Research Systems reside.

To change the value of !HELP_PATH for the duration of an IDL session, simply set the variable equal to a new string containing the desired path. See "Changing the Value of !PATH After IDL Starts" on page 3891 for tips that also apply to setting the value of !HELP_PATH.

!JOURNAL

A read-only long-integer variable containing the logical unit number of the file used for journal output.

!MAKE_DLL

The MAKE_DLL procedure and the CALL_EXTERNAL function's AUTO_GLUE keyword use the standard system C compiler and linker to generate sharable libraries that can be used by IDL in various contexts (CALL_EXTERNAL, DLMs, LINKIMAGE). There is a great deal of variation possible in the use of these tools between different platforms, operating system versions, and compiler releases. The !MAKE_DLL system variable is used to configure how IDL uses them for the current platform.

The !MAKE_DLL structure is defined as follows:

```
{ !MAKE_DLL, COMPILE_DIRECTORY:'', COMPILER_NAME:'', CC:'', LD:''}
```

The meaning of the fields of !MAKE_DLL are given in the following table. When expanding !MAKE_DLL.CC and !MAKE_DLL.LD, IDL substitutes text in place of the PRINTF style codes described in the following table. These codes are case-insensitive, and can be either upper or lower case.

It is possible to use C compilers other than the one assumed by RSI in !MAKE_DLL to build sharable libraries. To do so, you can alter the contents of !MAKE_DLL or use the CC and/or LD keyword to MAKE_DLL and CALL_EXTERNAL. Please understand that RSI cannot and does not maintain a list of all possible compilers and the necessary compiler options. This information is available in your compiler and

system documentation. It is the programmers responsibility to understand the rules for their chosen compiler.

Field	Meaning
COMPILE_DIRECTORY	IDL requires a place to create the intermediate files necessary to build a sharable library, and possibly the final library itself. Unless told to use an explicit directory, it uses the directory given by the COMPILE_DIRECTORY field of !MAKE_DLL. If the IDL_MAKE_DLL_COMPILE_DIRECTORY environment variable is set, IDL uses its value to initialize the COMPILE_DIRECTORY field. Otherwise, IDL supplies a standard location. **Note -** If the directory given by !MAKE_DLL.COMPILE_DIRECTORY does not exist when IDL needs it, IDL automatically creates it for you.
COMPILER_NAME	A string containing the name of the C compiler used by RSI to build the currently running IDL. This field is not used by IDL, and exists solely for informational purposes and to help the end user decide which C compiler to install on their system.
CC	A string used by IDL as a template to construct the command for using the C compiler. This template uses PRINTF style substitution codes, as described in the following table.
LD	A string used by IDL as a template to construct the command for using the linker. This template uses PRINTF style substitution codes, as described in the following table.

Table J-4: Meaning of !MAKE_DLL Fields

The following table describes the substitution codes for the CC and LD fields:

Code	Meaning
%B %b	The base name of a C file to compile. For example, if the C file is `moose.c`, then %B substitutes `moose`.
%C %c	The name of the C file.
%E %e	The name of the linker options file. This file, which is automatically generated by IDL as needed, is used to control the linker. Under UNIX, the system documentation refers to this as an export file, or a linker map file. Microsoft Windows calls it a `.DEF` file.
%F %f	This substitution code is no longer meaningful, and will be ignored.
%L %l	The name of the resulting sharable library. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (`.dll`, `.so`, `.sl`, `.exe`, ...).
%O %o	An object file name. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (`.o`, `.obj`).
%X %x	When expanding !MAKE_DLL.CC, any text supplied via the EXTRA_CFLAGS keyword to MAKE_DLL or CALL_EXTERNAL is inserted in place of %X. IDL does not interpret this text. It is the users responsibility to ensure that it is meaningful in the command. When expanding !MAKE_DLL.LD, the text from the EXTRA_LFLAGS keyword is substituted. The primary use for this code is to include necessary header include directories and link libraries.
%%	Replaced with a single % character.

Table J-5: Description of CC and LD Field Codes

!MORE

An integer variable indicating whether IDL should paginate help output sent to a tty device. Setting !MORE to zero (0) prevents IDL from paginating the output text. A non-zero value (the default) causes IDL to display output text one screen at a time.

!PATH

A string variable listing the directories IDL will search for libraries, include files, and executive commands.

Note

The current directory is always searched before consulting !PATH.

!PATH is initialized from the environment variable IDL_PATH when IDL starts. See "Environment Variables Used by IDL" in Chapter 1 of the *Using IDL* manual for details on setting the IDL_PATH environment variable.

Note

If the IDL_PATH environment variable does not exist, IDL uses the value set in the **Path** tab of the **Preferences** dialog of the IDLDE. If no preference value is set, or if you are using the UNIX command-line interface rather than the IDLDE, IDL uses a default value in order to initialize !PATH.

Note on Path Expansion

When IDL starts, it reads the IDL_PATH environment variable (or the default value, if IDL_PATH does not exist) and builds a value to be stored in !PATH from the specified initialization value. While the initialization value can consist of a "normal" path string specifying all directories to be included in !PATH, it can also take advantage of several special values that IDL uses to dynamically create the value of !PATH. These values (the "+" symbol and the "<IDL_*>" strings) are described in detail in "The Path Definition String" under EXPAND_PATH.

Changing the Value of !PATH After IDL Starts

Once IDL has started, you can alter the value of !PATH by setting it to a new string value. For example, on a UNIX system, to add a directory to !PATH for the duration of an IDL session, you would use a command like the following:

```
!PATH = '/usr2/project/idl_files:' + !PATH
```

Keep the following in mind when changing the value of !PATH by setting its value to a new string:

- Remember to use the proper path string separator character for your platform. If you are writing a cross-platform application that changes !PATH, you may want to use code that looks something like this:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = 'new_path' + pathsep + !PATH
```

where *new_path* is the path to the directory you want to add.

- You can use the EXPAND_PATH function to generate a path string. This method allows you to specify one or more directories and let IDL figure out whether those directories contain `.pro` or `.sav` files. It also allows you to use the "+" character path expansion technique. For example, the following commands add all directories below the *new_path* directory that contain `.pro` or `.sav` files to !PATH:

  ```
  pathsep = PATH_SEP(/SEARCH_PATH)
  !PATH = EXPAND_PATH('+new_path') + pathsep + !PATH
  ```

  See "EXPAND_PATH" in the *IDL Reference Guide* manual for details.

!PROMPT

A string variable containing the text string used by IDL to prompt the user for input. The default is `IDL>`.

!QUIET

A long-integer variable indicating whether informational messages should be printed (0) or suppressed (nonzero). By default, !QUIET is set to zero.

!VERSION

A structure variable containing information about the version of IDL in use. The structure is defined as follows:

```
{ !VERSION, ARCH:'', OS:'', OS_FAMILY:'', OS_NAME:'', $
   RELEASE:'', BUILD_DATE:'', MEMORY_BITS:0, FILE_OFFSET_BITS:0 }
```

The meaning of the fields of !VERSION are given in the following table.

Field	Meaning
ARCH	CPU hardware architecture of the system.

Table J-6: Meaning of the !VERSION Fields

Field	Meaning
OS	The vendor name of the operating system (for example: AIX, HP-UX, IRIX, linux, MacOS, OSF, sunos, Win32). This is the name of the underlying operating system kernel (not necessarily of the overall operating environment: see OS_NAME). Once an OS name is assigned to a platform by RSI, it is not altered in subsequent releases. This makes it safe for use in IDL programs that need to distinguish between platforms. RSI recommends that you first consider using the OS_FAMILY field before using the OS field, as most programs are mainly concerned with high level platform differences.
OS_FAMILY	The generic name of the operating system (UNIX, Windows). RSI recommends that whenever possible this field (rather than OS or OS_NAME) be used in code that must distinguish between platforms.
OS_NAME	The vendor's name for the operating system environment, as used by the vendor for casual descriptive and promotional purposes. For example, on Sun workstations, the name of the operating system kernel (!VERSION.OS) is "sunos", whereas the name of the overall system (!VERSION.OS_NAME) is "Solaris". Vendors change their descriptive environment names from time to time, and RSI updates the OS_NAME field to reflect this. As a result, RSI recommends that IDL users restrict their use of this field to descriptive textual uses, and that the OS_FAMILY or OS fields of !VERSION be used in code that must distinguish between platforms.
RELEASE	IDL version number.
BUILD_DATE	The date the IDL executable was compiled, in the format dictated by ANSI C for the `__DATE__` macro.

Table J-6: Meaning of the !VERSION Fields

Field	Meaning
MEMORY_BITS	The number of bits used to address memory. Possible values are 32 or 64. The number of bits used to address memory places a theoretical upper limit on the amount of memory available to IDL.
FILE_OFFSET_BITS	The number of bits used to position file offsets. Possible values are 32 or 64. The number of bits used to position files places a theoretical upper limit on the largest file IDL can access.

Table J-6: Meaning of the !VERSION Fields

If you need to differentiate between different IDL versions in your code, use !VERSION.OS_FAMILY. At present, two operating system families are supported: UNIX and Windows. For even more detail, you can use !VERSION.OS.

Graphics System Variables

The following system variables control various IDL Direct Graphics functions. These system variables are structures that contain many tags. For example, the command

```
!P.TITLE = 'Cross Section'
```

sets the default plot title.

Many of the functions of the graphics keywords described in Appendix H, “Graphics Keywords”, are also controlled by the system variables !P, !X, !Y, and !Z.

You can change the default style of plots, fonts, etc., by setting the corresponding field in the appropriate system variable. Also, some effects that persist longer than one call are controlled only by system variables. The field !P.MULTI is one example.

!C System Variable

The cursor system variable. Currently, the only function of this system variable is to contain the subscript of the largest or smallest element found by the MAX and MIN functions. That information is better obtained through the optional output arguments to those routines. !C is included only for compatibility with old versions of IDL.

!D System Variable

This system variable is a structure that contains information about the current graphics output device (or window, on a windowing system). Fields, in alphabetical order, are:

FILL_DIST

The line interval, in device coordinates, required to obtain a solid fill.

FLAGS

A longword of flags that provide information about the current device. Each bit is a flag encoded as shown in the following table.

Bit	Value	Function
0	1	Device has scalable pixel size (e.g., PostScript).
1	2	Device can output text at an arbitrary angle using hardware.
2	4	Device can control line thickness with hardware.
3	8	Device can display images.
4	16	Device supports color.
5	32	Device supports polygon filling with hardware.
6	64	Device hardware characters are monospace.
7	128	Device can read pixels (i.e., it supports TVRD).
8	256	Device supports windows.
9	512	Device prints black on a white background (e.g., printers are plotters).
10	1024	Device has *no* hardware characters.
11	2048	Device does line-fill style polygon filling in hardware.
12	4096	Device will apply Hershey-style embedded formatting commands to device fonts.
13	8192	Device is a pen plotter.
14	16384	Device can transfer 16-bit pixels.
15	32768	Device supports Kanji characters.
16	65536	Device supports widgets.
17	131072	Device has Z-buffer.
18	262144	Device supports TrueType fonts.

Table J-7: !D.FLAGS Bit Definitions

To test whether a particular bit is set on your system, use an IDL command like the following:

```
IF (!D.FLAGS AND value) NE 0 THEN PRINT, 'Bit is set.'
```

where value is the value associated with the bit you wish to examine. For example, to check whether the device supports color, use:

```
IF (!D.FLAGS AND 16) NE 0 THEN PRINT, 'Bit is set.'
```

N_COLORS

The number of allowed color values. In the case of devices with windows, this field is set after the window system is initialized. For a monochrome system, !D.N_COLORS is 2. For TrueColor displays, !D.N_COLORS is 2^24-1 (roughly 16.7 million colors).

NAME

A string containing the name of the device.

ORIGIN

A two-element integer array containing the current pan/scroll offset. An offset of (0, 0) is normal. Positive offsets shift the display memory to the right and upwards. This field has relevance only with devices with hardware pan and scroll abilities.

TABLE_SIZE

The number of color table indices.

Note

For TrueColor visuals, !D.TABLE_SIZE will always be 256. If the visual depth is less than 24 bits, IDL emulates 256 entries.

UNIT

The logical number of the file open for output by the current graphics device. This field only has meaning for devices that write to a file if the file is accessible to the user from IDL, and is 0 if no file is open.

For example, the PostScript driver fills this field with the unit number of the file open for PostScript output. In the case of Tektronix output to a file, !D.UNIT may be set to either + or – the logical unit number.

WINDOW

The index of the currently open window. This field is set to -1 if no window is currently open. This field is used only with devices that support windows.

X_CH_SIZE, Y_CH_SIZE

The width and height of the rectangle that encloses the “average” character in the current font, in device units (usually pixels).

These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width is the value of X_CH_SIZE. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines is determined explicitly by the value of Y_CH_SIZE.

For device fonts, the character size is fixed. When the device font system is in use, the value of X_CH_SIZE is silently ignored, and only the Y_CH_SIZE value is used.

X_PX_CM, Y_PX_CM

The approximate number of pixels per centimeter in the X and Y directions.

X_SIZE, Y_SIZE

The total size of the display or window in the X and Y directions, in device units.

X_VSIZE, Y_VSIZE

The size of the visible area of the display or window. This area can be smaller than the total size fields.

ZOOM

This field contains the current X and Y zoom factors for the display or window. This field has relevance only with devices equipped with hardware zoom. A zoom factor of [1, 1] is normal.

!ORDER System Variable

Controls the direction of image transfers when using the TV, TVSCL, and TVRD procedures. If !ORDER is 0, images are transferred from bottom to top, i.e. the row with a 0 subscript is written on the bottom. Setting !ORDER to 1, transfers images from top to bottom.

!P System Variable

The main plotting system variable structure. All fields, except !P.MULTI, have a directly corresponding keyword parameter in the plot procedures: PLOT, OPLOT, CONTOUR, and SURFACE. Fields, in alphabetical order, are:

BACKGROUND

The background color index. When erasing the screen or page, all pixels are set to this color. The default value is 0. Not all devices support this feature.

CHANNEL

The default source or destination channel. This field has meaning only on graphics devices that contain multiple display channels, and is device dependent. It may contain either a channel mask or index.

CHARSIZE

The overall character size of all annotations when Hershey fonts are selected. This field has no effect on the character size when hardware (device) fonts are selected, except for devices that support scalable pixel sizes (i.e., Postscript). Note, however, that !P.CHARSIZE always affects the layout and scaling of a plot, regardless of the font system being used. The default size is 1.0.

CHARTHICK

An integer specifying the thickness of the lines used to draw the characters when using the vector drawn fonts. This field has no effect on the appearance of characters drawn with the hardware fonts. Normal thickness is 1.

CLIP

The device coordinates of the clipping window, a 6-element vector of the form $[x_0, y_0, x_1, y_1, z_0, z_1]$, specifying two opposite corners of the volume to be displayed. In the case of two-dimensional displays, the Z coordinates can be omitted. Normally, the clipping window coordinates are implicitly set by PLOT, CONTOUR,

SHADE_SURF, and SURFACE to correspond to the plot window. You may also manually set !P.CLIP if you want to specify a different rectangular clipping window or if the clipping coordinates have not yet been set in the current IDL session.

COLOR

The default color index.

FONT

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to selects the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See Appendix N, “Fonts”, for a complete description of IDL’s font systems.

LINESTYLE

The default style of the lines used to connect points. A line style index of 0 yields a solid line. See “LINESTYLE” on page 3857 for a description of the linestyles.

MULTI

!P.MULTI allows making multiple plots on a page or screen. It is a 5-element integer array defined as follows:

!P.MULTI[0] contains the number of plots remaining on the page. If !P.MULTI[0] is less than or equal to 0, the page is cleared, the next plot is placed in the upper left hand corner, and !P.MULTI[0] is reset to the number of plots per page.

Setting !P.MULTI[0] to a value greater than zero can be used to manually set the plotting area to a specific row and column. For example, to plot in the lower left corner of a window of two rows and two columns, set !P.MULTI as follows:

```
!P.MULTI=[2,2,2]
PLOT, X, Y
```

!P.MULTI[1] is the number of plot columns per page. If this value is less than or equal to 0, one is assumed. If more than two plots are ganged in either the X or Y direction, the character size is halved.

!P.MULTI[2] is the number of rows of plots per page. If this value is less than or equal to 0, one is assumed.

!P.MULTI[3] contains the number of plots stacked in the Z dimension.

!P.MULTI[4] is 0 to make plots from left to right (column major), and top to bottom, and is 1 to make plots from top to bottom, left to right (row major).

Note

If !P.MULTI[0] is zero, an erase will occur before the current plot is displayed (unless the /NOERASE keyword is set). This is true no matter whether !P.POSITION and/or !P.REGION are set.

For example, to gang two plots across the page:

```
!P.MULTI = [0, 2, 0, 0, 0]
PLOT, X0, Y0                    ;Make left plot.
PLOT, X1, Y1                    ;Right plot.
```

To gang two plots vertically:

```
!P.MULTI = [0, 0, 2, 0, 0]
PLOT, X0, Y0                    ;Make top plot.
PLOT, X1, Y1                    ;Bottom plot.
```

To make four plots per page, two across and two up and down:

```
!P.MULTI = [0, 2, 2, 0, 0]
```

and then call plot four times.

To reset !P.MULTI back to the normal one plot per page:

```
!P.MULTI = 0
```

NOCLIP

A field which, if set, inhibits the clipping of the graphic vectors and vector-drawn text. By default, most routines clip to the plotting window, with the exception of PLOTS and XYOUTS. !P.CLIP contains the clipping rectangle.

NOERASE

Set this field to a non-zero value to inhibit erasing the screen before plotting.

NSUM

The number of adjacent points to average to obtain a plotted point.

POSITION

Specifies the normalized coordinates of the rectangular plot window. This is a four element floating point vector (x_0, y_0, x_1, y_1), where (x_0, y_0) is the origin, and (x_1, y_1) is the upper right corner.

!P.POSITION determines the plotting window if x_0 does not equal x_1, and the POSITION keyword is not present. If set, it overrides the effect of the MARGIN and !P.MULTI variables and keywords.

Note

If !P.POSITION (or the POSITION keyword) or !P.REGION is set, all but the first element of !P.MULTI are ignored.

PSYM

The default plotting symbol index. Each point drawn by PLOT, PLOTS, and OPLOT is marked with a symbol if this field is non-zero. The possible symbols are given in "PSYM" on page 3860.

REGION

A four element vector that specifies the normalized coordinates of the rectangle enclosing the plot region, which includes the plot data window and its surrounding annotation area. It is in the same form as !P.POSITION, (x_0, y_0, x_1, y_1), where (x_0, y_0) is the origin, and (x_1, y_1) is the upper right corner. It is ignored if !P.REGION[0] is equal to !P.REGION[2].

Note

!P.POSITION (or the POSITION keyword) takes precedence over !P.REGION.

SUBTITLE

The plot subtitle, placed under the X axis label.

T

Contains the homogeneous 4 x 4 transformation matrix. This field is a two-dimensional array of double-precision floating-point values. For more information about transformations, refer to "Three-Dimensional Graphics" in Chapter 18 of the *Using IDL* manual.

T3D

Enables the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix.

THICK

The thickness of the lines connecting points. 1.0 is normal.

TITLE

The main plot title.

TICKLEN

The length of the tick marks, expressed as a fraction of the plot size (from 0.0 to 1.0). The default is 0.02. A value of 0.5 makes a grid. Negative values make the tick marks point outward.

!X, !Y, !Z System Variables

The system variables !X, !Y, and !Z, are structures of type AXIS, that affect the appearance and scaling of the three axes. The fields for !X, !Y, and !Z have identical fields with identical meanings and usage. In addition, almost all fields have corresponding keyword parameters, with identical function, but with temporary effect. For example, to suppress the minor tick marks on the X axis using the !X system variable, you could use the command:

```
!X.MINOR = -1
```

To suppress the tick marks for just one call to plot, you could use the command:

```
PLOT, X, Y, XMINOR = -1
```

The name of the keyword parameter is simply the name of the system variable field, prefixed with the letter X, Y, or Z.

The fields for these system variables, in alphabetical order are:

CHARSIZE

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This field has no meaning when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor. For example, setting !P.CHARSIZE to 2.0, and !X.CHARSIZE to 0.5 results in a character size of 1.0 for the X axis.

CRANGE

The output axis range. Setting this variable has no effect; set ![XYZ].RANGE to change the range. ![XYZ].CRANGE[0]) always contains the minimum axis value,

and ![XYZ].CRANGE[1] contains the maximum axis value of the last plot before extending the axes.

Note

If the axis is logarithmic, the CRANGE field reports the log (base 10) of the minimum and maximum axis values.

Example 1:

```
;Create a 10-element array.
a = INDGEN(10)

;Plot the straight line.
PLOT, a

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

IDL prints:

```
0.00000      10.0000
```

Example 2:

```
;Plot a with logarithmic scaling on the X axis.
PLOT, a, /XLOG

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

The axis is scaled from 10^{-12} to 10^{2}. IDL prints:

```
-12.0000      2.00000
```

GRIDSTYLE

The index of the linestyle to be used for tick marks and grids. See “LINESTYLE” on page 3857 for a description of the linestyles

MARGIN

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. The plot window is the rectangular area that contains the plot data, i.e. the area enclosed by the axes.

The default values for !X.MARGIN are [10, 3] yielding a 10-character wide left margin and a 3-character wide right margin. The values for !Y.MARGIN are [4, 2], for a 4-character high bottom margin and a 2-character high top margin. While specifying !Z.MARGIN will not cause an error, Z margins are currently ignored.

When calculating the size and position of the plot window, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

MINOR

The number of minor tick mark intervals. If !X.MINOR is 0, the default, the number of minor tick intervals is automatically determined from the tick mark increment. You can force a given number of minor tick intervals by setting this field to the desired number. To suppress minor tick marks, set !X.MINOR to -1.

OMARGIN

A 2-element array specifying the “outer” margin on the left (bottom) and right (top) sides of a multi-plot window, in units of character size. A multi-plot window is created by setting the !P.MULTI system variable field. OMARGIN controls the amount of space around the entire plot area, including individual plot margins set with !X.MARGIN and !Y.MARGIN. The default values for !X.OMARGIN and !Y.OMARGIN are [0, 0].

When calculating the size and position of the individual plots, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

RANGE

The input axis range, a 2-element vector. The first element is the axis minimum, and the second is the maximum. Set this field, or use the corresponding keyword parameter, to specify the data range to plot. If axis end point rounding is selected (see STYLE above), the final axis range may not be equal to this input range. The field !X.CRANGE contains the axis range used for the plot before extending the axes. Set both elements equal to 0 for automatic axis ranges:

```
!X.RANGE = 0
```

For example, to force the X axis to run from 5.5 to 8.3:

```
!X.RANGE = [5.5, 8.3]
PLOT, X, Y
```

Alternatively, by using keywords:

```
PLOT, X, Y, XRANGE=[5.5, 8.3]
```

Note that even though the range was set to (5.5, 8.3), the resulting plot has a range of (5.5, 8.5), because axis rounding is the default.

REGION

Contains the normalized coordinates of the region. This field is similar to WINDOW, in that it is set by the graphics procedures and is a 2-element floating point array. To change the default plotting region, set !P.REGION.

S

The scaling factors for converting between data coordinates and normalized coordinates (a 2-element array). The formula for conversion from data (X_d) to normalized (X_n) coordinates is $X_n = S_1 X_d + S_0$

If logarithmic scaling is in effect, substitute $\log_{10}(X_d)$ for X_d.

The CONVERT_COORD function can be used to convert between coordinate systems. The user should save and restore these fields when switching between windows or devices with different sizes and/or scaling.

STYLE

The style of the axis encoded as bits in a longword. The axis style can be set to exact, extended, none, or no box using this field. The following table lists the axis style bit values:

Bit	Value	Function
0	1	Exact. By default, the end points of the axis are rounded in order to obtain even tick increments. Setting this bit inhibits rounding, making the axis fit the data range exactly.
1	2	Extend. If this bit is set, the axes are extended by 5% in each direction, leaving a border around the data.
2	4	None. If this bit is set, the axis and its annotation are not drawn.
3	8	No box. Normally, PLOT and CONTOUR draw a box-style axis with the data window surrounded by axes.
4	16	Inhibits setting the Y axis minimum value to zero when the data are all greater than 0. The keyword YNOZERO sets this bit temporarily.

Table J-8: Axis Style Bit Values

Note that this system variable field is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the !X.STYLE system variable to `1+8`, or 9.

For example, to set the Y axis style to exact using the !Y system variable:

```
!Y.STYLE = 1
```

or by using a keyword parameter:

```
PLOT, X, Y, YSTYLE = 1
```

THICK

The thickness of the axis line. 1.0 is normal.

TICKFORMAT

Set this field to a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels.

See “[XYZ]TICKFORMAT” on page 3865 for more information.

TICKINTERVAL

A scalar indicating the interval between major tick marks for the first axis level. This setting takes precedence over ![XYZ].TICKS.

For example, if !X.TICKUNITS=[“Seconds”, “Hours”, “Days”], and !X.TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

See “[XYZ]TICKINTERVAL” on page 3867 for more information.

TICKLAYOUT

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

See “[XYZ]TICKLAYOUT” on page 3868 for more information.

TICKLEN

The lengths of tick marks (expressed in normal coordinates) for the individual axes.

TICKNAME

The annotation for each tick. A string array of up to 60 elements. Setting elements of this array allows direct specification of the tick label. If this element contains a null string, the default value, IDL annotates the thick with its numeric value. Setting the element to a 1-blank string suppresses the tick annotation.

For example, to produce a plot with an abscissa labeled with the days of the week:

```
;Set up X axis tick labels.
!X.TICKNAME = ['SUN', 'MON', 'TUE', 'WED', $
    'THU', 'FRI', 'SAT']

;Use six tick intervals, requiring seven tick labels.
!X.TICKS = 6

;Plot the data, this assumes that Y contains 7 elements.
PLOT, Y
```

The same plot can be produced, using keyword parameters, with:

```
;Set fields, as above, only temporarily.
PLOT, Y, XTICKN = ['SUN', 'MON', 'TUE', 'WED',$
    'THU', 'FRI', 'SAT'], XTICKS = 6
```

TICKS

The number of major tick intervals to draw for the axis. If !X.TICKS is set to 0, the default, IDL will select from three to six tick intervals. Setting this field to *n*, where *n* > 1, produces exactly *n* tick intervals, and *n*+1 tick marks. Setting this field equal to 1 suppresses tick marks.

TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling.

Note

The singular form of each of the time value strings is also acceptable (e.g, !X.TICKUNITS='Day' is equivalent to !X.TICKUNITS='Days').

Note

To set the ![XYZ].TICKUNITS field to a single string, the following approach is recommended:

```
!X.TICKUNITS = ''     ; Clear all previous tick unit strings.
!X.TICKUNITS = ['Days']  ;Single unit string in array.
```

The following:

```
!X.TICKUNITS = 'Days'
```

will copy the 'Days' string to all levels, resulting in a multi-level axis.

See “[XYZ]TICKUNITS” on page 3869 for more information.

TICKV

An array of up to 60 elements containing the data values for each tick mark. You can directly specify the location of each tick by setting !X.TICKS to the number of tick marks (the number of intervals plus 1) and storing the data values of the tick marks in !X.TICKV. If, as is true by default, !X.TICKV[0] is equal to !X.TICKV[1], IDL automatically determines the value of the tick marks.

TITLE

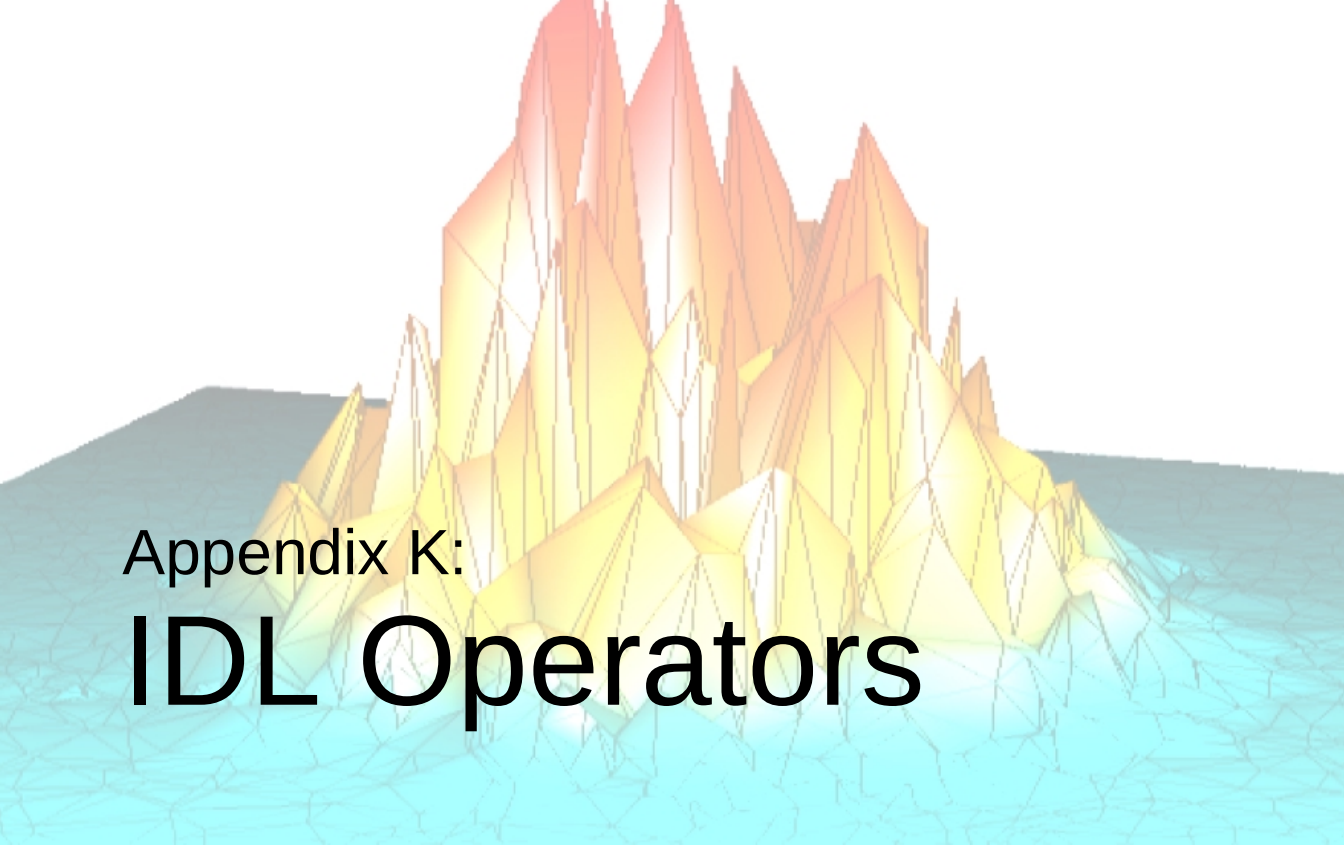
A string containing the axis title.

TYPE

The type of axis, 0 for linear, 1 for logarithmic.

WINDOW

Contains the normalized coordinates of the axis end points, the plot data window. This field is set by PLOT, CONTOUR, SHADE_SURF, and SURFACE. Changing its value has no effect. A 2-element floating point array. To change the default plotting window, set !P.POSITION. The keyword parameter POSITION sets the plot data window on a per call basis.



Appendix K: IDL Operators

This appendix lists all IDL operators and provides brief examples of their usage. For more information on IDL operators, see Chapter 2, “Expressions and Operators” in the *Building IDL Applications* manual. The following topics are covered in this appendix:

Mathematical Operators 3912
Minimum and Maximum Operators 3913
Matrix Operators 3914
Boolean Operators 3915
Relational Operators 3917
Other Operators 3918
Operator Precedence 3919

Mathematical Operators

Operator	Description	Example
+	Addition	;Store the sum of 3 and 6 in B: B = 3 + 6
	String Concatenation	;Store the string value of "John Doe" in B: B = 'John' + ' ' + 'Doe'
–	Subtraction	;Store the value of 5 subtracted from 9 in C: C = 9 - 5
	Negation	;Change the sign of C: C = -C
*	Multiplication	;Store the product of 2 and 5 in variable C: C = 2 * 5
	Pointer dereference	If `ptr` is a valid pointer (created via the PTR_NEW function), then `*ptr` is the value held by the heap variable that `ptr` points to. For more information on IDL pointers, see Chapter 8, "Pointers" in the *Building IDL Applications* manual.
/	Division	;Store result of 10.0 divided by 3.2 in ;variable D: D = 10.0/3.2
^	Exponentiation	;Store result of 2 raised to the 3rd power in ;variable B: B = 2^3
MOD	Modulo	;Print the value of 9 modulo 5: PRINT, 9 MOD 5 IDL Prints: 4

Table K-1: Mathematical Operators

Minimum and Maximum Operators

Operator	Description	Example
<	Minimum operator.The value of “A < B”is equal to the smallerof A or B. For complex numbersthe absolute value isused.	;Set A equal to 3. A = 5 < 3 ;Set all points in array ARR that are larger ;than 100 to 100: ARR = ARR < 100 ;Set X to the smallest of the three operands: X = X0 < X1 < X2
>	Maximum operator.“A > B” is equal tothe larger of A or B. For complex numbersthe absolute value isused.	;‘>’ is used to avoid taking the log of zero ;or negative numbers: C = ALOG(D > 1E - 6) ;Plot positive points only. Negative points ;are plotted as zero: PLOT, ARR > 0

Table K-2: Minimum and Maximum Operators

Matrix Operators

Operator	Description	Example
#	Computes array elementsby multiplying thecolumns of the first arrayby the rows of the secondarray.	;A 3-column by 2-row array: array1 = [[1, 2, 1], [2, -1, 2]] ;A 2-column by 3-row array: array2 = [[1, 3], [0, 1], [1, 1]] PRINT, array1#array2 IDL prints: 7 -1 7 2 -1 2 3 1 3
##	Computes array elementsby multiplying the rows ofthe first array by thecolumns of the secondarray.	;A 3-column by 2-row array: array1 = [[1, 2, 1], [2, -1, 2]] ;A 2-column by 3-row array: array2 = [[1, 3], [0, 1], [1, 1]] PRINT, array1##array2 IDL prints: 2 6 4 7

Table K-3: Matrix Operators

Boolean Operators

Operator	Description	Example

AND	Boolean AND. Returns“true” whenever both ofits operands are true;otherwise, the result is“false.” Any oddinteger is consideredtrue, and any eveninteger is consideredfalse. For integer,longword, and byteoperands, a bitwiseAND operation isperformed. Foroperations on othertypes, the result is equalto the second operand ifthe first operand is notequal to zero or the nullstring; otherwise, theresult is zero or the nullstring.	`PRINT, (5 GT 2) AND (4 GT 2)`
		IDL Prints: `1`
		
		`PRINT, (5 GT 2) AND (4 GT 5)`
		IDL Prints: `0`
		
		`PRINT, 5 AND 3`
		IDL Prints: `1`
		
		`PRINT, 5 AND 2`
		IDL Prints: `0`
		
		`PRINT, 4 AND 2`
		IDL Prints: `0`

NOT	Boolean complement.“NOT true” is equal to“false” and “NOTfalse” is equal to “true.”For floating-pointoperands, the result is1.0 if the operand iszero; otherwise, theresult is zero. Not validfor string or complexoperands.	`IF (NOT (5 GT 6)) THEN PRINT, 'True'`
		
		IDL Prints:
		`True`

Table K-4: Boolean Operators

Operator	Description	Example
OR	Boolean OR. Forinteger or byteoperands, a bitwiseinclusive OR isperformed. Forexample, `3 OR 5`equals 7. For floating-point operands, the ORoperator returns the firstoperand if it is non-zero, or the 2nd operandotherwise.	`IF ((5 GT 3) OR (4 GT 5)) THEN PRINT, 'True'`

XOR	Boolean exclusive OR.XOR is only valid forbyte, integer, andlongword operands. Abit in the result is set to1 if the correspondingbits in the operands aredifferent; if they areequal, it is set to zero.	`IF ((5 GT 3) XOR (4  GT 5)) THEN $`
		`  PRINT, 'Different' ELSE PRINT, 'Same'`
		
		IDL Prints:
		`Different`

Table K-4: Boolean Operators (Continued)

Relational Operators

Operator	Description	Example
EQ	Equal to	`;Determine if A equals B:` `IF (A EQ B) THEN PRINT, 'True'`

GE	Greater than or equal to	`;Determine if A is greater than or equal`
		`;to B:`
		`IF (A GE B) THEN PRINT, 'True'`

GT	Greater than	`;Determine if A is greater than B:` `IF (A GT B) THEN PRINT, 'True'`

LE	Less than or equal to	`;Determine if A is less than or equal`
		`;to B:`
		`IF (A LE B) THEN PRINT, 'True'`

LT	Less than	`; Determine if A is less than B:` `IF (A LT B) THEN PRINT, 'True'`
NE	Not equal to	`; Determine if A does not equal B:` `IF (A NE B) THEN PRINT, 'True'`

Table K-5: Relational Operators

Other Operators

Operator	Description	Example

[ ]	Array concatenation. Theexpression `[A,B]` is an arrayformed by concatenating Aand B.	`;Define C as three-point vector:`
		`C = [0, 1, 3]`
		
		`;Add 5 to the end of C:`
		`PRINT, [C, 5]`
		IDL Prints: `0 1 3 5`
		
		`;Insert -1 at the beginning of C:`
		`PRINT, [-1, C]`
		IDL Prints: `-1 0 1 3`

	Enclose array subscripts	`A = [2, 1, 5]`
		`;Print the 3rd element in A:`
		`PRINT, A[2]`
		IDL Prints: `5`

( )	Group expressions to controlorder of evaluation	`PRINT, 3 + 4 * 2 ^ 2 /2`
		IDL Prints: `11`
		
		`PRINT, (3 + (4 * 2) ^ 2 / 2)`
		IDL Prints: `35`

=	Assignment	`;Assign 5 to variable A:`
		`A = 5`
		
		`Assign "Hello World" to variable B:`
		`B='Hello World'`

?:	Conditional expression. For *value=expr1 ? expr2 : expr3* *expr1* is evaluated first. If*expr1* is true, then*value=expr2*. If *expr1* is false,*value=expr3*.	`A=6 & B=4`
		`;Set Z to the greater of A and B:`
		`Z = (A GT B) ? A : B`
		`PRINT, Z`
		
		IDL Prints: `6`

Table K-6: Other Operators

Operator Precedence

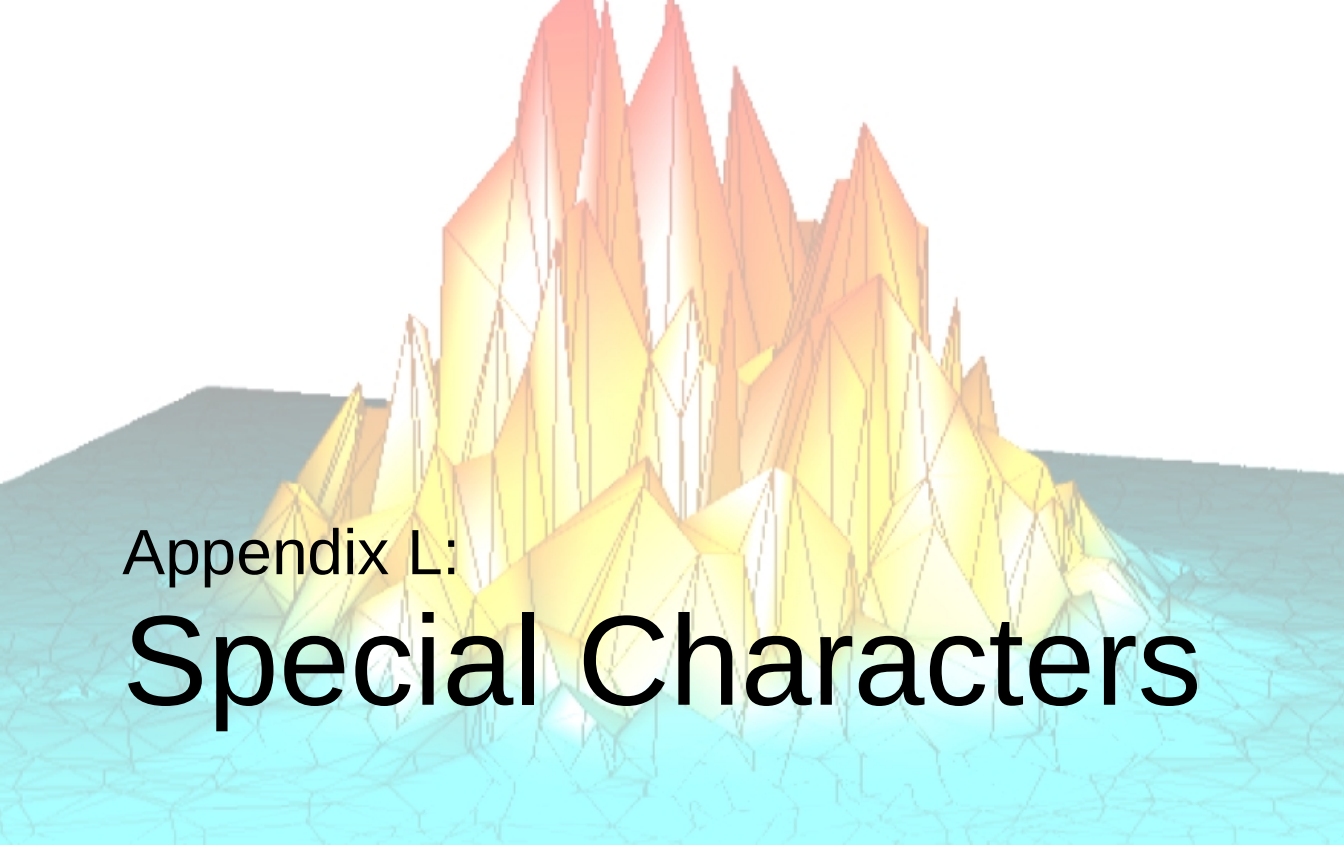
The following table lists IDL's operator precedence. Operators with the highest precedence are evaluated first. Operators with equal precedence are evaluated from left to right.

Priority	Operator
First (highest)	( ) (parentheses, to group expressions)
	[ ] (brackets, to concatenate arrays)
Second	. (structure field dereference)
	[ ] (brackets, to subscript an array)
	( ) (parentheses, used in a function call)
Third	* (pointer dereference)
	^ (exponentiation)
Fourth	* (multiplication)
	# and ## (matrix multiplication)
	/ (division)
	MOD (modulus)
Fifth	+ (addition)
	- (subtraction and negation)
	< (minimum)
	> (maximum)
	NOT (Boolean negation)

Table K-7: Operator Precedence

Priority	Operator
Sixth	EQ (equality)
	NE (not equal)
	LE (less than or equal)
	LT (less than)
	GE (greater than or equal)
	GT (greater than)
Seventh	AND (Boolean AND)
	OR (Boolean OR)
	XOR (Boolean exclusive OR)
Eighth	?: (conditional expression)

Table K-7: Operator Precedence (Continued)



Appendix L: Special Characters

Within the IDL environment, a number of characters have special meanings.

The following table lists characters with special interpretations and states their functions in IDL. These characters are discussed further in the descriptions following the table.

Character	Function
!	• First character of system variable names and font-positioning commands.
'	• Delimit string constants • Indicate part of octal or hex constant
;	• Begin comment field

Table L-1: Special Characters

Character	Function
$	• Continue current command on the next line • Issue operating system command if entered on a line by itself.
"	• Delimit string constants or precede octal constants
.	• Indicate constant is floating point • Start executive command
&	• Separate multiple statements on one line
:	• End label identifiers • Separate start and end subscript ranges
*	• Multiplication operator • Array subscript range • Pointer dereference (if in front of a valid pointer)
@	• Include file • Execute IDL batch file
?	• Invokes online help when entered at the IDL command line. • Part of the ?: ternary operator used in conditional expressions.

Table L-1: Special Characters (Continued)

Exclamation Point (!)

The exclamation point is the first character of names of IDL system-defined variables. System variables are predefined scalar variables of a fixed type. Their purpose is to override defaults for system procedures, to return status information, and to control the action of IDL.

Apostrophe (')

The apostrophe delimits string literals and indicates part of an octal or hex constant.

Semicolon (;)

The semicolon is the first character of the optional comment field of an IDL statement. All text on a line following a semicolon is ignored by IDL. A line can consist of a comment only or both a valid statement and a comment.

Dollar Sign ($)

The dollar sign at the end of a line indicates that the current statement is continued on the following line. The dollar sign character can appear anywhere a space is legal except within a string constant or between a function name and the first open parenthesis. Any number of continuation lines are allowed.

When the $ character is entered as the first character after the IDL prompt, the rest of the line is sent to the operating system as a command. If $ is the only character present, an interactive subprocess is started. Under UNIX, IDL execution suspends until the new shell process terminates.

Quotation Mark (")

The quotation mark precedes octal numbers, which are always integers, and delimits string constants. Example: "`100B` is a byte constant equal to 64 base 10 and "`Don't drink the water`" is a string constant.

Period (.)

The period or decimal point indicates in a numeric constant that the number is of floating-point or double-precision type. Example: 1.0 is a floating-point number. Also, in response to the IDL prompt, the period begins an executive command. For example,

```
.run myfile
```

causes IDL to compile the file *myfile.pro*. If *myfile.pro* contains a main program, the program also will be executed. In addition, the period precedes the name of a tag when referring to a field within a structure. For example, a reference to a tag called NAME in a structure stored in the variable A is A.NAME.

Ampersand (&)

The ampersand separates multiple statements on one line. Statements can be combined until the maximum line length is reached. For example, the following line contains two statements:

```
I = 1 & PRINT, 'value:', I
```

Colon (:)

The colon ends label identifiers. Labels can only be referenced by GOTO and ON_ERROR statements. The following line contains a statement with the label LOOP1.

```
LOOP1: X = 2.5
```

The colon also separates the starting and ending subscripts in subscript range specifiers. For example, A(3:6) designates elements three to six of the variable A.

Asterisk (*)

The asterisk represents one of the following, depending on context:

1. Multiplication (3 * 3).
2. An ending subscript range equal to the size of the dimension. For example, `A[3:*]` represents all elements of the vector A from A[3] to the last element, while `B[*,3]` represents all elements of row four of matrix B.
3. A pointer dereference operation. For example, if `ptr` is a valid pointer (created via the PTR_NEW function), then `*ptr` is the value held by the heap variable that `ptr` points to. For more information on IDL pointers, see Chapter 8, "Pointers" in the *Building IDL Applications* manual.

At Sign (@)

The "at" sign is used both as an include character and to signal batch execution.

@ as an Include Character

The "at" sign at the beginning of a line causes the IDL compiler to substitute the contents of the file whose name appears after the @ for the line. If the full path name is not specified after the @ symbol, IDL searches the current directory and a list of known locations where procedures are kept.

- **UNIX:** IDL searches for the file in the list of directories (as established by the environment variable IDL_PATH) stored in the system variable !PATH.
- **Windows:** IDL searches for the file in the list of directories stored in the system variable !PATH (specified in the “Preferences” dialog of the File menu).

For example, the line

```
@doit
```

when included in a file, causes the file *doit.pro* to be compiled in its place. (The suffix *.pro* is the default for IDL program files.) When the end of the file is reached, compilation resumes at the line after the @.

@ to Signal Batch Processing

When IDL is running in interactive mode, a line beginning with the character @ is entered in response to the IDL prompt and the file is opened for batch input. See Chapter 10, “Executing Batch Jobs in IDL” in the *Using IDL* manual for details.

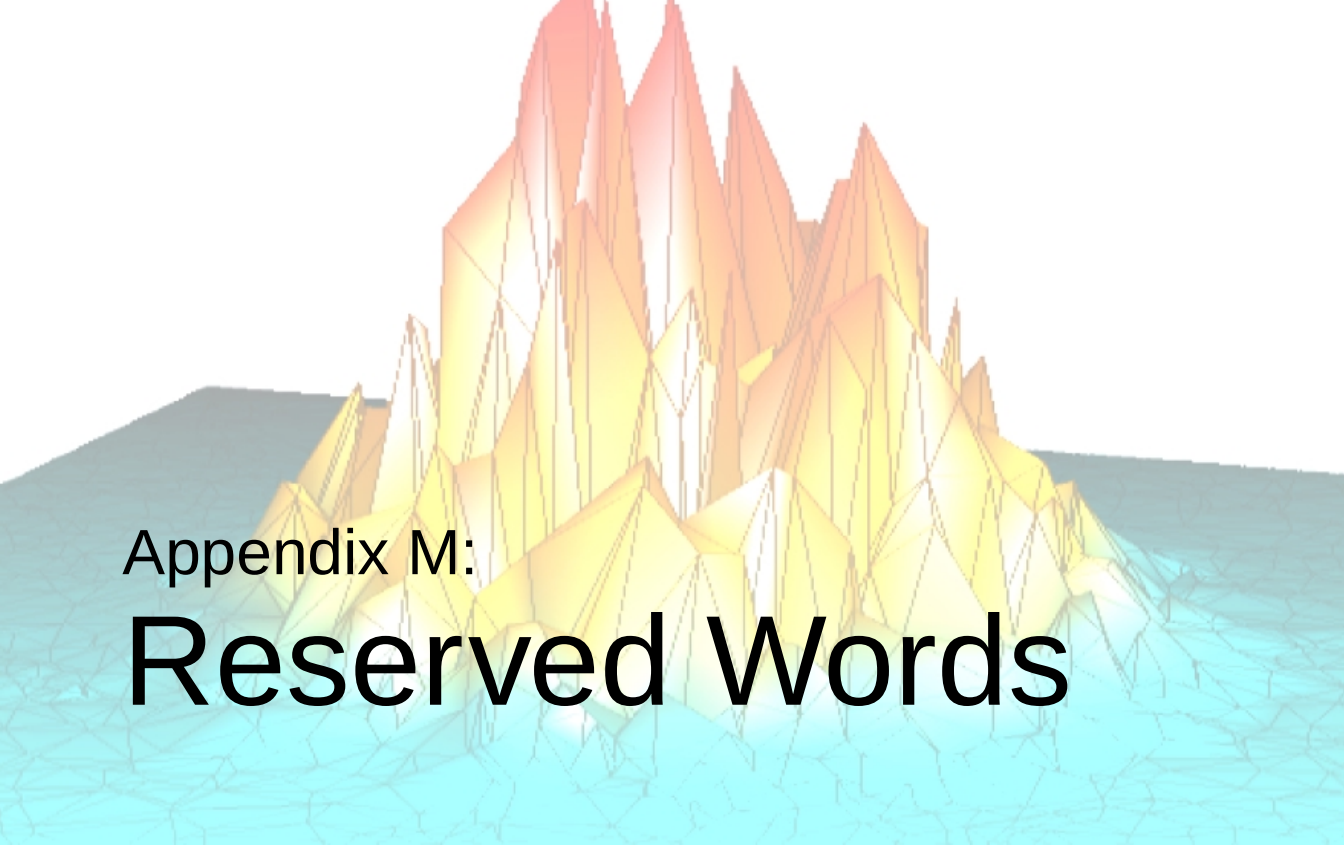
Question Mark (?)

The question mark is used as follows:

- When entered at the IDL command line, the IDL online help facility is invoked.
- Used in conditional expressions as part of the ?: ternary operator. For example:

```
; A shorter way of saying IF (a GT b) THEN z=a ELSE z=b:
z = (a GT b) ? a : b
```

For more on conditional expressions, see “Conditional Expression” in Chapter 2 of the *Building IDL Applications* manual.

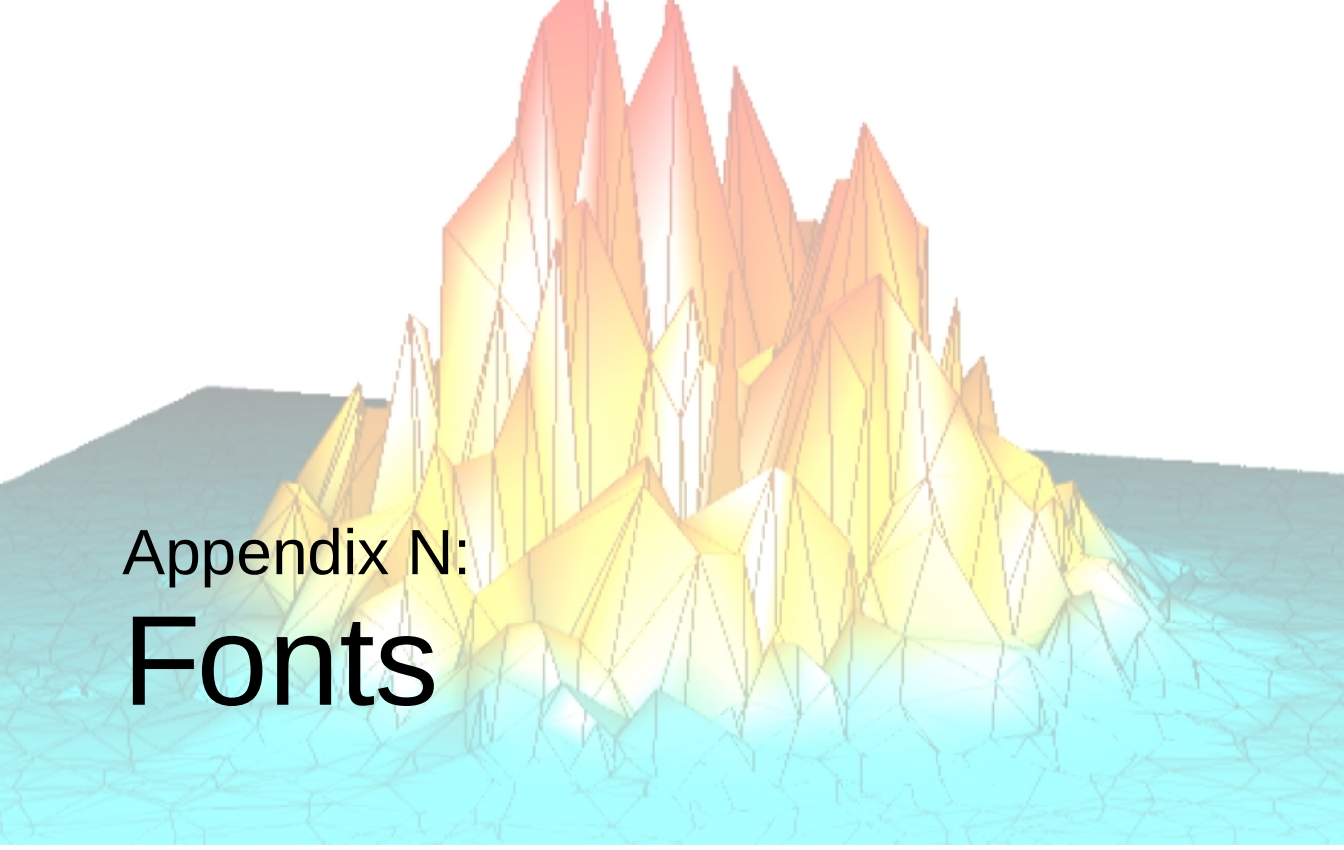


Appendix M: Reserved Words

Variables, user-written procedures, and user-written functions should not have the same names as IDL functions or procedures. Re-using names of IDL routines can lead to syntax errors or to “hiding” variables. In addition, certain words representing IDL language constructs are strictly forbidden—using any of these *reserved words* as a variable, procedure, or function name will cause an immediate syntax error. The following table lists all of the reserved words in IDL.

AND	BEGIN	BREAK
CASE	COMMON	COMPILE_OPT
CONTINUE	DO	ELSE
END	ENDCASE	ENDELSE
ENDFOR	ENDIF	ENDREP
ENDSWITCH	ENDWHILE	EQ
FOR	FORWARD_FUNCTION	FUNCTION

GE	GOTO	GT
IF	INHERITS	LE
LT	MOD	NE
NOT	OF	ON_IOERROR
OR	PRO	REPEAT
SWITCH	THEN	UNTIL
WHILE	XOR	



Appendix N: Fonts

The following topics are covered in this appendix:

Overview 3930
Fonts in IDL Direct vs. Object Graphics . 3931
About Vector Fonts 3932
About TrueType Fonts 3935
About Device Fonts 3940
Choosing a Font Type 3947
Embedded Formatting Commands 3949
Formatting Command Examples 3953
TrueType Font Samples 3958
Vector Font Samples 3961

Overview

IDL uses three font systems for writing characters on the graphics device: Hershey (vector) fonts, TrueType (outline) fonts, and device (hardware) fonts. This chapter describes each of the three types of fonts, discusses when to use each type, and explains how to use fonts when creating graphical output in IDL.

Vector-drawn fonts, also referred to as *Hershey fonts*, are drawn as lines. They are device-independent (within the limits of device resolution). All vector fonts included with IDL are guaranteed to be available in any IDL installation. See "About Vector Fonts" on page 3932 for additional details.

TrueType fonts, also referred to here as *outline fonts*, are drawn as character outlines, which are filled when displayed. They are largely device-independent, but do have some device-dependent characteristics. Four TrueType font families are included with IDL; these fonts should display in a similar way on any IDL platform. TrueType font support for IDL Object Graphics was introduced in IDL version 5.0 and support in IDL Direct Graphics was introduced in IDL version 5.1. See "About TrueType Fonts" on page 3935 for additional details.

Device fonts, also referred to as *hardware fonts*, rely on character-display hardware or software built in to a specific display device. Device fonts, necessarily, are device-dependent and differ from platform to platform and display device to display device. See "About Device Fonts" on page 3940 for additional details.

Fonts in IDL Direct vs. Object Graphics

This volume deals almost exclusively with IDL Direct Graphics. However, the vector and TrueType font systems described here are also available in the IDL Object Graphics system, described in *Using IDL*.

IDL Direct Graphics

When generating characters for Direct Graphics plots, IDL uses the font system specified by the value of the system variable !P.FONT. The normal default for this variable is -1, which specifies that the built-in, vector-drawn (Hershey) fonts should be used. Setting !P.FONT equal to 1 specifies that TrueType fonts should be used. Setting !P.FONT equal to zero specifies that fonts supplied by the graphics device should be used.

The setting of the IDL system variable !P.FONT can be overridden for a single IDL Direct Graphics routine (AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, or XYOUTS) by setting the FONT keyword equal to -1, 0, or 1.

Once a font system has been selected, an individual font can be chosen either via a formatting command embedded in a text string as described in “Embedded Formatting Commands” on page 3949, or by setting the value of the SET_FONT keyword to the DEVICE routine (see “SET_FONT” on page 3795).

IDL Object Graphics

IDL Object Graphics can use the vector and TrueType font systems. See *Using IDL* for more information on using fonts with Object Graphics. Any TrueType fonts you add to your IDL installation as described in “About TrueType Fonts” on page 3935 will also be available to the Object Graphics system.

About Vector Fonts

The vector fonts used by IDL were digitized by Dr. A.V. Hershey of the Naval Weapons Laboratory. Characters in the vector fonts are stored as equations, and can be scaled and rotated in three dimensions. They are drawn as lines on the current graphics device, and are displayed quickly and efficiently by IDL. The vector fonts are built into IDL itself, and are always available.

All the available fonts are illustrated in “Vector Font Samples” on page 3961. The default vector font (Font 3, Simplex Roman) is in effect if no font changes have been made.

Using Vector Fonts

To use the vector font system with IDL Direct Graphics, either set the value of the IDL system variable !P.FONT equal to -1 (negative one), or set the FONT keyword of one of the Direct Graphics routines equal to -1. The vector font system is the default font system for IDL.

Once the vector font system is selected, use an embedded formatting command to select a vector font (or fonts) for each string. (See “Embedded Formatting Commands” on page 3949 for details on embedded formatting commands.) The font selected “sticks” from string to string; that is, if you change fonts in one string, future strings will use the new font until you change it again or exit IDL.

For example, to use the Duplex Roman vector font for the title of a plot, you would use a command that looks like this:

```
PLOT, mydata, TITLE="!5Title of my plot"
```

Consult *Using IDL* for details on using the vector font system with IDL Object Graphics.

Specifying Font Size

To specify the size of a vector font, use the SET_CHARACTER_SIZE keyword to the DEVICE procedure. The SET_CHARACTER_SIZE keyword takes a two-

element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value [*x*, *y*] to the SET_CHARACTER_SIZE keyword may produce characters of different sizes in different fonts.

Note

While the first element of the vector specified to SET_CHARACTER_SIZE is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word “Hello There” on the screen, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines:

```
DEVICE, SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere'
```

You can also use the CHARSIZE keyword to the graphics routines or the CHARSIZE field of the !P System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note

Changing CHARSIZE adjusts both the character size and the space between lines.

ISO Latin 1 Encoding

The default font (Font 3, Simplex Roman) follows the ISO Latin 1 Encoding scheme and contains many international characters. The illustration of this font under “Vector Font Samples” on page 3961 can be used to find the octal codes for the special characters.

For example, suppose you want to display some text with an Angstrom symbol in it. Looking at the chart of font 3, we see that the Angstrom symbol has octal code 305. Non-printable characters can be represented in IDL using octal or hexadecimal

notation and the STRING function (see “Representing Non-Printable Characters” in Chapter 3 of the *Building IDL Applications* manual for details). So the Angstrom can be printed by inserting a `STRING("305B)` character in our text string as follows:

```
XYOUTS,.1, .5, 'Here is an Angstrom symbol: ' + STRING("305B), $
    /NORM, CHARSIZE=3
```

Customizing the Vector Fonts

The EFONT procedure is a widget application that allows you to edit the Hershey fonts and save the results. Use this routine to add special characters or completely new, custom fonts to the Hershey fonts.

About TrueType Fonts

Beginning with version 5.2, five TrueType font families are included with IDL. The fonts included are:

Font Family	Italic	Bold	BoldItalic
Courier	Courier Italic	Courier Bold	Courier Bold Italic
Helvetica	Helvetica Italic	Helvetica Bold	Helvetica Bold Italic
Monospace Symbol			
Times	Times Italic	Times Bold	Times Bold Italic
Symbol			

Table N-1: TrueType Font Names

When TrueType fonts are rendered on an IDL graphics device or destination object, the font outlines are first scaled to the proper size. After scaling, IDL converts the character outline information to a set of polygons using a triangulation algorithm. When text in a TrueType font is displayed, IDL is actually drawing a set of polygons calculated from the font information. This process has two side effects:

1. Computation time is used to triangulate and create the polygons. This means that you may notice a slight delay the first time you use text in a particular font and size. Once the polygons have been created, the information is cached by IDL and there is no need to re-triangulate each time text is displayed. Subsequent uses of the same font and size happen quickly.
2. Because the TrueType font outlines are converted into polygons, you may notice some chunkiness in the displayed characters, especially at small point sizes. The smoothness of the characters will vary with the quality of the TrueType font you are using, the point size, and the general smoothness of the font outlines.

Using TrueType Fonts

To use the TrueType font system with IDL Direct Graphics, either set the value of the IDL system variable !P.FONT equal to 1 (one), or set the FONT keyword to on one of the Direct Graphics routines equal to 1.

Once the TrueType font system is selected, use the SET_FONT keyword to the DEVICE routine to select the font to use. The value of the SET_FONT keyword is a *font name string*. The font name is the name by which IDL knows the font; the names of the TrueType fonts included with IDL are listed under “About TrueType Fonts” on page 3935. Finally, specify the TT_FONT keyword in the call to the DEVICE procedure. For example, to use Helvetica Bold Italic, use the following statement:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

To use Times Roman Regular:

```
DEVICE, SET_FONT='Times', /TT_FONT
```

IDL’s default TrueType font is 12 point Helvetica regular.

Specifying Font Size

To specify the size of a TrueType font, use the SET_CHARACTER_SIZE keyword to the DEVICE procedure. The SET_CHARACTER_SIZE keyword takes a two-element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value [*x*, *y*] to the SET_CHARACTER_SIZE keyword may produce characters of different sizes in different fonts.

Note

While the first element of the vector specified to SET_CHARACTER_SIZE is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word “Hello There” on the screen in Helvetica Bold, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines:

```
DEVICE, FONT='Helvetica Bold', /TT_FONT,
SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere'
```

You can also use the CHARSIZE keyword to the graphics routines or the CHARSIZE field of the !P System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note that changing the CHARSIZE adjusts both the character size and the space between lines.

Using Embedded Formatting Commands

Embedded formatting commands allow you to position text and change fonts within a single line of text. A subset of the embedded formatting commands available for use with the vector fonts are also available when using the TrueType font system. See “Embedded Formatting Commands” on page 3949 for a list of in-line formatting commands.

IDL TrueType Font Resource Files

The TrueType font system relies on a resource file named `ttfont.map`, located in the `resource/fonts/tt` subdirectory of the IDL directory. The format of the ttfont.map file is:

```
FontName    FileName    DirectGraphicsScale    ObjectGraphicsScale
```

where the fields in each column must be separated by white space (spaces and/or tabs). The fields contain the following information

The *Fontname* field contains the name that would be used for the SET_FONT keywords to the DEVICE routine.

The *Filename* field contains the name of the TrueType font file. On UNIX platforms, IDL will search for the file specified in the *FileName* field in the current directory (that is, in the `resource/fonts/tt` subdirectory of the IDL directory) if a bare filename is provided, or it will look for the file in the location specified by the fully-qualified file name if a complete path is provided. Because different platforms use different path-specification syntax, we recommend that you place any TrueType font files you wish to add to the `ttfont.map` file in the `resource/fonts/tt` subdirectory of the IDL directory. On Windows platforms, this entry may be '*', in which case the font will be loaded from the operating system font list, but that the following two scale entries will be honored.

The *DirectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Direct Graphics device. If you want the tallest character in the font to fit exactly within the vertical dimension of the device's current character size (as set via the SET_CHARACTER_SIZE keyword to the DEVICE procedure), set the scale factor equal to 1.0. Change the scale factor to a smaller number to scale a smaller portion of the tallest character into the character size.

For example, suppose the tallest character in your font is "Ã". Setting the scale factor to 1.0 will scale this character to fit the current character size, and then apply the same scaling to all characters in the font. As a result, the letter "M" will fill only approximately 85% of the full height of the character size. To scale the font such that the height of the "M" fills the vertical dimension of the character size, you would include the value 0.85 in the scale field of the `ttfont.map` file.

The *ObjectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Object Graphics device. (This field works just like the *DirectGraphicsScale* field.) This scale factor should be set to 1.0 if the maximum ascent among all glyphs within a given font is to fit exactly within the font size (as set via the SIZE property to the IDLgrFont object).

Adding Your Own Fonts

To add a your own font to the list of fonts known to IDL, use a text editor to edit the `ttfont.map` file, adding the *FontName*, *FileName*, *DirectGraphicsScale*, and *ObjectGraphicsScale* fields for your font. You will need to restart IDL for the changes to the `ttfont.map` file to take effect. On Windows systems, you can use fonts that are not mentioned in the `ttfont.map` file, as long as they are installed in the Fonts control panel, as described below.

Warning

If you choose to modify the `ttfont.map` file, be sure to keep a backup copy of the original file so you can restore the defaults if necessary. Note also that applications that use text may appear different on different platforms if the scale entries in the `ttfont.map` file have been altered.

Where IDL Searches for Fonts

The TrueType font files included with IDL are located in the `resource/fonts/tt` subdirectory of the IDL directory. When attempting to resolve a font name (specified via the FONT keyword to the DEVICE procedure), IDL will look in the

`ttfont.map` file first. If it fails to find the specified font file in the `ttfont.map` file, it will search for the font file in the following locations:

UNIX

No further search will be performed. If the specified font is not included in the `ttfont.map` file, IDL will substitute Helvetica.

Microsoft Windows

If the specified font is not included in the `ttfont.map` file, IDL will search the list of fonts installed in the system (the fonts installed in the Font control panel). If the specified font is not found, IDL will substitute Helvetica.

About Device Fonts

Device, or hardware, fonts are fonts that are provided directly by your system's hardware or by software other than IDL. In past releases of IDL, we have used the term "*hardware fonts*" extensively to discuss these types of fonts. This is because in the early days of IDL, computer displays were either text-only terminals or dedicated graphics display devices such as plotters or Tektronix graphics terminals. These graphics displays generally came with a set of fonts built-in; when IDL asked the device to display characters in a built-in font, it was making a request to the hardware to display those characters.

As computer displays have become more sophisticated, the concept of fonts provided "by the hardware" has expanded to include fonts provided by the computer's operating system, or by font-management software. For example, many computers now use font management software like Adobe Type Manager to manage the fonts made available by the operating system to all applications. We use the term "device font" to refer to a font that is available to one of IDL's graphics devices from a source *other than IDL itself*. (In this case, a "graphics device" can be either a Direct Graphics device as specified by the DEVICE routine or an Object Graphics "destination" such as a window or a printer.) While device fonts may include fonts only available because a particular piece of hardware knows how to draw characters in that font (a pen plotter is an example of a device that may still have its own special fonts), in most cases device fonts are fonts supplied by the operating system to any application that may want to use them.

Which Device Fonts Are Available?

To determine which device fonts are available on your system and the exact font strings to specify for each, use the GET_FONTNAMES keyword to the DEVICE procedure. You can also use an operating system specific method to determine which fonts are available:

UNIX

On most systems, the `xlsfonts` utility displays a list of fonts available to the operating system.

Microsoft Windows

Fonts available to the system are displayed in the Fonts control panel. You may also have other fonts available if you use font-management software such as Adobe Type Manager.

Using Device Fonts

To use the Device font system with IDL Direct Graphics, either set the value of the IDL system variable !P.FONT equal to 0 (zero), or set the FONT keyword to on one of the Direct Graphics routines equal to 0.

Once the Device font system is selected, use the SET_FONT keyword to the DEVICE routine to select the font to use. Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`. You can use the `xlsfonts` command to list available X Windows fonts.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

Microsoft Windows

The SET_FONT keyword should be set to a string with the following form:

```
DEVICE, SET_FONT="font*modifier1*modifier2*...modifiern"
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply "keywords" that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = "GARAMOND*ITALIC*24"
PLOT, FINDGEN(10), TITLE = "IDL Plot"
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

Fonts and the PostScript Device

A special set of device fonts are available when the current Direct Graphics device is PS (PostScript). IDL includes font metric information for 35 standard PostScript fonts, and can create PostScript language files that include text in these fonts. (The 35 fonts known to IDL are listed in the following table; they the standard fonts included in memory in the vast majority of modern PostScript printers.) The PostScript font

metric files (`*.afm` files) are located in the `resource/fonts/ps` subdirectory of the IDL directory.

AvantGarde-Book	Helvetica-Narrow-Oblique
AvantGarde-BookOblique	Helvetica-Oblique
AvantGarde-Demi	NewCenturySchlbk-Bold
AvantGarde-DemiOblique	NewCenturySchlbk-BoldItalic
Bookman-Demi	NewCenturySchlbk-Italic
Bookman-DemiItalic	NewCenturySchlbk-Roman
Bookman-Light	Palatino-Bold
Bookman-LightItalic	Palatino-BoldItalic
Courier	Palatino-Italic
Courier-Bold	Palatino-Roman
Courier-BoldOblique	Symbol
Courier-Oblique	Times-Bold
Helvetica	Times-BoldItalic
Helvetica-Bold	Times-Italic
Helvetica-BoldOblique	Times-Roman
Helvetica-Narrow	ZapfChancery-MediumItalic
Helvetica-Narrow-Bold	ZapfDingats
Helvetica-Narrow-BoldOblique	

Table N-2: Names of Supported PostScript Fonts

Using PostScript Fonts

To use a PostScript font in your Direct Graphics output, you must first specify that IDL use the device font system, they switch to the `PS` device, then choose a font using the SET_FONT keyword to the DEVICE procedure.

The following IDL commands choose the correct font system, set the graphics device, select the font Palatino Roman, open a PostScript file to print to, plot a simple data set, and close the PostScript file:

```
!P.FONT = 0
SET_PLOT, 'PS'
DEVICE, SET_FONT = 'Palatino-Roman', FILE = 'testfile.ps'
PLOT, INDGEN(10), TITLE = 'My Palatino Title'
DEVICE, /CLOSE
```

Note

Subsequent PostScript output will continue to use the font Palatino Roman until you explicitly change the font again, or exit IDL.

You can also specify PostScript fonts using a set of keywords to the DEVICE procedure. The keyword combinations for the fonts included with IDL are listed in the following table.

PostScript Font	DEVICE Keywords
Courier	/COURIER
Courier Bold	/COURIER, /BOLD
Courier Oblique	/COURIER, /OBLIQUE
Courier Bold Oblique	/COURIER, /BOLD, /OBLIQUE
Helvetica	/HELVETICA
Helvetica Bold	/HELVETICA, /BOLD
Helvetica Oblique	/HELVETICA, /OBLIQUE
Helvetica Bold Oblique	/HELVETICA, /BOLD, /OBLIQUE
Helvetica Narrow	/HELVETICA, /NARROW
Helvetica Narrow Bold	/HELVETICA, /NARROW, /BOLD
Helvetica Narrow Oblique	/HELVETICA, /NARROW, /OBLIQUE
Helvetica Narrow Bold Oblique	/HELVETICA, /NARROW, /BOLD, /OBLIQUE
ITC Avant Garde Gothic Book	/AVANTGARDE, /BOOK
ITC Avant Garde Gothic Book Oblique	/AVANTGARDE, /BOOK, /OBLIQUE
ITC Avant Garde Gothic Demi	/AVANTGARDE, /DEMI

Table N-3: The Standard 35 PostScript Fonts

PostScript Font	DEVICE Keywords
ITC Avant Garde Gothic Demi Oblique	/AVANTGARDE, /DEMI, /OBLIQUE
ITC Bookman Demi	/BKMAN, /DEMI
ITC Bookman Demi Italic	/BKMAN, /DEMI, /ITALIC
ITC Bookman Light	/BKMAN, /LIGHT
ITC Bookman Light Italic	/BKMAN, /LIGHT, /ITALIC
ITC Zapf Chancery Medium Italic	/ZAPFCHANCERY, /MEDIUM, /ITALIC
ITC Zapf Dingbats	/ZAPFDINGBATS
New Century Schoolbook	/SCHOOLBOOK
New Century Schoolbook Bold	/SCHOOLBOOK, /BOLD
New Century Schoolbook Italic	/SCHOOLBOOK, /ITALIC
New Century Schoolbook Bold Italic	/SCHOOLBOOK, /BOLD, /ITALIC
Palatino	/PALATINO
Palatino Bold	/PALATINO, /BOLD
Palatino Italic	/PALATINO, /ITALIC
Palatino Bold Italic	/PALATINO, /BOLD, /ITALIC
Symbol	/SYMBOL
Times	/TIMES
Times Bold	/TIMES, /BOLD
Times Italic	/TIMES, /ITALIC
Times Bold Italic	/TIMES, /ITALIC, /BOLD

Table N-3: The Standard 35 PostScript Fonts (Continued)

For example to use the PostScript font Palatino Bold Italic, you could use either of the following DEVICE commands:

```
DEVICE, SET_FONT = 'Palatino*Bold*Italic'
DEVICE, /PALATINO, /BOLD, /ITALIC
```

Changing the PostScript Font Assigned to an Index

You can change the PostScript font assigned to a given font index using the FONT_INDEX keyword to the DEVICE procedure. Font indices and their use are discussed in "Embedded Formatting Commands" on page 3949.

Changing the font index assigned to a font can be useful when changing PostScript fonts in the middle of a text string. For example, the following statements map Palatino Bold Italic to font index 4, and then output text using that font and the Symbol font:

```
; Map the font selected by !4 to be PalatinoBoldItalic:
DEVICE, /PALATINO, /BOLD, /ITALIC, FONT_INDEX=4
; Output "Alpha :" in PalatinoBoldItalic followed by an
; Alpha character:
XYOUTS, .3, .5, /NORMAL, "!4Alpha: !9a", FONT=0, SIZE=5.0
```

Adding Your Own PostScript Fonts

Because the 35 PostScript fonts included with IDL are built in to a PostScript printer's memory, the IDL distribution includes only the font metric files, which provide positioning information. In addition, the `.afm` files used by IDL are specially processed to provide the information in a format IDL expects.

You can add your own PostScript fonts to the list of fonts known to IDL if you have access to the PostScript font file (usually named *font*`.pfb`) to load into your printer and to the *font*`.afm` file supplied by Adobe. You can convert the standard `.afm` file into a file IDL understands using the IDL routine PSAFM. Consult the file `README.TXT` in the `resource/fonts/ps` subdirectory of the IDL directory for details on adding PostScript fonts to your system.

Choosing a Font Type

Some of the issues involved in choosing between vector, TrueType, and device fonts are explained below.

Appearance

Vector-drawn characters are of medium quality, suitable for most uses. TrueType characters are of relatively high quality, although at some point sizes the triangulation process (described in "About TrueType Fonts" on page 3935) may cause characters to appear slightly jagged. The appearance of device characters varies from mediocre (characters found in many graphics terminals) to publication quality (PostScript).

Three-Dimensional Transformations

Vector or TrueType fonts should always be used with three-dimensional transformations. Both vector and TrueType characters pass through the same transformations as the rest of the plot, yielding a better looking plot. See "Three-Dimensional Graphics" in Chapter 18 of the *Using IDL* manual for an example of vector-drawn characters with three-dimensional graphics. Device characters are not subject to the three-dimensional transforms.

Portability

The vector-drawn fonts work using any graphics device and look the same on every device (within the limitations of device resolution) on any system supported by IDL.

TrueType fonts are available only on the `X`, `WIN`, `PRINTER`, `PS`, and `Z` Direct Graphics devices, and in IDL's Object Graphics system. If you use only the fonts supplied with IDL, TrueType fonts also look the same on every supported device (again within the limits of the device resolution). If you use TrueType fonts other than those supplied with IDL, your font may not be installed on the system which runs your program. In this case, IDL will substitute a known font for the missing font.

The appearance, size, and availability of device fonts varies greatly from device to device. Many, if not most, of the positioning and font changing commands recognized by the vector-drawing routines are ignored when using device fonts. The exception to this rule is the Direct Graphics `PS` device; if you use one of the PostScript fonts supported by IDL, the PostScript output from the `PS` device will be identical between platforms.

Computational Time

Device fonts are generally rendered the most quickly, since the hardware device or operating system handles all computations and caching.

It takes more computer time to draw characters with line vectors and generally results in more input/output. However, this is not an important issue unless the plot contains a large number of characters or the transmission link to the device is very slow.

The initial triangulation step used when displaying TrueType fonts for the first time can be computationally expensive. However, since the font shapes are cached, subsequent uses of the same font are relatively speedy.

Flexibility

Vector-drawn fonts provide a great deal of flexibility. There are many different typefaces available, as shown in the tables at the end of this chapter. In addition, such fonts can be arbitrarily scaled, rotated, and transformed.

TrueType fonts support fewer embedded formatting commands than do the vector fonts, and cannot be scaled, rotated, or transformed.

The abilities of hardware-generated characters differ greatly between devices so it is not possible to make a blanket statement on when they should be used—the best font to use depends on the available hardware. In general, however, the vector or TrueType fonts are easier to use and often provide superior results to what is available from the hardware. See the discussion of the device you are using in Appendix G, "IDL Graphics Devices" for details on the hardware-generated characters provided by that device.

Print Quality

For producing publication-quality output, we recommend using either the TrueType font system or the Direct Graphics PS device and one of the PostScript fonts supported by IDL.

Embedded Formatting Commands

When you use vector, TrueType, and some device fonts, text strings can include embedded formatting commands that facilitate subscripting, superscripting, and equation formatting. The method used is similar to that developed by Grandle and Nystrom (1980). Embedded formatting commands are always introduced by the exclamation mark, (!). (The string " ! ! " is used to produce a literal exclamation mark.)

Note

Embedded formatting commands prefaced by the exclamation mark have no special significance for hardware-generated characters unless the ability is provided by the particular device in use. The IDL PostScript device driver accepts many of the standard embedded formatting commands, and is described here. If you wish to use hardware fonts with IDL Direct Graphics devices other than the PostScript device, consult the description of the device in Appendix G, "IDL Graphics Devices" before trying to use these commands with hardware characters.

You can determine whether embedded formatting commands are available for use with device fonts on your current graphics device by inspecting bit 12 of the *Flags* field of the !D System Variable. Use the IDL statement:

```
IF (!D.FLAGS AND 4096) NE 0 THEN PRINT, 'Bit is set.'
```

to determine whether bit 12 of the *Flags* field is set for the current graphics device.

Changing Fonts within a String

You can change fonts one or more times within a text string using the embedded font commands shown in the table below. The character following the exclamation mark can be either upper or lower case.

Examples of commands used to change fonts in mid-string are included in "Formatting Command Examples" on page 3953.

Command	Vector Font	TrueType Font	PostScript Font
!3	Simplex Roman (default)	Helvetica	Helvetica
!4	Simplex Greek	Helvetica Bold	Helvetica Bold
!5	Duplex Roman	Helvetica Italic	Helvetica Narrow

Table N-4: Embedded Font Selection Commands

Command	Vector Font	TrueType Font	PostScript Font
!6	Complex Roman	Helvetica Bold Italic	Helvetica Narrow Bold Oblique
!7	Complex Greek	Times	Times Roman
!8	Complex Italic	Times Italic	Times Bold Italic
!9	Math/special characters	Symbol	Symbol
!M	Math/special characters (change effective for one character only)	Symbol	Symbol
!10	Special characters	Symbol *	Zapf Dingbats
!11(!G)	Gothic English	Courier	Courier
!12(!W)	Simplex Script	Courier Italic	Courier Oblique
!13	Complex Script	Courier Bold	Palatino
!14	Gothic Italian	Courier Bold Italic	Palatino Italic
!15	Gothic German	Times Bold	Palatino Bold
!16	Cyrillic	Times Bold Italic	Palatino Bold Italic
!17	Triplex Roman	Helvetica *	Avant Garde Book
!18	Triplex Italic	Helvetica *	New Century Schoolbook
!19		Helvetica *	New Century Schoolbook Bold
!20	Miscellaneous	Helvetica *	Undefined User Font
!X	Revert to the entry font	Revert to the entry font	Revert to the entry font

* The font assigned to this index may be replaced in a future release of IDL.

Table N-4: Embedded Font Selection Commands (Continued)

Positioning Commands

The positioning and other font-manipulation commands are described in the following table. Examples of commands used to position text are included in “Formatting Command Examples” on page 3953.

Command	Action
!A	Shift above the division line .
!B	Shift below the division line .
!C	“Carriage return,” begins a new line of text. Shift back to the starting position and down one line.
!D	Shift down to the first level subscript and decrease the character size by a factor of 0.70.
!E	Shift up to the exponent level and decrease the character size by a factor of 0.44.
!I	Shift down to the index level and decrease the character size by a factor of 0.44.
!L	Shift down to the second level subscript. Decrease the character size by a factor of 0.62.
!N	Shift back to the normal level and original character size.
!R	Restore position. The current position is set from the top of the saved positions stack.
!S	Save position. The current position is saved on the top of the saved positions stack.
!U	Shift to upper subscript level. Decrease the character size by a factor of 0.70.
!X	Return to the entry font.
!Z(u_0,u_1,...,u_n)	Display one or more character glyphs according to their unicode value. Each u_i within the parentheses will be interpreted as a 16-bit hexadecimal unicode value. If more than one unicode value is to be included, the values should be separated by commas.

Table N-5: Vector-Drawn Positioning and Miscellaneous Commands

Command	Action
!!	Display the ! symbol.

Table N-5: Vector-Drawn Positioning and Miscellaneous Commands

Formatting Command Examples

The figure below illustrates the relative positions and effects on character size of the level commands. In this figure, the letters "!N" are normal level and size characters.

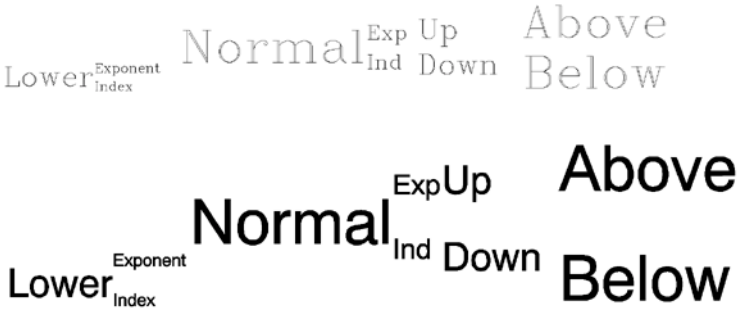


Figure N-1: Positioning Commands With Vector Fonts (Top) and TrueType Fonts (Bottom)

The positioning shown was created with the following command:

```
XYOUTS, 0.1, 0.3, $
'!LLower!S!EExponent!R!IIndex!N  Normal!S!EExp!R!IInd!N!S!U Up
!R!D Down!N!S!A Above!R!B Below'
```

Note that the string argument to the XYOUTS procedure must be entered on a single line rather than the two lines shown above.

A Complex Equation

Embedded positioning commands and the vector font system can be used to create the integral shown below:

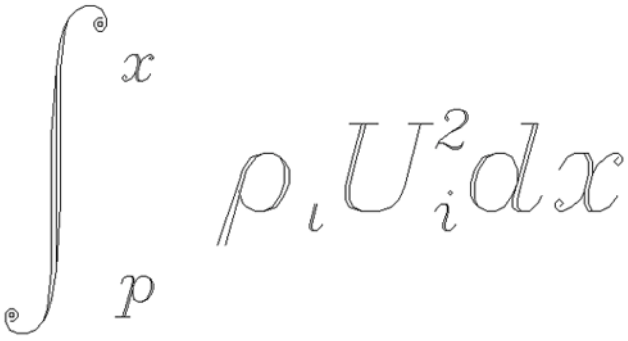

Figure N-2: An integral created with the vector fonts.

The command string used to produce the integral is:

```
XYOUTS, 0, .2, $
   '!MI!S!A!E!8x!R!B!Ip!N !7q!Ii!N!8U!S!E2!R!Ii!Ndx', $
   SIZE = 3, /NORMAL
```

Remember that the case of the letter in an embedded command is not important. The string may be broken down into the following components:

!MI

Changes to the math set and draws the integral sign, uppercase I.

!S

Saves the current position on the position stack.

!A!E!8x

Shifts above the division line and to the exponent level, switches to the Complex Italic font (Font 8), and draws the "*x*."

!R!B!Ip

Restores the position to the position immediately after the integral sign, shifts below the division line to the index level, and draws the "*p*."

!N !7q

Returns to the normal level, advances one space, shifts to the Complex Greek font (Font 7), and draws the Greek letter rho, which is designated by "*q*" in this set.

!Ii!N

Shifts to the index level and draws the "*i*" at the index level. Returns to the normal level.

!8U

Shifts to the Complex Italic font (Font 8) and outputs the upper case "*U*."

!S!E2

Saves the position and draws the exponent "2."

!R!Ii

Restores the position and draws the index "*i*."

!N dx

Returns to the normal level and outputs "dx."

Note

The equation shown in the figure above could not be created so simply using the TrueType font system, because the large integral symbol is broken into two or more characters in the TrueType fonts.

Vector-Drawn Font Example

IDL uses vector-drawn font when the value of the system variable !P.FONT is -1. This is the default condition. Initially, all characters are drawn using the Simplex Roman font (Font 3). When plotting, font changing commands may be embedded in the title strings keyword arguments (XTITLE, YTITLE, and TITLE) to select other fonts. For example, the following statement uses the Complex Roman font (Font 6) for the *x*-axis title:

```
PLOT, X, XTITLE = '!6X Axis Title'
```

This font remains in effect until explicitly changed. The order in which the annotations are drawn is main title, *x*-axis numbers, *x*-axis title, *y*-axis numbers, and *y*-axis title. Strings to be output also may contain embedded information selecting subscripting, superscripting, plus other features that facilitate equation formatting.

The following statements were used to produce the figure below. They serve as an example of a plot using vector-drawn characters and of equation formatting.

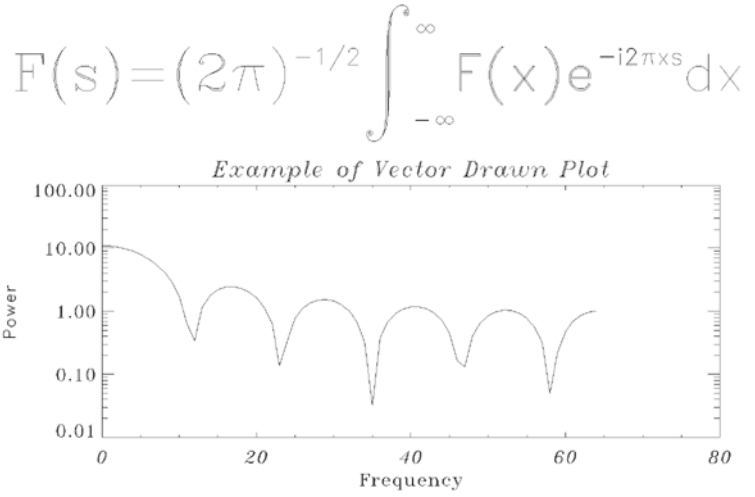

Figure N-3: Example of a Vector-drawn Plot

```
; Define an array:
X = FLTARR(128)
; Make a step function:
X[30:40] = 1.0
; Take FFT and magnitude:
X = ABS(FFT(X, 1))
; Produce a log-linear plot. Use the Triplex Roman font for the
; x title (!17), Duplex Roman for the y title (!5), and Triplex
; Italic for the main title (!18). The position keyword is used to
; shrink the plotting window:
PLOT, X[0:64], /YLOG, XTITLE = '!17Frequency', $
   YTITLE = '!5Power', $
   TITLE = '!18Example of Vector Drawn Plot', $
   POSITION = [.2, .2, .9, .6]
SS = '!6F(s) = (2!4p)!e-1/2!n !mi!s!a!e!m $
     !r!b!i ' + '-!m $
```

```
; String to produce equation:
     !nF(x)e !e-i2!4p!3xs!ndx'
XYOUTS, 0.1, .75, SS, SIZE = 3, $
; Output string over plot. The NOCLIP keyword is needed because
; the previous plot caused the clipping region to shrink:
     /NORMAL, /NOCLIP
```

TrueType Font Samples

The following figures show roman versions of the four TrueType font families included with IDL. The character sets for the bold, italic, and bold italic versions of these fonts are the same as the roman versions.

The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 'Helvetica', 'Helvetica', /TT_FONT
```

For more information, see “SHOWFONT” on page 1709.

Note

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the copyright symbol is octal 251.

Vector Font Samples

The following figures show samples of various vector-drawn fonts. The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 3, 'Simplex Roman'
```

To output this figure to a postscript file, you would use the following commands:

```
SET_PLOT, 'PS'
SHOWFONT, 3, 'Simplex Roman'
DEVICE, /CLOSE
```

For more information, see “SHOWFONT” on page 1709.

Note

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the “$” symbol is octal 44.

Appendix O: Obsolete Features

The following topics are covered in this appendix:

What Are Obsolete Features? 3972
Routines Obsoleted in IDL 5.6 3973
Routines Obsoleted in IDL 5.5 3974
Routines Obsoleted in IDL 5.4 3975
Routines Obsoleted in IDL 5.3 3976
SDF Routines Obsoleted in IDL 5.3 3977
Routines Obsoleted in IDL 5.2 3978
Routines Obsoleted in IDL 5.1 3979
Routines Obsoleted in IDL 5.0 3980
Routines Obsoleted in IDL 4.0 or Earlier 3981
Obsolete Arguments and Keywords 3987
Obsolete System Variables 3992
Obsolete Graphics Devices 3994

What Are Obsolete Features?

To improve the overall quality and functionality of IDL, Research Systems, Inc. occasionally replaces existing routines with new, improved routines. In many cases, existing routines are improved without changing their existing behavior—through improvements of the underlying algorithms, for example, or by adding keyword functionality. In some cases, however, the improved methods are incompatible with the old. In these situations, we consider the routines that we have replaced to be *obsolete*.

For similar reasons, arguments and keywords to existing routines may occasionally become obsolete. In many cases, the functionality activated by the obsolete argument or keyword can be achieved more efficiently using a new argument or keyword. If this is the case, existing code using the obsolete argument or keyword will generally continue to function as it always has, although performance may be better using the new, replacement argument or keyword. In cases where the obsolete argument or keyword activated functionality that is no longer available (perhaps as a result of an operating system upgrade or change), IDL will either quietly ignore the presence of the argument or keyword (if doing so does not affect the resulting output) or warn that an invalid parameter has been specified.

This chapter lists the routines that have become obsolete in each version of IDL. These routines are not documented in the online help. To view reference information for routines obsoleted in IDL version 5.0 and later, see the `obsolete.pdf` file in the `docs` subdirectory of the IDL distribution. Routines obsoleted in IDL 4.0 and earlier are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `lib/obsolete` subdirectory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the DOC_LIBRARY routine.

Routines Obsoleted in IDL 5.6

The following routines were present in IDL Version 5.5 but became obsolete in IDL Version 5.6.

Routine	Replaced by	.pro File?
HDF_VD_GETNEXT	HDF_VG_GETNEXT	
VAX_FLOAT	VAX_FLOAT keyword to OPEN	

Table O-1: Routines Obsoleted in IDL 5.6

Routines Obsoleted in IDL 5.5

The following routines were present in IDL Version 5.4 but became obsolete in IDL Version 5.5.

Routine	Replaced by	.pro File?
DELETE_SYMBOL	n/a	
DELLOG	n/a	
DO_APPLE_SCRIPT	n/a	
ERRORF	ERF	
GET_SYMBOL	n/a	
LJLCT	n/a	
REWIND	n/a	
SET_SYMBOL	n/a	
SETLOG	n/a	
SKIPF	n/a	
TAPRD	n/a	
TAPWRT	n/a	
TRNLOG	n/a	
WEOF	n/a	

Table O-2: Routines Obsoleted in IDL 5.5

Routines Obsoleted in IDL 5.4

The following routines were present in IDL Version 5.3 but became obsolete in IDL Version 5.4.

Routine	Replaced by	.pro File?
POLYFITW	POLY_FIT, MEASURE_ERRORS keyword	`polyfitw.pro`
RIEMANN	RADON	

Table O-3: Routines Obsoleted in IDL 5.4

Routines Obsoleted in IDL 5.3

The following routines were present in IDL Version 5.2 but became obsolete in IDL Version 5.3.

Routine	Replaced by	.pro File?
HDF_DFSD_* Routines	HDF_SD_* Routines	
RSTRPOS	STRPOS, /REVERSE_SEARCH	`rstrpos.pro`
STR_SEP	STRSPLIT for single character delimiters STRSPLIT, /REGEX for longer delimiters	`str_sep.pro`

Table O-4: Routines Obsoleted in IDL 5.3

SDF Routines Obsoleted in IDL 5.3

HDF_DFSD_* routines have been obsoleted in IDL 5.3.

What is DFSD and Why Are We Obsoleting It?

DFSD is an SD (Scientific Data Model). DFSD is the older, single-file SD form. The newer SD format, MFSD, is referred to in the IDL API as HDF_SD_*. New IDL code should use HDF_SD_* routines rather than HDF_DFSD_* routines.

Version HDF4.1r2 of HDF has obsoleted the DFSD interface, somewhat forcing us to do so as well. IDL 5.3 uses HDF4.1r3 (Version 4.1, revision 3). It is recommended that users convert their old HDF files to the 4.1r3 format.

The following HDF routines have been obsoleted in IDL 5.3.

- HDF_DFSD_ADDDATA
- HDF_DFSD_DIMGET
- HDF_DFSD_DIMSET
- HDF_DFSD_ENDSLICE
- HDF_DFSD_GETDATA
- HDF_DFSD_GETINFO
- HDF_DFSD_GETSLICE
- HDF_DFSD_PUTSLICE
- HDF_DFSD_READREF
- HDF_DFSD_SETINFO
- HDF_DFSD_STARTSLICE

Routines Obsoleted in IDL 5.2

The following routines were present in IDL Version 5.1 but became obsolete in IDL Version 5.2.

Routine	Replaced by	.pro File?
DEMO_MODE	LMGR	`demo_mode.pro`

Table O-5: Routines Obsoleted in IDL 5.2

Routines Obsoleted in IDL 5.1

The following routines were present in IDL Version 5.0 but became obsolete in IDL Version 5.1.

Routine	Replaced by	.pro File?
SLICER	SLICER3	`slicer3.pro`

Table O-6: Routines Obsoleted in IDL 5.1

Routines Obsoleted in IDL 5.0

The following routines were present in IDL Version 4.0 but became obsolete in IDL Version 5.0.

Routine	Replaced by	.pro File?
DDE Routines	n/a	
GETHELP	OUTPUT keyword to HELP	
HANDLE_CREATE	PTR_NEW	
HANDLE_FREE	PTR_FREE	
HANDLE_INFO	PTR_VALID	
HANDLE_MOVE	n/a	
HANDLE_VALUE	dereference operator	
INP, INPW, OUTP, OUTPW	n/a	
PICKFILE	DIALOG_PICKFILE	
Old RPC API	New RPC API	
.SIZE Executive Command	No longer needed	
TIFF_DUMP	n/a	
TIFF_READ	READ_TIFF	
TIFF_WRITE	WRITE_TIFF	
WIDED	n/a	
WIDGET_MESSAGE	DIALOG_MESSAGE	

Table O-7: Routines Obsoleted in IDL 5.0

Routines Obsoleted in IDL 4.0 or Earlier

The following routines became obsolete in IDL version 4.0 or earlier. These routines are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `obsolete` subdirectory of the `lib` directory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the DOC_LIBRARY routine.

Routine	Replaced by	.pro File?
ADDSYSVAR	DEFSYSV	`addsysvar.pro`

Obsolete Arguments and Keywords

The following arguments and keywords are obsolete and should not be used in new IDL code..

Routine	Argument or Keyword	Description
BYTEORDER	DTOGFLOAT keyword	This keyword was available only on the VMS platform
	GFLOATTOD keyword	This keyword was available only on the VMS platform.
CALL_EXTERNAL	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	PORTABLE keyword	This keyword was ignored on non-VMS platforms.
	VAX_FLOAT keyword	This keyword was available only on the VMS platform.
DEVICE	DEPTH keyword	This keyword was available only on the VMS platform.
	FONT keyword	This keyword was replaced by the SET_FONT keyword.
DOC_LIBRARY	FILE keyword	This keyword was ignored on non-VMS platforms.
	PATH keyword	This keyword was ignored on non-VMS platforms.
	OUTPUTS keyword	This keyword was available only on the VMS platform.
EXTRACT_SLICE	CUBIC keyword	EXTRACT_SLICE does not support cubic interpolation.
IDLgrMPEG::Save	CREATOR_TYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.

Table O-9: Arguments and Keywords Obsoleted in IDL 5.5

Routine	Argument or Keyword	Description
LINKIMAGE	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
LIVE_PRINT	SETUP keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
MAKE_DLL	VAX_FLOAT keyword	This keyword was ignored on non-VMS platforms.
ONLINE_HELP	HTML_HELP keyword	This keyword is no longer necessary; ONLINE_HELP parses the value of the BOOK keyword to determine file type.
OPEN	*Record_Length* argument	This argument was ignored on non-VMS platforms.
	BINARY keyword	Windows file I/O changed to function like UNIX file I/O.
	BLOCK keyword	This keyword was ignored on non-VMS platforms.
	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	EXTENDSIZE keyword	This keyword was ignored on non-VMS platforms.
	FIXED keyword	This keyword was ignored on non-VMS platforms.
	FORTRAN keyword	This keyword was ignored on non-VMS platforms.
	INITIALSIZE keyword	This keyword was ignored on non-VMS platforms.
	KEYED keyword	This keyword was ignored on non-VMS platforms.

Table O-9: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)

Routine	Argument or Keyword	Description
OPEN, *continued*	LIST keyword	This keyword was ignored on non-VMS platforms.
	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	MACTYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	NOAUTOMODE keyword	Windows file I/O changed to function like UNIX file I/O.
	NONE keyword	This keyword was ignored on non-VMS platforms.
	NOSDTIO	Keyword was renamed RAWIO.
	PRINT keyword	This keyword was ignored on non-VMS platforms.
	SEGMENTED keyword	This keyword was ignored on non-VMS platforms.
	SHARED keyword	This keyword was ignored on non-VMS platforms.
	STREAM keyword	This keyword was ignored on non-VMS platforms.
	SUBMIT keyword	This keyword was ignored on non-VMS platforms.
	SUPERSEDE keyword	This keyword was ignored on non-VMS platforms.
	TRUNCATE_ON_CLOSE keyword	This keyword was ignored on non-VMS platforms.

Table O-9: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)

Routine	Argument or Keyword	Description
OPEN, *continued*	UDF_BLOCK keyword	This keyword was ignored on non-VMS platforms.
	VARIABLE keyword	This keyword was ignored on non-VMS platforms.
PRINT/PRINTF	REWRITE keyword	This keyword was ignored on non-VMS platforms.
READ_TIFF	ORDER keyword	This keyword was replaced by the ORIENTATION keyword
	UNSIGNED keyword	This keyword became obsolete when IDL began supporting an unsigned 16-bit integer data type.
READ/READF	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
READU	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
SAVE	XDR keyword	IDL always writes XDR files.

Table O-9: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)

Routine	Argument or Keyword	Description
SPAWN	FORCE keyword	This keyword was incorrectly included in the SPAWN documentation.
	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	NOCLISYM keyword	This keyword was ignored on non-VMS platforms.
	NOLOGNAM keyword	This keyword was ignored on non-VMS platforms.
	NOTIFY keyword	This keyword was ignored on non-VMS platforms.
WIDGET_BASE	APP_MBAR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
WRITE_TIFF	*Order* argument	The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead.
WRITEU	REWRITE keyword	This keyword was ignored on non-VMS platforms.

Table O-9: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)

Obsolete System Variables

The following IDL system variables became obsolete in the change from VAX IDL (IDL version 1) to IDL version 2. While it is highly unlikely that you will find references to these system variables in existing code, we include them here because they are flagged when the OBS_SYSVARS field of the !WARN structure is set equal to one. See Appendix J, “System Variables” for information on IDL system variables.

System Variable	Replaced by
!BCOLOR	BOTTOM keyword to SURFACE
!COLOR	!P.COLOR
!CXMAX	!X.CRANGE[1]
!CXMIN	!X.CRANGE[0]
!CYMAX	!Y.CRANGE[1]
!CYMIN	!Y.CRANGE[0]
!FANCY	No direct equivalent. Use !P.FONT and !P.CHARSIZE
!FLIP	No equivalent.
!GRID	!P.TICKLEN
!HI	No equivalent.
!IGNORE	!P.NOCLIP
!LINETYPE	!P.LINESTYLE
!LO	No equivalent.
!MTITLE	!P.TITLE
!NOERAS	!P.NOERASE
!NORMALCONT	FOLLOW keyword to CONTOUR
!NSUM	!P.NSUM
!PSYM	!P.PSYM

Table O-10: Obsolete System Variables

System Variable	Replaced by
!SC1	!P.POSITION[0] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[0] * !D.X_VSIZE otherwise.
!SC2	!P.POSITION[2] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[1] * !D.X_VSIZE otherwise.
!SC3	!P.POSITION[1] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[0] * !D.X_VSIZE otherwise.
!SC4	!P.POSITION[3] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[1] * !D.X_VSIZE otherwise.
!TERM	DEVICE procedure.
!TYPE	!X.TYPE, !X.STYLE, !Y.TYPE, !Y.STYLE, !P.TICKLEN
!XMAX	!X.RANGE[1]
!XMIN	!X.RANGE[0]
!XTICKS	!X.TICKS
!XTITLE	!X.TITLE
!YMAX	!Y.RANGE[1]
!YMIN	!Y.RANGE[0]
!YTICKS	!Y.TICKS
!YTITLE	!Y.TITLE

Table O-10: Obsolete System Variables (Continued)

Obsolete Graphics Devices

The following arguments and keywords are obsolete and should not be used in new IDL code..

Graphics Device	Description
The LJ Device (LJ)	The LJ device was only available in IDL for VMS.
The Macintosh Device (MAC)	The MAC device was only available in IDL for Macintosh versions running under OS 9 and earlier. Versions of IDL for Macintosh running under OS X and later use the X device.

Table O-11: Obsolete Graphics Devices
