If the current node has no visible children, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[\[IDLffXMLDOMTreeWalker::\]LastChild\(\)](#)

### Return Value

Returns an object reference to the last child of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible children.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::NextNode

The `IDLffXMLDOMTreeWalker::NextNode` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is visited next after the walker's current node in document-order traversal.

If the current node has no next node or the search for the next node looks above the tree walker's root node, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- `IDLffXMLDOMTreeWalker::FirstChild`
- `IDLffXMLDOMTreeWalker::GetCurrentNode`
- `IDLffXMLDOMTreeWalker::LastChild`
- `IDLffXMLDOMTreeWalker::NextNode`
- `IDLffXMLDOMTreeWalker::NextSibling`
- `IDLffXMLDOMTreeWalker::ParentNode`
- `IDLffXMLDOMTreeWalker::PreviousNode`
- `IDLffXMLDOMTreeWalker::PreviousSibling`

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[`IDLffXMLDOMTreeWalker::`]NextNode()

### Return Value

Returns an object reference to the next node in the DOM tree in the tree walker's document-order traversal, or a null object reference if the current node has no next node or the search for the next node looks above the walker's root node.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::NextSibling

The `IDLffXMLDOMTreeWalker::NextSibling` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is the next sibling of the node to which the walker is currently pointing.

If the current node has no visible next sibling, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[[IDLffXMLDOMTreeWalker::](#)]NextSibling()

### Return Value

Returns an object reference to the next sibling of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible next sibling.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::ParentNode

The `IDLffXMLDOMTreeWalker::ParentNode` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is the parent of the node to which the walker is currently pointing.

If the search for a parent node attempts to look above the tree walker's root node or no visible ancestor node is found, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- `IDLffXMLDOMTreeWalker::FirstChild`
- `IDLffXMLDOMTreeWalker::GetCurrentNode`
- `IDLffXMLDOMTreeWalker::LastChild`
- `IDLffXMLDOMTreeWalker::NextNode`
- `IDLffXMLDOMTreeWalker::NextSibling`
- `IDLffXMLDOMTreeWalker::ParentNode`
- `IDLffXMLDOMTreeWalker::PreviousNode`
- `IDLffXMLDOMTreeWalker::PreviousSibling`

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[`IDLffXMLDOMTreeWalker::`]ParentNode()

### Return Value

Returns the object reference to the parent of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the search cannot find a visible ancestor node or attempts to look above the walker's root node.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::PreviousNode

The `IDLffXMLDOMTreeWalker::PreviousNode` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is visited before the walker's current node in document-order traversal.

If the current node has no previous node or the search for the previous node looks above the tree walker's root node, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- `IDLffXMLDOMTreeWalker::FirstChild`
- `IDLffXMLDOMTreeWalker::GetCurrentNode`
- `IDLffXMLDOMTreeWalker::LastChild`
- `IDLffXMLDOMTreeWalker::NextNode`
- `IDLffXMLDOMTreeWalker::NextSibling`
- `IDLffXMLDOMTreeWalker::ParentNode`
- `IDLffXMLDOMTreeWalker::PreviousNode`
- `IDLffXMLDOMTreeWalker::PreviousSibling`

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[`IDLffXMLDOMTreeWalker::`]PreviousNode()

### Return Value

Returns an object reference to the previous node in the DOM tree in the tree walker's document-order traversal, or a null object reference if the current node has no previous node or the search for the previous node looks above the walker's root node.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::PreviousSibling

The `IDLffXMLDOMTreeWalker::PreviousSibling` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is the previous sibling of the node to which the walker is currently pointing.

If the current node has no visible previous sibling, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[[IDLffXMLDOMTreeWalker::](#)]PreviousSibling()

### Return Value

Returns an object reference to the previous sibling of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible previous sibling.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::SetCurrentNode

The IDLffXMLDOMTreeWalker::SetCurrentNode procedure method sets the tree walker's current node to the specified node. You can use this method to position the walker at a particular node in the DOM tree.

### Syntax

*Obj*->[IDLffXMLDOMTreeWalker:]SetCurrentNode, *CurrentNode*

### Arguments

#### CurrentNode

An object reference to an object belonging to a subclass of [IDLffXMLDOMNode](#).  
For example:

```
oTop = oDocument->GetDocumentElement()
oWalker = oDocument->CreateTreeWalker( oTop )
oNode = oWalker->GetFirstChild()
oNode = oWalker->GetNextSibling()
; Move walker back to the top.
oWalker->SetCurrentNode, oTop
```

### Keywords

# IDLffXMLSAX

An IDLffXMLSAX object uses an XML SAX level 2 parser. The XML parser allows you to read an XML file and store arbitrary data from the file in IDL variables. The parser object's methods are *callbacks*. These methods are called automatically when the parser encounters different types of XML elements or attributes.

---

**Note**

To use the XML parser, you *must* write a subclass of this object class, overriding the object methods as necessary to process the data in a specific XML file or files. See [Chapter 20, “Using the XML Parser Object Class”](#) in the *Building IDL Applications* manual for further information and examples.

---

The IDLffXMLSAX object encapsulates the Xerces validating XML parser; see <http://xml.apache.org> for details.

---

**Note**

For more information on XML, see [“About XML”](#) in Chapter 20 of the *Building IDL Applications* manual.

---

## Superclasses

None

## Subclasses

You *must* write a subclass of this object, overriding object methods as necessary to retrieve information from the XML file.

## Creation

See [“IDLffXMLSAX::Init”](#) on page 3397

## Properties

Objects of this class have the following properties. See [“IDLffXMLSAX Properties”](#) on page 3374 for details on individual properties.

- [FILENAME](#)
- [NAMESPACE\\_PREFIXES](#)

- `PARSER_LOCATION`
- `PARSER_PUBLICID`
- `PARSER_URI`
- `SCHEMA_CHECKING`
- `VALIDATION_MODE`

## Methods

This class has the following methods:

- `IDLffXMLSAX::AttributeDecl`
- `IDLffXMLSAX::Characters`
- `IDLffXMLSAX::Cleanup`
- `IDLffXMLSAX::Comment`
- `IDLffXMLSAX::ElementDecl`
- `IDLffXMLSAX::EndCDATA`
- `IDLffXMLSAX::EndDocument`
- `IDLffXMLSAX::EndDTD`
- `IDLffXMLSAX::EndElement`
- `IDLffXMLSAX::EndEntity`
- `IDLffXMLSAX::EndPrefixMapping`
- `IDLffXMLSAX::Error`
- `IDLffXMLSAX::ExternalEntityDecl`
- `IDLffXMLSAX::FatalError`
- `IDLffXMLSAX::GetProperty`
- `IDLffXMLSAX::IgnorableWhitespace`
- `IDLffXMLSAX::Init`
- `IDLffXMLSAX::InternalEntityDecl`
- `IDLffXMLSAX::NotationDecl`
- `IDLffXMLSAX::ParseFile`
- `IDLffXMLSAX::ProcessingInstruction`

- [IDLffXMLSAX::SetProperty](#)
- [IDLffXMLSAX::SkippedEntity](#)
- [IDLffXMLSAX::StartCDATA](#)
- [IDLffXMLSAX::StartDocument](#)
- [IDLffXMLSAX::StartDTD](#)
- [IDLffXMLSAX::StartElement](#)
- [IDLffXMLSAX::StartEntity](#)
- [IDLffXMLSAX::StartPrefixmapping](#)
- [IDLffXMLSAX::StopParsing](#)
- [IDLffXMLSAX::UnparsedEntityDecl](#)
- [IDLffXMLSAX::Warning](#)

## Version History

## IDLffXMLSAX Properties

IDLffXMLSAX objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffXMLSAX::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffXMLSAX::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffXMLSAX::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [FILENAME](#)
- [NAMESPACE\\_PREFIXES](#)
- [PARSER\\_LOCATION](#)
- [PARSER\\_PUBLICID](#)
- [PARSER\\_URI](#)
- [SCHEMA\\_CHECKING](#)
- [VALIDATION\\_MODE](#)

### FILENAME

A string containing the filename of the XML file being parsed.

---

### Note

This property is only available during a parse operation.

---

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## NAMESPACE\_PREFIXES

A Boolean value indicating whether namespace prefixes are enabled. Namespace prefixes are enabled if this property is set to true. By default, namespace prefixes are disabled.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PARSER\_LOCATION

A two-element array containing the approximate location of the parser within the entity being parsed. The first element of the array is set to the line number and the second element is set to the column number.

### Note

---

This property is only available during a parse operation.

---

<b>Property Type</b>	Array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## PARSER\_PUBLICID

A string containing the Public ID for the entity being parsed, if it is available. If the Public ID is not available, an empty string is returned.

### Note

---

This property is only available during a parse operation.

---

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## PARSER\_URI

A string containing the base URI (System ID) for the entity being parsed, if it is available. If the value is available, it is always an absolute URI. If the System ID is not available, an empty string is returned.

### Note

This property can be used to identify the document or external entity in diagnostics, or to resolve relative URIs. However, it is only available during a parse operation.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## SCHEMA\_CHECKING

An integer value to indicating the type of validation the parser should perform. XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation will occur. Possible values are:

0	No validation.
1	Validate only if a schema is provided. This is the default value.
2	Perform full schema constraint checking, if a schema is provided. This feature checks the schema grammar itself for additional errors. It does not affect the level of checking performed on document instances that use schema grammars.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## VALIDATION\_MODE

An integer value indicating the type of XML validation that the parser should perform. XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. By default, the parser will validate the parsed XML file against the specified DTD, if one is provided; if no DTD specification is provided, no validation will occur. Possible values are:

0	No validation.
1	Validate only if a DTD is provided. This is the default value.
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffXMLSAX::AttributeDecl

The IDLffXMLSAX::AttributeDecl procedure method is called when the parser detects an `<!ATTLIST . . . >` declaration in a DTD. This method is called once for each attribute declared by the tag.

### Syntax

*Obj*->[IDLffXMLSAX::]AttributeDecl, *eName*, *aName*, *Type*, *Mode*, *Value*

### Arguments

#### eName

A string containing the name of the element for which the attribute is being declared.

#### aName

A string containing the name of the attribute being declared.

#### Type

A string that specifying the type of attribute being defined. Possible values are:

- 'CDATA'
- 'ID'
- 'IDREF'
- 'IDREFS'
- 'NMTOKEN'
- 'NMTOKENS'
- 'ENTITY'
- 'ENTITIES'

or two types of enumerated values. Enumerated values are encoded with parenthesized strings such as `(a|b|c)` to indicate that strings `a`, `b`, or `c` are permissible. If the string is an enumeration of notation names, the string "NOTATION " (note the space after the second "N") precedes the parenthesized string.

## Mode

A string specifying restrictions on the value of the attribute. Possible values are:

- '#IMPLIED' - the application determines the value
- '#REQUIRED' - the value must be given; defaulting is not permitted
- '#FIXED' - only one value is permitted
- "" - a null string (the value specified by the *Value* argument is used as the default)

## Value

A string containing the default value for the attribute. If *Value* contains a null string, no default value was specified.

## Keywords

None

## Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::Characters

The IDLffXMLSAX::Characters procedure method is called when the parser detects text in the parsed document.

### Syntax

*Obj*->[\[IDLffXMLSAX::\]Characters](#), *Chars*

### Arguments

#### Chars

A string containing the text detected by the parser.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::Cleanup

The IDLffXMLSAX::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLffXMLSAX:]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::Comment

The IDLffXMLSAX::Comment procedure method is called when the parser detects a comment section of the form `<!-- ... -->`.

### Syntax

*Obj*->[\[IDLffXMLSAX::\]Comment](#), *Comment*

### Arguments

#### Comment

A string containing the text within the detected comment section, without the delimiting characters (“<!--” and “-->”).

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::ElementDecl

The IDLffXMLSAX::ElementDecl procedure method is called when the parser detects an `<!ELEMENT . . . >` declaration in the DTD.

### Syntax

*Obj*->[\[IDLffXMLSAX::\]](#)ElementDecl, *Name*, *Model*

### Arguments

#### Name

A string containing the name of the element.

#### Model

A string containing the *content model* (sometimes called the *content specification*) for the element, with all whitespace removed.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::EndCDATA

The IDLffXMLSAX::EndCDATA procedure method is called when the parser detects the end of a `<![CDATA[ . . . ]>` text section.

### Syntax

*Obj*->[IDLffXMLSAX::](#)EndCDATA

### Arguments

None

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::EndDocument

The IDLffXMLSAX::EndDocument procedure method is called when the parser detects the end of the XML document.

### Syntax

*Obj*->[IDLffXMLSAX::EndDocument](#)

### Arguments

None

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::EndDTD

The IDLffXMLSAX::EndDTD procedure method is called when the parser detects the end of a Document Type Definition (DTD).

### Syntax

*Obj*->[\[IDLffXMLSAX::\]](#)EndDTD

### Arguments

None

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::EndElement

The IDLffXMLSAX::EndElement procedure method is called when the parser detects the end of an element.

### Syntax

*Obj*->[IDLffXMLSAX:]EndElement, *URI*, *Local*, *qName*

### Arguments

#### URI

A string containing the namespace URI with which the element is associated, if any.

---

**Note**

A URI (or Uniform Resource Identifier) refers to the generic set of all names and addresses which are short strings which refer to objects.

---

#### Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

#### qName

A string containing the element name found in the XML file.

---

**Note**

If the element is associated with a namespace URI, this variable may contain an empty string.

---

### Keywords

None

## Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::EndEntity

The IDLffXMLSAX::EndEntity procedure method is called when the parser detects the end of an internal or external entity expansion.

### Syntax

*Obj*->[IDLffXMLSAX:]EndEntity, *Name*

### Arguments

#### Name

A string containing the name of the entity.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::EndPrefixMapping

The IDLffXMLSAX::EndPrefixMapping procedure method is called when a previously declared prefix mapping goes out of scope.

### Syntax

*Obj*->[IDLffXMLSAX::]EndPrefixMapping, *Prefix*

### Arguments

#### Prefix

A string containing the namespace prefix that is going out of scope.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::Error

The IDLffXMLSAX::Error procedure method is called when the parser detects an error that is not expected to be fatal. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

For example, a violation of XML validity constraints is generally a non-fatal error.

### Note

---

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

---

## Syntax

*Obj*->[IDLffXMLSAX::Error](#), *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

## Arguments

### SystemID

A string containing the URI of the associated text.

### LineNumber

A longword integer representing the line number that contains the error.

### ColumnNumber

A longword integer representing the column number that contains the error.

### Message

A string containing the error message sent to the IDL output log.

## Keywords

None

## Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::ExternalEntityDecl

The IDLffXMLSAX::ExternalEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declarations in the DTD for a parsed external entity.

### Syntax

*Obj*->[IDLffXMLSAX::]ExternalEntityDecl, *Name*, *PublicID*, *SystemID*

### Arguments

#### Name

A string containing the entity name.

#### PublicID

A string containing the Public ID for the entity.

#### Note

---

If this value is not specified in the entity declaration, this variable will contain an empty string.

---

#### SystemID

A string containing the System ID for the entity, provided as an absolute URI.

### Keywords

None

### Version History

---

5.6	Introduced
-----	------------

---

## IDLffXMLSAX::FatalError

The IDLffXMLSAX::FatalError procedure method is called when the parser detects a fatal error. When called, parsing will normally stop, but may sometimes continue long enough to report further errors. This method prints an IDL error string to the IDL output log.

### Syntax

*Obj*->[IDLffXMLSAX::]FatalError, *SystemID*, *LineNumber*, *ColumnNumber*,  
*Message*

### Arguments

#### SystemID

A string containing the URI of the associated text.

#### LineNumber

A longword integer representing the line number that contains the error.

#### ColumnNumber

A longword integer representing the column number that contains the error.

#### Message

A string containing the error message sent to the IDL output log.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::GetProperty

The IDLffXMLSAX::GetProperty procedure method is used to get the values of various properties of the parser.

### Syntax

*Obj*->[IDLffXMLSAX::]GetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLffXMLSAX Properties” on page 3374 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::IgnorableWhitespace

The IDLffXMLSAX::IgnorableWhitespace procedure method is called when the parser detects whitespace that separates elements in an element content model.

### Syntax

*Obj*->[IDLffXMLSAX::]IgnorableWhitespace, *Chars*

### Arguments

#### Chars

A string containing the whitespace detected by the parser. Whitespace can consist of spaces, tabs, or newline characters in any combination.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::Init

The IDLffXMLSAX::Init function method initializes an XML parser object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. In most cases, you cannot call the Init method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLffXMLSAX' [, *PROPERTY=**value*])

or

*Result* = *Obj*->[IDLffXMLSAX::]Init( [, *PROPERTY=**value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLffXMLSAX Properties” on page 3374 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::InternalEntityDecl

The IDLffXMLSAX::InternalEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declaration in a DTD for (parsed) internal entities. The entity can be either a general entity or a parameter entity.

### Syntax

*Obj*->[\[IDLffXMLSAX::\]](#)InternalEntityDecl, *Name*, *Value*

### Arguments

#### Name

A string containing the entity name. Names that start with the “%” character are parameter entities; all others are general entities.

#### Value

A string containing the entity value. The entity value can contain arbitrary XML content, which will be reparsed when the entity is expanded.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::NotationDecl

The IDLffXMLSAX::NotationDecl procedure method is called when the parser detects a `<!NOTATION . . . >` declaration in a DTD.

### Syntax

*Obj*->[IDLffXMLSAX::]NotationDecl, *Name*, *PublicID*, *SystemID*

### Arguments

#### Name

A string containing the notation name.

#### PublicID

A string containing the Public ID for the notation.

#### Note

---

If this value is not specified in the notation declaration, this variable will contain an empty string.

---

#### SystemID

A string containing the System ID for the notation, provided as an absolute URI.

#### Note

---

If this value is not specified in the notation declaration, this variable will contain an empty string.

---

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::ParseFile

The IDLffXMLSAX::ParseFile procedure method parses the specified XML file. During the parsing operation, different object methods are called as different items within the XML file are detected. When this method returns, the parse operation is complete.

### Syntax

*Obj*->[IDLffXMLSAX::ParseFile](#), *Filename*

### Arguments

#### Filename

A string containing the full path name of the XML file to parse.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::ProcessingInstruction

The IDLffXMLSAX::ProcessingInstruction procedure method is called when the parser detects a processing instruction.

### Syntax

*Obj*->[IDLffXMLSAX::]ProcessingInstruction, *Target*, *Data*

### Arguments

#### Target

A string specifying the target, which is the application that should process the instruction.

#### Data

A string specifying the data to be passed to the application specified by *Target*.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX:: SetProperty

The IDLffXMLSAX::SetProperty procedure method is used to set the values of various properties of the parser.

### Syntax

*Obj*->[IDLffXMLSAX::]SetProperty [, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLffXMLSAX Properties” on page 3374 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::SkippedEntity

The IDLffXMLSAX::SkippedEntity procedure method is called when the parser skips an entity and validation is not being performed. This method is rarely called by SAX parsers.

### Syntax

*Obj*->[IDLffXMLSAX:]SkippedEntity, *Name*

### Arguments

#### Name

A string containing the name of the entity that was skipped.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StartCDATA

The IDLffXMLSAX::StartCDATA procedure method is called when the parser detects the beginning of a `<![CDATA[...]]>` text section.

### Syntax

*Obj*->[IDLffXMLSAX::StartCDATA](#)

### Arguments

None

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StartDocument

The IDLffXMLSAX::StartDocument procedure method is called when the parser begins processing a document, and before any data is processed.

### Syntax

*Obj*->[\[IDLffXMLSAX::\]](#)StartDocument

### Arguments

None

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StartDTD

The IDLffXMLSAX::StartDTD procedure method is called when the parser detects the beginning of a Document Type Definition (DTD).

### Syntax

*Obj*->[IDLffXMLSAX::]StartDTD, *Name*, *PublicID*, *SystemID*

### Arguments

#### Name

A string containing the declared name of the root element for the document.

#### PublicID

A string containing the *normalized* version of the Public ID (a URI) declared for the external subset, or an empty string if no external subset was declared. *Normalization* involves removal of unnecessary “.” and “. .” segments from the URI.

#### SystemID

A string containing the System ID (a URI) of the external subset, or an empty string if no external subset was declared.

#### Note

---

This URI has not been resolved into an absolute URI.

---

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StartElement

The IDLffXMLSAX::StartElement procedure method is called when the parser detects the beginning of an element.

### Syntax

*Obj*->[IDLffXMLSAX::]StartElement, *URI*, *Local*, *qName* [, *attName*, *attValue*]

### Arguments

#### URI

A string containing the namespace URI with which the element is associated, if any.

#### Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

#### qName

A string containing the element name found in the XML file.

#### Note

---

If the element is associated with a namespace URI, this variable may contain an empty string.

---

#### attrName

A string array representing the names of the attributes associated with the element, if any.

#### attrValue

A string array representing the values of each attribute associated with the element, if any. The returned array will have the same number of elements as the array returned in the *attrName* keyword variable.

### Keywords

None

## Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StartEntity

The IDLffXMLSAX::StartEntity procedure method is called when the parser detects the start of an internal or external entity expansion.

### Syntax

*Obj*->[IDLffXMLSAX:]StartEntity, *Name*

### Arguments

#### Name

A string containing the name of the entity.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StartPrefixmapping

The IDLffXMLSAX::StartPrefixMapping procedure method is called when the parser detects the beginning of a namespace declaration.

### Syntax

*Obj*->[IDLffXMLSAX::]StartPrefixmapping, *Prefix*, *URI*

### Arguments

#### Prefix

A string containing the prefix, which is being mapped. If the variable specified by *Prefix* contains an empty string, the mapping is for the default element namespace.

#### URI

A string containing the URI of the prefix namespace.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::StopParsing

Call the IDLffXMLSAX::StopParsing procedure method during a parse operation to halt the operation and cause the ParseFile method to return. This may be useful when parsing large XML files and the desired information is known to have been returned.

### Syntax

*Obj*->[IDLffXMLSAX::](#)StopParsing

### Arguments

None

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::UnparsedEntityDecl

The IDLffXMLSAX::UnparsedEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declaration that includes the `NDATA` keyword, indicating that the entity is not meant to be parsed. The value of the `NDATA` keyword generally specifies the name of a *notation*, which in turn specifies the type of data.

### Syntax

*Obj*->`[IDLffXMLSAX::]UnparsedEntityDecl, Name, PublicID, SystemID, Notation`

### Arguments

#### Name

A string containing the name of the unparsed entity.

#### PublicID

A string containing the Public ID of the notation specified by the entity's `NDATA` keyword, or an empty string if no Public ID was declared.

#### SystemID

A string containing the System ID of the notation specified by the entity's `NDATA` keyword. This value is normally an absolute URI.

#### Notation

A string containing the name of the notation specified by the entity's `NDATA` keyword.

### Keywords

None

### Version History

5.6	Introduced
-----	------------

## IDLffXMLSAX::Warning

The IDLffXMLSAX::Warning procedure method is called when the parser detects a problem during processing. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

---

**Note**

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

---

## Syntax

*Obj*->[IDLffXMLSAX::]Warning, *SystemID*, *LineNumber*, *ColumnNumber*,  
*Message*

## Arguments

### SystemID

A string containing the URI of the text that generated the error.

### LineNumber

A longword integer representing the line number that contains the error.

### ColumnNumber

A longword integer representing the column number that contains the error.

### Message

A string containing the error message.

## Keywords

None

## Version History

5.6	Introduced

# IDLitCommand

The IDLitCommand class provides a dynamic data dictionary storage system. Its methods and properties allow the iTool developer to store information about the execution of an iTool operation on a single target object. It provides a tag-based mechanism for storing and retrieving this information, which allows the iTool developer to easily implement undo and redo functionality for an operation.

This class is written in the IDL language. Its source code can be found in the file `idlitcommand__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitComponent](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitCommand::Init](#)” on page 3428.

## Properties

Objects of this class have the following properties. See “[IDLitCommand Properties](#)” on page 3420 for details on individual properties.

- [SKIP\\_REDO](#)
- [SKIP\\_UNDO](#)
- [TARGET\\_IDENTIFIER](#)
- [OPERATION\\_IDENTIFIER](#)

In addition, objects of this class inherit the properties of the superclass of this class.

## Methods

This class has the following methods:

- [IDLitCommand::AddItem](#)

- [IDLitCommand::Cleanup](#)
- [IDLitCommand::GetItem](#)
- [IDLitCommand::GetProperty](#)
- [IDLitCommand::GetSize](#)
- [IDLitCommand::Init](#)
- [IDLitCommand::SetProperty](#)

In addition, this class inherits the methods of its superclass.

## Examples

See “[Creating a New Generalized Operation](#)” in Chapter 7 of the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
6.2	Added SKIP_REDO, SKIP_UNDO properties

## IDLitCommand Properties

IDLitCommand objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitCommand::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitCommand::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitCommand::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [SKIP\\_REDO](#)
- [SKIP\\_UNDO](#)
- [TARGET\\_IDENTIFIER](#)
- [OPERATION\\_IDENTIFIER](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

### SKIP\_REDO

A Boolean value that determines whether the command object will be skipped when performing a Redo operation on the command set that contains this command. If this property is set to True (1), the command object will be skipped. The default is False (0), which includes this command during the Redo operation.

The SKIP\_REDO property is useful when you have a command that needs to be Undone, but not Redone.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SKIP\_UNDO

A Boolean value that determines whether the command object will be skipped when performing an Undo operation on the command set that contains this command. If this property is set to True (1), the command object will be skipped. The default is False (0), which includes this command during the Undo operation.

The SKIP\_UNDO property is useful when you have a command that needs to be Redone, but not Undone.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TARGET\_IDENTIFIER

The iTool identifier of the *target* object for this command. This is the item on which the operation associated with the command will execute.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## OPERATION\_IDENTIFIER

The iTool identifier for the *operation* associated with this command. When an undo-redo operation takes place, the command object is passed to this operation.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitCommand::AddItem

The IDLitCommand::AddItem function method adds the specified data item to the data dictionary associated with this object.

---

**Note**

If a data item with the specified identifying string is already in the data dictionary, the new value is not added unless the OVERWRITE keyword is set, in which case the old value is discarded.

---

## Syntax

*Result* = *Obj*->[IDLitCommand:]AddItem(*StrItem*, *Item*[, /OVERWRITE])

## Return Value

Returns 1 if the item was successfully added to the data dictionary, or 0 if the new value was not added.

## Arguments

### StrItem

A scalar string used to identify the data specified by the *Item* argument in the data dictionary. This string is treated in a case-insensitive manner.

### Item

A data item of any IDL data type.

## Keywords

### OVERWRITE

Normally, if an item already exists in the data dictionary of an IDLitCommand object, it is not overwritten. If this keyword is set, the original value will be overwritten.

---

**Note**

If the item being replaced uses dynamic memory (that is, if it is a pointer or object reference), the memory must be released by calling PTR\_FREE or OBJ\_DESTROY before overwriting the value.

---

## Version History

6.0	Introduced
-----	------------

## IDLitCommand::Cleanup

The IDLitCommand::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitCommand::]Cleanup() *(In a lifecycle method only.)*

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitCommand::GetItem

The IDLitCommand::GetItem function method retrieves the specified item from the data dictionary associated with this object.

### Syntax

*Result* = *Obj*->[IDLitCommand::]GetItem(*StrItem*, *Item*)

### Return Value

Returns 1 if the *Item* is retrieved successfully, or 0 if *Item* is not found in the data dictionary.

### Arguments

#### StrItem

A scalar string used to identify the data to be retrieved from the data dictionary. This string is treated in a case-insensitive manner.

#### Item

A named IDL variable that will contain the IDLitData object retrieved from the data dictionary.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitCommand::GetProperty

The IDLitCommand::GetProperty procedure method retrieves the value of a property or group of properties of a command object.

### Syntax

*Obj*->[IDLitCommand::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 3420 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

### Version History

6.0	Introduced
-----	------------

## IDLitCommand::GetSize

The IDLitCommand::GetSize function method returns an approximate value for the amount of memory being used by the items in the data dictionary associated with this object.

### Syntax

*Result* = *Obj*->[IDLitCommand::]GetSize([, /KILOBYTES])

### Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

### Arguments

None

### Keywords

#### KILOBYTES

Set this keyword to return the number of kilobytes of memory being used by the data dictionary. By default, this function returns the number of bytes of memory being used.

### Version History

6.0	Introduced
-----	------------

## IDLitCommand::Init

The IDLitCommand::Init function method initializes the object and allows specification of items associated with it.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLitCommand' [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLitCommand::]Init( [, *PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 3420 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object ([IDLitComponent](#)).

## Version History

6.0	Introduced
-----	------------

## IDLitCommand:: SetProperty

The IDLitCommand::SetProperty procedure method sets the value of a property or group of properties for the command object.

### Syntax

*Obj*->[IDLitCommand::](#)SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 3420 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitCommandSet

The IDLitCommandSet class stores a collection of IDLitCommand objects, allowing a group of commands to be managed as a single item. Command sets are useful as containers for IDLitCommand objects generated by the application of an iTool operation to multiple target items; the generated command set objects are used to provide undo/redo functionality to the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitcommandset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDL\\_Container](#)

[IDLitCommand](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitCommandSet::Init](#)” on page 3436.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLitCommandSet::Cleanup](#)
- [IDLitCommandSet::GetSize](#)
- [IDLitCommandSet::Init](#)

In addition, this class inherits the methods of its superclasses.

## Examples

See [“Creating a New Generalized Operation”](#) in Chapter 7 of the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
-----	------------

## IDLitCommandSet Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDL\\_Container](#)
- [IDLitCommand](#)

## IDLitCommandSet::Cleanup

The IDLitCommandSet::Cleanup procedure method performs all cleanup on the object.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

### Syntax

OBJ\_DESTROY, Obj

or

Obj->[IDLitCommandSet:]Cleanup() *(In a lifecycle method only.)*

### Arguments

None

### Keywords

None

### Version History

---

6.0	Introduced
-----	------------

---

## IDLitCommandSet::GetSize

The IDLitCommandSet::GetSize function method returns an approximate value for the amount of memory being used by the items contained by this command set. When called, the method will call the GetSize method on all of the command objects that it contains and generate a sum of the values.

### Syntax

```
Result = Obj->[IDLitCommand::]GetSize([/KILOBYTES])
```

### Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

### Arguments

None

### Keywords

#### KILOBYTES

Set this keyword to return the number of kilobytes of memory being used. By default, this function returns the number of bytes of memory being used.

### Version History

6.0	Introduced
-----	------------

## IDLitCommandSet::Init

The IDLitCommandSet::Init function method initializes the object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitCommandSet')
```

or

```
Result = Obj->[IDLitCommandSet:]Init() (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

All keywords are passed to the superclass of this object ([IDLitCommand](#)).

## Version History

6.0	Introduced
-----	------------

# IDLitComponent

The IDLitComponent class is the base component from which all iTool components should subclass. The IDLitComponent class provides support for property descriptors and property registration, and defines properties that are common to all iTool component objects.

---

**Note**

This class is now a superclass of all the atomic graphical (IDLgr\*) object classes.

---

## Superclasses

None

---

**Note**

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See [“IDLitComponent::Init”](#) on page 3451.

## Properties

Objects of this class have the following properties. See [“IDLitComponent Properties”](#) on page 3439 for details on individual properties.

- [COMPONENT\\_VERSION](#)
- [DESCRIPTION](#)
- [HELP](#)
- [ICON](#)
- [IDENTIFIER](#)
- [NAME](#)
- [PRIVATE](#)
- [UVALUE](#)

## Methods

This class has the following methods:

- [IDLitComponent::Cleanup](#)
- [IDLitComponent::EditUserDefProperty](#)
- [IDLitComponent::GetFullIdentifier](#)
- [IDLitComponent::GetProperty](#)
- [IDLitComponent::GetPropertyAttribute](#)
- [IDLitComponent::GetPropertyByIdentifier](#)
- [IDLitComponent::Init](#)
- [IDLitComponent::QueryProperty](#)
- [IDLitComponent::RegisterProperty](#)
- [IDLitComponent::Restore](#)
- [IDLitComponent::SetProperty](#)
- [IDLitComponent::SetPropertyAttribute](#)
- [IDLitComponent::SetPropertyByIdentifier](#)
- [IDLitComponent::UpdateComponentVersion](#)

## Version History

6.0	Introduced
6.1	Added COMPONENT_VERSION property

## IDLitComponent Properties

IDLitComponent objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitComponent::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitComponent::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitComponent::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [COMPONENT\\_VERSION](#)
- [DESCRIPTION](#)
- [HELP](#)
- [ICON](#)
- [IDENTIFIER](#)
- [NAME](#)
- [PRIVATE](#)
- [UVALUE](#)

### COMPONENT\_VERSION

A integer value representing the version of the component object. This value is set by RSI and is intended to aid in determining how a component object should be restored by the Restore method.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DESCRIPTION

A string giving the full name or description of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Description		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HELP

A scalar string representing the help topic associated with this object. If this property is not set, or is set to a null string, then the object class name will be used as the default help topic.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ICON

A string specifying the name of an icon to be associated with this object. Typically, this property is the name of a bitmap file used when displaying this object in a tree view. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for details.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDENTIFIER

A string containing the *object identifier* for this object. If this property is not specified, then the NAME property is used as the identifier. See “[iTool Object](#)”

**Identifiers**” in Chapter 2 of the *iTool Developer’s Guide* manual for details about how identifiers are named.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## NAME

A string giving the human-readable name of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Name		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PRIVATE

A boolean value that indicates whether the object should be marked as private. Objects marked private (and all of their children) are not displayed in the graphical iTool browser windows.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## UVALUE

A value of any type containing any information you wish.

**Note** \_\_\_\_\_  
 Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLitComponent object is destroyed.  
 \_\_\_\_\_

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitComponent::Cleanup

The IDLitComponent::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

### Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitComponent::]Cleanup (In a lifecycle method only.)

### Arguments

None

### Keywords

None

### Version History

---

6.0	Introduced
-----	------------

---

## IDLitComponent::EditUserDefProperty

The IDLitComponent::EditUserDefProperty function method defines the interface that is displayed when a user selects the “Edit” button on a user-defined property in the property sheet interface. Typically, this method will display an interactive dialog that allows the user to change the value of the property.

---

### Note

An iTool object class that includes a user-defined property *must* implement this method if the property is displayed in a property sheet — that is, if the property is registered and not hidden. If an iTool object class has no user-defined properties that are displayed in a property sheet, there is no need to supply an EditUserDefProperty method.

---

See “[User Defined Property Types](#)” in Chapter 4 of the *iTool Developer’s Guide* manual for a discussion of how the property sheet interface displays user-defined properties.

## Syntax

*Result* = *Obj*->[IDLitComponent::]EditUserDefProperty(*iTool*, *PropertyIdentifier*)

## Return Value

Returns a 1 if the property value was changed, or a 0 if the property value was not changed.

---

### Note

If the return value is 1, the property sheet interface automatically updates the displayed property value using the value of the property’s USERDEF attribute. If the return value is 0, no update takes place.

---

## Arguments

### iTool

An object reference to the current iTool object.

### PropertyIdentifier

A string containing the property identifier of the user-defined property.

**Tip**

---

Since there can only be one `EditUserDefProperty` method for each class, you can use the *PropertyIdentifier* argument to determine which user-defined property is being edited.

---

## Keywords

None

## Example

The following is the `EditUserDefProperty` method of the `IDLitOpConvolution` operation class. Selecting and editing the `Kernel` property of this operation displays a dialog that allows the user to edit a convolution kernel.

```
FUNCTION IDLitOpConvolution::EditUserDefProperty, oTool, $
    identifier

CASE identifier OF

    'KERNEL': RETURN, oTool->DoUIService('ConvolKernel', self)

ELSE:

ENDCASE

RETURN, 0

END
```

This method simply checks the property identifier to determine whether it matches the string `'KERNEL'`. If it does, it returns the value returned by the `DoUIService` method; otherwise it returns zero. In this case, the `DoUIService` method actually handles the modification of the property value. See [“User Defined Property Types”](#) in Chapter 4 of the *iTool Developer’s Guide* manual for additional discussion.

## Version History

6.0	Introduced
-----	------------

## IDLitComponent::GetFullIdentifier

The `IDLitComponent::GetFullIdentifier` function method navigates the iTool object container hierarchy of the object on which it is called and retrieves the fully-qualified object identifier. The full identifier is constructed by recursively retrieving the parent object reference and prepending this to the identifier, separated by `/` characters. The parent must inherit from the `IDLitContainer` class. The full identifier string has the following form:

```
/.../GRANDPARENTID/PARENTID/OBJID
```

If the *Objref* argument is specified, the function returns the object identifier path relative to the specified object.

See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for additional discussion of object identifiers.

### Syntax

```
Result = Obj->[IDLitComponent::]GetFullIdentifier([Objref])
```

### Return Value

Returns a string containing the object identifier.

#### Note

---

The full object identifier of a top-level *container* object is `/` even if the top-level container’s `IDENTIFIER` property is set to some other value. If the top-level object is *not* a container object, the full object identifier is a null string (`""`) even if the top-level object’s `IDENTIFIER` property is set to some other value.

---

### Arguments

#### Objref

An object reference to an iTool component object. If this argument is specified, the returned value is a relative object identifier, beginning with *Objref*. If this argument is not specified, the returned value is a fully-qualified object identifier.

### Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitComponent::GetProperty

The IDLitComponent::GetProperty procedure method retrieves the value of an IDLitComponent property or properties.

### Syntax

*Obj*->[IDLitComponent::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitComponent Properties](#)” on page 3439 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitComponent::GetPropertyAttribute

The IDLitComponent::GetPropertyAttribute procedure method retrieves property attribute values for a registered property.

### Syntax

```
Obj->[IDLitComponent::]GetPropertyAttribute, PropertyIdentifier  
[, TYPE=variable]
```

### Arguments

#### PropertyIdentifier

A string containing the property identifier of the registered property.

### Keywords

Any keywords to the RegisterProperty method followed by the word “Get” can be retrieved. In addition, the following keyword is available:

#### TYPE

Set this argument to a named variable that returns the TYPE code as an integer, as specified under the *Type* argument to IDLitComponent::RegisterProperty.

### Version History

6.0	Introduced
-----	------------

## IDLitComponent::GetPropertyByIdentifier

The IDLitComponent::GetPropertyByIdentifier function method retrieves the value of an IDLitComponent property.

### Tip

---

The IDLitComponent::GetPropertyByIdentifier method is similar to the IDLitComponent::GetProperty method, but is useful for cases where the *property identifier* is defined at runtime.

---

## Syntax

```
Result = Obj->[IDLitComponent:]GetPropertyByIdentifier(PropertyIdentifier,  
Value)
```

## Return Value

Returns 1 if the property value is defined, or 0 if the property value is undefined.

## Arguments

### PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the GetProperty method of the component.

### Value

A named variable that will contain the value of the property. If the property value is currently undefined, then the contents of the variable specified by *Value* will not be modified.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitComponent::Init

The IDLitComponent::Init function method initializes the IDLitComponent object, and should be called by the Init method of a subclass.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitComponent'[, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitComponent::]Init([, PROPERTY=value]) (In a lifecycle  
method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitComponent Properties” on page 3439 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitComponent::QueryProperty

The IDLitComponent::QueryProperty function method checks whether a property identifier is registered, or retrieves a list of all registered properties.

### Syntax

*Result* = *Obj*->[IDLitComponent::]QueryProperty([*PropertyIdentifier*])

### Return Value

Returns a 1 if *PropertyIdentifier* is a scalar string that corresponds to a valid registered property, or a 0 otherwise. If *PropertyIdentifier* is an array, the result is an array of 1s and 0s.

If *PropertyIdentifier* is not specified, *Result* is a string array containing the identifiers of all registered properties.

### Arguments

#### PropertyIdentifier

A scalar string or string array containing property identifiers.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitComponent::RegisterProperty

The IDLitComponent::RegisterProperty procedure method registers a property as belonging to the component. Only registered properties are displayed in the graphical property sheet interface for the object.

### Syntax

```
Obj->[IDLitComponent::]RegisterProperty, PropertyIdentifier[, Type]
  [, /BOOLEAN] [, /COLOR] [, DESCRIPTION=string]
  [, ENUMLIST=stringvector] [, /FLOAT] [, /HIDE] [, /INTEGER]
  [, /LINESTYLE] [, NAME=string] [, /SENSITIVE] [, /STRING] [, /SYMBOL]
  [, /THICKNESS] [, /UNDEFINED] [, USERDEF=string]
  [, VALID_RANGE=vector]
```

### Arguments

#### PropertyIdentifier

A scalar string containing the property identifier. GetProperty and SetProperty methods accept this string as a keyword.

#### Type

An optional integer argument representing the property type. Values recognized by Property Sheets are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT
- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

If *Type* is not supplied, then one of the type keywords must be set instead.

## Keywords

Some of the following keywords correspond to *attributes* of the property being registered. Keywords followed by the word “Get” indicate attributes that can be retrieved by the `IDLitComponent::GetPropertyAttribute` method. Keywords followed by the word “Set” indicate attributes that can be set by the `IDLitComponent::SetPropertyAttribute` method.

Some of the following keywords correspond to iTool property data types, which can also be specified via the *Type* argument. Note that if both the *Type* argument and one of the corresponding keywords are set, the keyword value will be honored.

### BOOLEAN

Set this keyword to indicate that the property type is BOOLEAN. Properties of type BOOLEAN must accept an integer value of either 0 (“False”) or 1 (“True”). Setting this keyword is equivalent to setting the TYPE argument equal to 1.

### COLOR

Set this keyword to indicate that the property type is COLOR. Properties of type COLOR must accept a three-element integer array containing an RGB triplet. Setting this keyword is equivalent to setting the TYPE argument equal to 5.

### DESCRIPTION

(*Get, Set*)

Set this keyword to a string containing the description of this property.

---

**Note**

Do not confuse the DESCRIPTION *property attribute* with the DESCRIPTION *property*. The DESCRIPTION property attribute is *not* displayed in the graphical property sheet interface.

---

### ENUMLIST

(*Get, Set*)

Set this keyword equal to an array of strings to be displayed in the dropdown menu displayed by a property of type ENUMLIST. The default is a scalar null string. Properties of type ENUMLIST report their value as an integer between 0 and  $n-1$ , where  $n$  is the number of elements in the enumerated list. Setting this keyword implies that the TYPE argument is equal to 9.

## FLOAT

Set this keyword to indicate that the property type is `FLOAT`. Properties of type `FLOAT` must accept a scalar double-precision floating-point value. Setting this keyword is equivalent to setting the `TYPE` argument equal to 3.

## HIDE

*(Get, Set)*

Set this keyword to hide the given property when displaying the graphical property sheet interface. By default, all registered properties are displayed.

## INTEGER

Set this keyword to indicate that the property type is `INTEGER`. Properties of type `INTEGER` must accept a scalar integer value. Setting this keyword is equivalent to setting the `TYPE` argument equal to 2.

## LINESTYLE

Set this keyword to indicate that the property type is `LINESTYLE`. Properties of type `LINESTYLE` must accept an integer specifying a pre-defined linestyle, as described under the `LINESTYLE` property of the `IDLgrPolyline` class. Setting this keyword is equivalent to setting the `TYPE` argument equal to 6.

## NAME

*(Get, Set)*

Set this keyword to a string giving the human-readable name for the property. The `NAME` string will be used when displaying the graphical property sheet interface. If `NAME` is not set, the value of the *PropertyIdentifier* argument is used.

### Note

---

Do not confuse the `NAME` *property attribute* with the `NAME` *property*.

---

## SENSITIVE

*(Get, Set)*

Set this keyword to zero to make the given property insensitive in the graphical property sheet interface. By default, registered properties are sensitive.

## STRING

Set this keyword to indicate that the property type is `STRING`. Properties of type `STRING` must accept a scalar string of any length. Setting this keyword is equivalent to setting the `TYPE` argument equal to 4.

## SYMBOL

Set this keyword to indicate that the property type is `SYMBOL`. Properties of type `SYMBOL` must accept an integer specifying one of the pre-defined symbol types described under `IDLgrSymbol::Init`. Setting this keyword is equivalent to setting the `TYPE` argument equal to 7.

## THICKNESS

Set this keyword to indicate that the property type is `THICKNESS`. Properties of type `THICKNESS` must accept an integer between 1 and 10 specifying the line thickness in points. Setting this keyword is equivalent to setting the `TYPE` argument equal to 8.

## UNDEFINED

*(Get, Set)*

Set this keyword to indicate that the property should appear as a blank cell when displayed in the graphical property sheet interface. This is useful in situations where properties of multiple objects are displayed in the property sheet (either because multiple objects are selected, or because the objects have been grouped).

### Note

---

It is the iTool developer's responsibility to set this property attribute back to zero. Use the `SET_DEFINED` field of the `WIDGET_PROPERTY SHEET` event structure to determine when to set the `UNDEFINED` attribute back to zero.

---

## USERDEF

*(Get, Set)*

Set this keyword to a string that represents a user-defined property. Properties of type `USERDEF` can accept and return variables of any type. When the actual property value changes, it is assumed that the string value of the `USERDEF` attribute will also be modified to reflect the new property value. Setting this keyword implies that the `TYPE` argument is equal to 0.

## VALID\_RANGE

(Get, Set)

For INTEGER or FLOAT types, set this keyword to a two- or three-element vector specifying the [minimum, maximum] or [minimum, maximum, increment] for valid values of the property.

What is displayed for the property sheet number cell depends upon the following:

- If this attribute is not specified — the property sheet displays an editable text field where masked editing is enforced, and the range is that of the data type. The only accepted keystrokes are the ten digits and the plus and minus signs. If the float type is specified, the decimal, and “d” and “e” (scientific exponent notation tokens) are also allowed.
- If a range is specified without an increment — the property sheet displays a spinner control that allows the user to click, or click and hold the up or down buttons to change the value. For an integer type, the increment is one. For a float type, the increment equals approximately 1/100 of the range. For example, a range of 100 results in an increment of 1. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The editable text field (featuring masked editing) also allows the user to enter a numerical value.
- If a range and increment are specified — the property sheet displays a slider with a marker that can be repositioned to change the value. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The increment value must be positive and will be converted to an integer for INTEGER types. Specifying an increment of 0 (zero) is the same as specifying a range without an increment. The editable text field (featuring masked editing) also allows the user to enter a numerical value.

The following code creates properties containing various number cells:

```
; Create a number cell that supports masked editing.
self->RegisterProperty, 'integer1', /INTEGER, $
    NAME = 'Integer1', description = 'Integer'

; Create a number cell with spinner control and masked
; editing as only the range is specified.
self->RegisterProperty, 'integer2', /INTEGER, $
    NAME = 'Integer2', VALID_RANGE = [ -100, 100 ]

; Creates a number cell with slider control and masked
; editing as a range and increment are specified.
self->RegisterProperty, 'float1', /FLOAT, $
```

```
NAME = 'Float1', VALID_RANGE = [ -20.0D, 5.0D, 0.5D ]
```

## Version History

6.0	Introduced
6.1	Added spinner control functionality to VALID_RANGE keyword

## IDLitComponent::Restore

The IDLitComponent::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

---

**Note**

This method is designed to be implemented by a subclass of IDLitComponent, to perform any transition work necessary when a component object is restored.

---

### Syntax

*Obj*->[IDLitComponent::Restore](#)

### Arguments

None

### Keywords

None

### Version History

---

6.1	Introduced
-----	------------

---

### See Also

[IDLitComponent::UpdateComponentVersion](#), [IDL\\_Savefile](#), [SAVE](#), [RESTORE](#)

## IDLitComponent:: SetProperty

The IDLitComponent::SetProperty procedure method sets the value of an IDLitComponent property or properties.

### Syntax

*Obj*->[IDLitComponent::](#)SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitComponent Properties](#)” on page 3439 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

## IDLitComponent:: SetPropertyAttribute

The IDLitComponent::SetPropertyAttribute procedure method sets one or more property attributes for a registered property.

### Syntax

*Obj*->[IDLitComponent::]SetPropertyAttribute , *PropertyIdentifier*

### Arguments

#### PropertyIdentifier

A string containing the property identifier of the registered property.

### Keywords

Any keywords to the [IDLitComponent::RegisterProperty](#) method followed by the word “Set” can be set.

### Version History

6.0	Introduced
-----	------------

## IDLitComponent:: SetPropertyByIdentifier

The IDLitComponent::SetPropertyByIdentifier procedure method sets the value of an IDLitComponent property.

### Tip

---

The IDLitComponent::SetPropertyByIdentifier method is similar to the IDLitComponent::SetProperty method, but is useful for cases where the *PropertyIdentifier* is defined at runtime, and avoids the overhead of creating an *\_EXTRA* structure to pass to SetProperty.

---

## Syntax

*Obj*->[IDLitComponent::]SetPropertyByIdentifier, *PropertyIdentifier*, *Value*

## Arguments

### PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the SetProperty method of the component.

### Value

The new value for the property.

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitComponent::UpdateComponentVersion

The IDLitComponent::UpdateComponentVersion procedure method updates the value of the COMPONENT\_VERSION property for the specified object to match the version associated with the current release of IDL. This method is intended for use after calling the Restore method on a component object, so that the object can be identified as having been restored.

### Syntax

*Obj*->[IDLitComponent::](#)UpdateComponentVersion

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

### See Also

[IDLitComponent::Restore](#)

# IDLitContainer

The IDLitContainer class is a specialization of the IDL\_Container class designed to manage collections of IDLitComponent objects and provide methods to work with the iTools *identifier* system. IDLitContainer object methods allow you to add, retrieve, and remove values from a IDLitContainer-based hierarchy using either object references or iTool identifiers.

This class is written in the IDL language. Its source code can be found in the file `idlitcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDL\\_Container](#)

[IDLitComponent](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitContainer::Init](#)” on page 3476.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLitContainer::Add](#)
- [IDLitContainer::AddByIdentifier](#)
- [IDLitContainer::Cleanup](#)
- [IDLitContainer::FindIdentifiers](#)
- [IDLitContainer::Get](#)

- [IDLitContainer::GetByIdentifier](#)
- [IDLitContainer::Init](#)
- [IDLitContainer::Remove](#)
- [IDLitContainer::RemoveByIdentifier](#)

In addition, this class inherits the methods of its superclasses.

## Version History

6.0	Introduced
-----	------------

## IDLitContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDL\\_Container](#)
- [IDLitComponent](#)

## IDLitContainer::Add

The IDLitContainer::Add procedure method adds items to the container object.

### Syntax

*Obj*->[IDLitContainer::]Add, *Components*[, /NO\_NOTIFY]

### Arguments

#### Components

An object reference (or array of object references) to the IDLitComponent object or objects to be added to the container. When this method is called, the IDENTIFIER properties of objects specified by *Components* are validated, verifying that no items in the container have the same value. If an object with the same identifier already exists in the container, a unique identifier is created by appending a number to the original value.

### Keywords

#### NO\_NOTIFY

Normally, when an item is added to a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

### Version History

6.0	Introduced
-----	------------

## IDLitContainer::AddByIdentifier

The `IDLitContainer::AddByIdentifier` procedure method adds an object to the container hierarchy in the position specified by the *Identifier* argument.

### Syntax

```
Obj->[IDLitContainer::]AddByIdentifier, Identifier, Item
    [, FOLDER_CLASSNAME=string]
```

### Arguments

#### Identifier

An object identifier specifying the location in the container hierarchy where *Item* should be added. *Identifier* can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called. If *Identifier* is a null string (‘ ’), *Item* is added to the root of the container object.

See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

#### Item

An object reference to the iTool component object being added to the container.

### Keywords

#### FOLDER\_CLASSNAME

If the container hierarchy specified by *Identifier* contains subfolders that do not exist, the necessary subfolders are created automatically. By default, the created subfolders are of the same class as the calling method (`IDLitContainer` or one of its subclasses). To create subfolders of a different class, set the `FOLDER_CLASSNAME` keyword equal to a string specifying the name of the class to be used.

### Version History

6.0	Introduced
6.2	Added <code>FOLDER_CLASSNAME</code> keyword

## IDLitContainer::Cleanup

The IDLitContainer::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitContainer::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitContainer::FindIdentifiers

The IDLitContainer::FindIdentifiers function method allows you to retrieve the full identifiers for items within an iTool container.

### Warning

---

The FindIdentifiers method recurses through the entire object hierarchy of the specified object, which may be slow for large container hierarchies. If you find it necessary to call FindIdentifiers multiple times, it may be more efficient to use a single call with one or more wildcards (“\*”) to return all relevant identifiers, and then perform the necessary searches using the returned list.

---

## Syntax

```
Result = Obj->[IDLitContainer::]FindIdentifiers([Pattern] [, COUNT=variable] [, /LEAF_NODES] )
```

## Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

## Arguments

### Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See [STRMATCH](#) for a description of the rules used when matching patterns.

### Note

---

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

---

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

### LEAF\_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

#### Note

---

If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

---

## Version History

6.1	Introduced
-----	------------

## See Also

[IDLitTool::FindIdentifiers](#)

## IDLitContainer::Get

The IDLitContainer::Get function method retrieves items from the container.

### Syntax

*Result = Obj->*[IDLitContainer::]Get([, /ALL] [, COUNT=*variable*] [, ISA=*string* or *array of strings*] [, POSITION=*index* or *array of indices*] [, /SKIP\_PRIVATE])

### Return Value

Returns an object reference or array of object references to the iTool components stored in the container. Unless either the ALL keyword or the POSITION keyword is specified, the first object in the container is returned. If no objects are found in the container, the return value is -1.

### Arguments

None

### Keywords

#### ALL

Set this keyword to return an array of object references to all of the objects in the container.

#### COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

#### ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

#### Note

---

This keyword is ignored if the ALL keyword is not provided.

---

## POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

## SKIP\_PRIVATE

Set this keyword to ignore any components for which the PRIVATE property is set to true. This keyword is ignored unless the ALL keyword is also set.

## Version History

6.0	Introduced
-----	------------

## IDLitContainer::GetByIdentifier

The IDLitContainer::GetByIdentifier function method retrieves an object from a container hierarchy using the specified identifier to locate the object.

### Syntax

*Result = Obj->*[IDLitContainer:]GetByIdentifier(*Identifier*)

### Return Value

Returns an object reference to the object that was requested from the hierarchy, or a null object reference if no object was located.

### Arguments

#### Identifier

The object identifier of the object that should be retrieved from the container hierarchy. *Identifier* can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called.

See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitContainer::Init

The IDLitContainer::Init function method initializes the object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitContainer')
```

or

```
Result = Obj->[IDLitContainer::]Init() (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitContainer::Remove

The IDLitContainer::Remove procedure method removes items from the container.

### Syntax

*Obj*->[IDLitContainer:]Remove, *Components* [, /NO\_NOTIFY]

### Arguments

#### Components

An object reference (or array of object references) to the objects to be removed from the container.

### Keywords

#### NO\_NOTIFY

Normally, when an item is removed from a container object that inherits from both the IDLitContainer class and the IDLitMessaging class, a REMOVEITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

### Version History

6.0	Introduced
-----	------------

## IDLitContainer::RemoveByIdentifier

The `IDLitContainer::RemoveByIdentifier` function method removes an object from a container hierarchy using the specified identifier to locate the object.

### Syntax

```
Result = Obj->[IDLitContainer:]RemoveByIdentifier(Identifier)
```

### Return Value

Returns an object reference to the object that was removed from the hierarchy, or a null object reference if no object was removed.

### Arguments

#### Identifier

The object identifier of the object that should be removed from the container hierarchy. The *Identifier* argument can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called.

See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

# IDLitData

The IDLitData class provides a generic data storage object that can hold data items of any IDL data type. The IDLitData class provides typing and data change notification functionality, and when coupled with the IDLitDataContainer object forms the base element for the construction of composite data types.

The IDLitData class implements the iTools *notifier interface*, which provides a mechanism by which observers of a data item can be alerted when the state of the information contained in the data object changes.

This class is written in the IDL language. Its source code can be found in the file `idlitdata__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitComponent](#)

### Note

---

---

## Creation

See “[IDLitData::Init](#)” on page 3491.

## Properties

Objects of this class have the following properties. See “[IDLitData Properties](#)” on page 3481 for details on individual properties.

- [HIDE](#)
- [READ\\_ONLY](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of the superclass.

## Methods

This class has the following methods:

- [IDLitData::AddDataObserver](#)
- [IDLitData::Cleanup](#)
- [IDLitData::Copy](#)
- [IDLitData::GetByType](#)
- [IDLitData::GetData](#)
- [IDLitData::GetProperty](#)
- [IDLitData::GetSize](#)
- [IDLitData::Init](#)
- [IDLitData::NotifyDataChange](#)
- [IDLitData::NotifyDataComplete](#)
- [IDLitData::RemoveDataObserver](#)
- [IDLitData::SetData](#)
- [IDLitData::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

## Examples

See [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
6.2	Removed NO_COPY property as it should only be documented as a keyword

## IDLitData Properties

IDLitData objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitData::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitData::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitData::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [HIDE](#)
- [READ\\_ONLY](#)
- [TYPE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

### HIDE

A Boolean value that controls the visibility of the data with respect to queries performed by the IDLitDataContainer methods `GetData`, `SetData` and `GetIdentifiers`. If the HIDE property has a True value, the data object is not found by these methods and the methods behave as if the data object did not exist.

<b>Property Type</b>	BOOLEAN		
<b>Name String</b>	HIDE		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## READ\_ONLY

A Boolean value that controls the ability to modify the data with the `SetData` method. If the `READ_ONLY` property has a `True` value, an attempt to use `SetData` on the object fails. IDL prints an informational message in this case.

<b>Property Type</b>	BOOLEAN		
<b>Name String</b>	READ_ONLY		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TYPE

A scalar string containing the type of the data object. The default value of this property is `NULL ( ' ' )` and cannot be changed after the class is instantiated. Subclasses of this class set the value of this property to a value that reflects the type of data that the subclass is implementing.

<b>Property Type</b>	STRING		
<b>Name String</b>	TYPE		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## IDLitData::AddDataObserver

The IDLitData::AddDataObserver procedure method specifies an object (the *Observer*) that will be notified when the contents of the data object are changed.

The object specified as the *Observer* must implement three methods that form the data observer interface:

- onDataChange
- onDataComplete
- onDelete

The onDataChange method is called when the contents of a data object are changed, and the onDataComplete method is called when the change messages are completed. This two-part notification process is used to allow observers of data to transact the change event and minimize the required system updates (such as graphic redrawing). The onDelete method is called when the data item is deleted.

## Syntax

*Obj*->[IDLitData::]AddDataObserver, *Observer*

## Arguments

### Observer

An object reference to an iTool component object that implements the data observer interface methods. When the contained data value changes, the *Observer* is notified of this change.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitData::Cleanup

The IDLitData::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method removes all data stored in the IDLitData object.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitData::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitData::Copy

The IDLitData::Copy function method returns an exact copy of the data object and its contents, including registered property values.

The following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

---

**Note**

If an object has been added to the data object, only the object reference to the added object is copied.

---

## Syntax

*Result* = *Obj*->[IDLitData::]Copy()

## Return Value

Returns a copy of the object on which it is called. If the copy operation fails, a null object is returned.

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitData::GetByType

The IDLitData::GetByType function method returns all contained objects of the specified iTool data type.

### Syntax

*Result* = *Obj*->[IDLitData::]GetByType(*Type*[, **COUNT**=*variable*])

### Return Value

Returns an object array containing references to the contained data objects that are of the iTool data type specified by *Type*. If no objects matching *Type* exist, a null object reference is returned.

### Arguments

#### Type

A string containing the iTool data type to search for in the data hierarchy rooted by this data container.

### Keywords

#### COUNT

Set this keyword equal to a named variable that will contain the number of valid objects returned by this method.

### Version History

6.0	Introduced
-----	------------

## IDLitData::GetData

The IDLitData::GetData function method retrieves the data stored in the object.

### Syntax

```
Result = Obj->[IDLitData::]GetData(Data[, Identifier] [, NAN=variable]  
[, /NO_COPY])
```

### Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

### Arguments

#### Data

A named variable that will contain the data retrieved from the data object. If the GetData method fails, the variable is not modified.

#### Identifier

A string argument that is not used by this method, but is accepted for parameter compatibility with the IDLitDataContainer::GetData method. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

### Keywords

#### NAN

Set this keyword to a named variable that will contain 1 if *Data* contains any non-finite values (either NaN or Infinity), or 0 otherwise.

#### NO\_COPY

Set this keyword to move the data from the data object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

## Version History

6.0	Introduced
-----	------------

## IDLitData::GetProperty

The IDLitData::GetProperty procedure method retrieves the value of an IDLitData property, and should be called by the GetProperty method of any subclass of this class.

### Syntax

*Obj*->[IDLitData::](#)GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitData Properties](#)” on page 3481 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitData::GetSize

The IDLitData::GetSize function method returns an approximate value for the amount of memory being used by the data object.

### Syntax

*Result* = *Obj*->[IDLitData:]GetSize()

### Return Value

Returns the number of bytes of memory used by the data object. The returned value is an approximation.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitData::Init

The IDLitData::Init function method initializes the IDLitData object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitData'[, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitData::]Init([Data] [, PROPERTY=value]) (In a lifecycle  
method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Data

An IDL variable of any type that is stored in the data object.

## Keywords

Any property listed under “IDLitData Properties” on page 3481 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitData::NotifyDataChange

The IDLitData::NotifyDataChange procedure method is called when a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataComplete method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the onDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' onDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

---

**Note**

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

---

## Syntax

*Obj*->[IDLitData::]NotifyDataChange

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitData::NotifyDataComplete

The IDLitData::NotifyDataComplete procedure method is called after a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataChange method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the onDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' onDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

### Note

---

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

---

## Syntax

*Obj*->[IDLitData:]NotifyDataComplete

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitData::RemoveDataObserver

The `IDLitData::RemoveDataObserver` method unregisters an object that has been registered as an *observer* of this data object. After this method is called, the `Observer` will no longer be notified when the contents of the data object change. If the specified *Observer* doesn't exist, this method will return quietly.

### Syntax

*Obj*->[IDLitData::]RemoveDataObserver, *Observer*

### Arguments

#### Observer

An object reference to an iTool component object that was previously registered as an observer of this data object.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitData::SetData

The IDLitData::SetData function method copies the data from an IDL variable or expression into the data object, and notifies all its observers that the data has changed.

### Syntax

```
Result = Obj->[IDLitData::]SetData(Data[, Identifier] [, /NO_COPY] [, /NULL])
```

### Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

### Arguments

#### Data

An IDL variable or expression whose value is copied into the data object.

#### Identifier

A string argument that is not used by this method. It is accepted by this method only for parameter compatibility with IDLitDataContainer::SetData. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

### Keywords

#### NO\_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

#### NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored.

## Version History

6.0	Introduced
-----	------------

## IDLitData:: SetProperty

The IDLitData::SetProperty procedure method sets the value of an IDLitData property, and should be called by the SetProperty method of any subclass of this class.

### Syntax

*Obj*->[IDLitData::]SetProperty[, *PROPERTY=**value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitData Properties](#)” on page 3481 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitDataContainer

The IDLitDataContainer class is used to store collections of IDLitData and IDLitDataContainer objects to form hierarchical data structures. Objects can be added to and removed from an IDLitDataContainer at any time, allowing for the dynamic creation of composite data types.

Objects stored in an IDLitDataContainer hierarchy are referenced using iTool *object identifiers*. Object identifiers are simple scalar strings assigned to the IDENTIFIER property of an object when it is created. For a complete discussion of object identifiers and their role in the iTool system, see “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitdatacontainer__define.pro` in the `lib/itool/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitContainer](#)

[IDLitData](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitDataContainer::Init](#)” on page 3509.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLitDataContainer::Add](#)
- [IDLitDataContainer::Cleanup](#)

- [IDLitDataContainer::GetData](#)
- [IDLitDataContainer::GetIdentifiers](#)
- [IDLitDataContainer::GetProperty](#)
- [IDLitDataContainer::Init](#)
- [IDLitDataContainer::SetData](#)
- [IDLitDataContainer::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

## Examples

See [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
-----	------------

## IDLitDataContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDLitContainer](#)
- [IDLitData](#)

## IDLitDataContainer::Add

The IDLitDataContainer::Add procedure method adds items to the data container object, and sends out an onDataChange and onDataComplete messages to all observers of the data container.

### Syntax

*Obj*->[IDLitDataContainer::]Add, *Data* [, /NO\_NOTIFY]

### Arguments

#### Data

An object reference (or array of object references) to the IDLitData object or objects to be added to the container. Objects that are not of class IDLitData are quietly ignored.

### Keywords

#### NO\_NOTIFY

Normally, when an item is added, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no ADDITEMS message is sent.

#### Note

---

Regardless of the setting of NO\_NOTIFY, the onDataChange and onDataComplete messages are always sent.

---

### Version History

6.1	Introduced
-----	------------

## IDLitDataContainer::Cleanup

The IDLitDataContainer::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method destroys all data objects stored in this container.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitDataContainer::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitDataContainer::GetData

The IDLitDataContainer::GetData function method retrieves the data value contained in the data object specified by the *Identifier* argument.

### Syntax

```
Result = Obj->[IDLitDataContainer::]GetData(Data [, Identifier] [, /NO_COPY])
```

### Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

### Arguments

#### Data

A named variable that will contain the data value of the specified data object.

#### Identifier

A string containing the relative object identifier path to the target data object for this method. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

If *Identifier* is not set, or is set to a null string, the data contained in the data container itself is returned.

### Keywords

#### NO\_COPY

Set this keyword to move the data from the data container object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

### Version History

6.0	Introduced
-----	------------

## IDLitDataContainer::GetIdentifiers

The IDLitDataContainer::GetIdentifiers function method retrieves the object identifiers for all data and data container objects contained in the data container object.

### Syntax

```
Result = Obj->[IDLitDataContainer::]GetIdentifiers([Pattern] [, /LEAF])
```

### Return Value

Returns an array of strings containing the object identifiers for all data and data container objects contained by the data container object. If the container is empty, or if the *Pattern* argument is supplied and no object identifiers are matched, the function returns a scalar null string.

### Arguments

#### Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. See [STRMATCH](#) for a description of the rules used when matching patterns.

### Keywords

#### LEAF

Set this keyword to return only object identifiers whose final node is *not* a container object.

### Version History

6.0	Introduced
-----	------------

## IDLitDataContainer::GetProperty

The IDLitDataContainer::GetProperty procedure method retrieves the value of an IDLitDataContainer property, and should be called by the GetProperty method of any subclass of this class.

### Syntax

*Obj*->[IDLitDataContainer::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 3503 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitDataContainer::Init

The IDLitDataContainer::Init function method initializes the IDLitDataContainer object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitDataContainer'[, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitDataContainer::]Init([Data] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Data

An IDL variable of any type or shape that is stored into the object at initialization.

## Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 3503 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitDataContainer::SetData

The IDLitDataContainer::SetData function method stores data in the IDLitData object specified by *Identifier*. This method acts in exactly the same way as the IDLitData::SetData method.

### Syntax

```
Result = Obj->[IDLitDataContainer::]SetData(Data, Identifier[, /NO_COPY]  
[, /NULL])
```

### Return Value

Returns a 1 if the operation succeeds, or 0 if it fails.

### Arguments

#### Data

An IDL variable of any type that is copied into the specified data object.

#### Identifier

A scalar string containing the object identifier of the IDLitData object in which the data specified by *Data* should be stored. This path must specify a valid IDLitData object, or the function fails. See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

### Keywords

#### NO\_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

#### NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored, but must still be present.

## Version History

6.0	Introduced
-----	------------

## IDLitDataContainer:: SetProperty

The IDLitDataContainer::SetProperty procedure method sets the value of an IDLitDataContainer property, and should be called by the SetProperty method of any subclass of this class.

### Syntax

*Obj*->[IDLitDataContainer::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 3503 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitDataOperation

The IDLitDataOperation class is a subclass of IDLitOperation that automates data access and automatically records information for the undo-redo system. By automating this functionality, the IDLitDataOperation class eliminates much of the work required to implement a standard subclass of the IDLitOperation class. See [IDLitOperation](#) for additional information on iTool operations.

---

**Note**

The IDLitDataOperation class is designed for use in operations that affect data values. If you are creating an operation that acts on items other than the data that underlies a visualization, you should base your operation class on the IDLitOperation class.

---

While the implementation of a standard subclass of an IDLitOperation class requires the developer to provide implementations of the DoAction, UndoOperation, and RedoOperation methods, the IDLitDataOperation class provides these methods automatically. The only method the developer of an IDLitDataOperation class is *required* to implement is the Execute method, which contains the logic for the specific operation being performed. Depending on the operation being performed, the developer of an IDLitDataOperation may also implement methods to undo the operation, display a user interface before performing the operation, get and set properties specific to the operation, and initialize the IDLitDataOperation object.

When an IDLitDataOperation is requested by a user, the following things occur:

1. As with any operation, execution commences when the DoAction method is called on this object. When called, the IDLitDataOperation retrieves the currently-selected items. If nothing is selected, the operation returns.
2. For each selected item, the data objects of the parameters registered as “operation targets” are retrieved.
3. The data objects are queried for iTool data types that match the types supported by the IDLitDataOperation.

For each data object that includes data of an iTool data type supported by the IDLitDataOperation, the following things occur:

1. The data from the data object is retrieved.
2. If the IDLitDataOperation does not have the REVERSIBLE\_OPERATION property set, a copy of the data is created and placed into the undo-redo command set.

3. The Execute method is called, with the retrieved data as its argument.
4. If the Execute method succeeds and the IDLitDataOperation has the EXPENSIVE\_OPERATION property set, a copy of the results is placed into the undo-redo command set.
5. The result of the IDLitDataOperation is placed in the data object. This action will cause all visualization items that use the data object to update when the operation is completed.

Once all selected data items have been processed, the undo-redo command set is placed into the system undo-redo buffer for later use.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitdataoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitOperation](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitDataOperation::Init](#)” on page 3524.

## Properties

Objects of this class have the following properties. See “[IDLitDataOperation Properties](#)” for details on individual properties.

- [WITHIN\\_UI](#)

## Methods

This class has the following methods:

- [IDLitDataOperation::Cleanup](#)

- [IDLitDataOperation::DoExecuteUI](#)
- [IDLitDataOperation::Execute](#)
- [IDLitDataOperation::GetProperty](#)
- [IDLitDataOperation::Init](#)
- [IDLitDataOperation::SetProperty](#)
- [IDLitDataOperation::UndoExecute](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See “[Creating a New Data-Centric Operation](#)” in Chapter 7 of the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
6.2	Added WITHIN_UI property

## See Also

[IDLitOperation](#)

## IDLitDataOperation Properties

IDLitDataOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitDataOperation::GetProperty](#).

Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitDataOperation::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitDataOperation::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [WITHIN\\_UI](#)

In addition, objects of this class inherit properties from the following superclass:

- [IDLitOperation](#)

### WITHIN\_UI

A Boolean value that indicates whether the operation is currently within the [IDLitDataOperation::DoExecuteUI](#) method (i.e., it is currently displaying a dialog). This property is automatically set to one (True) just before the method is called, and is reset to zero (False) after the method returns.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLitDataOperation::Cleanup

The IDLitDataOperation::Cleanup procedure method performs all cleanup on the object.

---

### Note

An operation based on the IDLitDataOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

---

---

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitDataOperation::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitDataOperation::DoExecuteUI

The IDLitDataOperation::DoExecuteUI function method provides a way for the iTool developer to request user input before performing an operation. If the [SHOW\\_EXECUTION\\_UI](#) property is set, this method will be called before the operation's Execute method is called.

---

### Note

Every operation based directly on the IDLitDataOperation class that requires user interaction before execution must implement its own DoExecuteUI method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer's Guide* manual for details.

---

The DoExecuteUI method itself can present any interface. In practice, most iTool DoExecuteUI methods use the IDLitTool::DoUIService method to display a user interface requesting user input. User interfaces and UI Services are discussed in [Chapter 11, “iTool User Interface Architecture”](#) in the *iTool Developer's Guide* manual.

---

### Warning

If the DoExecuteUI method does not return success, the Execute method will not be called.

---

## Syntax

```
Result = Obj->[IDLitDataOperation::]DoExecuteUI()
```

## Return Value

Returns a 1 if the displayed user interface code executed successfully, and the operation should be executed. If user interface code does not execute successfully, or if the user cancels the operation, this function returns a 0.

## Arguments

None

## Keywords

None

## Example

The following is an example of a DoExecuteUI method, taken from the iTools “Scale Factor” operation:

```
FUNCTION IDLitopScalefactor::DoExecuteUI

oTool = self->GetTool()
IF (oTool EQ OBJ_NEW()) THEN RETURN, 0

RETURN, oTool->DoUIService('ScaleFactor', self)

END
```

This implementation of the DoExecuteUI method does the following:

1. Retrieves an object reference to the current iTool using the GetTool method.
2. Checks to make sure the returned object reference is not a null object (which would be the case if the GetTool method failed).
3. Calls the ScaleFactor UI Service.

## Version History

6.0	Introduced
-----	------------

## IDLitDataOperation::Execute

The IDLitDataOperation::Execute function method contains the execution logic for the operation. This method is called automatically when the iTool user requests an operation based on the IDLitDataOperation class.

### Note

Every operation based directly on the IDLitDataOperation class must implement its own Execute method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

When the iTool system executes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the Execute method. This means that the Execute method itself does not need to “unpack” a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

## Syntax

*Result* = *Obj*->[IDLitDataOperation:]Execute(*Data*)

## Return Value

The return value is 1 if the operation executed successfully, or 0 otherwise.

## Arguments

### Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## See Also

[IDLitDataOperation::UndoExecute](#)

## IDLitDataOperation::GetProperty

The IDLitDataOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

### Note

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

## Syntax

```
Obj->[IDLitDataOperation::]GetProperty[, PROPERTY=variable]
```

## Arguments

None

## Keywords

Any property listed under [“IDLitDataOperation Properties”](#) on page 3517 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Example

To retrieve the value of the REVERSIBLE\_OPERATION property:

```
Obj->IDLitDataOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

## Version History

6.0	Introduced
-----	------------

## IDLitDataOperation::Init

The IDLitDataOperation::Init function method initializes the IDLitDataOperation object and sets properties that define the behavior the operation provides.

---

**Note**

An operation based on the IDLitDataOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

---

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Obj = OBJ_NEW('IDLitDataOperation' [, PROPERTY=variable] )
```

or

```
Result = Obj->[IDLitDataOperation::]Init([, PROPERTY=variable]) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under [“IDLitDataOperation Properties”](#) on page 3517 that contains the word “Yes” in the “Init” column of the properties table can be initialized

during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitDataOperation::SetProperty

The IDLitDataOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

---

**Note**

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

### Syntax

*Obj*->[IDLitDataOperation::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under [“IDLitDataOperation Properties”](#) on page 3517 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

---

6.0	Introduced
-----	------------

---

## IDLitDataOperation::UndoExecute

The IDLitDataOperation::UndoExecute function method is called when a user selects the Undo operation after executing an IDLitDataOperation that sets the value of the [REVERSIBLE\\_OPERATION](#) property to 1. (If the IDLitDataOperation does not set this property, the UndoExecute method is not called.) If implemented, this method generally applies the inverse of the operation performed by the Execute method.

### Note

---

An operation based on the IDLitDataOperation class *must* implement this method if the operation sets the [REVERSIBLE\\_OPERATION](#) property. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

When the iTool system undoes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the UndoExecute method. This means that the UndoExecute method itself does not need to “unpack” a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

## Syntax

```
Result = Obj->[IDLitDataOperation:]UndoExecute(Data)
```

## Return Value

The return value is 1 if the operation was undone successfully, or 0 otherwise.

## Arguments

### Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## See Also

[IDLitDataOperation::Execute](#)

# IDLitMessaging

The IDLitMessaging interface class provides a set of methods used to allow an object that implements the interface to send notification messages and to react appropriately when notification messages are received from other iTool component objects. This class also provides methods that allow the iTool developer to notify the iTool user of error conditions via graphical dialogs, to prompt the user for input, and to retrieve a reference to the current iTool object.

IDLitMessaging objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

---

**Note**

In the iTools system, management of messages is handled by the IDLitVisualization class, of which the IDLitMessaging class is a superclass. In practice, this means that if you need to override any methods of the IDLitMessaging class, you will do so in the definition of your visualization class.

---

This class is written in the IDL language. Its source code can be found in the file `idlitmessaging__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

None

---

**Note**

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

Objects of this class are not created as standalone objects.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- [IDLitIMessaging::AddOnNotifyObserver](#)
- [IDLitIMessaging::DoOnNotify](#)
- [IDLitIMessaging::ErrorMessage](#)
- [IDLitIMessaging::GetTool](#)
- [IDLitIMessaging::ProbeStatusMessage](#)
- [IDLitIMessaging::ProgressBar](#)
- [IDLitIMessaging::PromptUserText](#)
- [IDLitIMessaging::PromptUserYesNo](#)
- [IDLitIMessaging::RemoveOnNotifyObserver](#)
- [IDLitIMessaging::SignalError](#)
- [IDLitIMessaging::StatusMessage](#)

## Version History

6.0	Introduced
-----	------------

## IDLitMessaging Properties

Objects of this class have no properties of their own.

## IDLitMessaging::AddOnNotifyObserver

The `IDLitMessaging::AddOnNotifyObserver` procedure method is used to register a specified iTool component object to receive messages generated by the `DoOnNotify` method of another specified iTool component object.

### Syntax

*Obj*->[IDLitMessaging::]AddOnNotifyObserver, *IdObserver*, *IdSubject*

### Arguments

#### IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the `OnNotify` callback method, which is called when a notification message is dispatched to *IdObserver* by the `DoOnNotify` method of another iTool component object (usually the object specified by *IdSubject*). The `OnNotify` method has the following signature:

```
PRO ::OnNotify, idOriginator, idMessage, message
```

where

- *idOriginator* is the object identifier of the iTool component that is the source of the message
- *idMessage* is a string that identifies the type of message being sent
- *message* is the message itself.

In general, the *idMessage* string is used by the `OnNotify` method to determine what type of action to take. See “[IDLitMessaging::DoOnNotify](#)” on page 3534 for additional details.

#### IdSubject

A string value identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via `IDLitMessaging::DoOnNotify` specifies *IdSubject* as the originator, the *IdObserver* object’s `OnNotify` method is called.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitMessaging::DoOnNotify

The `IDLitMessaging::DoOnNotify` procedure method is used to broadcast a notification message to iTool component objects that are observing the source of the message.

See the “[IDLitMessaging::AddOnNotifyObserver](#)” on page 3532, and “[IDLitMessaging::RemoveOnNotifyObserver](#)” on page 3544 methods for more information on notification messages.

See “[iTool Messaging System](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a more in-depth discussion of notification.

### Syntax

*Obj*->[\[IDLitMessaging::\]DoOnNotify](#), *IdOriginator*, *IdMessage*, *Value*

### Arguments

#### IdOriginator

A string value identifying the item that is the source of the message. Normally, *IdOriginator* is the object identifier of the object that calls this method, but it can be any string value.

#### IdMessage

A string that will uniquely identify the message being sent. The value of *IdMessage* is determined by the iTool developer; it is used by the `OnNotify` methods of any observer objects to determine what type of message has been received, and to act accordingly. For example, if a property value has changed, this argument might be set to the string `SETPROPERTY`.

#### Value

Any value that is associated with the message being sent. For example, if a `SETPROPERTY` message was sent, *Value* might contain the name of the property changed. If no value is associated with the message, set this argument to a null string (`''`).

### Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitMessaging::ErrorMessage

The IDLitMessaging::ErrorMessage procedure method is used to display an error message to the user.

The actual method used to display the message to the user depends on the user interface in use. Normally, this method will display a modal dialog.

### Syntax

```
Obj->[IDLitMessaging::]ErrorMessage, StrMessage[, SEVERITY=integer]  
[, TITLE=string] [, /USE_LAST_ERROR]
```

### Arguments

#### StrMessage

A scalar string or string array containing a description of the error.

### Keywords

#### SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

#### TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

#### USE\_LAST\_ERROR

If this keyword is set, the system will use the information that was part of the last error signaled to the iTool. The last error may have been set either by a previous call to this method or by a call to the [IDLitMessaging::SignalError](#) method.

## Version History

6.0	Introduced
-----	------------

## IDLitMessaging::GetTool

The IDLitMessaging::GetTool function method returns an object reference to the iTool object associated with the object on which it is called.

### Syntax

*Result* = *Obj*->[IDLitMessaging::]GetTool()

### Return Value

Returns an object reference to the iTool object associated with the object on which the GetTool is called. If the object is not contained by an iTool, this function returns a null object reference.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitMessaging::ProbeStatusMessage

The IDLitMessaging::ProbeStatusMessage procedure method is used to display a status message to the user, which is displayed in a data-specific region of the user interface. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower right corner of the iTool window.

### Syntax

*Obj*->[\[IDLitMessaging::\]ProbeStatusMessage](#), *StrMessage*

### Arguments

#### StrMessage

A scalar string that is displayed in the data-specific status area.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitIMessaging::ProgressBar

The IDLitIMessaging::ProgressBar function method is used to display a progress bar to the user and update the displayed values.

On the initial call to this method, a dialog is displayed. The dialog remains active until the method is called with the /SHUTDOWN keyword.

The actual method used to display the message to the user depends on the user interface in use. Normally, the progress bar is displayed as a modal dialog.

### Syntax

```
Result = Obj->[IDLitIMessaging::]ProgressBar(StrMessage [, CANCEL=string]  
[, PERCENT=value] [, /SHUTDOWN])
```

### Return Value

Returns 1 if the progress bar was displayed successfully, or 0 otherwise.

### Arguments

#### StrMessage

A scalar string or string array containing a description of the action taking place.

### Keywords

#### CANCEL

Set this keyword to a string containing the text for the Cancel button on the Progress Bar. If this keyword is not specified, or is set to a null string, then the string “Cancel” is used.

#### PERCENT

Set this keyword to a value between 0 and 100 that represents the “percentage complete” value to be shown on the progress bar.

#### SHUTDOWN

If set, any progress bar that is being displayed is removed from the user interface.

## Version History

6.0	Introduced
6.1	Added CANCEL keyword

## IDLitMessaging::PromptUserText

The IDLitMessaging::PromptUserText function method is used to prompt the iTool user with a question and retrieve a text answer. The text answer is returned to the caller of this method via a supplied IDL variable.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

### Syntax

```
Result = Obj->[IDLitMessaging::]PromptUserText(StrPrompt, Answer
    [, TITLE=string])
```

### Return Value

Returns 1 if the prompt was displayed and the user clicked the **OK** button. If the user clicks the **Cancel** button or dismisses the dialog, the return value is 0.

### Arguments

#### StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

#### Answer

A named variable that will contain the string value entered by the user.

### Keywords

#### TITLE

Set this keyword to a string representing the title of the prompt. This value is placed in the title bar of the modal dialog.

### Version History

6.0	Introduced
-----	------------

## IDLitMessaging::PromptUserYesNo

The IDLitMessaging::PromptUserYesNo function method is used to prompt the user with a yes or no question and return an answer.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

### Syntax

```
Result = Obj->[IDLitMessaging::]PromptUserYesNo(StrPrompt, Answer  
[, TITLE=string])
```

### Return Value

Returns 1 if the dialog executed properly and returned a value in the variable specified. You must check the value stored in the variable specified as the *Answer* argument to determine which button the user pressed.

### Arguments

#### StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

#### Answer

A named variable that will contain 1 if the user answered Yes to the prompt and 0 if the user answered No.

### Keywords

#### TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

### Version History

6.0	Introduced
-----	------------

## IDLitMessaging::RemoveOnNotifyObserver

The `IDLitMessaging::RemoveOnNotifyObserver` procedure method is used to unregister a specified iTool component object as wishing to receive messages generated by the `DoOnNotify` method of another specified iTool component object. This method reverses the action of calling the [IDLitMessaging::AddOnNotifyObserver](#) method.

### Syntax

*Obj*->[\[IDLitMessaging::\]RemoveOnNotifyObserver, IdObserver, IdSubject](#)

### Arguments

#### IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

#### IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can be any scalar string.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitMessaging::SignalError

The IDLitMessaging::SignalError procedure method is used to signal an error in the system. No user interface is displayed to the user, but the error is registered with the system, made the current error, and recorded by the iTool log service (if enabled).

---

**Note**

If this method is used to signal an error, the [IDLitMessaging::ErrorMessage](#) method can be called with the /USE\_LAST\_ERROR keyword to use the information set by this method.

---

## Syntax

```
Obj->[IDLitMessaging::]SignalError, StrMessage [, CODE=integer]
      [, SEVERITY=integer]
```

## Arguments

### StrMessage

A scalar string or string array containing a description of the error.

## Keywords

### CODE

Set this keyword to an integer that represents an error code that can be associated with the error. Error codes can be any integer value specified by the iTool developer.

### SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

## Version History

6.0	Introduced
-----	------------

## IDLitMessaging::StatusMessage

The IDLitMessaging::StatusMessage procedure method is used to display a status message to the user. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower left corner of the iTool window.

### Syntax

```
Obj->[IDLitMessaging::]StatusMessage, StrMessage
[, SEGMENT_IDENTIFIER=string]
```

### Arguments

#### StrMessage

A scalar string that is displayed as a status message to the user.

### Keywords

#### SEGMENT\_IDENTIFIER

Set this keyword to a string containing the relative identifier of the status bar segment in which the message is to be displayed. By default, iTools have two status bar segments, a described in “[Status Messages](#)” in Chapter 12 of the *iTool Developer’s Guide* manual. By default, the StatusMessage method changes the value of the Status segment; that segment’s identifier is 'MESSAGE'.

To change the value of the Probe Status segment, use the segment identifier 'PROBE'. Alternately, you can use the [IDLitMessaging::ProbeStatusMessage](#) method.

### Version History

6.0	Introduced
6.1	Added SEGMENT_IDENTIFIER keyword

# IDLitManipulator

The IDLitManipulator class provides the base functionality of the iTools manipulator system. Most automation and functional capabilities of the manipulator system are provided by this class. Tasks performed by this class include:

- Selection operations and associated selection state management.
- Automated mouse cursor management (changing the cursor as the mouse traverses different items in the current visualization).
- System event settings management.
- Coordination between the manipulator and manipulator visualization system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulator__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

---

**Note**

See [Chapter 8, “Creating a Manipulator”](#) in the *iTool Developer’s Guide* manual for information on creating a custom manipulator.

---

## Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

---

**Note**

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See [“IDLitManipulator::Init”](#) on page 3563.

## Properties

Objects of this class have the following properties. See [“IDLitManipulator Properties”](#) on page 3551 for details on individual properties.

- [BUTTON\\_EVENTS](#)

- [DEFAULT\\_CURSOR](#)
- [DESCRIPTION](#)
- [DISABLE](#)
- [KEYBOARD\\_EVENTS](#)
- [MOTION\\_EVENTS](#)
- [OPERATION\\_IDENTIFIER](#)
- [PARAMETER\\_IDENTIFIER](#)
- [TRANSIENT\\_DEFAULT](#)
- [TRANSIENT\\_MOTION](#)
- [TYPES](#)
- [VIEWS\\_ONLY](#)
- [VISUAL\\_TYPE](#)

In addition, objects of this class inherit the properties of the superclass of this class.

## Methods

This class has the following methods:

- [IDLitManipulator::Cleanup](#)
- [IDLitManipulator::CommitUndoValues](#)
- [IDLitManipulator::GetCursorType](#)
- [IDLitManipulator::GetProperty](#)
- [IDLitManipulator::Init](#)
- [IDLitManipulator::OnKeyboard](#)
- [IDLitManipulator::OnLoseCurrentManipulator](#)
- [IDLitManipulator::OnMouseDown](#)
- [IDLitManipulator::OnMouseMotion](#)
- [IDLitManipulator::OnMouseUp](#)
- [IDLitManipulator::RecordUndoValues](#)
- [IDLitManipulator::RegisterCursor](#)
- [IDLitManipulator::SetCurrentManipulator](#)

- [IDLitManipulator::SetProperty](#)

In addition, this class inherits the methods of its superclass.

## Examples

See [Chapter 8, “Creating a Manipulator”](#) in the *iTool Developer’s Guide* manual for examples.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator Properties

IDLitManipulator objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitManipulator::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitManipulator::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitManipulator::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [BUTTON\\_EVENTS](#)
- [DEFAULT\\_CURSOR](#)
- [DESCRIPTION](#)
- [DISABLE](#)
- [KEYBOARD\\_EVENTS](#)
- [MOTION\\_EVENTS](#)
- [OPERATION\\_IDENTIFIER](#)
- [PARAMETER\\_IDENTIFIER](#)
- [TRANSIENT\\_DEFAULT](#)
- [TRANSIENT\\_MOTION](#)
- [TYPES](#)
- [VIEWS\\_ONLY](#)
- [VISUAL\\_TYPE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)
- [IDLitMessaging](#)

## BUTTON\_EVENTS

A boolean value controlling whether mouse button events are generated. If set, mouse button up and button down events will be dispatched to this manipulator. These events are enabled by default.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEFAULT\_CURSOR

A string containing the name of the default cursor for the manipulator. This is the name of the cursor that is displayed if no items are hit during mouse cursor motion. The default manipulator cursor is set to 'ARROW'. Allowable values are:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE\_NE
- SIZE\_NW
- SIZE\_SE
- SIZE\_SW
- SIZE\_NS
- SIZE\_EW
- UP\_ARROW

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

### Note

Set a pre-defined default cursor using the `Init` or `SetProperty` method. Set a custom cursor as the default cursor using the `IDLitManipulator::RegisterCursor` method's `DEFAULT` keyword.

## DESCRIPTION

A string representing the full name or description of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Description		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DISABLE

A boolean value indicating that the manipulator should be disabled. Disabling a manipulator prevents it from being chosen by a user or by the iTool system. The default value is 0b (false).

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## KEYBOARD\_EVENTS

A boolean value controlling whether keyboard events are generated. If set, keyboard events will be dispatched to the manipulator. These events are enabled by default.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MOTION\_EVENTS

A boolean value controlling whether motion events are generated. If set, motion events will be dispatched to this manipulator. These events are enabled by default.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## OPERATION\_IDENTIFIER

A string identifier for the operation that is associated with the manipulator. This identifier specifies the operation that is used by the undo-redo system to transact the actions performed by this manipulator. If not specified, the manipulator actions are not recorded by the undo-redo system.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

### Note

See [“Manipulators and the Undo/Redo System”](#) in Chapter 8 of the *iTool Developer’s Guide* manual for information on configuring a custom manipulator to support undo/redo operations.

## PARAMETER\_IDENTIFIER

A string identifier specifying which parameter the operation should query when transacting the manipulator. If specified, this identifier is used in conjunction with the operation specified by the OPERATION\_IDENTIFIER property to transact the operations performed by a manipulator. The parameter is primarily used to specify the property identifier for manipulators that change the values of properties.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

### Note

See [“Retrieving Property Information”](#) in Appendix A of the *iTool Developer’s Guide* manual for more information about property identifiers and names. See [“Manipulators and the Undo/Redo System”](#) in Chapter 8 of the *iTool Developer’s Guide* manual for information on configuring a custom manipulator to support undo/redo operations.

## TRANSIENT\_DEFAULT

An integer value used to indicate that the manipulator is *transient*, which causes the system to automatically switch to the default manipulator when this manipulator's mouse actions are complete (that is, when the `OnMouseUp` method has been called) or when an end-of-keyboard-entry character (carriage return or escape key) is detected. The default value is 0.

This property can be set to any of the following values:

- 0 = No transient behavior
- 1 = Mouse transient behavior is enabled. When a mouse button up is detected, the manipulation system will switch to the default manipulator for the system
- 2 = Keyboard transient behavior is enabled. When a carriage return or escape key is pressed, the system will switch to the default manipulator for the system
- 3 = Both keyboard and mouse transient behavior are enabled

<b>Property Type</b>	Enumerated List		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TRANSIENT\_MOTION

A boolean value controlling whether transient motion events are generated. If set, the manipulator will generate motion events beginning when the `OnMouseDown` method is called and ending when the `OnMouseUp` method is called. The default value is 0b (false).

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TYPES

A string array specifying the visualization types that this manipulator can operate on. If not specified, the manipulator will support all registered visualization types.

Allowable TYPES values are those returned by the `IDLitVisualization::GetTypes` method.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## VIEWS\_ONLY

A boolean value controlling the content of the manipulator hierarchy. If set, the manipulator will only operate on views in the manipulator hierarchy. The default value is 0b (false).

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## VISUAL\_TYPE

A string representing the type of selection visual to use with this manipulator. The VISUAL\_TYPE property should match the corresponding property of an IDLitManipulatorVisual object. This high-level abstraction allows similar selection visuals to be assigned across multiple manipulators. The default value is an empty string.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitManipulator::Cleanup

The IDLitManipulator::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitManipulator::]Cleanup() *(In a lifecycle method only.)*

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::CommitUndoValues

The IDLitManipulator::CommitUndoValues function method is used to complete a transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the RecordUndoValues method.

When a manipulator interaction is complete, the manipulator should call this method, which in turn calls the RecordFinalValues method of the operation associated with the manipulator. The RecordFinalValues method records any information needed to undo the operation and places the information in the iTool's undo-redo transaction buffer.

For interactive manipulators, the CommitUndoValues method should be called by the OnMouseUp method.

### Note

---

This method must be called on the current manipulator before being called on a superclass to ensure that the current selection state maintained by the manipulator is valid.

---

## Syntax

*Result* = *Obj*->[IDLitManipulator::]CommitUndoValues([UNCOMMIT])

## Return Value

Returns 1 if the commit was successful, or 0 otherwise.

## Arguments

None

## Keywords

### UNCOMMIT

Set this keyword to discard any pending information from a previous call to RecordUndoValues. The interaction is not recorded in the iTool's undo-redo transaction buffer.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::GetCursorType

The IDLitManipulator::GetCursorType function method retrieves the name of the cursor to display for the manipulator. The name of the cursor can be used with the SetCurrentCursor method of the IDLitWindow component.

The system will use this method to automatically change the cursor when the mouse traverses the contents of a visualization window. As the mouse transverses the window, the name for the hit item that is part of the current selection group is retrieved and passed to this routine. This action gives the manipulator the ability to change cursors depending on the area of the visualization the cursor is over.

### Syntax

*Result* = *Obj*->[\[IDLitManipulator::\]GetCursorType](#)(*TypeIn*, *KeyMods*)

### Return Value

Returns a string containing the name of the cursor. If nothing is matched, an empty string is returned.

#### Note

---

This name is defined during cursor registration using the [IDLitManipulator::RegisterCursor](#) method.

---

### Arguments

#### TypeIn

A string variable containing the name of the portion of the selection visual for which the cursor is being requested.

#### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values

1 = SHIFT Key

2 = CTRL Key

4 = CAPS LOCK key

8 = ALT key

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::GetProperty

The IDLitManipulator::GetProperty procedure method retrieves the value of an IDLitManipulator property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

### Syntax

*Obj*->[IDLitManipulator::](#)GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitManipulator Properties](#)” on page 3551 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitManipulator::Init

The IDLitManipulator::Init function method initializes the IDLitManipulator object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitManipulator'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulator::]Init([, PROPERTY=value]) (In a lifecycle  
method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLitManipulator Properties](#)” on page 3551 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::OnKeyboard

The IDLitManipulator::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow.

### Syntax

*Obj*->[IDLitManipulator::OnKeyboard](#), *Win*, *IsASCII*, *Character*, *KeyValue*, *X*, *Y*,  
*Press*, *Release*, *KeyMods*

### Arguments

#### Win

An object reference for the IDLitWindow from which the event came.

#### IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

#### KeyValue

The numeric value representing the key pressed if the key is non-ASCII. The possible numeric values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

## Character

A string containing the ASCII character of the key pressed.

## X

A floating-point value representing the *x*-coordinate in the window's coordinates.

## Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

## Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

## Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

## KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::OnLoseCurrentManipulator

The IDLitManipulator::OnLoseCurrentManipulator procedure method is used when this manipulator is no longer the current manipulator in the system.

**Note**

This method is designed to be implemented by a subclass of IDLitManipulator, to perform any cleanup work necessary when a new manipulator is selected.

### Syntax

*Obj*->[IDLitManipulator::](#)OnLoseCurrentManipulator

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulator::OnMouseDown

The IDLitManipulator::OnMouseDown procedure method is used when a mouse down event occurs on the target IDLitWindow. When applied, this method will perform a select operation on the current contents of the target IDLitWindow.

When overriding this method in a sub-class, this method is normally the first task performed so that the instance data of the object is properly setup.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.
- nSelectionList — The number of items selected.
- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed. See “Using Manipulator Public Instance Data” in Chapter 8 of the *iTool Developer’s Guide* manual for more information.

## Syntax

*Obj*->[IDLitManipulator::OnMouseDown](#), *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

## Arguments

### Win

An object reference for the IDLitWindow from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window’s coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window’s coordinates.

### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle

- 4 = Right

## KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## NClicks

An integer value representing number of clicks

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::OnMouseMotion

The IDLitManipulator::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down, this method manages the setting of the cursor on the IDLitWindow object.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.
- nSelectionList — The number of items selected.
- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed. See “[Using Manipulator Public Instance Data](#)” in Chapter 8 of the *iTool Developer’s Guide* manual for more information.

### Syntax

*Obj*->[IDLitManipulator:]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

### Arguments

#### Win

An object reference for the IDLitWindow object from which the event came.

#### X

A floating-point value representing the *x*-coordinate in the window’s coordinates.

#### Y

A floating-point value representing the *y*-coordinate in the window’s coordinates.

#### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key

- 8 = ALT key

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::OnMouseUp

The IDLitManipulator::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object.

When overriding this method in a sub-class, this method is normally the last task performed so that the instance data of the object is properly setup.

### Syntax

*Obj->*[IDLitManipulator:]OnMouseUp, *Win*, *X*, *Y*, *IButton*

### Arguments

#### Win

An object reference for the IDLitWindow object from which the event came.

#### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

#### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

#### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulator::RecordUndoValues

The IDLitManipulator::RecordUndoValues function method is used to begin recording the transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the CommitUndoValues method.

To capture information for the undo-redo system of the tools framework, the initial and final values for the items that the manipulator will adjust must be recorded. This recording process is accomplished with the RecordUndoValues and CommitUndoValues methods.

These two methods make use of the operation that is associated with this manipulator (specified by the OPERATION\_IDENTIFIER keyword to the Init method) to capture the needed information. When the RecordUndoValues method is called, the manipulator will retrieve the operation associated with this manipulator and call the RecordInitialValues method on this operation. The RecordInitialValues method is called with a command set, the list of currently selected items (which the manipulator is operating on) and the value that was provided by the PARAMETER\_IDENTIFIER keyword to this manipulator. This method will record any information needed to undo the operation and place the values in the provided command set. See IDLitOperation for more information on operations.

For interactive manipulators, the RecordUndoValues method is called as part of the OnMouseDown method.

### Syntax

*Result* = *Obj*->[IDLitManipulator::]RecordUndoValues()

### Return Value

Returns a 1 if recording was successful, or 0 otherwise.

### Arguments

None

### Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulator::RegisterCursor

The IDLitManipulator::RegisterCursor procedure method defines the appearance and name of a cursor associated with the manipulator.

### Syntax

*Obj*->[IDLitManipulator::](#)RegisterCursor, *ArrCursor*, *Name* [, /DEFAULT]

### Return Value

None

### Arguments

#### ArrCursor

This must be a 16 element string array of 16 characters each that represents a window cursor. The array can consist of the “#” character, space and non-space characters, and optionally, a “\$” character as follows:

- The “#” characters define the black outline of the cursor.
- Any non-space characters define the shape of the white mask. Adding a mask ensures the cursor’s visibility in light and dark areas of a visualization.
- The “\$” defines a hot spot.

See [CREATE\\_CURSOR](#) for more information on the structure of the cursor array.

#### Name

A string value identifying the cursor.

#### Note

---

This name should be returned by the GetCursorType function method for your manipulator.

---

### Keywords

#### DEFAULT

Set this keyword to specify this cursor as the default cursor for the manipulator. If no cursor is specified as the default cursor, then the standard arrow is used.

**Note**

---

This will be the cursor used if the `GetCursorType` method returns a null string.

---

## Example

The `RegisterCursor` method is typically called within the scope of a manipulator's initialization so that the cursor appears when the manipulator (`my_manip`) is activated. The following code defines the appearance of the manipulator cursor and sets it as the default.

```
; Define the default cursor for this manipulation.
strArray = [ $
'          ', $
'          ', $
'          ', $
'          ', $
'          ', $
'          ', $
' .# .# ', $
' .#.....# ', $
'##### ', $
'###...$...### ', $
'##### ', $
' .#.....# ', $
' .# .# ', $
'          ', $
'          ', $
'          ', $
'          ', $
'          ', $
'          ', $
'          ' ]

; Register the new cursor with the manipulator.
my_manip->RegisterCursor, strArray, 'SCROLL', /DEFAULT
```

## Version History

6.1	Introduced
-----	------------

## IDLitManipulator::SetCurrentManipulator

The IDLitManipulator::SetCurrentManipulator procedure method sets the manipulator as the current manipulator in the system.

### Syntax

*Obj*->[IDLitManipulator:]SetCurrentManipulator [, *Item*]

### Arguments

#### Item

If this method is being called on a manipulator container object, *Item* can optionally be set to a string containing the relative object ID of the manipulator that should be set as the current manipulator. If *Item* is not supplied, the manipulator on which the method is called is set as the current manipulator.

### Keyword

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulator:: SetProperty

The IDLitManipulator::SetProperty procedure method sets the value of an IDLitManipulator property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj*->[IDLitManipulator::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitManipulator Properties](#)” on page 3551 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitManipulatorContainer

The IDLitManipulatorContainer class allows for the construction of manipulator hierarchies. Building on the functionality provided by the IDLitManipulator class, the manipulator container implements the concept of a *current manipulator* for the items it contains.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatorcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitContainer](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitManipulatorContainer::Init](#)” on page 3586.

## Properties

Objects of this class have the following properties. See “[IDLitManipulatorContainer Properties](#)” on page 3581 for details on individual properties.

- [AUTO\\_SWITCH](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLitManipulatorContainer::Add](#)
- [IDLitManipulatorContainer::GetCurrent](#)
- [IDLitManipulatorContainer::GetCurrentManipulator](#)
- [IDLitManipulatorContainer::GetProperty](#)

- [IDLitManipulatorContainer::Init](#)
- [IDLitManipulatorContainer::OnKeyboard](#)
- [IDLitManipulatorContainer::OnMouseDown](#)
- [IDLitManipulatorContainer::OnMouseMotion](#)
- [IDLitManipulatorContainer::OnMouseUp](#)
- [IDLitManipulatorContainer::SetCurrent](#)
- [IDLitManipulatorContainer::SetCurrentManipulator](#)
- [IDLitManipulatorContainer::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer Properties

IDLitManipulatorContainer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the table are retrieved via [IDLitManipulatorContainer::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table are set via [IDLitManipulatorContainer::Init](#). Properties with the word “Yes” in the “Set” column in the property table are set via [IDLitManipulatorContainer::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [AUTO\\_SWITCH](#)

In addition, objects of this class inherit:

- [IDLitContainer](#)

### AUTO\_SWITCH

A boolean that, if set, causes the manipulator container to automatically change the value of its current child manipulator depending on the portion of the selection visual hit during a mouse down operation. This is performed by matching the name of the portion of the selection visual hit during the mouse down operation and the name of the sub-manipulators of this container.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitManipulatorContainer::Add

The IDLitManipulatorContainer::Add procedure method is used to add a new manipulator to the container.

### Syntax

*Obj->*[IDLitManipulatorContainer::]Add, *Manipulator*

### Arguments

#### Manipulator

The new manipulator to add to this manipulator container. When completed, this manipulator is also set to the current manipulator for this manipulator container.

### Keywords

All keywords are passed to the IDLitContainer superclass during the add operation.

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::GetCurrent

The IDLitManipulatorContainer::GetCurrent function method is used to get the object reference of the current manipulator of the container.

### Syntax

*Result* = *Obj*->[IDLitManipulatorContainer::]GetCurrent()

### Return Value

Returns an object reference to the current manipulator for this container or a null object reference if no manipulators are contained by the container.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::GetCurrentManipulator

The IDLitManipulatorContainer::GetCurrentManipulator function method is used to get the current manipulator of the system. When applied, this function method causes a traversal of the manipulator hierarchy, returning the current leaf manipulator of the system.

### Syntax

```
Result =  
Obj->[IDLitManipulatorContainer::]GetCurrentManipulator([, /IDENTIFIER])
```

### Return Value

Returns an object reference to the current manipulator in the system. If the IDENTIFIER keyword is set, the routine will return the identifier for the current manipulator.

### Arguments

None

### Keywords

#### IDENTIFIER

If set, the identifier of the current manipulator is returned. If not set, the current manipulator itself is returned.

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::GetProperty

The IDLitManipulatorContainer::GetProperty procedure method retrieves the value of an IDLitManipulatorContainer property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

### Syntax

*Obj->*[IDLitManipulatorContainer:]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 3581 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::Init

The IDLitManipulatorContainer::Init function method initializes the IDLitManipulatorContainer object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLitManipulatorContainer'[, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLitManipulatorContainer::]Init( [, *PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorContainer Properties” on page 3581 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::OnKeyboard

The IDLitManipulatorContainer::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow object. If the current child manipulator supports keyboard events, the OnKeyboard method for that manipulator is called.

### Syntax

*Obj->*[IDLitManipulatorContainer:]OnKeyboard, *Win, IsASCII, Character, Key Value, X, Y, Press, Release, KeyMods*

### Arguments

#### Win

An object reference for the IDLitWindow object from which the event came.

#### IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

#### KeyValue

The numeric value representing a non-ASCII key pressed. The possible values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home

- 12 = End

## Character

A string containing the ASCII character of the key pressed

## X

A floating-point value representing the *x*-coordinate in the window's coordinates.

## Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

## Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

## Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

## KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::OnMouseDown

The `IDLitManipulatorContainer::OnMouseDown` procedure method is used when a mouse down event occurs on the target `IDLitWindow` object. When applied and auto-switch mode is enabled in the container, the current child manipulator will be determined by matching the type of the visualization hit with the identifier of the sub-manipulators contained in this container. If no match is made, the default child manipulator is selected. Once complete, normal processing continues.

If the current sub-manipulator supports mouse button events, its `OnMouseDown` method is called.

### Syntax

*Obj*->[IDLitManipulatorContainer:]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*,  
*NClicks*

### Arguments

#### Win

An object reference for the `IDLitWindow` object from which the event came.

#### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

#### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

#### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

## KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## NClicks

An integer value representing number of clicks

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::OnMouseMotion

The IDLitManipulatorContainer::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down and auto-switch mode is enabled, this method manages the setting of the cursor on the IDLitWindow object. Otherwise if the current sub-manipulator supports motion events, its OnMouseMotion method is called.

### Syntax

*Obj*->[IDLitManipulatorContainer:]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

### Arguments

#### Win

An object reference for the IDLitWindow object from which the event came.

#### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

#### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

#### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

### Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::OnMouseUp

The IDLitManipulatorContainer::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object. When applied, the container will call the OnMouseUp method of the current child manipulator if that manipulator supports button events.

### Syntax

*Obj*->[IDLitManipulatorContainer:]OnMouseUp, *Win*, *X*, *Y*, *IButton*

### Arguments

#### Win

An object reference for the IDLitWindow object from which the event came.

#### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

#### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

#### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

### Keywords

None

### Version History

-----	------------

## IDLitManipulatorContainer::SetCurrent

The IDLitManipulatorContainer::SetCurrent procedure method is used to set a manipulator within the container to be the current manipulator.

### Syntax

*Obj->*[IDLitManipulatorContainer::]SetCurrent, *Manipulator*

### Arguments

#### Manipulator

The object reference of the manipulator to be set as current in the manipulator container. This manipulator must be contained in the container or an error is thrown.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer::SetCurrentManipulator

The IDLitManipulatorContainer::SetCurrentManipulator procedure method is used to set the current child manipulator in a manipulator hierarchy. When applied, the manipulator will use the provided identifier to call the SetCurrentManipulator on the target child manipulator. If the provided identifier is null, the default manipulator is set as current.

### Syntax

*Obj*->[IDLitManipulatorContainer::]SetCurrentManipulator, *Identifier*

### Arguments

#### Identifier

Either the identifier for the manipulator that is to be made current in the system or its object reference.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorContainer:: SetProperty

The IDLitManipulatorContainer::SetProperty procedure method sets the value of an IDLitManipulatorContainer property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj*->[IDLitManipulatorContainer::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 3581 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitManipulatorManager

The IDLitManipulatorManager class is a specialization of a IDLitManipulatorContainer class that acts as the root of a manipulator hierarchy. In addition, this class provides the functionality that allows it to interface with external elements in the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatormanager__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitManipulatorContainer](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitManipulatorManager::Init](#)” on page 3604.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLitManipulatorManager::Add](#)
- [IDLitManipulatorManager::AddManipulatorObserver](#)
- [IDLitManipulatorManager::GetDefaultManipulator](#)
- [IDLitManipulatorManager::Init](#)
- [IDLitManipulatorManager::RemoveManipulatorObserver](#)

In addition, this class inherits the methods of its superclass.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorManager Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclass.

Objects in this class inherit:

- [IDLitManipulatorContainer](#)

## IDLitManipulatorManager::Add

The IDLitManipulatorManager::Add procedure method is used to add manipulators to the manipulator manager. This method uses the add functionality of its superclass to add the given manipulator to the hierarchy and checks the default keyword to determine if the given manipulator should be treated as the default for the system.

### Syntax

*Obj*->[IDLitManipulatorManager::]Add, *Manipulator* [, /DEFAULT]

### Arguments

#### Manipulator

A manipulator to add to the manipulator manager

### Keywords

#### DEFAULT

If set, the added manipulator is made default for the system. This is primarily used with manipulators that implement transient behavior (mouse or keyboard). When these manipulators complete interaction, the current manipulator of the system is set to the default manipulator.

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorManager::AddManipulatorObserver

The IDLitManipulatorManager::AddManipulatorObserver procedure method is used to add an observer to the manipulator system. An observer object is notified when the current manipulator of the manipulator hierarchy changes.

To perform this action, the observer object must implement the method OnManipulatorChange. This method has the following signature:

```
PRO ObjectClass::OnManipulatorChange, Subject
```

Where *Subject* is this class, the manipulator manager.

### Syntax

```
Obj->[IDLitManipulatorManager::]AddManipulatorObserver, Observer
```

### Arguments

#### Observer

A scalar or array of objects that implement the manipulator observer interface.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorManager::GetDefaultManipulator

The IDLitManipulatorManager::GetDefaultManipulator function method returns a reference to the manipulator that was most recently added as the default manipulator. The return value is a reference to an IDLitManipulator object, or the NULL object reference if no manipulators have been added as a default.

### Syntax

```
Result = Obj->[IDLitManipulatorManager::]GetDefaultManipulator()
```

### Keywords

None

### Arguments

None

### Version History

6.1	Introduced
-----	------------

## IDLitManipulatorManager::Init

The IDLitManipulatorManager::Init function method initializes the IDLitManipulatorManager object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

### Note

---

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

*Obj* = OBJ\_NEW('IDLitManipulatorManager' [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLitManipulatorManager::]Init([*PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorManager Properties” on page 3600 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorManager::RemoveManipulatorObserver

The `IDLitManipulatorManager::RemoveManipulatorObserver` procedure method is used to remove a manipulator observer from the manipulator object. If the value for the *Observer* argument is not a valid manipulator observer, this method does nothing and no error is reported.

### Syntax

*Obj*->[\[IDLitManipulatorManager::\]](#)RemoveManipulatorObserver, *Observer*

### Arguments

#### Observer

A scalar or array of objects that are to be removed from this container

### Keywords

None

### Version History

6.0	Introduced
-----	------------

# IDLitManipulatorVisual

The IDLitManipulatorVisual class implements methods that allow the iTool developer to create visual elements that are associated with an interactive manipulator. IDLitManipulatorVisual objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

## Superclasses

[IDLgrModel](#)

[IDLitIMessaging](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitManipulatorVisual::Init](#)” on page 3613.

## Properties

Objects of this class have the following properties. See “[IDLitManipulatorVisual Properties](#)” on page 3609 for details on individual properties.

- [UNIFORM\\_SCALE](#)
- [VISUAL\\_TYPE](#)

## Methods

This class has the following methods:

- [IDLitManipulatorVisual::Cleanup](#)
- [IDLitManipulatorVisual::GetProperty](#)
- [IDLitManipulatorVisual::Init](#)
- [IDLitManipulatorVisual::SetProperty](#)

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorVisual Properties

IDLitManipulatorVisual objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitManipulatorVisual::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitManipulatorVisual::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitManipulatorVisual::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [UNIFORM\\_SCALE](#)
- [VISUAL\\_TYPE](#)

In addition, objects of this class inherit:

- [IDLgrModel](#)
- [IDLitIMessaging](#)

### UNIFORM\_SCALE

Set this property to create a manipulator visual which should be scaled equally in all three dimensions when fitting the manipulator visual to the size of its associated visualization. If this property is not set, then the manipulator visual will use a different scale factor in the  $x$ ,  $y$ , and  $z$  dimensions, in order to match its associated visualization.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not applicable</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

### VISUAL\_TYPE

Set this keyword to a string representing the manipulator visual type. The VISUAL\_TYPE property should match the corresponding string in its associated IDLitManipulator object. When a new manipulator is selected in an iTool, the

VISUAL\_TYPE property on the manipulator object is used to search for a corresponding manipulator visual.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not applicable</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitManipulatorVisual::Cleanup

The IDLitManipulatorVisual::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitManipulatorVisual::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorVisual::GetProperty

The IDLitManipulatorVisual::GetProperty procedure method retrieves the value of an IDLitManipulatorVisual property.

### Syntax

*Obj*->[\[IDLitManipulatorVisual::\]GetProperty](#)

### Arguments

None

### Keywords

Any property listed under “[IDLitManipulatorVisual Properties](#)” on page 3609 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitManipulatorVisual::Init

The IDLitManipulatorVisual::Init function method initializes the IDLitManipulatorVisual object, and should be called by the Init method of a subclass.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitManipulatorVisual'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulatorVisual::]Init([, PROPERTY=value]) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLitManipulatorVisual Properties](#)” on page 3609 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitManipulatorVisual:: SetProperty

The IDLitManipulatorVisual::SetProperty procedure method sets the value of an IDLitManipulatorVisual property.

### Syntax

*Obj*->[IDLitManipulatorVisual::](#)SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitManipulatorVisual Properties](#)” on page 3609 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitOperation

The IDLitOperation class is the basis for all iTool operations. It defines how an operation is executed and how information about the operation is recorded for the command transaction (undo-redo) system.

An operation encapsulates a specific set of tasks that perform some atomic action on a target. Between executions of the operation, no state values other than properties of the operation itself are maintained by this object. Two major areas of functionality are provided: automated operation execution and undo-redo capabilities.

Once defined, the operation object exposes a set of properties whose values can affect how the operation executes. The properties that an operation exposes are valid across multiple executions; properties can be set interactively via the Operation browser or programmatically using the operation object's `GetProperty` and `SetProperty` methods.

---

**Note**

For operations that act directly on data items that underlie a visualization, consider basing your operation class on the IDLitDataOperation class. IDLitDataOperation is a subclass of IDLitOperation that automates many of the target-selection and undo-redo mechanisms that must be provided by operation classes based directly on this class.

---

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see [Chapter 7, “Creating an Operation”](#) in the *iTool Developer's Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitComponent](#)

[IDLitIMessaging](#)

---

**Note**

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitOperation::Init](#)” on page 3625.

## Properties

Objects of this class have the following properties. See “[IDLitOperation Properties](#)” on page 3619 for details on individual properties.

- [EXPENSIVE\\_COMPUTATION](#)
- [REVERSIBLE\\_OPERATION](#)
- [SHOW\\_EXECUTION\\_UI](#)
- [TYPES](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

---

### Note

By default, for `IDLitOperation` and its subclasses, the `NAME` property is hidden and the `DESCRIPTION` property is desensitized. This prevents a user from changing the name of an operation via the property sheet, which could change the name of a menu item. If you wish to expose these properties for your own subclass of `IDLitOperation`, you will need to unhide and sensitize the `NAME` and `DESCRIPTION` properties in your `Init` method.

---

## Methods

This class has the following methods:

- [IDLitOperation::Cleanup](#)
- [IDLitOperation::DoAction](#)
- [IDLitOperation::GetProperty](#)
- [IDLitOperation::Init](#)
- [IDLitOperation::QueryAvailability](#)
- [IDLitOperation::RecordFinalValues](#)
- [IDLitOperation::RecordInitialValues](#)
- [IDLitOperation::RedoOperation](#)
- [IDLitOperation::SetProperty](#)

- [IDLitOperation::UndoOperation](#)

In addition, this class inherits the methods of its superclasses.

## Examples

See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
6.2	Added QueryAvailability method

## See Also

[IDLitDataOperation](#)

## IDLitOperation Properties

IDLitOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via [IDLitOperation::GetProperty](#). Properties with the word “Yes” in the “Init” column of the properties table can be initialized via [IDLitOperation::Init](#). Properties with the word “Yes” in the “Set” column of the properties table can be set via [IDLitOperation::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [EXPENSIVE\\_COMPUTATION](#)
- [REVERSIBLE\\_OPERATION](#)
- [SHOW\\_EXECUTION\\_UI](#)
- [TYPES](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)
- [IDLitMessaging](#)

### EXPENSIVE\_COMPUTATION

Set this property to 1 to indicate that a computation of the operation is *expensive*. Expensive computations are those that require significant memory or processing time to execute. Individual operations should use the value of this property to determine whether the results of the operation should be cached to avoid re-execution when undoing or redoing.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## REVERSIBLE\_OPERATION

Set this property to 1 to indicate that the operation is *reversible*. When an operation is reversible, it can be undone by applying an operation rather than restoring a stored value. Rotation by a specified angle is an example of an operation that is reversible, since applying another rotation by the complementary angle returns the visualization to its original state. Individual operations should use the value of this property to determine how the operation should be undone.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## SHOW\_EXECUTION\_UI

Set this property to 1 to indicate that the operation should display a user interface element such as a dialog when the operation is executed. The flag is ignored by the IDLiteOperation itself, but can be used by subclasses (notably IDLiteDataOperation) to determine when to display user interface elements. This property is registered, but it is hidden by default.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Show Dialog		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TYPES

Set this property to a string or an array of strings indicating the types of data to which the operation can be applied. iTools data types are described in [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual. Set this property to a null string ( ' ' ) to specify that the operation can be applied to all types of data.

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitOperation::Cleanup

The IDLitOperation::Cleanup procedure method performs all cleanup on the object.

---

**Note**

An operation based on the IDLitOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

---

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitOperation::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitOperation::DoAction

The `IDLitOperation::DoAction` function method is called when an operation is requested by the iTools system, either as the result of a user action such as selection of a menu item or toolbar button, or by another operation.

---

### Note

Every operation based directly on the `IDLitOperation` class must implement its own `DoAction` method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

A specific operation class’ implementation of this method must create an initialized `IDLitCommandSet` object, execute the operation, and return the command set object to the caller. `DoAction` can also call the [IDLitOperation::RecordInitialValues](#) and [IDLitOperation::RecordFinalValues](#) methods to ensure that the appropriate values are committed to the undo-redo transaction buffer.

If your operation changes the values of its own registered properties (as the result of user interaction with a dialog or other interface element called by `DoUIService`, for example), be sure to call the `RecordInitialValues` and `RecordFinalValues` methods. This ensures that changes made through the dialog are placed in the undo-redo transaction buffer.

---

### Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo/Redo mechanism.

---

## Syntax

*Result* = *Obj*->[IDLitOperation::]DoAction(*Tool*)

## Return Value

If successful, this method returns an `IDLitCommandSet` object or array of `IDLitCommandSet` objects that will be placed in the iTool’s command buffer. The command set object will be passed to the `UndoOperation` and `RedoOperation` methods as necessary. If not successful, this method returns a null object reference.

**Note**

---

The OPERATION\_IDENTIFIER property of the command set object returned by the IDLitOperation::DoAction method is set equal to the full identifier of the operation itself. This implies that UndoOperation and RedoOperation methods exist for the operation, and that they implement the necessary undo and redo mechanisms. If you are overriding this method, you must either ensure that the appropriate UndoOperation and RedoOperation methods exist, or manually create an IDLitCommandSet object with the OPERATION\_IDENTIFIER set to another operation that is capable of undoing or redoing the changes made by your method.

---

## Arguments

### Tool

An object reference to the iTool object on which the operation executes.

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitOperation::GetProperty

The IDLitOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

### Note

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

## Syntax

```
Obj->[IDLitOperation::]GetProperty [, PROPERTY=variable]
```

## Arguments

None

## Keywords

Any property listed under [“IDLitOperation Properties”](#) on page 3619 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Example

To retrieve the value of the REVERSIBLE\_OPERATION property:

```
Obj->IDLitOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

## Version History

6.0	Introduced
-----	------------

## IDLitOperation::Init

The IDLitOperation::Init function method initializes the IDLitOperation object and sets properties that define the behavior the operation provides.

---

**Note**

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Obj = OBJ_NEW('IDLitOperation' [, PROPERTY=variable] )
```

or

```
Result = Obj->[IDLitOperation::]Init( [, PROPERTY=variable] ) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLitOperation Properties](#)” on page 3619 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitOperation::QueryAvailability

The IDLitOperation::QueryAvailability function method is automatically called by the iTool to determine whether this operation is applicable for the selected data and/or visualization. By default, whenever selection changes in the tool, the operation is queried to determine if its type matches the type of the visualization or the data within the visualization. The menu item or toolbar button associated with the operation is then enabled or disabled automatically.

If you are writing a subclass of [IDLitOperation](#) and you do not want to use the standard type matching, you might want to override this method in your own subclass.

### Syntax

*Result* = Obj->[IDLitOperation::](#)QueryAvailability( *Tool*, *SelTypes* )

### Return Value

This method returns a 1 if the object is applicable for the selected items, or 0 (zero) otherwise.

### Arguments

#### Tool

An object reference to the iTool object on which the operation executes.

#### SelTypes

A string array containing the types of the currently selected visualizations. For an explanation of iTool types, see “[Predefined iTool Visualization Classes](#)” in Chapter 6 of the *iTool Developer’s Guide* manual.

### Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLitOperation::RecordFinalValues

The `IDLitOperation::RecordFinalValues` function method records the information needed to redo an operation. Information about individual operations is recorded in `IDLitCommand` objects, which are in turn stored in an `IDLitCommandSet` object that is passed to the [IDLitOperation::UndoOperation](#) and [IDLitOperation::RedoOperation](#) methods.

### Note

---

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

---

If this method is implemented for an operation, it should do the following:

- Retrieve the appropriate `IDLitCommand` object from the `IDLitCommandSet` object specified as the first parameter,
- Record any information necessary to redo the operation in the `IDLitCommand` object,
- Return 1 for success.

## Syntax

```
Result = Obj->[IDLitOperation::]RecordFinalValues(CommandSet, Targets  
[, IdProperty])
```

## Return Value

The return value is 1 if the final values were recorded successfully, or zero otherwise.

## Arguments

### CommandSet

An `IDLitCommandSet` object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the [IDLitOperation::DoAction](#) method, which then calls the `RecordInitialValues` method to store the initial state of the target object.

## Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the [IDLitTool::GetSelectedItems](#) method.

## IdProperty

A property identifier string specifying the target property or parameter of the operation.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitOperation::RecordInitialValues

The `IDLitOperation::RecordInitialValues` function method records the information needed to undo an operation. Information about individual operations is recorded in `IDLitCommand` objects, which are in turn stored in an `IDLitCommandSet` object that is passed to the [IDLitOperation::UndoOperation](#) and [IDLitOperation::RedoOperation](#) methods.

### Note

---

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

---

If this method is implemented for an operation, it should do the following:

- Create an `IDLitCommand` object, setting its `TARGET_IDENTIFIER` property to the identifier of the target object
- Record any information necessary to redo the operation in the `IDLitCommand` object
- Add the `IDLitCommand` object to the `IDLitCommandSet` object specified as the first parameter
- Return 1 for success

## Syntax

```
Result = Obj->[IDLitOperation::]RecordInitialValues(CommandSet, Targets  
[, IdProperty])
```

## Return Value

The return value is 1 if the initial values were recorded successfully, or zero otherwise.

## Arguments

### CommandSet

An `IDLitCommandSet` object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the

[IDLitOperation::DoAction](#) method, which then calls the [RecordInitialValues](#) method to store the initial state of the target object.

## Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the [IDLitTool::GetSelectedItems](#) method.

## IdProperty

A property identifier string specifying the target property or parameter of the operation.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitOperation::RedoOperation

The IDLitOperation::RedoOperation function method is called by the iTool system when the user requests the re-execution of an operation (usually by selecting Redo from the iTool Edit menu or toolbar).

---

**Note**

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

**Note**

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

---

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,
- For each IDLitCommand object, retrieve the target of the operation, using the TARGET\_IDENTIFIER property,
- Retrieve the stored information and use it to redo the operation,
- Return 1 for success.

## Syntax

```
Result = Obj->[IDLitOperation:]RedoOperation(CommandSet)
```

## Return Value

The return value is 1 if the operation was redone successfully, or zero otherwise.

## Arguments

### CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## See Also

[IDLitOperation::RecordFinalValues](#), [IDLitOperation::RecordInitialValues](#),  
[IDLitOperation::UndoOperation](#)

## IDLitOperation:: SetProperty

The IDLitOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

### Note

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

## Syntax

*Obj*->[IDLitOperation::]SetProperty [, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under [“IDLitOperation Properties”](#) on page 3619 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitOperation::UndoOperation

The `IDLitOperation::UndoOperation` function method is called by the iTool system when the user requests the un-execution of an operation (usually by selecting Undo from the iTool Edit menu or toolbar).

---

### Note

An operation based on the `IDLitOperation` class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

---

### Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the `IDLitDataOperation` class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

---

If this method is implemented for an operation, it should do the following:

- Retrieve the `IDLitCommand` objects from the `IDLitCommandSet` object passed as the first argument,
- For each `IDLitCommand` object, retrieve the target of the operation, using the `TARGET_IDENTIFIER` property,
- Retrieve the stored information and use it to undo the operation,
- Return 1 for success.

## Syntax

```
Result = Obj->[IDLitOperation:]UndoOperation(CommandSet)
```

## Return Value

The return value is 1 if the operation was undone successfully, or zero otherwise.

## Arguments

### CommandSet

An `IDLitCommandSet` object that contains all the `IDLitCommand` objects that were stored during the original execution of the operation.

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

[IDLitOperation::RedoOperation](#)

# IDLitParameter

The IDLitParameter class implements parameter management methods that allow parameter names to be associated with IDLitData objects. IDLitParameter objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

---

**Note**

In the iTools system, management of data parameters is handled by the IDLitVisualization class, of which the IDLitParameter class is a superclass. In practice, this means that if you need to override any methods of the IDLitParameter class, you will do so in the definition of your visualization class. In most cases, the only method you will need to implement is the OnDataChangeUpdate method.

---

When an object that inherits from the IDLitParameter class is created, the following are created as part of the new object's instance data:

- An IDL\_Container object, which will contain parameter names for all parameters registered with the object. Parameter names are discussed in [“Parameters”](#) in Chapter 3 of the *iTool Developer's Guide* manual,
- A pointer to a string array containing the parameter names for all parameters registered with the object,
- An IDLitParameterSet object, which will contain the actual IDLitData objects associated with the object's parameters. Parameter sets are discussed in [“Parameter Sets”](#) in Chapter 3 of the *iTool Developer's Guide* manual, and in [“IDLitParameterSet”](#) on page 3661.

This class is written in the IDL language. Its source code can be found in the file `idlitparameter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

None

---

**Note**

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

The objects of this class are not created as standalone objects.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- [IDLitParameter::Cleanup](#)
- [IDLitParameter::GetParameter](#)
- [IDLitParameter::GetParameterAttribute](#)
- [IDLitParameter::GetParameterSet](#)
- [IDLitParameter::Init](#)
- [IDLitParameter::OnDataChangeUpdate](#)
- [IDLitParameter::OnDataDisconnect](#)
- [IDLitParameter::QueryParameter](#)
- [IDLitParameter::RegisterParameter](#)
- [IDLitParameter::SetData](#)
- [IDLitParameter::SetParameterAttribute](#)
- [IDLitParameter::SetParameterSet](#)

## Version History

6.0	Introduced
-----	------------

## IDLitParameter Properties

Objects of this class have no properties of their own.

## IDLitParameter::Cleanup

The IDLitParameter::Cleanup procedure method removes the *data observer* from each data object in the visualization object's parameter set, and cleans up the objects and pointers defined to hold parameter data when the visualization object was created.

### Note

---

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitParameter:]Cleanup() (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitParameter::GetParameter

The IDLitParameter::GetParameter function method retrieves the IDLitData object associated with a registered parameter.

### Syntax

```
Result = Obj->[IDLitParameter::]GetParameter(Name [, /ALL]  
[, COUNT=variable] )
```

### Return Value

Returns an object reference to the IDLitData object associated with the specified parameter name, or a null object reference if no data objects are associated with the specified parameter name.

### Arguments

#### Name

A scalar string containing the parameter name associated with the IDLitData object to be retrieved.

### Keywords

#### ALL

Set this keyword to retrieve all of the IDLitData objects contained in the visualization object's IDLitParameterSet object.

#### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

### Version History

6.0	Introduced
-----	------------

## IDLitParameter::GetParameterAttribute

The IDLitParameter::GetParameterAttribute procedure method retrieves one or more parameter attributes for a registered parameter.

### Syntax

```
Obj->[IDLitParameter:]GetParameterAttribute(ParamName  
[, BY_VALUE=variable] [, DESCRIPTION=variable] [, INPUT=variable]  
[, OPTARGET=variable] [, OPTIONAL=variable] [, OUTPUT=variable]  
[, TYPES=variable] )
```

### Arguments

#### ParamName

A scalar string or string array containing names of registered parameters.

### Keywords

#### BY\_VALUE

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is marked as being a by-value parameter, or a 0 (zero) if *ParamName* is marked as being a by-reference parameter.

#### DESCRIPTION

Set this keyword equal to a named variable that will contain the full name or description of this object.

#### INPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an input parameter, or a 0 (zero) otherwise.

#### OPTARGET

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* may be the target of any operations, or a 0 (zero) otherwise.

## OPTIONAL

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an optional parameter, or a 0 (zero) otherwise.

## OUTPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an output parameter, or a 0 (zero) otherwise.

## TYPES

Set this keyword equal to a named variable that will contain a scalar string or string array giving the data types that correspond to this parameter. See “[iTool Data Types](#)” in Chapter 3 of the *iTool Developer’s Guide* manual for more on parameter data types.

## Example

This example creates an iPlot tool and retrieves the description attribute of the registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc
```

IDL prints:

```
Vertex Data
```

## Version History

6.1	Introduced
-----	------------

## See Also

[IDLitParameter::QueryParameter](#), [IDLitParameter::RegisterParameter](#),  
[IDLitParameter::SetParameterAttribute](#)

## IDLitParameter::GetParameterSet

The IDLitParameter::GetParameterSet function method returns a reference to the IDLitParameterSet object associated with the visualization object.

### Syntax

```
Result = Obj->[IDLitParameter::]GetParameterSet( [/DEEP_COPY] )
```

### Return Value

Returns an IDLitParameterSet object that contains the IDLitData objects and associated parameter names for the visualization object.

### Arguments

None

### Keywords

#### DEEP\_COPY

Set this keyword to cause GetParameterSet to return a parameter set that contains *copies* of the IDLitData objects used by the visualization object's registered parameters. If this keyword is not set, the parameter set returned by this function will contain *references* to the IDLitData objects that are being used by the visualization object's registered parameters.

### Version History

6.0	Introduced
-----	------------

## IDLitParameter::Init

The IDLitParameter::Init function method initializes object instance fields that contain parameter data. Since the IDLitParameter class is always used as a superclass of another class (IDLitVisualization, in the context of the iTool system), initializing this class simply initializes the objects and pointers used to store parameter information in the IDLitVisualization object.

---

**Note**

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

*Result = Obj->[IDLitParameter::]Init()* (In a lifecycle method only.)

## Return Value

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitParameter::OnDataChangeUpdate

The IDLitParameter::OnDataChangeUpdate method is called when a data value has been updated or a new data object has been associated with the visualization object.

### Note

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

## Syntax

*Obj*->[IDLitParameter:]OnDataChangeUpdate, *Data*, *ParameterName*

## Arguments

### Data

An object reference to the IDLitData object or the IDLitParameterSet object containing the changed parameter data. If *Data* is an IDLitParameterSet object, the *ParameterName* argument must be set to the string '<PARAMETER SET>'.

### ParameterName

An upper-case scalar string containing the name of the parameter that has changed. The parameter specified via this argument must be registered with the visualization object. If *oData* is an IDLitParameterSet object, this argument must be set to the string '<PARAMETER SET>'.

## Keywords

None

## Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following code handles a parameter named Z:

```
PRO MyVis::OnDataChangeUpdate, oData, ParameterName

CASE ParameterName OF
```

```

    'Z': BEGIN
        ;; do something with the z data
    END
    '<PARAMETER SET>': BEGIN
        oZ = oData->GetByName('Z')
        ;; do something with the z data.
    END
ENDCASE

END

```

**Note**

---

The Z parameter is handled twice — once if supplied as an individual IDLitData object and once if supplied via the IDLitParameterSet object.

---

See [“Creating an onDataChangeUpdate Method”](#) in the section [“Creating a New Visualization Type”](#) in Chapter 6 of the *iTool Developer’s Guide* manual for more discussion of the onDataChangeUpdate method.

## Version History

6.0	Introduced
-----	------------

## IDLitParameter::OnDataDisconnect

The IDLitParameter::OnDataDisconnect procedure method is called when a data value has been disconnected from a parameter. The general idea is that when a data item is disassociated from a visualization parameter, one or more properties of the visualization may need to be reset to reasonable default values.

### Note

---

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

---

## Syntax

*Obj*->[IDLitParameter:]OnDataDisconnect, *ParameterName*

## Arguments

### ParameterName

An upper-case string containing the name of the parameter that was disconnected. The parameter must have been previously registered with the visualization.

## Keywords

None

## Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following sample code performs some action when the parameter name is TEXTURE:

```
PRO MyVis::OnDataDisconnect, ParameterName

CASE ParameterName OF
  'TEXTURE': BEGIN
    ;; do something to remove the ref. of the texture
  END
ENDCASE

END
```

## Version History

6.0	Introduced
-----	------------

## IDLitParameter::QueryParameter

The IDLitParameter::QueryParameter function method checks whether a parameter is registered, or retrieves a list of the names of all registered parameters.

### Syntax

```
Result = Obj->[IDLitParameter::]QueryParameter([ParamName]
[, COUNT=variable])
```

### Return Value

If *ParamName* is a scalar string, this function returns a 1 if *ParamName* corresponds to a valid registered parameter, or a 0 otherwise. If *ParamName* is an array, the result is an array of 1s and 0s. If *ParamName* is not specified, *Result* is a string array containing the names of all registered parameters.

### Arguments

#### ParamName

A scalar string or string array containing parameter names. If *ParamName* is not supplied, this function returns a list of all registered parameters.

### Keywords

#### COUNT

Set this keyword equal to a named variable that will contain the number of parameters in *Result*. If *ParamName* is not supplied, then COUNT contains the number of registered parameters. If *ParamName* is supplied then COUNT contains the total number of matched parameters.

### Example

This example creates an iPlot tool and tests whether the plot visualization has a registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
PRINT, oPlot->QueryParameter('vertices')
```

IDL prints:

```
1
```

Continuing the same example, we now query for the names of all parameters of the plot visualization:

```
Params = oPlot->QueryParameter(COUNT=count)
FOR i=0,count-1 DO PRINT, Params[i]
```

IDL prints:

```
Y
X
VERTICES
Y ERROR
X ERROR
PALETTE
VERTEX_COLORS
```

## Version History

[IDLitParameter::RegisterParameter](#), [IDLitParameter::SetParameterAttribute](#)

## IDLitParameter::RegisterParameter

The IDLitParameter::RegisterParameter procedure method registers a parameter with the visualization object. Registered parameters are displayed in the iTool parameter editor dialog, allowing users to interactively assign data values to individual visualization parameters.

### Syntax

```
Obj->[IDLitParameter:]RegisterParameter, Name [, /BY_VALUE]
      [, DESCRIPTION=string] [, /INPUT] [, /OPTARGET] [, /OPTIONAL]
      [, /OUTPUT] [, TYPES=string]
```

### Arguments

#### Name

Set this argument to a string specifying the name of the parameter.

### Keywords

#### BY\_VALUE

Set this keyword to indicate that this parameter is a by-value parameter. If a parameter is marked as by value, when data is associated with it a copy of the data is made and managed by this class.

#### DESCRIPTION

Set this keyword to a string giving the full name or description of this object.

#### INPUT

Set this keyword to indicate that this is an input parameter.

#### OPTARGET

Set this keyword to indicate that this parameter may be the target of any operations.

## OPTIONAL

If this keyword is set, then this parameter is an optional parameter, and it is not required to be set. The default is OPTIONAL=0, indicating that it is required to be set.

## OUTPUT

Set this keyword to indicate that this is an output parameter.

## TYPES

Set this keyword to a scalar string or string array giving the data types that correspond to this parameter. See “[iTool Data Types](#)” in Chapter 3 of the *iTool Developer’s Guide* manual for more on parameter data types.

## Version History

6.0	Introduced
-----	------------

## IDLitParameter::SetData

The IDLitParameter::SetData function method is used to set data in this interface, associating a data object with a given parameter. This method can automatically perform type matching to determine which parameter to associate with a particular parameter or the user can specify a parameter name.

If a parameter name is provided by the user via the PARAMETER\_NAME keyword, this method will query the given data object for a data item that is of one of the types supported by this parameter and associate the found data item with the parameter. This could be the data object provided or if the data object contains other data objects, one of its children. If a type match doesn't occur, the method will return 0.

If no parameter name is provided, this method will start with the first available parameter (non-associated parameters, starting with op-targets first) and attempt to perform a data type match. When a data type match between the parameter and the provided data item (or one of its contained items) the association between the two are made.

When a data match has been made, this object is made an observer of the data object and if the NO\_UPDATE keyword is not set, the onDataChangeUpdate() method is called on this object.

If a type match is found, but the given parameter already has a data object associated with it, the type match will continue.

If a match cannot be found, a value of 0 is returned.

## Syntax

```
Result = Obj->[IDLitParameter::]SetData(Data [, /BY_VALUE] [, /NO_UPDATE]  
[, PARAMETER_NAME=string] )
```

## Return Value

Returns 1 if the IDLitData object was successfully matched with a parameter registered with the visualization object, or 0 otherwise.

## Arguments

### Data

An IDLitData object to be matched with a parameter registered with the visualization object.

## Keywords

### BY\_VALUE

Set this keyword to cause *Data* to be copied and managed by the visualization's parameter interface. If this keyword is not set, the data object is managed by the iTool system, and can be altered by other iTools.

### NO\_UPDATE

Set this keyword to prevent the `OnChangeUpdate` method from being called when *Data* is associated with one of the visualization object's registered parameters. If this keyword is not set, the `OnChangeUpdate` method is called, providing the opportunity for subclasses of the visualization object to be notified that data associated with the parameter interface has changed.

### PARAMETER\_NAME

Set this keyword to a scalar string containing the name of the registered parameter with which *Data* should be associated. If the iTool data type of the data contained in *Data* does not match one of the data types supported by the specified registered parameter, *Data* will not be associated with the registered parameter and this function will return zero.

## Version History

6.0	Introduced
-----	------------

## IDLitParameter::SetParameterAttribute

The IDLitParameter::SetParameterAttribute procedure method sets one or more parameter attributes for a registered parameter.

### Syntax

```
Obj->IDLitParameter::SetParameterAttribute(ParamName  
    [, /BY_VALUE=variable] [, /DESCRIPTION=variable] [, /INPUT=variable]  
    [, /OPTARGET=variable] [, /OPTIONAL=variable] [, /OUTPUT=variable]  
    [, /TYPES=variable] )
```

### Arguments

#### ParamName

A scalar string or string array containing names of registered parameters. If *ParamName* is an array, the specified attribute values are set on all parameters in the array.

### Keywords

#### BY\_VALUE

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is marked as being a by-value parameter, or a 0 (zero) if *ParamName* is marked as being a by-reference parameter.

#### DESCRIPTION

Set this keyword equal to a named variable that will contain the full name or description of this object.

#### INPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an input parameter, or a 0 (zero) otherwise.

#### OPTARGET

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* may be the target of any operations, or a 0 (zero) otherwise.

## OPTIONAL

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an optional parameter, or a 0 (zero) otherwise.

## OUTPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an output parameter, or a 0 (zero) otherwise.

## TYPES

Set this keyword equal to a named variable that will contain a scalar string or string array giving the data types that correspond to this parameter. See “[iTool Data Types](#)” in Chapter 3 of the *iTool Developer’s Guide* manual for more on parameter data types.

## Example

This example creates an *iPlot* tool sets the description attribute of the registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->SetParameterAttribute, 'vertices', $
    DESCRIPTION='My Vertex Data'
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc
```

IDL prints:

```
My Vertex Data
```

## Version History

6.1	Introduced
-----	------------

## See Also

[IDLitParameter::GetParameterAttribute](#), [IDLitParameter::QueryParameter](#),  
[IDLitParameter::RegisterParameter](#)

## IDLitParameter::SetParameterSet

The IDLitParameter::SetParameterSet function method is used to associate an IDLitParameterSet object with the visualization object's parameter interface. IDLitData objects contained in the parameter set object will be associated with the registered parameters of the visualization object, either based on the parameter names included in the parameter set object or on the iTool data types of the data objects. When the association of the parameter set's data objects with the visualization object's registered parameters is complete, the onDataChangeUpdate method is called with the IDLitParameterSet object and the string '<PARAMETER SET>' as the arguments.

### Note

---

When this method is called, the IDLitParameterSet object created when the visualization object was initialized will be disassociated from the object's parameter interface. This means that any individual data objects or parameter names previously added to the initial parameter set object will also be disassociated from the visualization object's parameter interface.

---

This method will not destroy or delete the information contained in the specified IDLitParameterSet object.

## Syntax

*Result* = *Obj*->[IDLitParameter::]SetParameterSet(*ParamSet*)

## Return Value

Returns 1 if the IDLitParameterSet object was successfully associated with the visualization object's parameter interface, or 0 otherwise.

## Arguments

### ParamSet

An IDLitParameterSet object to be associated with the visualization object's parameter interface.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

# IDLitParameterSet

The IDLitParameterSet class is a specialized subclass of the IDLitDataContainer class that provides the ability to associate names with the contained IDLitData objects. This association allows the iTool developer to package a set of data parameters in a single container, which is then provided to the iTools system for processing a display.

In addition to providing a mechanism for associating IDLitData objects with parameter names, the IDLitParameterSet class allows you to incorporate an IDLitData object for which no parameter name is provided. These *auxiliary data* items are treated as parameters for which the parameter name is a null string ( ' '). The auxiliary data mechanism allows you to associate any amount of data with a parameter set without the need to define parameter names.

This class is written in the IDL language. Its source code can be found in the file `idlitparameterset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitDataContainer](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitParameterSet::Init](#)” on page 3674.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

## Methods

This class has the following methods:

- [IDLitParameterSet::Add](#)

- [IDLitParameterSet::Cleanup](#)
- [IDLitParameterSet::Copy](#)
- [IDLitParameterSet::Get](#)
- [IDLitParameterSet::GetByName](#)
- [IDLitParameterSet::GetParameterName](#)
- [IDLitParameterSet::Init](#)
- [IDLitParameterSet::Remove](#)

In addition, this class inherits the methods of its superclass.

## Examples

See [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
-----	------------

## IDLitParameterSet Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

Objects in this class inherit:

- [IDLitDataContainer](#)

## IDLitParameterSet::Add

The IDLitParameterSet::Add procedure method is used to add a data object to the parameter set.

### Syntax

```
Obj->[IDLitParameterSet::]Add, Data [, PARAMETER_NAME=string]  
[, /PRESERVE_LOCATION]
```

### Arguments

#### Data

An object reference or array of object references to IDLitData objects to be added to the parameter set.

#### Note

---

The objects to be added must be of class type IDLitData or a subclass of IDLitData. You cannot add the same Parameter Set object to itself."

---

### Keywords

#### PARAMETER\_NAME

Set this keyword to a string or array of strings containing the names of parameters to be associated with the data objects. If this value is not provided, a null string ( ' ' ) is associated with the data object. If the value of this keyword is an array with fewer elements than the array specified as the *Data* argument, null strings are associated with data objects for which no parameter name is specified.

#### PRESERVE\_LOCATION

Set this keyword to leave the PARENT property of all data items specified by the *Data* argument unchanged. Normally, when an item is added to a parameter set (or any data container), the item's PARENT property is changed to be the parameter set or data container object. This, in turn, changes the data item's identifier string, since the item's location in the iTools hierarchy has changed. (See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer's Guide* manual for details.) In many cases, it is desirable to leave the PARENT property unchanged when adding items to a parameter set.

## Version History

6.0	Introduced
-----	------------

## See Also

[IDLitParameterSet::Remove](#)

## IDLitParameterSet::Cleanup

The IDLitParameterSet::Cleanup procedure method performs all cleanup on the parameter set object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitParameterSet::]Cleanup() (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitParameterSet::Copy

The IDLitParameterSet::Copy function method will return a copy of the parameter set and its contents. All items contained in the parameter set (and their data) are copied and added to the new parameter set.

For individual data objects contained in the parameter set, the following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

---

### Note

If the data within the contained data object consists of object references, only the object references are copied.

---

---

### Note

When a parameter set is copied, a new copy of each item in the parameter set is created with a new, unique, iTool identifier, even if the data item was originally added with the PRESERVE\_LOCATION keyword set.

---

## Syntax

*Result* = *Obj*->[IDLitParameterSet::]Copy()

## Return Value

Returns an IDLitParameterSet object that is a copy of the parameter set object on which the method was called.

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitParameterSet::Get

The IDLitParameterSet::Get function method is used to retrieve one or more IDLitData objects from the parameter set.

### Syntax

```
Result = Obj->[IDLitParameterSet::]Get( [, /ALL] [, COUNT=variable]  
[, NAME=variable] [, POSITION=integer] )
```

### Return Values

Returns an object reference or array of object references to the IDLitData objects specified, or returns -1 if the method fails.

### Arguments

None

### Keywords

#### ALL

Set this keyword to return an array containing object references to all IDLitData items in the parameter set.

#### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

#### NAME

Set this keyword equal to a named variable that will contain a string or string array of the parameter names associated with the returned IDLitData objects. If a returned data object has no parameter name, a null string ( ' ' ) is returned.

#### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the desired IDLitData objects within the parameter set.

## Version History

6.0	Introduced
-----	------------

## IDLitParameterSet::GetByName

The IDLitParameterSet::GetByName function method returns the IDLitData object associated with a specified named parameter.

### Syntax

```
Result = Obj->[IDLitParameterSet:]GetByName( Names [, COUNT=variable]
[, NAME=variable] )
```

### Return Value

An object reference or array of object references to the IDLitData objects specified by the *Names* argument. If no matching parameter names are found, a null object is returned.

#### Note

---

If multiple parameter names are specified, the IDLitData objects are returned in the order in which they are stored in the IDLitParameterSet object, which is not necessarily the same as the order specified in the *Names* argument. Use the value returned by the NAME keyword to associate the parameter names with IDLitData objects in the returned array.

---

### Arguments

#### Names

A scalar string or string array that contains the parameter names of the IDLitData objects to be retrieved from the parameter set.

#### Note

---

Parameter names can be supplied in any case; the search is case insensitive.

---

### Keywords

#### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

## NAME

Set this keyword equal to a named variable that will contain a scalar string or string array of the parameter names of the IDLitData objects returned by this method. When multiple parameter names are specified via the *Names* argument, the array returned in the NAME variable can be used to sort through the returned IDLitData objects by matching the indices of the two returned arrays.

## Version History

6.0	Introduced
-----	------------

## IDLitParameterSet::GetParameterName

The IDLitParameterSet::GetParameterName function method retrieves the name of a specified parameter using a provided data object.

### Syntax

*Result* = *Obj*->[IDLitParameterSet:]GetParameterName(*Data*, *Name*)

### Return Value

Returns an integer 1 if a parameter name was found for the specified IDLitData object, or 0 if no parameter name was found.

### Arguments

#### Data

An IDLitData object for which the parameter name is being requested.

#### Name

A named variable that will contain the parameter name associated with the object specified by the *oData* argument. If no parameter name is associated with the object specified by the *oData* argument, a null string ( ' ' ) is returned.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitParameterSet::Init

The IDLitParameterSet::Init function method initializes the IDLitParameter object.

### Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitParameterSet')
```

or

```
Result = Obj->[IDLitParameterSet:]Init() (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

## Arguments

None

## Keywords

The IDLitParameterSet object has no properties of its own, but inherits the properties of its superclass, IDLitDataContainer. Any property listed under [“IDLitDataContainer Properties”](#) on page 3503 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitParameterSet::Remove

The IDLitParameterSet::Remove procedure method is used to remove a data item from the parameter set.

### Syntax

```
Obj->[IDLitParameterSet::]Remove [, Items] [, /ALL] [, POSITION=integer]
```

### Arguments

#### Items

An object reference or array of object references to IDLitData objects to be removed from the parameter set.

### Keywords

#### ALL

Set this keyword to remove all items from the parameter set. If this keyword is set, the *Items* parameter is not required.

#### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices within the parameter set of the specified IDLitData objects to be removed. If this keyword is set, the *Items* parameter is not required

### Version History

6.0	Introduced
-----	------------

[IDLitParameterSet::Add](#)

# IDLitReader

The IDLitReader class defines the interface used to construct file readers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file reader class.

This class is written in the IDL language. Its source code can be found in the file `idlitreader__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitComponent](#)

[IDLitIMessaging](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitReader::Init](#)” on page 3685.

## Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLitReader::Cleanup](#)
- [IDLitReader::GetData](#)
- [IDLitReader::GetFileExtensions](#)
- [IDLitReader::GetFilename](#)
- [IDLitReader::GetProperty](#)

- [IDLitReader::Init](#)
- [IDLitReader::IsA](#)
- [IDLitReader::SetFilename](#)
- [IDLitReader::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

## Examples

See [Chapter 9, “Creating a File Reader”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
-----	------------

## IDLitReader Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDLitComponent](#)
- [IDLitMessaging](#)

## IDLitReader::Cleanup

The IDLitReader::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitReader:]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitReader::GetData

The IDLitReader::GetData function method is called by the system to retrieve the data from the current file. When called, the reader should access the current filename and read the desired data. Once the information is loaded, the reader should place the obtained data in a data object, which is then passed back to the system.

This method will contain a majority of the implementation for a new reader class.

### Syntax

```
Result = Obj->[IDLitReader::]GetData(Data)
```

### Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

### Arguments

#### Data

A data object that contains the read information. The reader determines the exact type and format of this data object, which keys off the type of information being read and what the format supports.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitReader::GetFileExtensions

The IDLitReader::GetFileExtensions function method is called by the system to retrieve the file extensions supported by this particular reader.

### Syntax

*Result = Obj->*[IDLitReader::]GetFileExtensions( [, COUNT=*variable*])

### Return Value

Returns a scalar or string array that contains the file extensions associated with this reader.

### Arguments

None

### Keywords

#### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

### Version History

6.0	Introduced
-----	------------

## IDLitReader::GetFilename

The IDLitReader::GetFilename function method is called by the system to retrieve the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then read at a later time. This method allows direct access to the file currently associated with the reader.

In addition, this methodology is helpful when multiple reads are performed from a given file.

### Syntax

```
Result = Obj->[IDLitReader::]GetFilename()
```

### Return Value

Returns a string containing the current file name associated with this reader, or an empty string if no filename has been associated.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitReader::GetProperty

The IDLitReader::GetProperty procedure method retrieves the value of an IDLitReader property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

### Syntax

*Obj->*[IDLitReader::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitReader Properties](#)” on page 3679 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitReader::Init

The IDLitReader::Init function method initializes the IDLitReader object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW( 'IDLitReader' [, Extensions] [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitReader::]Init( [, Extensions] [, PROPERTY=value] ) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Extensions

A optional argument containing a scalar or string array with the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (i.e., a correct value is 'jpeg' and not '.jpeg'). If this argument is not set, or if a null string is provided, IDL does not include this file reader in the list of filters in a file-selection dialog, but still uses it when attempting to match a file to a reader.

## Keywords

Any property listed under [“IDLitReader Properties”](#) on page 3679 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitReader::IsA

The IDLitReader::IsA function method is called by the system to determine if the given file is of the type supported by this file reader. Often this is used to determine what file reader to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new reader is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

### Syntax

```
Result = Obj->[IDLitReader::]IsA(Filename)
```

### Return Value

Returns a 1 if the reader supports this type of file, or a 0 if the reader does not support this type of file.

### Arguments

#### Filename

A string representing of the filename, which is used to check and determine if the reader supports its format.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitReader::SetFilename

The IDLitReader::SetFilename procedure method is called by the system to set the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then the read at a later time.

### Syntax

*Obj*->[IDLitReader:]SetFilename, *Filename*

### Arguments

#### Filename

A string that contains the filename associated with this reader.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitReader:: SetProperty

The IDLitReader::SetProperty procedure method sets the value of an IDLitReader property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj*->[IDLitReader::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitReader Properties](#)” on page 3679 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLitTool

The IDLitTool class represents all the functionality provided by a particular instance of an IDL Intelligent Tool. It provides the management systems for the underlying iTool functionality and implements the desired interfaces for external parties to interact with this functionality in a known manner.

This class is written in the IDL language. Its source code can be found in the file `idlittool__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Note on the IDLitToolbase Class

All iTools included with the IDL release are based on a subclass of the IDLitTool class named IDLitToolbase. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in “[Subclassing from the IDLitToolbase Class](#)” in Chapter 5 of the *iTool Developer's Guide* manual.

## Superclasses

[IDLitContainer](#)

[IDLitMessaging](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitTool::Init](#)” on page 3724.

## Properties

Objects of this class have the following properties. See “[IDLitTool Properties](#)” on page 3694 for details on individual properties.

- [DESCRIPTION](#)

- [ICON](#)
- [NAME](#)
- [TYPE](#)
- [UPDATE\\_BYTYPE](#)
- [VERBOSE](#)
- [VERSION](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLitTool::ActivateManipulator](#)
- [IDLitTool::Add](#)
- [IDLitTool::AddService](#)
- [IDLitTool::Cleanup](#)
- [IDLitTool::CommitActions](#)
- [IDLitTool::DisableUpdates](#)
- [IDLitTool::DoAction](#)
- [IDLitTool::DoSetProperty](#)
- [IDLitTool::DoUIService](#)
- [IDLitTool::EnableUpdates](#)
- [IDLitTool::FindIdentifiers](#)
- [IDLitTool::GetCurrentManipulator](#)
- [IDLitTool::GetFileReader](#)
- [IDLitTool::GetFileWriter](#)
- [IDLitTool::GetManipulators](#)
- [IDLitTool::GetOperations](#)
- [IDLitTool::GetProperty](#)
- [IDLitTool::GetSelectedItems](#)
- [IDLitTool::GetService](#)

- `IDLitTool::GetVisualization`
- `IDLitTool::Init`
- `IDLitTool::RefreshCurrentWindow`
- `IDLitTool::Register`
- `IDLitTool::RegisterCustomization`
- `IDLitTool::RegisterFileReader`
- `IDLitTool::RegisterFileWriter`
- `IDLitTool::RegisterManipulator`
- `IDLitTool::RegisterOperation`
- `IDLitTool::RegisterStatusBarSegment`
- `IDLitTool::RegisterVisualization`
- `IDLitTool::SetProperty`
- `IDLitTool::UnRegister`
- `IDLitTool::UnRegisterCustomization`
- `IDLitTool::UnRegisterFileReader`
- `IDLitTool::UnRegisterFileWriter`
- `IDLitTool::UnRegisterManipulator`
- `IDLitTool::UnRegisterOperation`
- `IDLitTool::UnRegisterStatusBarSegment`
- `IDLitTool::UnRegisterVisualization`

In addition, this class inherits the methods of its superclasses.

## Examples

See “[Example: Simple iTool](#)” in Chapter 5 of the *iTool Developer’s Guide* manual.

## Version History

6.0	Introduced
-----	------------

## See Also

[Chapter 5, “Creating an iTool”](#) in the *iTool Developer’s Guide* manual

## IDLitTool Properties

IDLitTool objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLitTool::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLitTool::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLitTool::SetProperty`.

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- `DESCRIPTION`
- `ICON`
- `NAME`
- `TYPE`
- `UPDATE_BYTYPE`
- `VERBOSE`
- `VERSION`

In addition, objects of this class inherit:

- `IDLitContainer`
- `IDLitMessaging`

### DESCRIPTION

This property contains a string representing the full name or description of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Description		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ICON

A string identifying the icon that should be used when displaying the iTool object. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## NAME

A string representing the name of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Name		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TYPE

A string or vector of strings that identify the type(s) that this iTool represents.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## UPDATE\_BYTYPE

A Boolean value controlling whether the given iTool will add new functionality to it as new visualization types are added. By default, when a new visualization is added to the iTool, any functionality associated with that visualization type is added to the iTool. If this property is set to zero (False), this updating is disabled.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## VERBOSE

A named variable that will control the verbose logging of the iTool. If set to a non-zero value, the iTool will log more information than normal. If this keyword is set to 0, minimal logging (error conditions only) will be sent to the logging system.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## VERSION

A named variable that will be set to the version of the iTool system.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

# IDLitTool::ActivateManipulator

## Version History

The IDLitTool::ActivateManipulator procedure method activates a manipulator that has been registered with this tool.

## Syntax

*Obj*->[IDLitTool::]ActivateManipulator, *Identifier* [, /DEFAULT]

## Arguments

### Identifier

A string representing the identifier of the manipulator to activate.

## Keywords

### DEFAULT

Set this keyword to a non-zero value to indicate that the default manipulator registered with this tool should be activated. If this keyword is set, the Identifier argument is ignored.

## Version History

6.1	Introduced
-----	------------

## IDLitTool::Add

The IDLitTool::Add procedure method adds any item to the iTool. If called with a Visualization, that visualization is added to the current IDLitWindow object. If called with a data object, that data object is placed in the systems data manager. All other items are added to the iTool container.

### Syntax

*Obj*->[IDLitTool::]Add, *Item*

### Arguments

#### Item

The item to add to the iTool.

### Keywords

This method passes keywords to the Add method of the appropriate object. If the target destination is a data object, no keywords are passed. If the target destination is a visualization object, the keywords are passed to the IDLitWindow::Add method; otherwise, the keywords are passed to the IDLitContainer::Add method.

### Version History

6.0	Introduced
-----	------------

## IDLitTool::AddService

The IDLitTool::AddService procedure method adds a service to the iTool. Unlike registration methodologies provided by the iTool, the method takes an existing object and adds it to the service repository in the iTool.

When a service is added to the system, a description of this service class is placed in the tools service folder. If it is desired to retrieve this descriptor at a later time, the iTool relative identifier would be SERVICES/identifier, where identifier is the identifier provided to this method.

### Syntax

*Obj*->[IDLitTool::]AddService, *Service*

### Arguments

#### Service

Set this variable to the service to add to the tools service repository. This service can be retrieved at a later point in time using its identifier (specified when creating the service object via the identifier keyword).

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::Cleanup

The IDLitTool::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitTool:]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitTool::CommitActions

The IDLitTool::CommitActions procedure method commits all pending transactions to the undo-redo buffer and causes a refresh of the current window.

This method is designed to be used in conjunction with the [IDLitTool::DoSetProperty](#) method.

### Syntax

*Obj*->[\[IDLitTool::\]](#)CommitActions

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

### See Also

[IDLitTool::DoSetProperty](#)

## IDLitTool::DisableUpdates

The IDLitTool::DisableUpdates procedure method disables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates are re-enabled by calling the EnableUpdates method.

### Syntax

*Obj*->[IDLitTool::]DisableUpdates ([, PREVIOUSLY\_DISABLED=*variable*])

### Arguments

None

### Keywords

#### PREVIOUSLY\_DISABLED

Set this keyword to a named variable that upon return will be 1 if the tool had previously been disabled, or 0 otherwise.

### Version History

6.0	Introduced
6.1	Added PREVIOUSLY_DISABLED keyword

## IDLitTool::DoAction

The IDLitTool::DoAction function method initiates an operation or action in the iTool object. The identifier that is passed in as the argument to this method specifies the action that executes.

### Syntax

*Result* = *Obj*->[IDLitTool::]DoAction(*Identifier*)

### Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

### Arguments

#### Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation that it implements.

### Keywords

All keywords are passed to the DoAction function of the object in the iTool that performs the operation.

### Version History

6.0	Introduced
-----	------------

## IDLitTool::Do SetProperty

The IDLitTool::Do SetProperty function method sets the value of a registered property on a target component object, and places the change in the undo/redo transaction buffer.

---

### Note

In order to commit the change to the undo/redo transaction buffer, you must call the [IDLitTool::CommitActions](#) method. The property change is not actually undoable until it has been committed.

---

The separation of addition of the change to the buffer and commit of the change allows you to “package” several property changes into a single undo/redo transaction. The call to the CommitActions method will commit any changes that have been performed but not committed. For example, the following statements change two properties on an iTool component (oTarget) and commit them together:

```
targetID = oTarget->GetFullIdentifier()
status = oTool->DoSetProperty(targetID, 'Property1', 'Value 1')
status = oTool->DoSetProperty(targetID, 'Property2', 'Value 2')
oTool->CommitActions
```

If the user later undoes the action, both property value changes will be reversed in one step.

## Syntax

*Result* = *Obj*->[IDLitTool::]DoSetProperty(*TargetIdentifier*, *PropertyIdentifier*, *Value*)

## Return Value

Returns 1 if the SetProperty was successful, or 0 otherwise.

---

### Note

If successful, you are responsible for calling IDLitTool::CommitActions to complete the transaction.

---

## Arguments

### TargetIdentifier

A scalar string or a string array containing the full object identifiers of the objects on which the property is being set.

### PropertyIdentifier

A scalar string containing the identifier of the property whose value is being changed. *PropertyIdentifier* must be a registered property of the target objects.

### Value

The new property value.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## See Also

[IDLitTool::CommitActions](#)

## IDLitTool::DoUIService

The IDLitTool::DoUIService function method initiates a request for a UI service to execute. This method allows underlying iTool functionality to perform user-interface interactions without having a direct connection to the user interface portion of the iTool.

An example of an iTool UI service would be the **File** → **Open** command, which will prompt the user to select a file using the standard file open dialog. This command is identified by setting the *ServiceIdentifier* argument to FileOpen. See [Chapter 13, “Creating a User Interface Service”](#) in the *iTool Developer’s Guide* manual for more information about UI services.

### Syntax

*Result* = *Obj*->[IDLitTool:]DoUIService(*ServiceIdentifier*, *Requestor*)

### Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

### Arguments

#### ServiceIdentifier

A string identifier that specifies the UI service being requested. This identifier is passed to the tools user interface for control dispatching purposes.

#### Requestor

An object reference to the object that is requesting the UI service. The UI service uses this object to obtain any information particular to the interaction taking place.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::EnableUpdates

The IDLitTool::EnableUpdates procedure method re-enables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates can be disabled by calling the DisableUpdates method.

### Syntax

*Obj*->[\[IDLitTool::\]](#)EnableUpdates

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::FindIdentifiers

The IDLitTool::FindIdentifiers function method allows you to retrieve the full identifiers for items within the tool container.

### Warning

---

The FindIdentifiers method recurses through the entire object hierarchy of the specified object, which may be slow for large container hierarchies. If you find it necessary to call FindIdentifiers multiple times, it may be more efficient to use a single call with one or more wildcards (“\*”) to return all relevant identifiers, and then perform the necessary searches using the returned list.

---

## Syntax

```
Result = Obj->[IDLitTool::]FindIdentifiers([Pattern] [, /ANNOTATIONS]  
[, COUNT=variable] [, /DATA_MANAGER] [, /FILE_READERS]  
[, /FILE_WRITERS] [, /LEAF_NODES] [, /MANIPULATORS]  
[, /OPERATIONS] [, /VISUALIZATIONS] )
```

## Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

## Arguments

### Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See [STRMATCH](#) for a description of the rules used when matching patterns. See “[Retrieving Component Identifiers](#)” in Appendix A of the *iTool Developer’s Guide* manual for additional information and examples.

**Note**

---

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

---

## Keywords

### ANNOTATIONS

Set this keyword to only return identifiers for items within the annotation layer of all views within the graphics window.

### COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

### DATA\_MANAGER

Set this keyword to only return identifiers for items within the Data Manager container.

### FILE\_READERS

Set this keyword to only return identifiers for items within the File Readers container.

### FILE\_WRITERS

Set this keyword to only return identifiers for items within the File Writers container.

### LEAF\_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

**Note**

---

If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

---

## MANIPULATORS

Set this keyword to only return identifiers for items within the Manipulators container.

## OPERATIONS

Set this keyword to only return identifiers for items within the Operations container.

## VISUALIZATIONS

Set this keyword to only return identifiers for items within the Visualization layer of all views within the graphics window.

## Example

This example finds the plot visualization and changes the color:

```
I PLOT, RANDOMU(s,100)
void = ITGETCURRENT(TOOL=oTool)

; Find the Plot visualization and change the color.
id = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)

void = oTool->DoSetProperty(id, 'COLOR', [255,0,0])
```

This example finds the file open operation and loads in an image:

```
I IMAGE
void = ITGETCURRENT(TOOL=oTool)

; Find the File Open operation and open a file.
id = oTool->FindIdentifiers('*File/Open*', /OPERATIONS)

oOp = oTool->GetByIdentifier(id)
oOp->SetProperty, SHOW_EXECUTION_UI=0, $
    FILENAMES=FILEPATH('rose.jpg', SUBDIR=['examples','data'])
void = oTool->DoAction(id)
oOp->SetProperty, SHOW_EXECUTION_UI=1
```

## Version History

6.1	Introduced
-----	------------

## See Also

[“Retrieving Component Identifiers”](#) in Appendix A of the *iTool Developer’s Guide* manual

## IDLitTool::GetCurrentManipulator

The IDLitTool::GetCurrentManipulator function method returns the current manipulator in the system.

### Syntax

*Result* = *Obj*->[IDLitTool::]GetCurrentManipulator()

### Return Value

Returns an object reference to the current manipulator.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::GetFileReader

The IDLitTool::GetFileReader function method retrieves a file reader registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

### Syntax

```
Result = Obj->[IDLitTool:]GetFileReaders(Identifier [, /ALL]  
[, COUNT=variable])
```

### Return Value

Returns the object descriptors constructed for the registered file reader.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file readers registered with the system.

### Arguments

#### Identifier

A string representing the single level identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

### Keywords

#### ALL

Set this keyword to return all file readers registered with the iTool and the system.

#### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

## Version History

6.0	Introduced
-----	------------

## IDLitTool::GetFileWriter

The IDLitTool::GetFileWriter function method retrieves a file writer registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

### Syntax

```
Result = Obj->[IDLitTool:]GetFileWriters(Identifier [, /ALL]  
[, COUNT=variable])
```

### Return Value

Returns the object descriptors constructed for the registered file writer.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file writers registered with the system.

### Arguments

#### Identifier

A string representing the identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

### Keywords

#### ALL

Set this keyword to return all file writers registered with the iTool and the system.

#### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

## Version History

6.0	Introduced
-----	------------

## IDLitTool::GetManipulators

The IDLitTool::GetManipulators function method retrieves the manipulators registered with the iTool object. Unlike other items in the iTool and due to the active nature of the subsystem, manipulators are instantiated when registered.

### Syntax

*Result = Obj->*[IDLitTool:]GetManipulators( [, COUNT=*variable*])

### Return Value

Returns the object references to the manipulators that were instantiated when items were registered with the iTool.

### Arguments

None

### Keywords

#### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

### Version History

6.0	Introduced
-----	------------

## IDLitTool::GetOperations

The IDLitTool::GetOperations function method retrieves the operations registered with the iTool object.

---

**Note**

This routine returns a set of object descriptor classes that reference the items registered with the iTool. In addition, if the operation folder in the registry contains sub-folders, the returned list will contain IDLitContainer classes, each containing sub-operations.

---

## Syntax

```
Result = Obj->[IDLitTool:]GetOperations([, COUNT=variable]  
[, IDENTIFIER=string])
```

## Return Value

Returns the object descriptors constructed for the registered operations.

## Arguments

None

## Keywords

### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

### IDENTIFIER

Set this keyword to an optional identifier that identifies the location in the operation hierarchy to retrieve the operation object descriptors from.

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitTool::GetProperty

The IDLitTool::GetProperty procedure method retrieves the value of an IDLitTool property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

### Syntax

*Obj*->[\[IDLitTool::\]](#)GetProperty, [*PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under [“IDLitTool Properties”](#) on page 3694 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitTool::GetSelectedItems

The IDLitTool::GetSelectedItems function method returns a vector of references to the objects currently selected within the current window in the iTool. If no objects are currently selected, this function returns -1.

### Syntax

*Result* = *Obj*->[IDLitTool:]GetSelectedItems( [, **COUNT**=*variable*]

### Return Value

Returns a vector of references to the currently selected objects. If no objects are currently selected, this function returns -1.

### Arguments

None

### Keywords

#### **COUNT**

Set this keyword to a named variable that will contain the number of valid items returned by this function.

### Version History

6.0	Introduced
-----	------------

## IDLitTool::GetService

The IDLitTool::GetService method retrieves a service that has been registered with the iTool.

### Syntax

*Result* = *Obj*->[IDLitTool:]GetService(*IdService*)

### Return Value

Returns an object reference to the service.

### Arguments

#### IdService

The identifier of the desired service.

#### Note

---

*IdService* should specify only the relative identifier, not the fully-qualified identifier. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for details.

---

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::GetVisualization

The IDLitTool::GetVisualization function method retrieves a visualization registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

### Syntax

```
Result = Obj->[IDLitTool:]GetVisualization(Identifier [, /ALL]  
[, COUNT=variable])
```

### Return Value

Returns the object descriptors constructed for the registered visualizations. (See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool as well as those visualizations registered with the system.

### Arguments

#### Identifier

A string containing the relative identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call. (See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of relative vs. fully-qualified identifiers.)

### Keywords

#### ALL

Set this keyword to return all visualizations registered with the iTool and the system.

## COUNT

Set this keyword to a variable that will contain the number of object descriptors returned by this method. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

## Version History

6.0	Introduced
-----	------------

## IDLitTool::Init

The IDLitTool::Init function method initializes the IDLitTool object, and should be called by the Init method of a subclass.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLitTool'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitTool::]Init( [, PROPERTY=value]) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitTool Properties” on page 3694 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitTool::RefreshCurrentWindow

The IDLitTool::RefreshCurrentWindow procedure method redraws the current window of the iTool. The redraw will occur only if updates are enabled in the iTool.

### Syntax

*Obj*->[\[IDLitTool::\]](#)RefreshCurrentWindow

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::Register

The `IDLitTool::Register` procedure method registers a generic object subclassed from the `IDLitComponent` class with the `iTool`. Once registered, the `iTool` has the ability to instantiate this type of component when needed. Unlike the other provided methods to register components, this method is generic.

This method allows items to be registered in the standard registry folders of the `IDLitTool` object, and can be used as well for the creation of new folders. If the provided identifier specifies a folder that does not currently exist in the `iTool`, it is created.

### Note

---

For information on registering functionality with the `iTool` system, making the registered functionality available to all `iTools`, see [ITREGISTER](#).

---

This method performs none of the validation performed by the specific registration functions. As such, it can cause issues with `iTool` operation, if used incorrectly. You should use the following related methods for registering certain, specific components to insure validation:

- File readers — “[IDLitTool::RegisterFileReader](#)” on page 3731
- File writers — “[IDLitTool::RegisterFileWriter](#)” on page 3734
- Manipulators — “[IDLitTool::RegisterManipulator](#)” on page 3737
- Operations — “[IDLitTool::RegisterOperation](#)” on page 3739
- Visualizations — “[IDLitTool::RegisterVisualization](#)” on page 3744

## Syntax

```
Obj->[IDLitTool::]Register, Name, ClassName [, /DEFAULT]  
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]  
    [, PROXY=string]
```

## Arguments

### Name

A string containing the human readable name of the component type being registered with the `iTool`.

**Note** 

---

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

---

**ClassName**

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

**Keywords****Note** 

---

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

---

**DEFAULT**

Set this keyword to specify that the item being registered should be the *default item* of its type. Making an item the default places the item first in the list of items of its type. When the iTool system chooses an item, it will use the first item in the list that matches the data type of the selected data. When items are displayed in a list for the user to select from, the default item will appear at the top of the list.

For example, if you register a visualization type with the DEFAULT keyword set, your visualization type will be used by the iTool (assuming the selected data is of the proper type) unless you specifically choose a different visualization type.

**Note** 

---

If you register more than one item with the DEFAULT keyword set, the *last* item registered will appear *first* in the list of items of that type.

---

**DESCRIPTION**

Set this keyword to a string that provides a brief description of the component being registered.

## ICON

Set this keyword to the icon that should be used when displaying the iTool object. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier that should be used by the system for this component type. If not provided, an identifier is constructed from the provided *Name* value.

To use one of the iTool-provided registration locations, the value of this keyword should contain the destination for the new component that is being registered. Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

---

### Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

---

## PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed to this item are routed to the item specified by the identifier provide to this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

## Version History

6.0	Introduced
6.1	Added DEFAULT keyword

## IDLitTool::RegisterCustomization

The IDLitTool::RegisterCustomization procedure method registers an operation class that represents the graphics customization operation to be associated with this tool.

### Syntax

*Obj*->[IDLitTool::]RegisterCustomization, *Name*, *ClassName*

### Arguments

#### Name

A string representing the name of the customization operation.

#### ClassName

A string representing the classname of the operation being registered.

### Keywords

#### Note

---

Any keywords provided to this routine are treated as property defaults for the registered operation and applied to the registered object when it is created.

---

### Version History

6.1	Introduced
-----	------------

## IDLitTool::RegisterFileReader

The IDLitTool::RegisterFileReader procedure method registers a file reader component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a reader class is registered with the iTool, an object descriptor for this operation class is placed in the iTool's file reader folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE_READERS/identifier`, where `identifier` is the identifier provided to this method.

### Syntax

```
Obj->[IDLitTool::]RegisterFileReader, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

### Arguments

#### Name

The human readable name of the component type being registered with the iTool.

#### Note

---

If the `IDENTIFIER` keyword is not supplied, the `Name` argument will be used as the basis for the component's identifier.

---

#### ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

### Keywords

#### Note

---

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

---

## DEFAULT

Set this keyword to specify that the file reader being registered should be the *default* file reader. When the iTool system picks a reader for a file of the specified type, it will attempt to use the specified file reader first. The file reader will also be displayed at the top of the list of file readers displayed for the user to select from.

---

### Note

If you register more than one file reader with the DEFAULT keyword set, the *last* file reader registered will appear *first* in the list of items of file readers.

---

## DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

## ICON

Set this keyword to the icon that should be used when displaying the file reader in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file reader registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

---

### Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

---

## PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

## Version History

6.0	Introduced
6.1	Added DEFAULT keyword

## See Also

[ITREGISTER](#)

## IDLitTool::RegisterFileWriter

The IDLitTool::RegisterFileWriter procedure method registers a file writer component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a writer class is registered with the system, an object descriptor for this operation class is placed in the iTool's file writer folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE WRITERS/identifier`, where `identifier` is the identifier provided to this method.

### Syntax

```
Obj->[IDLitTool::]RegisterFileWriter, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

### Arguments

#### Name

A string containing the human readable name of the component type being registered with the iTool.

#### Note

If the `IDENTIFIER` keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

#### ClassName

A string containing the class name of the component being registered. The iTool object uses this class name to instantiate a component of this type when requested by the system.

### Keywords

#### Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

## DEFAULT

Set this keyword to specify that the file writer being registered should be the *default* file writer. When the iTool system picks a writer for a file of the specified type, it will attempt to use the specified file writer first. The file writer will also be displayed at the top of the list of file writers displayed for the user to select from.

---

### Note

If you register more than one file writer with the DEFAULT keyword set, the *last* file writer registered will appear *first* in the list of file writers.

---

## DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

## ICON

Set this keyword to the icon that should be used when displaying the file writer in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file writer registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

---

### Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

---

## PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

## Version History

6.0	Introduced
6.1	Added DEFAULT keyword

## See Also

[ITREGISTER](#)

## IDLitTool::RegisterManipulator

The IDLitTool::RegisterManipulator procedure method registers a manipulator component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a manipulator class is registered with the system, an object of the given class is created and added to the tools manipulator manager (an instance of IDLitManipulatorManager). To reference the new manipulator, the identifier that is provided should be prepended with the MANIPULATORS identifier level.

### Syntax

```
Obj->[IDLitTool::]RegisterManipulator, Name, ClassName [, /DEFAULT]  
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
```

### Arguments

#### Name

A string containing the human readable name of the component type being registered with the iTool.

#### Note

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

#### ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

### Keywords

#### Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

## DEFAULT

If set, this registered item will be treated as the default manipulator for this iTool. Only one default manipulator can exist at anytime.

## DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

## ICON

Set this keyword to the icon that should be used when displaying the manipulator in an iTool menubar. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

### Note

---

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

---

## Version History

6.0	Introduced
-----	------------

## IDLitTool::RegisterOperation

The IDLitTool::RegisterOperation procedure method registers an operation component with the iTool. Once registered, the iTool has the ability to instantiate this type of operation when needed.

When an operation class is registered with the system, an object descriptor for this operation class is placed in the tools operations folder. To retrieve this descriptor at a later time, the iTool relative identifier would be OPERATIONS/identifier, where identifier is the identifier provided to this method.

### Syntax

```
Obj->[IDLitTool::]RegisterOperation, Name, ClassName  
    [, ACCELERATOR=string] [, /CHECKED] [, DESCRIPTION=string]  
    [, /DROPLIST_EDIT] [, DROPLIST_INDEX=value]  
    [, DROPLIST_ITEMS=string array] [, ICON=string] [, IDENTIFIER=string]  
    [, PROXY=string] [, /SEPARATOR]
```

### Arguments

#### Name

A string containing the human readable name of the operation type being registered with the iTool.

#### Note

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

#### ClassName

A string containing the class name of the operation component being registered. This class name is used by the iTool object to instantiate an operation component of this type when requested.

## Keywords

---

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

---

### ACCELERATOR

Set this keyword to a string giving the keyboard accelerator to be used for the menu item associated with this operation. For valid values see the ACCELERATOR keyword to WIDGET\_BUTTON.

---

**Note**

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

---

### CHECKED

Set this keyword to indicate that a "checked" menu item should be used for this operation.

---

**Note**

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

---

### DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

### DROPLIST\_EDIT

Set this keyword to indicate that a droplist associated with this operation should be editable (that is, the droplist should be a combobox widget). The default is to create a non-editable droplist widget. The DROPLIST\_ITEMS keyword must be set for this keyword to have any effect.

---

**Note**

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

---

## DROPLIST\_INDEX

Set this keyword equal to the starting index of the droplist associated with this operation. The default is 0 (zero). The DROPLIST\_ITEMS keyword must be set for this keyword to have any effect.

---

**Note**

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

---

## DROPLIST\_ITEMS

Set this keyword equal to a scalar string or string array containing values to be used for the droplist. If this keyword is set, the DoAction method for the associated operation must accept a keyword called OPTION. When an item from the droplist is selected, the DoAction method will be called with the OPTION keyword set equal to the selected string value.

---

**Note**

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

---

## ICON

Set this keyword to the icon that should be used when displaying the operation in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier for the iTool for this component type. If not provided, an identifier is constructed from the *Name*.

Operations are placed in the `operation` folder of the iTool component hierarchy. If a multiple level identifier is provided (indicated by the presence of one or more “/” characters), the item is placed in the corresponding subfolder of the tool’s `operation` folder. If the specified subfolder is not present, it is created. This functionality allows operations to be classified in logical groupings and results in sub-menu items in the menus of the iTool interface.

See “[iTool Object Hierarchy](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifiers and the iTool component hierarchy.

**Note**

---

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

---

**PROXY**

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

**SEPARATOR**

Set this keyword to indicate that a menu separator should be placed before this operation, if this operation appears in a menu.

**Note**

---

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

---

**Version History**

6.0	Introduced
6.1	Added ACCELERATOR, CHECKED, DISABLE, DROPLIST_EDIT, DROPLIST_INDEX, DROPLIST_ITEMS, SEPARATOR keywords
6.2	Deprecated DISABLE keyword

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## IDLitTool::RegisterStatusBarSegment

The IDLitTool::RegisterStatusBarSegment procedure method registers a status message bar segment with the tool.

### Syntax

```
Obj->[IDLitTool:]RegisterStatusBarSegment, Name [, IDENTIFIER=string]  
    [, NORMALIZED_WIDTH=scalar]
```

### Arguments

#### Name

A scalar string containing the name of the status bar segment.

### Keywords

#### IDENTIFIER

Set this keyword to a string containing the relative identifier for the status bar segment being registered. If this keyword is not specified, the *Name* argument is used as the identifier. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

#### NORMALIZED\_WIDTH

Set this keyword to a floating-point integer between 0 and 1.0 indicating the normalized width (relative to the overall width of the status bar) that this segment should occupy.

### Version History

6.1	Introduced

## IDLitTool::RegisterVisualization

The IDLitTool::RegisterVisualization procedure method registers a visualization component with the iTool. Once registered, the iTool has the ability to instantiate this type of visualization when needed.

When a visualization class is registered with the system, an object descriptor for this visualization class is placed in the iTool's visualization folder. To retrieve this descriptor at a later time, the iTool relative identifier would be:

VISUALIZATIONS/*identifier* where *identifier* is the identifier provided to this method.

### Syntax

```
Obj->[IDLitTool::]RegisterVisualization, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

### Arguments

#### Name

A string containing the human readable name of the visualization type being registered with the iTool.

#### Note

---

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

---

#### ClassName

A string containing the class name of the visualization component being registered. The iTool object uses this class name to instantiate a visualization component of this type when requested.

### Keywords

#### Note

---

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

---

## DEFAULT

If set, this registered item will be treated as the default visualization for this iTool. Only one default visualization can exist at a time.

## DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

## ICON

Set this keyword to the icon that should be used when displaying the visualization in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the visualization registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

---

### Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

---

## PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword.

## IDLitTool:: SetProperty

The IDLitTool::SetProperty procedure method sets the value of an IDLitTool property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj*->[IDLitTool::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitTool Properties](#)” on page 3694 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

### See Also

[IDLitTool::DoSetProperty](#)

## IDLitTool::UnRegister

The IDLitTool::UnRegister procedure method unregisters a component with the iTool. When a component is unregistered, it is no longer available to perform whatever function it performs, and it is removed from iTool menus and toolbars.

### Syntax

*Obj*->[IDLitTool::]UnRegister, *Identifier*

### Arguments

#### Identifier

Set this to the relative identifier of the component to be removed from the iTool. To remove a component from the standard folders in the iTool's content registry, this identifier should contain the location of the component as well as the component identifier itself. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

## IDLitTool::UnRegisterFileWriter

The IDLitTool::UnRegisterFileWriter procedure method unregisters a component with the iTool. When a file writer is unregistered, it is no longer available to export files from the iTool, and it is removed from iTool menus and toolbars.

### Syntax

*Obj*->[IDLitTool::]UnRegisterFileWriter, *Identifier*

### Arguments

#### Identifier

Set this to the relative identifier of the file writer to be removed from the iTool. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::UnRegisterManipulator

The IDLitTool::UnRegisterManipulator procedure method unregisters a manipulator component with the iTool. When a manipulator is unregistered, it is removed from iTool menus and toolbars.

### Syntax

*Obj*->[IDLitTool:]UnRegisterManipulator, *Identifier*

### Arguments

#### Identifier

Set this to the relative identifier of the manipulator to be removed from the iTool. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitTool::UnRegisterOperation

The IDLitTool::UnRegisterOperation procedure method unregisters an operation component with the iTool. When an operation is unregistered, it is no longer available to perform actions within the iTool, and it is removed from iTool menus and toolbars.

### Syntax

*Obj*->[IDLitTool:]UnRegisterOperation, *Identifier*

### Arguments

#### Identifier

Set this to the relative identifier of the component to be removed from the iTool. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

### Keywords

-----	------------

# IDLitToolbase

The IDLitToolbase class is a subclass of the IDLitTool class that *registers* all of the features (menu items, operations, manipulators, *etc.*) of a standard iTool provided by RSI. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in “[Subclassing from the IDLitToolbase Class](#)” in Chapter 5 of the *iTool Developer's Guide* manual.

## Warning

---

RSI may change the list of items registered by the IDLitToolbase class from release to release. If your aim is to have your tool present the same features as the standard iTools provided by RSI, subclass your tool from IDLitToolbase. If your aim is to create your own interface that stays static between releases of IDL, use IDLitToolbase as a template for your own tool, but do not subclass it directly.

---

This class is written in the IDL language. Its source code can be found in the file `idlittoolbase__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitTool](#)

## Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitTool::Init](#)” on page 3724.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

Objects of this class have no methods of their own, but do have methods inherited from any superclasses.

# IDLitUI

The IDLitUI class serves as the link between the underlying functionality of an iTool and the IDL Widget interface that is displayed to the user. The user interface object provides the following functionality:

- Access to and communication with the underlying iTool object.
- Registration of various user interface elements that are part of the iTool.
- Registration and management of dialog sub-elements that are used by the iTool to perform specific tasks.

For additional information on the IDLitUI class, and user interface issues in general, see [Chapter 11, “iTool User Interface Architecture”](#) in the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitui__define.pro` in the `lib/itools/ui_widgets` subdirectory of the IDL distribution.

## Superclasses

[IDLitContainer](#)

### Note

---

## IDLitUI Properties

IDLitUI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitUI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitUI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitUI::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [GROUP\\_LEADER](#)

In addition, objects of this class inherit:

- [IDLitContainer](#)

### GROUP\_LEADER

A long integer containing the IDL Widget ID of the group leader widget for the user interface.

<b>Property Type</b>	Long Integer (Widget ID)		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLitUI::AddOnNotifyObserver

The IDLitUI::AddOnNotifyObserver procedure method is used to register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object.

### Syntax

*Obj*->[IDLitUI::AddOnNotifyObserver](#), *IdObserver*, *IdSubject*

### Arguments

#### IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idObject, idMessage, message
```

where

- *idObject* is the object identifier of the iTool component that is the source of the message.
- *idMessage* is a string that identifies the type of message being sent.
- *message* is the message data itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See “[IDLitMessaging::DoOnNotify](#)” on page 3534 for additional details.

#### IdSubject

A string identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via [IDLitMessaging::DoOnNotify](#) specifies *IdSubject* as the originator, the *IdObserver* object’s OnNotify method is called.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitUI::Cleanup

The IDLitUI::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitUI::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

6.0	Introduced
-----	------------

---

## IDLitUI::DoAction

The IDLitUI::DoAction function method initiates an operation or action in the iTool object associated with this user interface. The identifier that is passed in as the argument to this method specifies the action that executes.

### Syntax

*Result* = *Obj*->[IDLitUI::]doAction(*Identifier*)

### Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

### Arguments

#### Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation or action that it implements.

### Keywords

None.

### Version History

6.0	Introduced
-----	------------

## IDLitUI::GetProperty

The IDLitUI::GetProperty procedure method retrieves the value of an IDLitUI property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

### Syntax

*Obj*->[IDLitUI:]GetProperty, [*PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitUI Properties](#)” on page 3760 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitUI::GetTool

The IDLitUI::GetTool function method returns an object reference to the iTool with which the user interface is associated.

### Syntax

*Result* = *Obj*->[IDLitUI::]GetTool()

### Return Value

Returns an object reference to the iTool associated with the current user interface, or a null object if there is no associated iTool.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitUI::GetWidgetByName

The IDLitUI::GetWidgetByName function method returns the IDL Widget ID of a widget that has been registered with the user interface object via a call to the [IDLitUI::RegisterWidget](#) method.

### Syntax

*Result* = *Obj*->[IDLitUI::]GetWidgetByName(*Name*)

### Return Value

Returns the widget identifier (a long integer) of the widget specified by the *Name* argument, or 0 if the widget was not registered with the iTool system.

### Arguments

#### Name

Set this argument to the name that the desired widget was registered with.

### Keywords

None

### Example

This method can be used to determine whether a given widget already exists and act accordingly. For example, the following code checks to determine whether a widget registered as `myWidget` exists; if it does, that widget is mapped and un-iconified:

```
wID = oUI->GetWidgetByName(myWidget)
IF(wID NE 0) THEN BEGIN
    WIDGET_CONTROL, wID, /MAP, ICONIFY=0 ;; show the widget
    RETURN
ENDIF
```

Similar code is used in many of the widget interface elements used by the standard iTools included with IDL.

## Version History

6.0	Introduced
-----	------------

## IDLitUI::Init

The IDLitUI::Init function method initializes the IDLitUI object, and should be called by the Init method of a subclass.

### Note

---

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Obj = OBJ_NEW('IDLitUI', oTool)
```

or

```
Result = Obj->[IDLitUI::]Init(oTool) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### oTool

An object reference to the IDLitTool object with which the user interface object is associated.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitUI::RegisterUIService

The IDLitUI::RegisterUIService function method registers a *user interface service* with the user interface. Once the user interface service has been registered, the iTool with which the user interface is associated can call the UI service to display dialogs or other UI elements.

---

### Note

Every UI service must implement a callback function that displays the requested user interface. See [Chapter 13, “Creating a User Interface Service”](#) in the *iTool Developer’s Guide* manual for details.

---

## Syntax

*Result* = *Obj*->[IDLitUI:]RegisterUIService(*Name*, *Callback*)

## Return Value

Returns an iTool object identifier for the UI service specified by *Name*.

## Arguments

### Name

A string containing the human readable name of the user interface being registered.

### Callback

A string containing the name of the callback function for this UI service. The callback function is called when execution of the UI service is requested. The callback should have the following calling signature:

```
FUNCTION NAME, oUI, oTarget
```

where:

- *NAME* is the name of the callback function,
- *oUI* is an object reference to the user interface object of which the UI service is a part
- *oTarget* is an object reference to the object that is the target of the operation or action with which the UI service is associated.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitUI::RegisterWidget

The IDLitUI::RegisterWidget function method registers an IDL widget hierarchy with the user interface object. Once a widget has been registered with the UI object, the UI can route messages to that widget and manage visibility if the widget is registered with the FLOATING property set.

### Syntax

```
Result = Obj->[IDLitUI::]RegisterWidget(wID, Name, Callback[, /FLOATING])
```

### Return Value

The iTool object identifier of the user interface adaptor that links the widget specified by *wID* with the iTool.

### Arguments

#### wID

A long integer containing the widget ID of the widget being registered. This value is provided to the routine specified by the *Callback* argument when it is called.

#### Name

A string containing the human readable name for the widget being registered.

#### Callback

A string containing the name of a *callback procedure* for the widget. Any notification messages sent by the iTool to this widget are sent to this callback procedure. The callback procedure should have the following calling signature:

```
PRO NAME, wID, strID, message, messageData
```

where:

- *NAME* is the name of the callback procedure,
- *wID* is the widget ID provided to the IDLitUI::RegisterWidget method,
- *strID* is a string containing the object identifier of the iTool object that triggered the message,
- *message* is the message being sent to the callback procedure,

- *messageData* is any data associated with the message.

**Note**

---

If this argument is set to an empty string, no callbacks will be made to this widget.

---

## Keywords

### FLOATING

Set this keyword to treat the widget as a floating element of the specified iTool user interface, to be managed by the user interface object. If this keyword is set, the widget will only be visible if the associated iTool is “current,” and the widget will be destroyed when the iTool is destroyed.

## Version History

6.0	Introduced
-----	------------

## IDLitUI::RemoveOnNotifyObserver

The `IDLitUI::RemoveOnNotifyObserver` procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the `DoOnNotify` method of another specified iTool component object. This method reverses the action of calling the `IDLitUI::AddOnNotifyObserver` method.

### Syntax

*Obj*->[IDLitUI:]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

### Arguments

#### IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

#### IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can also be a string that references a global system service.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitUI:: SetProperty

The IDLitUI::SetProperty procedure method sets the value of an IDLitUI property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj*->[IDLitUI::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitUI::UnRegisterUIService

The IDLitUI::UnRegisterUIService procedure method unregisters a user interface service with the user interface object.

### Syntax

*Obj*->[IDLitUI::](#)UnRegisterUIService, *Name*

### Arguments

#### Name

A string containing the name of the UI service to be unregistered.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitUI::UnRegisterWidget

The IDLitUI::UnRegisterWidget procedure method unregisters a widget with the user interface object.

### Syntax

*Obj*->[IDLitUI:]UnRegisterWidget, *Name*

### Arguments

#### Name

A string containing the name of the widget to be unregistered.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

# IDLitVisualization

The IDLitVisualization class represents the base visualization component, from which all iTool visualization classes should subclass. IDLitVisualization acts as a container and provides methods for adding, removing, and grouping visualization components.

This class is written in the IDL language. Its source code can be found in the file `idlitvisualization__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLgrModel](#)

[IDLitMessaging](#)

[IDLitParameter](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitVisualization::Init](#)” on page 3808.

## Properties

Objects of this class have the following properties. See “[IDLitVisualization Properties](#)” on page 3783 for details on individual properties.

- [CENTER\\_OF\\_ROTATION](#)
- [IMPACTS\\_RANGE](#)
- [ISOTROPIC](#)
- [MANIPULATOR\\_TARGET](#)
- [PROPERTY\\_INTERSECTION](#)
- [SELECT\\_TARGET](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has all the methods associated with the superclasses, plus the following methods:

- [IDLitVisualization::Add](#)
- [IDLitVisualization::Aggregate](#)
- [IDLitVisualization::BeginManipulation](#)
- [IDLitVisualization::Cleanup](#)
- [IDLitVisualization::EndManipulation](#)
- [IDLitVisualization::Get](#)
- [IDLitVisualization::GetCenterRotation](#)
- [IDLitVisualization::GetCurrentSelectionVisual](#)
- [IDLitVisualization::GetDataSpace](#)
- [IDLitVisualization::GetDataString](#)
- [IDLitVisualization::GetDefaultSelectionVisual](#)
- [IDLitVisualization::GetManipulatorTarget](#)
- [IDLitVisualization::GetProperty](#)
- [IDLitVisualization::GetRequestedAxesStyle](#)
- [IDLitVisualization::GetSelectionVisual](#)
- [IDLitVisualization::GetTypes](#)
- [IDLitVisualization::GetXYZRange](#)
- [IDLitVisualization::Init](#)
- [IDLitVisualization::Is3D](#)
- [IDLitVisualization::IsIsotropic](#)
- [IDLitVisualization::IsManipulatorTarget](#)
- [IDLitVisualization::IsSelected](#)
- [IDLitVisualization::Move](#)
- [IDLitVisualization::On2DRotate](#)

- `IDLitVisualization::OnAxesRequestChange`
- `IDLitVisualization::OnAxesStyleRequestChange`
- `IDLitVisualization::OnDataChange`
- `IDLitVisualization::OnDataComplete`
- `IDLitVisualization::OnDataRangeChange`
- `IDLitVisualization::OnDimensionChange`
- `IDLitVisualization::OnWorldDimensionChange`
- `IDLitVisualization::Remove`
- `IDLitVisualization::RequestsAxes`
- `IDLitVisualization::Restore`
- `IDLitVisualization::Rotate`
- `IDLitVisualization::Scale`
- `IDLitVisualization::Select`
- `IDLitVisualization::Set3D`
- `IDLitVisualization::SetAxesRequest`
- `IDLitVisualization::SetAxesStyleRequest`
- `IDLitVisualization::SetCurrentSelectionVisual`
- `IDLitVisualization::SetData`
- `IDLitVisualization::SetDefaultSelectionVisual`
- `IDLitVisualization::SetParameterSet`
- `IDLitVisualization::SetProperty`
- `IDLitVisualization::UpdateSelectionVisual`
- `IDLitVisualization::VisToWindow`
- `IDLitVisualization::WindowToVis`

In addition, this class inherits the methods of its superclasses.

## Examples

See [Chapter 6, “Creating a Visualization”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
6.1	Deprecated GROUP_PARENT property

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

## IDLitVisualization Properties

IDLitVisualization objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitVisualization::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be initialized via [IDLitVisualization::Init](#). Properties with the word “Yes” in the “Set” column of the property table can be set via [IDLitVisualization::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [CENTER\\_OF\\_ROTATION](#)
- [IMPACTS\\_RANGE](#)
- [ISOTROPIC](#)
- [MANIPULATOR\\_TARGET](#)
- [PROPERTY\\_INTERSECTION](#)
- [SELECT\\_TARGET](#)
- [TYPE](#)

In addition, objects of this class inherit:

- [IDLgrModel](#)
- [IDLitIMessaging](#)
- [IDLitParameter](#)

### CENTER\_OF\_ROTATION

A two- or three-element vector,  $[x, y]$  or  $[x, y, z]$  indicating the center (in data coordinates) of rotation for this visualization. If a two-element vector is supplied, the

$z$  value remains unchanged. When retrieving the value of this property, the center of rotation is always returned as a three-element vector.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IMPACTS\_RANGE

A boolean that, when set to 0, indicates that the  $x$ ,  $y$ , and  $z$  range of the contents of this visualization should not impact the  $x$ ,  $y$ , and  $z$  range of any visualization that contains it. By default, IMPACTS\_RANGE is 1.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ISOTROPIC

A boolean that, when set to a non-zero value, indicates that this object should have isotropic scaling applied to it. By default, ISOTROPIC is 0 (isotropic scaling is not enforced).

Setting isotropic scaling to True implies that the dimensions of the visualization can be related to physical dimensions and that the ratio of the dimensions must be preserved. An example is an image, where the pixels are usually square and should remain square.

Setting isotropic scaling to False implies that the visualization dimensions do not relate to physical dimensions and that the ratio of the dimensions is arbitrary. An example is a plot, where the aspect ratio of the X and Y coordinates is arbitrary and can be changed for appearance's sake.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MANIPULATOR\_TARGET

A boolean that, when set to a non-zero value, indicates that this object should be treated as a target for manipulations. By default, MANIPULATOR\_TARGET is 0 (this object is not a target for manipulations).

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PROPERTY\_INTERSECTION

A boolean value that indicates whether the visualization should display the intersection or the union of the properties of any aggregated objects. Visualizations that display the union of their aggregated objects' properties appear in iTool browsers as a single visualization with one set of properties. Visualizations that display the intersection of their aggregated objects' properties appear in iTool browsers as a container for the aggregated objects, allowing access to the contained objects' properties as well as to those of the container. See [“Working with Aggregated Properties”](#) in Chapter 4 of the *iTool Developer's Guide* manual for additional discussion of aggregated properties.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>no default value</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## SELECT\_TARGET

A Boolean value that tags the visualization object as the target object to be returned when any object contained by the visualization is selected via the [IDLitVisualization::Select](#) method.

- 0 = Do not tag the visualization object as the target object.
- 1 = Tag the visualization object as the target object (default).

This property is registered as a Boolean property, but it is hidden by default.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Select target		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TYPE

A string or vector of strings that identify the type(s) that this visualization represents. See [“Predefined iTool Visualization Classes”](#) in Chapter 6 of the *iTool Developer’s Guide* manual for a list of predefined types.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitVisualization::Add

The IDLitVisualization::Add procedure method adds objects to the visualization container.

This method overrides the superclass [IDLgrModel::Add](#) method. This specialized implementation performs the following actions:

- Stores visualizations in the correct order based on type so that they are correctly displayed
- Adds the objects to appropriate positions
- Handles property aggregation (if the AGGREGATE keyword is set)
- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate
- Sends notification that the scene needs to be redrawn (unless the NO\_UPDATE keyword is set)

## Syntax

```
Obj->[IDLitVisualization::]Add, Objects [, /AGGREGATE] [, /NO_UPDATE]  
[, POSITION=index]
```

## Arguments

### Objects

An object reference (or array of object references), each referring to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be added to the visualization container.

## Keywords

### AGGREGATE

Set this keyword to indicate that the object(s) being added should become part of this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (accessible via the GetProperty and SetProperty methods).

## NO\_UPDATE

Set this keyword to indicate that the overall scene should not be updated after the addition of the object(s). By default, the overall scene is updated.

## POSITION

Set this keyword equal to a scalar or vector of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within this visualization container at which the corresponding object should be placed. The default is to add new objects at the end of the list of contained items.

## Version History

6.0	Introduced
6.1	Deprecated GROUP keyword

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

## IDLitVisualization::Aggregate

The IDLitVisualization::Aggregate procedure method adds the given object(s) to this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (via ::GetProperty and ::SetProperty).

### Syntax

*Obj*->[IDLitVisualization::]Aggregate, *Objects*

### Arguments

#### Objects

An object reference (or array of object references), each of which refers to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be aggregated within this visualization container.

### Keywords

None.

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::BeginManipulation

The IDLitVisualization::BeginManipulation procedure method handles notifications that an [IDLitManipulator](#) object is about to manipulate this visualization.

---

**Note**

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in [“Predefined iTool Visualization Classes”](#) in Chapter 6 of the *iTool Developer’s Guide* manual).

---

### Syntax

*Obj->*[IDLitVisualization::]BeginManipulation, *Manipulator*

### Arguments

#### Manipulator

An object reference to the manipulator object sending notification.

### Keywords

None

### Version History

---

6.1	Introduced
-----	------------

---

## IDLitVisualization::Cleanup

The IDLitVisualization::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

### Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitVisualization::]Cleanup (In a lifecycle method only.)

### Arguments

None

### Keywords

None

### Version History

---

6.0	Introduced
-----	------------

---

## IDLitVisualization::EndManipulation

The IDLitVisualization::EndManipulation procedure method handles notifications that an [IDLitManipulator](#) object has finished manipulating this visualization.

---

**Note**

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in [“Predefined iTool Visualization Classes”](#) in Chapter 6 of the *iTool Developer’s Guide* manual).

---

### Syntax

*Obj*->[IDLitVisualization::]EndManipulation, *Manipulator*

### Arguments

#### Manipulator

An object reference to the manipulator object sending notification.

### Keywords

None

### Version History

---

6.1	Introduced
-----	------------

---

## IDLitVisualization::Get

The IDLitVisualization::Get function method retrieves object(s) from the visualization.

### Syntax

```
Result = Obj->[IDLitVisualization::]Get([, /ALL] [, COUNT=variable]
    [, ISA=string or array of strings] [, POSITION=index or array of indices]
    [, /SKIP_PRIVATE])
```

### Return Value

Returns the reference of the object retrieved from the visualization. If the object is not contained by this visualization, a NULL object reference is returned.

### Arguments

None

### Keywords

#### ALL

Set this keyword to return an array of object references to all of the objects in the container.

#### COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

#### ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

#### Note

---

This keyword is ignored if the ALL keyword is not provided.

---

## POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

## SKIP\_PRIVATE

Set this keyword to indicate that this method should return only those objects that do not have the PRIVATE property set.

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetCenterRotation

The IDLitVisualization::GetCenterRotation function method returns the center of rotation for this visualization.

### Syntax

```
Result = Obj->[IDLitVisualization::]GetCenterRotation([, /NO_TRANSFORM]  
[, X RANGE=[xmin, xmax]] [, Y RANGE=[ymin, ymax]] [, Z RANGE=[zmin,  
zmax]))
```

### Return Value

Returns a two- or three-element vector,  $[x, y]$  or  $[x, y, z]$  indicating the center (in data coordinates) of the bounding box for this visualization if the center of rotation was not explicitly specified with the CENTER\_OF\_ROTATION property of this visualization. See the [CENTER\\_OF\\_ROTATION](#) property for more details.

### Arguments

None

### Keywords

#### NO\_TRANSFORM

Set this keyword to indicate that this visualization's transform should not be applied when computing the  $x$ ,  $y$ , and  $z$  ranges. By default, the transform is applied.

#### XRANGE

Set this keyword to a named variable that will contain a 2-element vector,  $[xmin, xmax]$ , representing the  $x$  range of the bounding box for this visualization.

#### YRANGE

Set this keyword to a named variable that will contain a 2-element vector,  $[ymin, ymax]$ , representing the  $y$  range of the bounding box for this visualization.

#### ZRANGE

Set this keyword to a named variable that will contain a 2-element vector,  $[zmin, zmax]$ , representing the  $z$  range of the bounding box for this visualization.

## Version History

6.0	Introduced
6.1	Deprecated DATA keyword

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

## IDLitVisualization::GetCurrentSelectionVisual

The IDLitVisualization::GetCurrentSelectionVisual function method returns the currently active selection visual object for this visualization.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]GetCurrentSelectionVisual()

### Return Value

Returns a reference to an IDLitManipulatorVisual object. If no selection visual is currently active, the NULL object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetDataSpace

The IDLitVisualization::GetDataSpace function method returns a reference to the parent data space object within the graphics hierarchy that contains the visualization.

### Syntax

*Result* = *Obj*->[IDLitVisualization:]GetDataSpace([, /UNNORMALIZED])

### Return Value

Returns a reference to the nearest data space object in the graphics hierarchy. If no data space objects are found by walking up the hierarchy, then a null object reference is returned.

### Arguments

None

### Keywords

#### UNNORMALIZED

Set this keyword to indicate that the returned data space should be the parent data space that subclasses from the IDLitVisDataSpace class (which is not normalized) rather than the IDLitVisNormDataSpace class (which is normalized).

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetDataString

The IDLitVisualization::GetDataString function method retrieves a description of this visualization's data at the given  $x$ ,  $y$ , and  $z$  location.

### Note

---

This method is designed to be implemented as needed by subclasses. The IDLitVisualization::GetDataString method simply always returns an empty string

---

## Syntax

*Result = Obj->*[IDLitVisualization::]GetDataString(*XYZLocation*)

## Return Value

Returns a string describing the visualization's data at the given location.

## Arguments

### XYZLocation

A three-element vector representing the  $x$ ,  $y$ , and  $z$  location of the data for which a string description is to be returned.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetDefaultSelectionVisual

The IDLitVisualization::GetDefaultSelectionVisual function method returns an object that serves as the default selection visual for this visualization.

---

**Note**

If the visualization on which this method is called is not a manipulator target (see “[MANIPULATOR\\_TARGET](#)” on page 3785), the default selection visual returned by this method will be used as the current selection visual whenever the visualization is selected.

---

### Syntax

*Result* = *Obj*->[IDLitVisualization:]GetDefaultSelectionVisual()

### Return Value

Returns a reference to an IDLitManipulatorVisual object.

### Arguments

None

### Keywords

None

### Version History

---

6.0	Introduced
-----	------------

---

## IDLitVisualization::GetManipulatorTarget

The IDLitVisualization::GetManipulatorTarget function method retrieves the manipulator target associated with this visualization. The manipulator target may be this visualization itself.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]GetManipulatorTarget()

### Return Value

Returns an object reference to the manipulator target, or a NULL object reference if none is found.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetProperty

The IDLitVisualization::GetProperty procedure method retrieves the value of a property or group of properties for the object.

### Syntax

*Obj*->[IDLitVisualization::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 3783 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetRequestedAxesStyle

The IDLitVisualization::GetRequestedAxesStyle function method returns a scalar value indicating the axes style requested by this visualization. This method returns the axes style request made by the first visualization within the hierarchy (beginning with the root visualization) to make a request. If none of the visualizations in the hierarchy requests an axes style then -1 is returned.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]GetRequestedAxesStyle( )

### Return Value

Returns a scalar value indicating the requested axes style. Possible return values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 7-1: Axes Style Values

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::GetSelectionVisual

The IDLitVisualization::GetSelectionVisual function method retrieves the selection visual for this visualization that corresponds to the given manipulator.

### Syntax

*Result* = *Obj*->[IDLitVisualization:]GetSelectionVisual(*Manipulator*)

### Return Value

Returns a reference to an IDLitManipulatorVisual object that corresponds to the given manipulator. If this visualization already has a selection visual for the given manipulator, a reference to that selection visual is returned. Otherwise, a default selection visual will be requested from the manipulator, added to the visualization, and returned.

### Arguments

#### Manipulator

Set this argument to a reference to an IDLitManipulator object that identifies the manipulator for which a selection visual is to be retrieved.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetTypes

The IDLitVisualization::GetTypes function method identifies the types that this visualization represents, including base types and any specializations.

### Note

This method is designed to be implemented as needed by subclasses of the IDLitVisualization class. Calling this method on the IDLitVisualization class itself returns the following string array: ['VISUALIZATION', '\_VISUALIZATION', *AnySpecifiedTypes*] where *AnySpecifiedTypes* are provided by any value set for the TYPE property of the IDLitVisualization class.

## Syntax

*Result* = *Obj*->[IDLitVisualization::]GetTypes()

## Return Value

Returns a vector of strings identifying the types that this visualization represents. See “[Predefined iTool Visualization Classes](#)” in Chapter 6 of the *iTool Developer’s Guide* manual for a list of predefined types

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::GetXYZRange

The IDLitVisualization::GetXYZRange function method computes the *x*, *y*, and *z* ranges of the overall contents of the visualization, taking into account the IMPACTS\_RANGE property setting for itself and its contents.

### Syntax

```
Result = Obj->[IDLitVisualization::]GetXYZRange(XRange,YRange,ZRange  
[, /DATA] [, /NO_TRANSFORM])
```

### Return Value

Returns a 1 if the *x*, *y*, and *z* ranges were successfully computed, or 0 otherwise.

### Arguments

#### XRange

A named variable that, upon return, will contain a two-element vector, [*xmin*, *xmax*], representing the *x*-range of the contents of this visualization that impact ranges.

#### YRange

A named variable that, upon return, will contain a two-element vector, [*ymin*, *ymax*], representing the *y*-range of the contents of this visualization that impact ranges.

#### ZRange

A named variable that, upon return, will contain a two-element vector, [*zmin*, *zmax*], representing the *z*-range of the contents of this visualization that impact ranges.

### Keywords

#### DATA

Set this keyword to indicate that the ranges should be computed for the full data sets of the contents of this visualization. By default, if the keyword is not set, the ranges are computed for the displayed portions of the data sets.

## **NO\_TRANSFORM**

Set this keyword to indicate that this visualization's transform matrix should not be applied when computing the  $x$ ,  $y$ , and  $z$  ranges. By default, the transform matrix is applied.

## **Version History**

6.0	Introduced
-----	------------

## IDLitVisualization::Init

The IDLitVisualization::Init function method initializes the visualization object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLitVisualization' [, *PROPERTY=value*] )

or

*Result* = *Obj*->[IDLitVisualization::]Init( [, *PROPERTY=value*] )    (*In a lifecycle method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitVisualization Properties” on page 3783 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::Is3D

The IDLitVisualization::Is3D function method determines whether or not this visualization is marked as being three-dimensional.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]Is3D()

### Return Value

Returns 1 if this visualization is marked as being three-dimensional, or 0 if it is not three-dimensional.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::IsIsotropic

The IDLitVisualization::IsIsotropic function method indicates whether or not this visualization (or any of its contents) is marked as being isotropic. See the [ISOTROPIC](#) property for more information.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]IsIsotropic()

### Return Value

Returns 1 if the visualization or any of the items it contains has the ISOTROPIC property set, or 0 otherwise.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::IsManipulatorTarget

The IDLitVisualization::IsManipulatorTarget function method determines whether or not this visualization is a manipulator target.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]IsManipulatorTarget()

### Return Value

Returns 1 if this visualization is a manipulator target, or 0 if it is not.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::IsSelected

The IDLitVisualization::IsSelected function method determines if this visualization is currently selected or not.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]IsSelected()

### Return Value

Returns 1 if this visualization is currently selected, or 0 if it is not selected.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::Move

The IDLitVisualization::Move procedure method moves an object from one position in the visualization container to a new position. Use the [IDLitVisualization::Get](#) method to return the objects within the visualization.

The positions of the objects within a container controls how they are rendered. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later.

---

### Note

This method overrides the [IDL\\_Container::Move](#) method, which IDLitVisualization inherits since IDL\_Container is a superclass of IDLgrModel. This specialized implementation of the Move method ensures visualizations are stored in the correct order based on type when they are moved. Those items that must appear on top of other objects are stored as the last items in the list of objects contained by this visualization.

---

## Syntax

*Obj->*[IDLitVisualization::]Move, *Source*, *Destination*

## Arguments

### Source

The zero-based index of the current location of the object to be moved.

### Destination

The zero-based index of the new location where the object will reside after being moved.

## Keywords

None

## Version History

6.1	Introduced
-----	------------

## IDLitVisualization::On2DRotate

The IDLitVisualization::On2DRotate procedure method notifies objects that use the visualization's data when the rotation of the parent dataspace changes.

### Syntax

*Obj->*[IDLitVisualization::]On2DRotate, *Notifier*, *IsRotated*

### Arguments

#### Notifier

An object reference to the parent object that is sending notification when the dataspace rotation changes.

#### IsRotated

A scalar value that is non-zero if the dataspace is now rotated, or zero otherwise.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::OnAxesRequestChange

The IDLitVisualization::OnAxesRequestChange procedure method notifies objects that use the visualization's data when the axes of a contained object change.

### Syntax

*Obj*->[IDLitVisualization::]OnAxesRequestChange, *Notifier*, *AxesRequest*

### Arguments

#### Notifier

An object reference to the object that is sending notification when axes change.

#### AxesRequest

A scalar value representing the new axes request. Allowable values are:

Value	Requested Axes
0	No axes requested.
1	Axes requested.
2	Axes should be automatically computed.

*Table 7-2: Allowable AxesRequest Values*

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::OnAxesStyleRequestChange

The IDLitVisualization::OnAxesStyleRequestChange procedure method notifies objects that use the visualization's data when the axes style of a contained object changes.

### Syntax

*Obj*->[IDLitVisualization::]OnAxesStyleRequestChange, *Notifier*, *StyleRequest*

### Arguments

#### Notifier

An object reference to the object that is sending notification when the axes style changes.

#### StyleRequest

A scalar value representing the new axes style request. Allowable values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

*Table 7-3: Axes Style Values*

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::OnDataChange

The IDLitVisualization::OnDataChange procedure method notifies objects that use the visualization's data when the visualization's data changes.

**Note**

This method is generally not called explicitly.

## Syntax

*Obj*->[IDLitVisualization::](#)OnDataChange, *Notifier*

## Arguments

### Notifier

A reference to the object that is sending notification when the data changes.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::OnDataComplete

The IDLitVisualization::OnDataComplete procedure method notifies objects that use the visualization's data when changes to the visualization's data are complete.

**Note**

This method is generally not called explicitly.

## Syntax

*Obj*->[IDLitVisualization::]OnDataComplete, *Notifier*

## Arguments

### Notifier

A reference to the object that is sending notification when the data changes are complete.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::OnDataRangeChange

The IDLitVisualization::OnDataRangeChange procedure method notifies objects that use the visualization's data when the range of the visualization's data changes.

**Note**

This method is generally not called explicitly.

### Syntax

*Obj*->[IDLitVisualization::](#)OnDataRangeChange, *Notifier*, *XRange*, *YRange*, *Zrange*

### Arguments

#### Notifier

A reference to the object that is sending notification when the data range changes.

#### XRange

A two-element vector, [*xmin*, *xmax*], representing the new *x*-range.

#### YRange

A two-element vector, [*ymin*, *ymax*], representing the new *y*-range.

#### ZRange

A two-element vector, [*zmin*, *zmax*], representing the new *z*-range.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::OnDimensionChange

The IDLitVisualization::OnDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's data changes.

### Syntax

*Obj*->[IDLitVisualization::]OnDimensionChange, *Notifier*, *Is3D*

### Arguments

#### Notifier

An object reference to the object that is sending notification when the dimensionality changes.

#### Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::OnWorldDimensionChange

The IDLitVisualization::OnWorldDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's parent dataspace changes.

### Syntax

*Obj->*[IDLitVisualization::]OnWorldDimensionChange, *Notifier*, *Is3D*

### Arguments

#### Notifier

An object reference to the parent object that is sending notification when the dimensionality changes.

#### Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::Remove

The IDLitVisualization::Remove procedure method removes the given object(s) from the visualization.

This method overrides the [IDL\\_Container::Remove](#) method, which IDLitVisualization inherits since IDL\_Container is a superclass of IDLgrModel. This specialized implementation of the Remove method performs the following actions:

- Handles property aggregation
- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate
- Sends notification that the scene needs to be redrawn (unless the NO\_UPDATE keyword is set)

### Syntax

*Obj*->[IDLitVisualization::]Remove, *Object* [, /NO\_UPDATE]

### Arguments

#### Object

A reference (or vector of references) to the object(s) to be removed from this visualization.

### Keywords

#### NO\_UPDATE

Set this keyword to indicate the scene should not be updated after objects are removed. By default, the overall scene is updated.

### Version History

6.0	Introduced
6.1	Added NO_UPDATE keyword

## IDLitVisualization::RequestsAxes

The IDLitVisualization::RequestsAxes function method indicates whether or not the visualization requests axes. Most visualization classes do request axes. However, axes, images, ROIs, map grids, profile lines, and backgrounds do not request axes.

### Syntax

*Result* = *Obj*->[IDLitVisualization::]RequestsAxes( )

### Return Value

Returns a 1 if the visualization does request axes, or 0 if does not request axes.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLitVisualization::Restore

The IDLitVisualization::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

---

**Note**

This method overrides the implementation in the IDLitComponent class. This specialized implementation ensures that all axes requests and axis style requests are set properly.

---

## Syntax

*Obj*->[IDLitVisualization::]Restore

## Arguments

None

## Keywords

None

## Version History

---

6.1	Introduced
-----	------------

---

## See Also

[IDL\\_Savefile](#), [SAVE](#), [RESTORE](#)

## IDLitVisualization::Rotate

The IDLitVisualization::Rotate procedure method rotates this visualization about the given axis by the given angle.

This method overrides the superclass's [IDLgrModel::Rotate](#) method. This specialized implementation rotates about a center of rotation rather than about the origin, [0,0,0].

### Syntax

```
Obj->[IDLitVisualization::]Rotate, Axis, Angle [, CENTER_OF_ROTATION=[x, y, z]] [, /PREMULTIPLY]
```

### Arguments

#### Axis

A three-element vector of the form [x, y, z] describing the axis about which the visualization is to be rotated.

#### Angle

A scalar value indicating the angle of rotation (measured in degrees).

### Keywords

#### CENTER\_OF\_ROTATION

Set this keyword to a three-element vector, [x, y, z], representing the center of the rotation. By default, the visualization's own center of rotation (accessible through [“IDLitVisualization::GetCenterRotation”](#) on page 3795) will be used.

#### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to this visualization's current transformation matrix. By default, the rotation matrix is post-multiplied.

#### Note

---

In pre-multiplication, the current visualization's transform and scaling are applied before the specified rotation. In post-multiplication, the specified rotation is applied before the visualization's transformation and scaling.

---

## Version History

6.1	Introduced
-----	------------

## IDLitVisualization::Scale

The IDLitVisualization::Scale procedure method scales the visualization by the given scale factors.

### Syntax

*Obj*->[IDLitVisualization::]Scale, SX, SY, SZ [, CENTER\_OF\_ROTATION=[x, y] | [x, y, z]] [, /PREMULTIPLY]

### Arguments

#### SX

The factor in the  $x$ -dimension by which the visualization is to be scaled.

#### SY

The factor in the  $y$ -dimension by which the visualization is to be scaled.

#### SZ

The factor in the  $z$ -dimension by which the visualization is to be scaled.

### Keywords

#### CENTER\_OF\_ROTATION

Set this keyword to a 2- or 3-element vector, [x, y] or [x,y,z], representing the center of rotation (in data coordinates) to be used as the center for scaling. By default, if PREMULTIPLY is set, then this visualization's own center of rotation will be used as the center for scaling; if PREMULTIPLY is not set, the result of transforming this visualization's center of rotation by its own transformation matrix will be used as the center for scaling.

#### PREMULTIPLY

Set this keyword to cause the scaling matrix specified by  $S_x$ ,  $S_y$ , and  $S_z$  to be pre-multiplied to this visualization's transformation matrix. By default, the scaling matrix is post-multiplied.

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::Select

The IDLitVisualization::Select procedure method handles notification of mechanisms that key off the current selection (such as the visualization browser) when this visualization has been selected.

### Syntax

```
Obj->[IDLitVisualization::]Select[, Mode]  
    [, /ADDITIVE | /SELECT | /TOGGLE | /UNSELECT] [, /NO_NOTIFY]
```

### Arguments

#### Mode

A scalar that indicates the selection mode. Valid values include:

- 0 - Unselect (deselect this visualization).
- 1 - Select (set this visualization as the current selection). This mode is the default.
- 2 - Toggle (toggle the selection of this visualization). Use the **CRTL** key to toggle.
- 3 - Additive (add this visualization to the current selection list). Use the **SHIFT** key to add.

### Keywords

#### ADDITIVE

Set this keyword to indicate that the selection mode is additive. This is equivalent to setting *Mode* to 3.

#### NO\_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of this selection. By default, the parent is notified.

#### SELECT

Set this keyword to indicate that the selection mode is select. This is equivalent to setting *Mode* to 1.

## TOGGLE

Set this keyword to indicate that the selection mode is toggle. This is equivalent to setting *Mode* to 2.

## UNSELECT

Set this keyword to indicate that the selection mode is unselect. This is equivalent to setting *Mode* to 0.

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::Set3D

The IDLitVisualization::Set3D procedure method sets a flag indicating this visualization is three-dimensional.

### Syntax

```
Obj->[IDLitVisualization::]Set3D, Is3D [, /ALWAYS] [, /AUTO_COMPUTE]
```

### Arguments

#### Is3D

A non-zero value indicates that the visualization is three-dimensional; 0 indicates that it is two-dimensional.

### Keywords

#### ALWAYS

Set this keyword to indicate that the given 3-D setting always applies.

#### AUTO\_COMPUTE

Set this keyword to indicate that the 3-D setting for this visualization should be auto-computed based upon the dimensionality of its contents. This keyword is mutually exclusive of the ALWAYS keyword, and the *Is3D* argument is ignored if AUTO\_COMPUTE is set.

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::SetAxesRequest

The IDLitVisualization::SetAxesRequest procedure method sets the current axes request for this visualization.

### Syntax

```
Obj->[IDLitVisualization::]SetAxesRequest [, AxesRequest]  
[, /ALWAYS | /AUTO_COMPUTE] [, /NO_NOTIFY]
```

### Arguments

#### AxesRequest

A scalar value indicating whether this visualization requests axes:

- 0 – Axes are not requested by the visualization
- 1 – Axes are requested by the visualization.

#### Note

---

If this argument is not present, the visualization is marked as requesting axes.

---

### Keywords

#### ALWAYS

Set this keyword to always request or not request axes as specified by the *AxesRequest* argument. This setting will override the requests made by children of the visualization.

#### AUTO\_COMPUTE

Set this keyword to compute the axes for this visualization based on the axes requested by objects contained in the visualization.

#### Note

---

This keyword is mutually exclusive of the ALWAYS keyword. If this keyword is set, the *AxesRequest* argument is ignored.

---

## **NO\_NOTIFY**

Set this keyword to indicate that this visualization's parent should not be notified of a change in axes request. By default, the parent is notified.

## **Version History**

6.1	Introduced
-----	------------

## IDLitVisualization::SetAxesStyleRequest

The IDLitVisualization::SetAxesStyleRequest procedure method sets the current axes style request for this visualization. The axes container is automatically created whenever a data space is instantiated, but the default axes style property is 0 (None) until visualizations are added.

Whenever a visualization is added to the visualization container, it is queried for axes requirements. Most visualization classes do request axes (with the exception of axes, images, ROIs, map grids, profile lines, and backgrounds). When visualizations are added, and the current axes style value is 0 (None), then the axes style will be changed as follows:

- The axes style is set according to the request of the first visualization in the hierarchy to request a *particular* axes style. By default, most visualizations do not request a particular style. The exceptions are plots, which request style 2 (Box Axes) if non-polar, or style 3 (Crosshairs) if polar.
- The default style 1 (At Dataspace Minimum) is used if none of the visualizations in the hierarchy request a particular axes style.

### Syntax

*Obj*->[IDLitVisualization::]SetAxesStyleRequest, *StyleRequest* [, /NO\_NOTIFY]

### Arguments

#### StyleRequest

A scalar value representing the requested axes style. The value should correspond to one of the values listed in the following table:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested a particular axes style.

Table 7-4: Axes Style Values

## Keywords

### NO\_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in the axes style request. By default, the parent is notified.

## Version History

6.1	Introduced
-----	------------

## IDLitVisualization::SetCurrentSelectionVisual

The IDLitVisualization::SetCurrentSelectionVisual procedure method sets the current selection visual for the given manipulator.

### Syntax

*Obj->*[IDLitVisualization::]SetCurrentSelectionVisual, *Manipulator*

### Arguments

#### Manipulator

An object reference (that subclasses from IDLitManipulator) identifying the manipulator that corresponds to the selection visual to be set as current.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::SetData

The IDLitVisualization::SetData function method sets the data parameter of the visualization.

### Note

If the SetData method returns successfully, notification of a data change is issued to all observers of the data object.

## Syntax

```
Result = Obj->[IDLitVisualization::]SetData(Data)
```

## Return Value

Returns a 1 if successful, or 0 if it fails.

## Arguments

### Data

A reference to the data object to be associated with the visualization parameter.

## Keywords

This method accepts all keywords accepted by the IDLitParameter::SetData method.

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::SetDefaultSelectionVisual

The IDLitVisualization::SetDefaultSelectionVisual procedure method sets the default selection visual to be associated with this visualization.

### Note

If the visualization on which this method is called is not a manipulator target (see “[MANIPULATOR\\_TARGET](#)” on page 3785) the default selection visual set by this method will be used as the current selection visual whenever the visualization is selected.

## Syntax

```
Obj->[IDLitVisualization::]SetDefaultSelectionVisual, SelectionVisual
[, POSITION=value]
```

## Arguments

### SelectionVisual

A reference to the IDLitManipulatorVisual object that is added to the visualization object and serves as the default selection visual for this visualization.

## Keywords

### POSITION

Set this keyword equal to the zero-based position at which the selection visual should be inserted within the container. The default is to add the object to the end of the container (the visualization object).

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::SetParameterSet

The IDLitVisualization::SetParameterSet function method associates a parameter set with this visualization.

### Note

If the SetParameterSet method returns successfully, notification of a data change is issued to all observers of the visualization's data.

## Syntax

*Result = Obj->*[IDLitVisualization::]SetParameterSet(*ParameterSet*)

## Return Value

Returns a 1 if successful, or a 0 otherwise.

## Arguments

### ParameterSet

A reference to the IDLitParameterSet object to be associated with the visualization.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization:: SetProperty

The IDLitVisualization::SetProperty procedure method sets the value of a property or group of properties for the object.

### Syntax

*Obj*->[IDLitVisualization::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 3783 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::UpdateSelectionVisual

The IDLitVisualization::UpdateSelectionVisual procedure method transforms this visualization's selection visual to match the visualization's geometry.

### Syntax

*Obj*->[IDLitVisualization::](#)UpdateSelectionVisual

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitVisualization::VisToWindow

The IDLitVisualization::VisToWindow procedure method transforms given points from visualization data space to window device coordinates.

### Syntax

```
Obj->[IDLitVisualization::]VisToWindow, InX, InY, InZ, OutX, OutY, OutZ  
    [, /NO_TRANSFORM]
```

or

```
Obj->[IDLitVisualization::]VisToWindow, InX, InY, OutX, OutY  
    [, /NO_TRANSFORM]
```

or

```
Obj->[IDLitVisualization::]VisToWindow, InVerts, OutVerts [, /NO_TRANSFORM]
```

### Arguments

#### InX

A vector of input X values (in visualization data space).

#### InY

A vector of input Y values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

#### InZ

A vector of input Z values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

#### InVerts

A [2, *n*] or [3, *n*] array of input vertices (in visualization data space).

#### OutX

A named variable that will contain a vector of output X values (in window device coordinates).

## OutY

A named variable that will contain a vector of output Y values (in window device coordinates).

## OutZ

A named variable that will contain a vector of output Z values (in window device coordinates).

## OutVerts

A named variable that will contain a vector of output vertices (in window device coordinates).

## Keywords

### NO\_TRANSFORM

If this keyword is set, the current transformation matrix is not included in the computation. Setting this keyword is useful when computing selection visual scaling.

## Version History

6.0	Introduced
-----	------------

## IDLitVisualization::WindowToVis

The IDLitVisualization::WindowToVis procedure method transforms given points from window device coordinates to visualization data space.

### Syntax

*Obj*->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *InZ*, *OutX*, *OutY*, *OutZ*

or

*Obj*->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *OutX*, *OutY*

or

*Obj*->[IDLitVisualization::]WindowToVis, *InVerts*, *OutVerts*

### Arguments

#### InX

A vector representing the input x values (in window device coordinates).

#### InY

A vector representing the input y values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

#### InZ

A vector representing the input z values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

#### InVerts

A [2, *n*] or [3, *n*] array representing the input vertices (in window device coordinates).

#### OutX

A named variable that upon return will contain a vector representing the output x values (in visualization data space).

#### OutY

A named variable that upon return will contain a vector representing the output y values (in visualization data space).

## OutZ

A named variable that upon return will contain a vector representing the output z values (in visualization data space).

## OutVerts

A named variable that upon return will contain a vector representing the output vertices (in visualization data space).

## Keywords

None

## Version History

6.0	Introduced
-----	------------

# IDLitWindow

The IDLitWindow class serves as the base class for all windows within the iTools framework.

## Superclasses

[IDLgrWindow](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitWindow::Init](#)” on page 3862.

## Properties

Objects of this class inherit properties from the IDLgrWindow superclass. See “[IDLgrWindow Properties](#)” on page 4567 for descriptions of these properties.

## Methods

This class has the following methods:

- [IDLitWindow::Add](#)
- [IDLitWindow::AddWindowEventObserver](#)
- [IDLitWindow::Cleanup](#)
- [IDLitWindow::ClearSelections](#)
- [IDLitWindow::DoHitTest](#)
- [IDLitWindow::GetEventMask](#)
- [IDLitWindow::GetProperty](#)
- [IDLitWindow::GetSelectedItems](#)
- [IDLitWindow::Init](#)
- [IDLitWindow::OnKeyboard](#)

- [IDLitWindow::OnMouseDown](#)
- [IDLitWindow::OnMouseMove](#)
- [IDLitWindow::OnMouseUp](#)
- [IDLitWindow::OnScroll](#)
- [IDLitWindow::OnTimer](#)
- [IDLitWindow::Remove](#)
- [IDLitWindow::RemoveWindowEventObserver](#)
- [IDLitWindow::SetCurrentZoom](#)
- [IDLitWindow::SetEventMask](#)
- [IDLitWindow::SetManipulatorManager](#)
- [IDLitWindow::SetProperty](#)
- [IDLitWindow::SetTimerInterval](#)
- [IDLitWindow::ZoomIn](#)
- [IDLitWindow::ZoomOut](#)

In addition, this class inherits the methods of its superclass.

## Version History

6.0	Introduced
6.2	Added OnTimer and SetTimerInterval methods

## IDLitWindow Properties

IDLitWindow objects inherit properties from the IDLgrWindow superclass. See [“IDLgrWindow Properties”](#) on page 4567 for descriptions of these properties.

Properties with the word “Yes” in the “Get” column of the table can be retrieved via [IDLitWindow::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitWindow::SetProperty](#).

## IDLitWindow::Add

The IDLitWindow::Add procedure method adds the given object(s) to the window.

### Syntax

*Obj*->[IDLitWindow::]Add, *Objects* [, POSITION=*value*]

### Arguments

#### Objects

A reference (or array of references) to the object(s) to be added to the window. Any of the objects that inherit from IDLgrViewGroup are added directly to the window's scene, which represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window. The remaining objects are added to the current view within the window's scene.

### Keywords

#### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the position within the container at which the new object should be placed.

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::AddWindowEventObserver

The IDLitWindow::AddWindowEventObserver procedure method adds the given object(s) to the list of observers that are to be notified of events that occur within the window. Each observer must support one or both of the following interfaces by implementing all methods that comprise each desired interface:

### Mouse/Keyboard Interface

- OnKeyboard
- OnMouseDown
- OnMouseMove
- OnMouseUp

### Timer Interface

- OnTimer

---

#### Note

See “[Designing a Behavior Object](#)” in Chapter 10 of the *Object Programming* manual for examples that implement the OnTimer event in an animation display.

---

When an event occurs within this window, the corresponding method (from the list above) will be called for each observer in the window’s list.

## Syntax

*Obj*->[IDLitWindow::]AddWindowEventObserver, *Objects*

## Arguments

### Objects

A reference (or vector of references) to the object(s) to be added as window event observers.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWindow::Cleanup

The IDLitWindow::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitWindow::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWindow::ClearSelections

The IDLitWindow::ClearSelections procedure method clears the window's list of currently selected items (within its current view). The items within the current view that had been selected are deselected.

### Syntax

*Obj*->[IDLitWindow::](#)ClearSelections

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::DoHitTest

The IDLitWindow::DoHitTest function method performs a hit test to determine which visualizations within the destination are displayed at a given pixel location.

### Note

The objects returned in *Result* are the “top-level” objects (usually IDLgrModel or IDLitVisualization objects). Objects *contained* by the returned objects can be returned using the SUB\_HIT keyword.

## Syntax

```
Result = Obj->[IDLitWindow::]DoHitTest(X, Y [, DIMENSIONS=[width, height]]
    [, /ORDER] [, SUB_HIT=variable] [, UNITS={0 | 1 | 2 | 3}])
```

## Return Value

Returns a vector of references to the objects (usually IDLgrModel or IDLitVisualization objects) that appear at the given location. If no visualizations are displayed at that location, a null reference is returned.

## Arguments

### X

A floating-point value representing the *x*-location at which the hit test is to be performed

### Y

A floating-point value representing the *y*-location at which the hit test is to be performed.

## Keywords

### DIMENSIONS

Set this keyword to a two-element integer vector, [*w*, *h*], to specify the dimensions (width and height) of the hit test box. The hit test box is centered at the location specified by the *X* and *Y* arguments. Any object that falls within this hit test box will be included in the return vector. By default, the hit test box is 3 pixels by 3 pixels.

## ORDER

Set this keyword to control the ordering of objects in the returned hit test list when the objects are at the same distance from the viewer. Set ORDER=0 (the default) to return the objects in the order in which they were drawn. Set ORDER=1 to return objects in the reversed order from which they were drawn.

### Note

If the visualization objects use DEPTH\_TEST\_FUNCTION=4 (less than or equal), then it is recommended that the ORDER keyword be set to 1 to ensure that objects at the same depth are returned in the same order in which they appear visually.

## SUB\_HIT

Set this keyword to a named variable that will contain references to all *contained* visualization objects that satisfy all of the following conditions:

- The objects are contained by the nearest hit visualization (the first object in the return value)
- The objects are SELECT\_TARGETs (see “IDLgrModel” on page 4153)
- The objects are actively displayed at the given X and Y coordinates

The results of SUB\_HIT are returned in the order in which the sub-hit visualizations appear in the graphics hierarchy. Sub-hits are only returned for the first visualization.

## UNITS

Set this keyword to a scalar value to indicate the units of measure for the X, Y arguments and the DIMENSIONS keyword. Valid values include:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of this window

## Version History

6.0	Introduced
6.1	Added ORDER keyword

## IDLitWindow::GetEventMask

The IDLitWindow::GetEventMask function method returns a bitwise mask representing the events that are enabled for this window.

### Syntax

```
Result = Obj->[IDLitWindow::]GetEventMask([, BUTTON_EVENTS=variable]
[, KEYBOARD_EVENTS=variable] [, MOTION_EVENTS=variable]
[, TIMER_EVENTS=variable] [, TRACKING_EVENTS=variable])
```

### Return Value

Returns the bitwise mask as an unsigned long integer. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events
4	16	Timer Events

Table 7-5: Bits of the Event Mask

### Arguments

None

### Keywords

#### BUTTON\_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if mouse button events are currently enabled for this window, or a 0 otherwise.

## KEYBOARD\_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if keyboard events are currently enabled for this window, or a 0 otherwise.

## MOTION\_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if mouse motion events are currently enabled for this window, or a 0 otherwise.

## TIMER\_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if timer events are currently enabled for this window, or a 0 otherwise.

## TRACKING\_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if tracking events are currently enabled for this window, or a 0 otherwise.

## Version History

6.0	Introduced
6.2	Added TIMER_EVENTS keyword

## IDLitWindow::GetProperty

The IDLitWindow::GetProperty procedure method retrieves the value of an IDLitWindow property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

### Syntax

*Obj*->[IDLitWindow::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 3850 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::GetSelectedItems

The IDLitWindow::GetSelectedItems function method returns the objects (visualizations only, by default) currently selected within this window's scene.

### Syntax

```
Result = Obj->[IDLitWindow::]GetSelectedItems([, /ALL] [, COUNT=named variable])
```

### Return Value

Returns a vector of references to the objects currently selected within this window's scene. If no objects are currently selected, this function returns a -1.

### Arguments

None

### Keywords

#### ALL

Set this keyword to return all classes of selected items. By default, only visualizations are returned.

#### COUNT

Set this keyword to a named variable that will contain the number of items returned by this method.

### Version History

6.0	Introduced
6.1	Added ALL keyword

## IDLitWindow::Init

The IDLitWindow::Init function method initializes the window object.

This function method initializes the IDLitWindow object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

### Note

---

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Obj = OBJ_NEW('IDLitWindow'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitWindow::]Init([, PROPERTY=value]) (In a lifecycle method  
only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 3850 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitWindow::OnKeyboard

The IDLitWindow::OnKeyboard procedure method handles notification (from the native window device) that a keyboard event has occurred, and passes along that notification to all observers in the list of window event observers. With proper event handling, these values are passed into the procedure arguments. Alternatively, keyboard events can be simulated by calling this method directly.

### Syntax

*Obj*->[IDLitWindow:]OnKeyboard, *Window*, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*,  
*Press*, *Release*, *Modifiers*

### Arguments

#### Window

An object reference to the IDLitWindow object in which the event was generated.

#### IsASCII

A scalar value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to that ASCII character. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

#### Character

If *IsASCII* is non-zero, this argument is set to the ASCII character that corresponds to the key that was pressed. Otherwise, this argument is set to zero.

#### KeySymbol

If *IsASCII* is zero, this argument is set to an unsigned long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt

- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

## X,Y

The *x*-coordinate and *y*-coordinate of the mouse cursor (in device coordinates) at the time of the event.

## Press

A scalar value indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

## Release

A scalar value indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

## Modifiers

A bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

*Table 7-6: Modifier Values*

## Keywords

None

## Version History

6.0	Introduced
6.1	Corrected syntax to read <i>IsASCII</i> instead of <i>IsAlphaNumeric</i> Corrected <i>KeySymbol</i> values Added <i>X, Y, Press, Release, Modifiers</i> arguments

## IDLitWindow::OnMouseDown

The IDLitWindow::OnMouseDown procedure method handles notification (from the native window device) that a mouse down event has occurred, and passes along that notification to all observers in the list of window event observers.

---

**Note**

The IDLitWindow object *does not* emulate a middle mouse button press when the user holds down the CONTROL key and presses the left mouse button, as does the WIDGET\_DRAW routine. See [“Note on Middle Mouse Button Emulation”](#) on page 2609 for information on the behavior of the draw widget.

---

## Syntax

*Obj*->[IDLitWindow:]OnMouseDown, *Window*, *X*, *Y*, *ButtonMask*, *Modifiers*,  
*NumClicks*

## Arguments

### Window

An object reference to the IDLitWindow object in which the event was generated.

### X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

### Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

## ButtonMask

An integer value of a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

*Table 7-7: Bitmask for Button Events*

## Modifiers

An integer value of a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

*Table 7-8: Bits of the Modifier Key Mask*

## NumClicks

An integer value indicating the number of times the mouse button was clicked.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWindow::OnMouseMotion

The IDLitWindow::OnMouseMotion procedure method handles notification (from the native window device) that a mouse motion event has occurred, and passes along that notification to all observers in the list of window event observers.

---

**Note**

The IDLitWindow object *does not* emulate a middle mouse button press when the user holds down the CONTROL key and presses the left mouse button, as does the WIDGET\_DRAW routine. See “[Note on Middle Mouse Button Emulation](#)” on page 2609 for information on the behavior of the draw widget.

---

### Syntax

*Obj->*[IDLitWindow:]OnMouseMotion, *Window*, *X*, *Y*, *Modifiers*

### Arguments

#### Window

An object reference to the IDLitWindow object in which the event was generated.

#### X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

#### Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

## Modifiers

An integer value of a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

*Table 7-9: Bits of the Modifier Key Mask*

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWindow::OnMouseUp

The IDLitWindow::OnMouseUp procedure method handles notification (from the native window device) that a mouse up event has occurred, and passes along that notification to all observers in the list of window event observers.

### Note

The IDLitWindow object *does not* emulate a middle mouse button press when the user holds down the CONTROL key and presses the left mouse button, as does the WIDGET\_DRAW routine. See “[Note on Middle Mouse Button Emulation](#)” on page 2609 for information on the behavior of the draw widget.

## Syntax

*Obj*->[IDLitWindow::]OnMouseUp, *Window*, *X*, *Y*, *ButtonMask*

## Arguments

### Window

An object reference to the IDLitWindow object in which the event was generated.

### X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

### Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

### ButtonMask

An integer value of a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left

Table 7-10: Bitmask for Button Events

Bitmask	Mouse Button
2	Middle
4	Right

*Table 7-10: Bitmask for Button Events*

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWindow::OnScroll

The `IDLitWindow::OnScroll` procedure method handles notification (from the native window device) that a scrolling event has occurred. This notification is passed on to the window's scene, which handles the cropping of each of its contained views. A scene represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window.

### Syntax

*Obj*->[IDLitWindow::]OnScroll, *X*, *Y*

### Arguments

#### X

A floating-point value representing the *x*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

#### Y

A floating-point value representing the *y*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::OnTimer

The IDLitWindow::OnTimer procedure method handles notification (from the native window device) that a timer event has occurred, and passes that notification to all observers in the list of window event observers by calling each observer's OnTimer method. IDL stops with an error if the observer class does not implement an OnTimer method.

### Note

See “[Designing a Behavior Object](#)” in Chapter 10 of the *Object Programming* manual for examples that implement the OnTimer method in an animation display.

## Syntax

*Obj*->[IDLitWindow::]OnTimer, *Window*

## Arguments

### Window

The window parameter is the object reference to the window on which the timer event occurred.

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLitWindow::Remove

The IDLitWindow::Remove procedure method removes the given object(s) from the window.

### Syntax

*Obj*->[IDLitWindow::]Remove, *Object* [, /ALL] [, POSITION=index]

### Arguments

#### Object

A reference (or vector of references) to the object(s) to be removed from this window.

### Keywords

#### ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Object* argument is not required.

#### POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Object* argument is supplied, this keyword is ignored.

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::RemoveWindowEventObserver

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

### Syntax

*Obj*->[IDLitWindow::]RemoveWindowEventObserver, *Objects*

### Arguments

#### Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::SetCurrentZoom

The `IDLitWindow::SetCurrentZoom` procedure method sets the current zoom factor for this window by changing its virtual dimensions. Setting the zoom factor on this window overrides any zoom factor inherited from the `IDLgrWindow`. The contents of the window are updated to reflect the new zoom factor.

### Syntax

*Obj*->[`IDLitWindow::`]SetCurrentZoom, *ZoomFactor* [, /RESET]

### Arguments

#### ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 result in a zooming out; values greater than 1.0 result in a zooming in on the contents of the window.

### Keywords

#### RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::SetEventMask

The IDLitWindow::SetEventMask procedure method enables the given events within this window.

When an event occurs within this window, if the corresponding event type is enabled, then the list of its window event observers will be notified of the event. See “IDLitWindow::AddWindowEventObserver” on page 3852 for more details.

### Syntax

```
Obj->[IDLitWindow::]SetEventMask([EventMask] [, /BUTTON_EVENTS]
    [, /KEYBOARD_EVENTS] [, /MOTION_EVENTS] [, /TIMER_EVENTS]
    [, /TRACKING_EVENTS])
```

### Arguments

#### EventMask

An unsigned long integer representing the bitwise mask for the events that are to be enabled for this window. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events
4	16	Timer Events

Table 7-11: Bits of the Event Mask

This argument is optional; the keywords described below may be used instead.

### Keywords

#### BUTTON\_EVENTS

Set this keyword to indicate that mouse button events are to be enabled for this window.

## **KEYBOARD\_EVENTS**

Set this keyword to indicate the keyboard events are to be enabled for this window.

## **MOTION\_EVENTS**

Set this keyword to indicate that mouse motion events are to be enabled for this window.

## **TIMER\_EVENTS**

Set this keyword to indicate that timer events are to be enabled for this window.

## **TRACKING\_EVENTS**

Set this keyword to indicate that tracking events are to be enabled for this window.

## **Version History**

6.0	Introduced
6.2	Added <code>TIMER_EVENTS</code> keyword

## IDLitWindow::SetManipulatorManager

The IDLitWindow::SetManipulatorManager procedure method sets the given IDLitManipulatorManager object as the current manager of this window's manipulators.

### Syntax

*Obj*->[IDLitWindow::](#)SetManipulatorManager, *Manager*

### Arguments

#### Manager

A reference to the IDLitManipulatorManager object that is to serve as the manager for this window's manipulators.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWindow:: SetProperty

The IDLitWindow::SetProperty procedure method sets the value of an IDLitWindow property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj*->[IDLitWindow::]SetProperty[, *PROPERTY=*value]

### Arguments

None

### Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 3850 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::SetTimerInterval

The IDLitWindow::SetTimerInterval procedure method specifies the floating-point number of seconds between timer events. When a timer event occurs, the window calls the OnTimer method of all window event observers. The generation of timer events is controlled by the window event mask.

See “[Controlling the Animation Rate](#)” in Chapter 10 of the *Object Programming* manual for examples of using this method in an animation display.

### Syntax

*Obj*->[IDLitWindow::](#)SetTimerInterval, *Interval*

### Arguments

#### Interval

The default interval value is 0, which indicates that the timer event interval is the smallest amount of time allowed by the system.

### Keywords

None

### Version History

6.2	Introduced
-----	------------

## IDLitWindow::ZoomIn

The `IDLitWindow::ZoomIn` procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the inherited `IDLgrWindow ZOOM_BASE` property). The contents of the window are updated to reflect the new zoom factor. See “[IDLitWindow::SetCurrentZoom](#)” on page 3878 for additional details.

### Syntax

*Obj*->`[IDLitWindow::]ZoomIn`

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWindow::ZoomOut

The IDLitWindow::ZoomOut procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the inherited IDLgrWindow `ZOOM_BASE` property). The current contents of the window are updated to reflect the new zoom factor. See “IDLitWindow::SetCurrentZoom” on page 3878 for additional details.

### Syntax

*Obj*->[IDLitWindow::]ZoomOut

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

# IDLitWriter

The IDLitWriter class defines the interface used to construct file writers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file writer class.

This class is written in the IDL language. Its source code can be found in the file `idlitwriter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

### Note

---

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

---

## Creation

See “[IDLitWriter::Init](#)” on page 3893.

## Properties

Objects of this class have the following properties. See “[IDLitWriter Properties](#)” on page 3888 for details on individual properties.

- [TYPES](#)

## Methods

This class has the following methods:

- [IDLitWriter::Cleanup](#)
- [IDLitWriter::GetFileExtensions](#)
- [IDLitWriter::GetFilename](#)
- [IDLitWriter::GetProperty](#)

- [IDLitWriter::Init](#)
- [IDLitWriter::IsA](#)
- [IDLitWriter::SetData](#)
- [IDLitWriter::SetFilename](#)
- [IDLitWriter::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

## Examples

See [Chapter 10, “Creating a File Writer”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

6.0	Introduced
-----	------------

## IDLitWriter Properties

IDLitWriter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via [IDLitWriter::GetProperty](#). Properties with the word “Yes” in the “Init” column of the properties table can be initialized via [IDLitWriter::Init](#). Properties with the word “Yes” in the “Set” column of the properties table can be set via [IDLitWriter::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [TYPES](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)
- [IDLitIMessaging](#)

### TYPES

Set this property to a string or an array of strings indicating the types of data that this file writer accepts. iTools data types are described in [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual. Set this property to a null string ( ' ' ) to specify that the file reader can accept all types of data.

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLitWriter::Cleanup

The IDLitWriter::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLitWriter::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWriter::GetFileExtensions

The IDLitWriter::GetFileExtensions method is called by the system to retrieve the file extensions supported by this particular writer.

### Syntax

*Result* = *Obj*->[IDLitWriter:]GetFileExtensions( [, **COUNT**=*count*])

### Return Value

Returns a scalar or string array that contains the file extensions associated with this writer.

### Arguments

None

### Keywords

#### COUNT

Set this keyword to a named variable that will contain the number of file extensions returned by this method.

### Version History

6.0	Introduced
-----	------------

## IDLitWriter::GetFilename

The IDLitWriter::GetFilename function method is called by the system to retrieve the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time. This method allows direct access to the file currently associated with the writer.

In addition, this methodology is helpful when multiple writes are performed from a given file.

### Syntax

```
Result = Obj->[IDLitWriter:]GetFilename()
```

### Return Value

Returns a string containing the current file name associated with this writer, or an empty string if no filename has been associated.

### Arguments

None

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWriter::GetProperty

The IDLitWriter::GetProperty procedure method retrieves the value of an IDLitWriter property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

### Syntax

*Obj->*[IDLitWriter::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 3888 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.0	Introduced
-----	------------

## IDLitWriter::Init

The IDLitWriter::Init function method initializes the IDLitWriter object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW( 'IDLitWriter' [, Extensions] [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitWriter::]Init( [, Extensions] [, PROPERTY=value] ) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

## Arguments

### Extensions

A optional argument containing a scalar or string array with the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (i.e., a correct value is 'jpeg' and not '.jpeg'). If this argument is not set, or if a null string is provided, IDL does not include this file writer in the list of filters in a file-selection dialog, but still uses it when attempting to match a file to a writer.

## Keywords

Any property listed under [“IDLitWriter Properties”](#) on page 3888 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.0	Introduced
-----	------------

## IDLitWriter::IsA

The IDLitWriter::IsA function method is called by the system to determine if the given file is of the type supported by this file writer. Often this is used to determine what file writer to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new writer is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

## Syntax

```
Result = Obj->[IDLitWriter:]IsA(Filename)
```

## Return Value

Returns a 1 if the writer supports this type of file, or a 0 if the writer does not support this type of file.

## Arguments

### Filename

A string scalar representing of the filename, which is used to check and determine if the writer supports its format.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLitWriter::SetData

The IDLitWriter::SetData function method is called by the system to set the data for the current file. When called, the writer should access the current filename and write the desired data.

This method will contain a majority of the implementation for a new writer class.

### Syntax

*Result = Obj->[IDLitWriter::]SetData(Data)*

### Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

### Arguments

#### Data

A data object that contains the information to be written.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWriter::SetFilename

The IDLitWriter::SetFilename procedure method is called by the system to set the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time.

### Syntax

*Obj*->[IDLitWriter::]SetFilename, *Filename*

### Arguments

#### Filename

A string that contains the filename associated with this writer.

### Keywords

None

### Version History

6.0	Introduced
-----	------------

## IDLitWriter:: SetProperty

The IDLitWriter::SetProperty procedure method sets the value of an IDLitWriter property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

### Syntax

*Obj->*[IDLitWriter::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 3888 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.0	Introduced
-----	------------

# IDLgrAxis

An axis object represents a single vector that may include a set of tick marks, tick labels, and a title.

An IDLgrAxis object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrAxis::Init](#)” on page 3930.

## Properties

Objects of this class have the following properties. See “[IDLgrAxis Properties](#)” on page 3902 for details on individual properties.

- [ALL](#)
- [AM\\_PM](#)
- [COLOR](#)
- [DAYS\\_OF\\_WEEK](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DIRECTION](#)
- [EXTEND](#)
- [HIDE](#)
- [LOG](#)
- [MINOR](#)
- [NOTEXT](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [ALPHA\\_CHANNEL](#)
- [CLIP\\_PLANES](#)
- [CRANGE](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [EXACT](#)
- [GRIDSTYLE](#)
- [LOCATION](#)
- [MAJOR](#)
- [MONTHS](#)
- [PALETTE](#)
- [RANGE](#)
- [SUBTICKLEN](#)

- [TEXTALIGNMENTS](#)
- [TEXTPOS](#)
- [THICK](#)
- [TICKFORMAT](#)
- [TICKINTERVAL](#)
- [TICKLEN](#)
- [TICKUNITS](#)
- [TITLE](#)
- [XCOORD\\_CONV](#)
- [YCOORD\\_CONV](#)
- [ZCOORD\\_CONV](#)

- [TICKLAYOUT](#)
- [TICKTEXT](#)
- [TICKVALUES](#)
- [USE\\_TEXT\\_COLOR](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrAxis::Cleanup](#)
- [IDLgrAxis::GetCTM](#)
- [IDLgrAxis::GetProperty](#)
- [IDLgrAxis::Init](#)
- [IDLgrAxis::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property

## IDLgrAxis Properties

IDLgrAxis objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrAxis::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrAxis::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrAxis::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [AM\\_PM](#)
- [COLOR](#)
- [DAYS\\_OF\\_WEEK](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DIRECTION](#)
- [EXTEND](#)
- [HIDE](#)
- [LOG](#)
- [MINOR](#)
- [NOTEXT](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [TEXTALIGNMENTS](#)
- [TEXTPOS](#)
- [THICK](#)
- [TICKFORMAT](#)
- [TICKINTERVAL](#)
- [ALPHA\\_CHANNEL](#)
- [CLIP\\_PLANES](#)
- [CRANGE](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [EXACT](#)
- [GRIDSTYLE](#)
- [LOCATION](#)
- [MAJOR](#)
- [MONTHS](#)
- [PALETTE](#)
- [RANGE](#)
- [SUBTICKLEN](#)
- [TEXTBASELINE](#)
- [TEXTUPDIR](#)
- [TICKDIR](#)
- [TICKFRMTDATA](#)
- [TICKLAYOUT](#)

- [TICKLEN](#)
- [TICKUNITS](#)
- [TITLE](#)
- [XCOORD\\_CONV](#)
- [YCOORD\\_CONV](#)
- [ZCOORD\\_CONV](#)
- [TICKTEXT](#)
- [TICKVALUES](#)
- [USE\\_TEXT\\_COLOR](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

---

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the entire axis, including tick text and title text. The default value of 1.0 causes IDL to draw the axis completely opaque. If the value of this property is less than 1.0, then the pixels of the axis are blended with the pixels already on the screen, where the color of the axis is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color mode. When the `USE_TEXT_COLOR` property is set to a non-zero value, the tick and title text is drawn using the value of the `ALPHA_CHANNEL` property from the tick and/or title text objects. In other words, `USE_TEXT_COLOR` also implies using the text objects' alpha as well as its color.

**Note**

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**AM\_PM**

A string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the TICKFORMAT property.

<b>Property Type</b>	String array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**CLIP\_PLANES**

A 4 by  $n$  floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**COLOR**

The color to be used as the foreground color for this axis. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

<b>Property Type</b>	Color		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**CRANGE**

A double-precision floating-point vector of the form [*minval*, *maxval*] that will contain the actual full range of the axis. This computed range may not exactly match the requested range provided via the `RANGE` property due to tick mark rounding and effects of the `EXTEND` property.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DAYS\_OF\_WEEK

A string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the TICKFORMAT property.

<b>Property Type</b>	String array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

### Note

---

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH\_TEST\_FUNCTION and DEPTH\_WRITE\_DISABLE properties are effectively ignored.

---

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value.

The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIRECTION

An integer value that specifies which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis. Specifying this property is the same as specifying the optional *Direction* argument.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Direction		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## EXACT

A Boolean value that determines whether to force the axis range to be exactly as specified. If this property is not set, the range may be lengthened or shortened slightly to allow for evenly spaced tick marks.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Use exact axis range		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## EXTEND

A Boolean value that determines whether to extend the axis slightly beyond the range of data to be plotted, which is a value specified by the RANGE property. This can be useful when you specify the axis range based on the minimum and maximum data values, but do not want the graphic to extend all the way to the end of the axis. The amount by which the axis is extended is determined by the system using a number of factors, including the MAJOR property of the axis.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Extend axis		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## GRIDSTYLE

An integer or two-element vector that indicates the line style that should be used to draw the axis' tick marks. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the GRIDSTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq repeat \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `GRIDSTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as a Linestyle drop-down list, with the following options:

<b>Property Type</b>	Linestyle		
<b>Name String</b>	Line style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value indicating whether this object should be drawn. Options:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In property sheets, this property appears as an enumerated list, with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LOCATION

A two- or three-element floating-point vector of the form  $[x, y]$  or  $[x, y, z]$  to specify the coordinate through which the axis should pass. The default is  $[0, 0, 0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LOG

A Boolean value that indicates whether the axis is logarithmic.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Use logarithmic axis		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MAJOR

An integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of major ticks		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of minor ticks		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MONTHS

A string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the TICKFORMAT property.

<b>Property Type</b>	String array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## NOTEXT

A Boolean value indicating whether the tick labels and the axis title should be drawn.

- 0 = Draw tick labels and axis title (the default).
- 1 = Do not draw tick labels and axis title.

In a property sheet, this property appears as an enumerated list. Options:

- True = Draw tick labels and axis title (the default).
- False = Do not draw the tick labels and axis title.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Text show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

The object reference of a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## RANGE

A two-element floating-point vector containing the minimum and maximum data values covered by the axis. The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Minor tick length		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TEXTALIGNMENTS

A two-element floating-point vector, [*horizontal*, *vertical*], specifying the horizontal and vertical alignments for the tick text. Each alignment value should be a value between 0.0 and 1.0. For horizontal alignment, 0.0 left-justifies the text; 1.0 right-justifies the text. For vertical alignment, 0.0 bottom-justifies the text, 1.0 top-justifies the text.

The defaults are as follows:

- X-Axis: [0.5, 1.0] (centered horizontally, top-justified vertically)
- Y-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)
- Z-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)

Set this property to a scalar value to *restore* the default values after they have been explicitly set.

<b>Property Type</b>	Floating-point scalar or vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TEXTBASELINE

A two- or three-element floating-point vector describing the direction in which the baseline of the tick text is to be oriented. Use this property in conjunction with the

TEXTUPDIR property to specify the plane on which the tick text lies. The default is [1,0,0].

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TEXTPOS

An integer that indicates on which side of the axis to draw the tick text labels. The table below describes the placement of the tick text with each setting.

Axis	TEXTPOS = 0	TEXTPOS = 1
<b>X</b>	Tick text will be drawn <i>below</i> the X axis, where <i>below</i> is defined as being toward the direction of the negative Y axis (this is the default).	Tick text will be drawn <i>above</i> the X axis, where <i>above</i> is described as being toward the direction of the positive Y axis.
<b>Y</b>	Tick text will be drawn to the <i>left</i> of the Y Axis, where <i>left</i> is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the <i>right</i> of the Y axis, where <i>right</i> is defined as being toward the direction of the positive X axis.
<b>Z</b>	Tick text will be drawn to the <i>left</i> of the Z axis, where <i>left</i> is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the <i>right</i> of the Z axis, where <i>right</i> is defined as being toward the direction of the positive X axis.

*Table 8-1: Values for the TEXTPOS property*

In a property sheet, this property appears as an enumerated list. Options:

- Below/left: Text will be drawn below the axis and to the left.
- Above/right: Text will be drawn above the axis and to the right.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Text position		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TEXTUPDIR

A two- or three-element floating-point vector describing the direction in which the up-vector of the tick text is to be oriented. Use this property in conjunction with the TEXTBASELINE property to specify the plane on which the tick text lies.

TEXTUPDIR should be orthogonal to TEXTBASELINE. The default is as follows:

- X-Axis: [0, 1, 0]
- Y-Axis: [0, 1, 0]
- Z-Axis: [0, 0, 1]

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value in points between 1.0 and 10.0 that specifies the line thickness used to draw the axis. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as a Thickness drop-down list with the following options:

<b>Property Type</b>	Thickness		
<b>Name String</b>	Line thickness		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKDIR

An integer value of zero or one to indicate the tick mark direction.

Axis	TICKDIR = 0	TICKDIR = 1
X	Tick marks will be drawn above the X axis, in the direction of the positive Y axis (this is the default).	Tick marks will be drawn below the X axis.
Y	Tick marks will be drawn to the right of the Y axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Y axis.
Z	Tick marks will be drawn to the right the Z axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Z axis.

*Table 8-2: Tick Mark Direction Values*

In a property sheet, this property appears as an enumerated list, with the following options:

- Right/above: Tick marks will be drawn above the axis and to the right.
- Left/below: Tick marks will be drawn below the axis and to the left.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Tick direction		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKFORMAT

A string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. (The [TICKUNITS](#) property determines the number of levels for an axis.) If the number of strings stored in this property is one, `GetProperty` returns a scalar string, otherwise `GetProperty` returns an array of strings.

If the string begins with an open parenthesis, it is treated as a standard format string. (See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.)

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [TICKUNITS](#) is specified.

### If [TICKUNITS](#) are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

### If [TICKUNITS](#) are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Whether or not [TICKUNITS](#) is specified, the callback function can also define a `DATA` keyword. If the callback function accepts the `DATA` keyword, it will be set equal to the value (if any) of the [TICKFRMTDATA](#) property.

**Note**

For more information, see “[XYZ]TICKFORMAT” on page 4790.

Used with the LABEL\_DATE function, this property can easily create axes with date/time labels.

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**TICKFRMTDATA**

A value of any type that will be passed to the user-supplied formatting callback function (specified via the TICKFORMAT property) as the value of the DATA keyword. By default, this value is undefined, indicating that the value of the DATA keyword will be undefined.

**Note**

TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrAxis::GetProperty method.

<b>Property Type</b>	Scalar of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**TICKINTERVAL**

A floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis RANGE and the number of major tick marks (MAJOR). This property takes precedence over MAJOR.

For example, if TICKUNITS=['S','H','D'], and TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Tick interval		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKLAYOUT

An integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

### Note

---

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

In a property sheet, this property appears as an enumerated list with the following options:

- Axis plus labels: Same as the 0 value above.
- Labels only: Same as the 1 value above.
- Box style: Same as the 2 value above.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Tick layout		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Major tick length		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKTEXT

An object reference to a single instance of the [IDLgrText](#) object class (with multiple strings) or a vector of instances of the [IDLgrText](#) object class (one per major tick) to specify the annotations to be assigned to the tickmarks. By default, with `TICKTEXT` set equal to a null object, IDL computes the tick labels based on major tick values. The positions of the provided text objects may be overwritten; position is determined according to tick mark location. The tickmark text will have the same color as the [IDLgrAxis](#) object, regardless of the color specified by the `COLOR` property of the [IDLgrText](#) object or objects, unless the `USE_TEXT_COLOR` property is specified.

### Note

If IDL computes the tick labels, the text object it creates will be destroyed automatically when the axis object is destroyed, even if you have altered the properties of the text object. If you create your own text object containing tickmark text, however, it will *not* be destroyed automatically.

<b>Property Type</b>	Object reference or string vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TICKUNITS

A string (or a vector of strings) indicating the units to be used for axis tick labeling. If the number of levels in the axis is one, `GetProperty` returns a scalar string, otherwise `GetProperty` returns an array of strings.

If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

#### Note

---

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 A.D., respectively.

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	STRING		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKVALUES

A floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis

range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TITLE

An object reference to an instance of the [IDLgrText](#) object class that specifies the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location. The title will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object, unless the USE\_TEXT\_COLOR property is specified.

The IDLgrText object becomes a child of the IDLgrAxis object; therefore, to use the same IDLgrText object for multiple axes, you must use multiple IDLgrAxis objects.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## USE\_TEXT\_COLOR

A Boolean value that indicates whether, for the tick text and/or title of the axis, the color property values set for the given [IDLgrText](#) objects are to be used to draw those text items. By default, this value is zero, indicating that the color properties of the IDLgrText objects will be ignored, and that the COLOR property for the axis object will be used for these text items instead.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element double-precision floating-point vector of the form  $[x_{min}, x_{max}]$  that specifies the range of  $x$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element double-precision floating-point vector of the form  $[ymin, ymax]$  that specifies the range of  $y$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element double-precision floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrAxis::Cleanup

The IDLgrAxis::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrAxis::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrAxis::GetCTM

The IDLgrAxis::GetCTM function method returns the graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrAxis::]GetCTM([, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref])
```

### Return Value

Returns the 4 x 4 double-precision floating-point graphics transform matrix.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the axis object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrAxis::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrAxis::GetProperty

The IDLgrAxis::GetProperty procedure method retrieves the value of a property or group of properties for the axis.

### Syntax

*Obj*->[IDLgrAxis::](#)GetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3902 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.0	Introduced
-----	------------

## IDLgrAxis::Init

The IDLgrAxis::Init function method initializes an axis object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrAxis' [, *Direction*] [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrAxis::]Init([*Direction*] [, *PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Direction

An integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis.

## Keywords

Any property listed under “IDLgrAxis Properties” on page 3902 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

5.0	Introduced
-----	------------

## IDLgrAxis:: SetProperty

The IDLgrAxis::SetProperty procedure method sets the value of a property or group of properties for the axis.

### Syntax

*Obj*->[IDLgrAxis::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3902 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrBuffer

An IDLgrBuffer object is an in-memory, off-screen destination object. Object trees can be drawn to instances of the IDLgrBuffer object and the resulting image can be retrieved from the buffer using the Read() method. The off-screen representation avoids dithering artifacts by providing a full-resolution buffer for objects using either the RGB or Color Index color models.

---

**Note**

Objects or subclasses of this type can not be saved or restored.

---

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrBuffer::Init](#)” on page 3955.

## Properties

Objects of this class have the following properties. See “[IDLgrBuffer Properties](#)” on page 3935 for details on individual properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS\\_TREE](#)
- [IMAGE\\_DATA](#)
- [N\\_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN\\_DIMENSIONS](#)

- [UNITS](#)
- [ZBUFFER\\_DATA](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrBuffer::Cleanup](#)
- [IDLgrBuffer::Draw](#)
- [IDLgrBuffer::Erase](#)
- [IDLgrBuffer::GetContiguousPixels](#)
- [IDLgrBuffer::GetDeviceInfo](#)
- [IDLgrBuffer::GetFontnames](#)
- [IDLgrBuffer::GetProperty](#)
- [IDLgrBuffer::GetTextDimensions](#)
- [IDLgrBuffer::Init](#)
- [IDLgrBuffer::PickData](#)
- [IDLgrBuffer::QueryRequiredTiles](#)
- [IDLgrBuffer::Read](#)
- [IDLgrBuffer::Select](#)
- [IDLgrBuffer::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
6.2	Added QueryRequiredTiles method

## IDLgrBuffer Properties

IDLgrBuffer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrBuffer::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrBuffer::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrBuffer::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS\\_TREE](#)
- [IMAGE\\_DATA](#)
- [N\\_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN\\_DIMENSIONS](#)
- [UNITS](#)
- [ZBUFFER\\_DATA](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object (except IMAGE\_DATA and ZBUFFER\_DATA).

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR\_MODEL

A Boolean value that determines the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Color model		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DIMENSIONS

A two-element integer vector of the form [*width, height*] that specifies the dimensions of the buffer in units specified by the UNITS property. The default is [640,480].

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GRAPHICS\_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS\_TREE property is set equal to the null-object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IMAGE\_DATA

A byte array representing the image that is currently rendered within the buffer. If the buffer uses an RGB color model, the returned array will have dimensions (3, *xdim*, *ydim*). If the window object uses an indexed color model, the returned array will have dimensions (*xdim*, *ydim*).

<b>Property Type</b>	Byte array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## N\_COLORS

An integer that determines the number of colors (between 2 and 256) to be used if COLOR\_MODEL is set to Color Index.

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of colors		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values to be loaded into the buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## QUALITY

An integer that indicates the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Draw quality		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] that specifies the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Resolution		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SCREEN\_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the buffer object.

### Note

---

The maximum buffer dimension size is always 4096 by 4096.

---

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to 1600 x 1200

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZBUFFER\_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrBuffer::Cleanup

The IDLgrBuffer::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrBuffer:]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::Draw

The IDLgrBuffer::Draw procedure method draws the given picture to this graphics destination.

### Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

## Syntax

```
Obj->[IDLgrBuffer::]Draw [, Picture] [, CREATE_INSTANCE={1 | 2}]  
[, DRAW_INSTANCE={1 | 2}]
```

## Arguments

### Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object) or scene (an instance of an [IDLgrScene](#) object) to be drawn.

## Keywords

### CREATE\_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

### DRAW\_INSTANCE

Set this keyword to specify that the instance, or unchanging part of the drawing, is drawn to the device first. IDL then draws the changing part of the drawing, indicated by the scene, view or viewgroup specified by the Picture argument.

If the value of this keyword is 1, IDL copies both the instance image (color buffer) and the instance depth buffer to the device.

If the value of this keyword is 2, IDL copies only the instance image to the device.

## Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::Erase

The IDLgrBuffer::Erase procedure method erases this graphics destination.

### Syntax

*Obj*->[IDLgrBuffer::]Erase [, COLOR=*index or RGB vector*]

### Arguments

None

### Keywords

#### COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*].

### Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::GetContiguousPixels

The `IDLgrBuffer::GetContiguousPixels` function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the `N_COLORS` property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the `SHADE_RANGE` property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

## Syntax

*Result* = *Obj*->[[IDLgrBuffer::](#)]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::GetDeviceInfo

The IDLgrBuffer::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

### Syntax

```
Obj->[IDLgrBuffer:]GetDeviceInfo [, ALL=variable]
    [, MAX_NUM_CLIP_PLANES=variable]
    [, MAX_TEXTURE_DIMENSIONS=variable]
    [, MAX_TILE_DIMENSIONS=variable]
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

### Arguments

None

### Keywords

#### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

#### MAX\_NUM\_CLIP\_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

#### MAX\_TEXTURE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_TEXTURE\_DIMENSIONS contains a two-element integer array that specifies the maximum texture size supported by the device.

## MAX\_TILE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_TILE\_DIMENSIONS contains a two element integer array that specifies the maximum tile size supported by the device.

## MAX\_VIEWPORT\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_VIEWPORT\_DIMENSIONS contains a two-element integer array that specifies the maximum size of a graphics display supported by the device.

## NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

## NUM\_CPUS

Set this keyword equal to a named variable. Upon return, NUM\_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

### Note

---

The NUM\_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

---

## VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

## VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

## Version History

5.0	Introduced
-----	------------

5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

## IDLgrBuffer::GetFontnames

The `IDLgrBuffer::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned. See [Appendix H, “Fonts”](#) for more information.

### Syntax

```
Result = Obj->[IDLgrBuffer::]GetFontnames( FamilyName[, IDL_FONTS={0 | 1 | 2  
}] [, STYLES=string] )
```

### Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

### Arguments

#### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “\*”.

### Keywords

#### IDL\_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

#### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “\*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::GetProperty

The IDLgrBuffer::GetProperty procedure method retrieves the value of a property or group of properties for the buffer.

### Syntax

*Obj*->[IDLgrBuffer::](#)GetProperty[, *PROPERTY=variable*]

### Keywords

Any property listed under “[IDLgrBuffer Properties](#)” on page 3935 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

### Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::GetTextDimensions

The `IDLgrBuffer::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector  $[xDim, yDim, zDim]$  representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

### Syntax

```
Result = Obj->[IDLgrBuffer::]GetTextDimensions( TextObj [, DESCENT=variable]
[, PATH=objref(s)] )
```

### Return Value

Returns the dimensions of a text or axis object that will be rendered in a window.

### Arguments

#### TextObj

The object reference to a text or axis object for which text dimensions are requested.

### Keywords

#### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values represent the distance to travel (parallel to the `UPDIR` vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an `IDLgrText` object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the `PARENT` properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If

IDLgrBuffer::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

## Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::Init

The IDLgrBuffer::Init function method initializes the buffer object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrBuffer' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrBuffer::]Init( [, PROPERTY=value)  (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrBuffer Properties” on page 3935 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::PickData

The IDLgrBuffer::PickData function method maps a point in the two-dimensional device space of the buffer to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

### Note

---

The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData. For example, you may use the DEPTH\_WRITE\_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn. This prevents the object from affecting the result returned by the PickData method.

---

## Syntax

```
Result = Obj->[IDLgrBuffer::]PickData( View, Object, Location, XYZLocation  
    [, DIMENSIONS=[width,height]][, PATH=objref(s)]  
    [, PICK_STATUS=variable])
```

## Return Value

Returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

## Arguments

### View

The object reference of an IDLgrView object that contains the object being picked.

### Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

**Note**

---

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

---

**Location**

A two-element vector  $[x, y]$  specifying the location in the buffer's device space of the point to pick data from.

**XYZLocation**

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

**Note**

---

If the atomic graphic object specified as the target has been transformed using either the `LOCATION` or `DIMENSIONS` properties (this is only possible with `IDLgrAxis`, `IDLgrImage`, and `IDLgrText` objects), these transformations will *not* be included in the data coordinates returned by the `PickData` function. This means that you may need to re-apply the transformation accomplished by specifying `LOCATION` or `DIMENSIONS` once you have retrieved the data coordinates with `PickData`. This situation does not occur if you transform the axis, text, or image object using the `[XYZ]COORD_CONV` properties.

---

**Keywords****DIMENSIONS**

Set this keyword to a two-element array  $[w, h]$  to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates  $[x, y]$  specified in the *Location* argument, and will occupy the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions  $[3, w, h]$ .

## PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

### Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

## PICK\_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK\_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK\_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK\_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 8-3: PICK\_STATUS Keyword Values

## Version History

5.0	Introduced
5.6	Added PICK_STATUS keyword

## IDLgrBuffer::QueryRequiredTiles

The IDLgrBuffer::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

### Note

If the device is in Color Index mode (COLOR\_MODEL=1) or the image has [RENDER\\_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

## Syntax

```
Result = Obj->[IDLgrBuffer::]QueryRequiredTiles( View, Image
  [, COUNT=variable] [, ALL_VISIBLE=value] )
```

## Return Value

Returns an array of structures for required tiles or 0 (zero) if no tiles are required. Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.

Table 8-4: IDLIMAGETILE Structure

Field	Data Type	Description
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of $n$ ( $n > 0$ ) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 8-4: IDLIMAGETILE Structure (Continued)

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

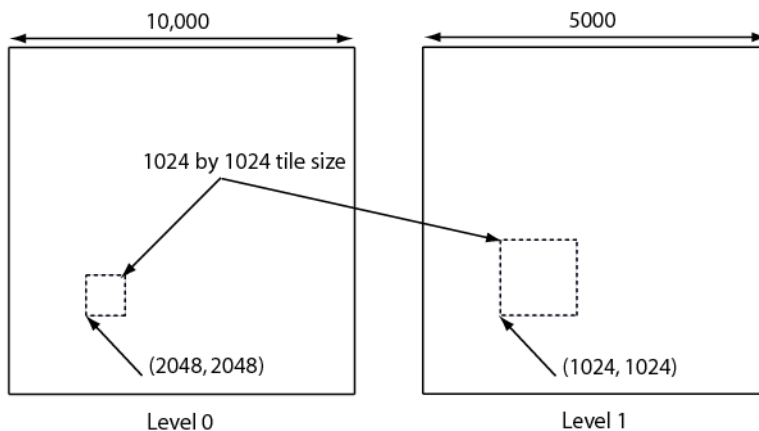

Figure 8-1: Interaction Between Image Level and Zoom with Equal Tile Sizes

**Note**

---

See “[Image Tiling](#)” in Chapter 4 of the *Object Programming* manual for more information on creating an image pyramid and for tiling examples.

---

## Arguments

### View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

### Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

## Keywords

### COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

### ALL\_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

## Version History

6.2	Introduced
-----	------------

## IDLgrBuffer::Read

The IDLgrBuffer::Read function method reads an image from a buffer. The returned value is an instance of the [IDLgrImage](#) object class.

### Syntax

*Result* = *Obj*->[IDLgrBuffer::]Read()

### Return Value

Returns an instance of the [IDLgrImage](#) object class.

### Arguments

None

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrBuffer::Select

The IDLgrBuffer::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

---

**Note**

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

---

## Syntax

```
Result = Obj->[IDLgrBuffer::]Select(Picture, XY [, DIMENSIONS=[width, height]]  
[, /ORDER] [, SUB_SELECTION=variable] [, UNITS={0 | 1 | 2 | 3}])
```

## Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

## Arguments

### Picture

The view, viewgroup, or scene (an instance of the [IDLgrView](#), IDLgrViewgroup, or [IDLgrScene](#) class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT\_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

### XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

# Keywords

## DIMENSIONS

Set this keyword to a two-element array  $[w, h]$  to specify that the selection box will have a width  $w$  and a height  $h$ , and will be centered about the coordinates  $[x, y]$  specified in the  $XY$  argument. The box occupies the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

Any object which intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

## ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If  $ORDER=0$  (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If  $ORDER=1$ , the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

### Tip

---

If you are using  $DEPTH\_TEST\_FUNCTION=4$  (“less than or equal”) on your graphics objects, set  $ORDER=1$  to return objects at the same depth in the order in which they appear visually.

---

## SUB\_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)
- Select targets (IDLgrModel objects with the  $SELECT\_TARGET$  property set)
- Graphic objects displayed at the given  $XY$  location

## UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)

- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination.

## Version History

5.0	Introduced
6.1	Added SUB_SELECTION keyword

## IDLgrBuffer:: SetProperty

The IDLgrBuffer::SetProperty procedure method sets the value of a property or group of properties for the buffer.

### Syntax

*Obj*->[IDLgrBuffer::]SetProperty[, *PROPERTY=**value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrBuffer Properties” on page 3935 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrClipboard

An IDLgrClipboard object sends Object Graphics output to the operating system native clipboard or to a file in bitmap or vector format. The FILENAME, VECTOR, and POSTSCRIPT keyword values in the IDLgrClipboard::Draw method, and the platform on which the call is issued determine the file type and destination. See [IDLgrClipboard::Draw](#) for details.

---

**Note**

Objects or subclasses of this type can not be saved or restored.

---

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrClipboard::Init](#)” on page 3995.

## Properties

Objects of this class have the following properties. See “[IDLgrClipboard Properties](#)” on page 3973 for details on individual properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS\\_TREE](#)
- [N\\_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN\\_DIMENSIONS](#)
- [UNITS](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrClipboard::Cleanup](#)
- [IDLgrClipboard::Draw](#)
- [IDLgrClipboard::GetContiguousPixels](#)
- [IDLgrClipboard::GetDeviceInfo](#)
- [IDLgrClipboard::GetFontnames](#)
- [IDLgrClipboard::GetProperty](#)
- [IDLgrClipboard::GetTextDimensions](#)
- [IDLgrClipboard::Init](#)
- [IDLgrClipboard::QueryRequiredTiles](#)
- [IDLgrClipboard::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

This example demonstrates the process of copying the contents of an IDL graphics display object (a buffer or a window) to the system clipboard, where it becomes available for pasting into another application. The example also uses the `IDLgrClipboard::Draw` method to create a platform-dependent file type in the current directory.

```
PRO SendingPlotToClipboard

; Determine the path to the "damp_sn2.dat" file.
signalFile = FILEPATH('damp_sn2.dat', $
    SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the data within the file.
signalSize = 512
signal = BYTARR(signalSize, /NOZERO)

; Open the file, read in data, and then close the file.
OPENR, unit, signalFile, /GET_LUN
READU, unit, signal
FREE_LUN, unit
```

```

; Determine viewplane size and margins.
offsetScale = 150.
viewOffset = offsetScale*[-1., -1., 1., 1.]
signalRange = MAX(signal) - MIN(signal)

; Initialize the display objects.

; Cleanup object references. Before destroying the
; IDLgrClipboard object, reset its GRAPHICS_TREE
; to NULL so the IDLgrViewgroup can remain associated
; with the IDLgrWindow. Interactive destruction
; of the IDLgrWindow will free the other graphics objects
; implicitly.
oClipboard->SetProperty, GRAPHICS_TREE = OBJ_NEW()
OBJ_DESTROY, oClipboard

END

```

## Version History

5.1	Introduced
6.2	Added QueryRequiredTiles method

## IDLgrClipboard Properties

IDLgrClipboard objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrClipboard::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrClipboard::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrClipboard::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS\\_TREE](#)
- [N\\_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN\\_DIMENSIONS](#)
- [UNITS](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure that contains the values of all of the retrievable properties associated with this object.

<b>Property Type</b>	Anonymous structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR\_MODEL

An integer value that determines whether to use the indexed color model for the clipboard buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Color model		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the clipboard buffer in units specified by the UNITS property. The default is [640,480].

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GRAPHICS\_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphic tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS\_TREE property is set equal to the null-object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_COLORS

An integer value that determines the number of colors (between 2 and 256) to be used if COLOR\_MODEL is set to Color Index.

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of colors		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the clipboard buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to the clipboard buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Draw quality		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESOLUTION

A two-element floating-point vector of the form  $[xres, yres]$  specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is:  $[0.035277778, 0.035277778]$  (72 DPI).

### Note

To match screen rendering on an IDLgrClipboard object, the following properties should be matched between the devices: DIMENSIONS, UNITS, RESOLUTION, COLOR\_MODEL and N\_COLORS.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Resolution		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SCREEN\_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the clipboard object.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrClipboard::Cleanup

The IDLgrClipboard::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrClipboard::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrClipboard::Draw

The IDLgrClipboard::Draw procedure method draws the given picture to this graphics destination.

### Writing to a File

The file type produced when the IDLgrClipboard::Draw method is passed an IDLgrView, IDLgrViewgroup, or IDLgrScene object varies depending upon keyword settings and the platform on which the call is issued. If the FILENAME keyword is set to a non-empty string, the name of the file IDL creates is specified by the string. If the FILENAME keyword is a non-zero, numeric value, IDL creates a file named `idl.ext` where `ext` is replaced with the appropriate extension shown in parentheses in the following table.

Keyword Settings	Windows File Type	UNIX File Type
VECTOR = 1, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 1, POSTSCRIPT = 0	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 0	Bitmap (BMP)	Encapsulated PostScript (EPS)

*Table 8-5: File Types Produced by IDLgrClipboard Draw Method*

### Writing to the Clipboard

Objects can be written to the operating system clipboard using IDLgrClipboard::Draw. When the FILENAME keyword equals an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

#### Note

The IDLgrClipboard object empties the Windows clipboard before writing to it.

**Note**

---

When `VECT_SORTING=0`, objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them. Otherwise, objects are drawn to the destination device based on their average depth value.

---

## Syntax

```
Obj->[IDLgrClipboard::]Draw [, Picture] [, /CMYK] [, FILENAME=string]
  [, POSTSCRIPT=value] [, VECT_SHADING={ 0 | 1 } ]
  [, VECT_SORTING={ 0 | 1 } ]
  [, VECT_TEXT_RENDER_METHOD={ 0 | 1 } ] [, VECTOR={ 0 | 1 } ]
```

## Arguments

### Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

## Keywords

### CMYK

This keyword has an effect only when the output format is Encapsulated PostScript (`POSTSCRIPT=1`). Set this keyword to create a PostScript file using the CMYK (cyan, magenta, yellow, and black) color model. The default is a PostScript file using the RGB (red, green, blue) color model. This keyword applies to both bitmap and vector graphic PostScript files.

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

## FILENAME

To write to a file, set this keyword as follows:

- Set to a string that represents the name of the file to which the output should be written.
- Set to any non-zero numerical value. IDL generates a filename based upon the values of the `POSTSCRIPT` and `VECTOR` keywords, and the platform. See [“Writing to a File”](#) in the introductory section for details.

If the value is an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

---

### Note

You are strongly encouraged to specify a string for this value. The ability to specify a numerical value is maintained for backward compatibility, but its usage should be deprecated.

---

## POSTSCRIPT

Set this keyword to a non-zero value to indicate that the generated output should be in Encapsulated PostScript format. By default, the generated output is in Bitmap format on Windows platforms and Encapsulated PostScript on UNIX platforms.

## VECT\_SHADING

This keyword has an effect only when generating vector output (`VECTOR=1`) and when the output format is Encapsulated PostScript (`POSTSCRIPT=1`).

This keyword controls the appearance of smooth (Gouraud) shaded `IDLgrPolygon` and `IDLgrSurface` objects. Valid values are:

- 0 = disable smooth shading. This causes all polygons and surfaces to be rendered with flat shading. This may be valuable when using slower PostScript interpreters or when memory and stack space are limited. Smoothly shaded polygons require more resources as well as time.
- 1 = enable smooth shading (default). This renders smooth (Gouraud) shaded polygons and surfaces in the Encapsulated PostScript file.

**Note**

Polygons and surfaces in Enhanced MetaFiles (EMF) files will be rendered using flat shading. Only the output in Encapsulated PostScript (EPS) files is affected by this keyword, and only when the VECTOR keyword has been set. See [“Bitmap and Vector Graphic Output”](#) in Chapter 12 of the *Object Programming* manual for details about vector graphic output.

**VECT\_SORTING**

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. The object primitives appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.
- 1 = enable sorting (default). The objects are ordered from back to front based on each primitive object's average depth value.

**Note**

Objects that intersect each other, IDLgrImage objects (which do not update the depth buffer), and objects contained within transparent views might not sort correctly. See [“Controlling What is Displayed in Vector Graphics”](#) in Chapter 12 of the *Object Programming* manual.

**VECT\_TEXT\_RENDER\_METHOD**

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). The output device renders the text as text primitives. This allows the text to be edited by object-based graphics programs.
- 1 = render text as triangles. The text is rendered as a series of filled triangles in the vector file. This produces text that closely matches the text on the display device, but the output file size is larger, and the text can not be easily edited.

**Note**

The results of attempting to edit the text primitives depends upon the sophistication of the graphics program. An Enhanced MetaFile (EMF) inserted into a Microsoft Word document can be edited. However, not all versions of Microsoft Word support advanced 3-D graphic primitives such as those associated with obliquely or vertically aligned text. Choosing to edit a file with non-horizontally aligned text may result in the text being flattened into two dimensions. Typically, each letter becomes its own string and alignment is altered. To edit non-horizontal text and preserve the original quality, create an Encapsulated PostScript (EPS) file that can be modified in a more sophisticated object-oriented image editing program.

**Note**

See [“Text Rendering in Vector Graphics”](#) in Chapter 12 of the *Object Programming* manual for more information.

## VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the clipboard or file in bitmap format. The bitmap retains the quality of the original image, but the bitmaps cannot be effectively scaled on all devices.
- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable. The vector representation does not retain all the attributes of the original image, but it can be effectively scaled on other devices. On Windows, the representation is the Windows Enhanced Metafile (EMF). On UNIX platforms, the representation is Encapsulated PostScript (EPS).

**Note**

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See [“Bitmap and Vector Graphic Output”](#) in Chapter 12 of the *Object Programming* manual for a complete discussion of when to output to bitmap or vector graphics based on picture content.

## Version History

5.1	Introduced
6.1	Added CMYK, VECT_SHADING, VECT_SORTING, and VECT_TEXT_RENDER_METHOD keywords

## IDLgrClipboard::GetContiguousPixels

The IDLgrClipboard::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N\_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE\_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

## Syntax

*Result* = *Obj*->[IDLgrClipboard::]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrClipboard::GetDeviceInfo

The IDLgrClipboard::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

### Syntax

```
Obj->[IDLgrClipboard::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [MAX_TILE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

### Arguments

None

### Keywords

#### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

#### MAX\_NUM\_CLIP\_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

#### MAX\_TEXTURE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_TEXTURE\_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

## MAX\_TILE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_TILE\_DIMENSIONS contains a two element integer array that specifies the maximum tile size supported by the device.

## MAX\_VIEWPORT\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_VIEWPORT\_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

## NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

## NUM\_CPUS

Set this keyword equal to a named variable. Upon return, NUM\_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

### Note

---

The NUM\_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

---

## VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

## VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

## Version History

5.1	Introduced
5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

## IDLgrClipboard::GetFontnames

The `IDLgrClipboard::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

### Syntax

```
Result = Obj->[IDLgrClipboard:]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

### Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

### Arguments

#### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “\*”.

### Keywords

#### IDL\_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

#### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ' ', only fontnames without style modifiers will be returned. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “\*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

5.1	Introduced
-----	------------

## IDLgrClipboard::GetProperty

The IDLgrClipboard::GetProperty procedure method retrieves the value of a property or group of properties for the clipboard buffer.

### Syntax

*Obj*->[IDLgrClipboard::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrClipboard Properties](#)” on page 3973 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrClipboard::GetTextDimensions

The IDLgrClipboard::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in the clipboard buffer. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

### Syntax

```
Result = Obj->[IDLgrClipboard::]GetTextDimensions( TextObj  
[, DESCENT=variable] [, PATH=objref(s)] )
```

### Return Value

Returns the dimensions of a text or axis object that will be rendered in the clipboard buffer.

### Arguments

#### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

### Keywords

#### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this

keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrClipboard::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

---

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

---

## Version History

5.1	Introduced
-----	------------

## IDLgrClipboard::Init

The IDLgrClipboard::Init function method initializes the clipboard object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrClipboard' [, *PROPERTY=**value*])

or

*Result* = *Obj*->[IDLgrClipboard::]Init( [, *PROPERTY=**value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrClipboard Properties” on page 3973 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrClipboard::QueryRequiredTiles

The IDLgrClipboard::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

### Note

Clipboard support of tiled images is not available in vector mode (when the IDLgrClipboard::Draw method VECTOR keyword is set to 1).

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

### Note

If the device is in Color Index mode (COLOR\_MODEL=1) or the image has [RENDER\\_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

## Syntax

```
Result = Obj->[IDLgrClipboard:]QueryRequiredTiles( View, Image
    [, COUNT=variable] [, ALL_VISIBLE=value] )
```

## Return Value

Returns an array of structures for required tiles or 0 (zero) if no tiles are required. Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.

Table 8-6: IDLIMAGETILE Structure

Field	Data Type	Description
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of $n$ ( $n > 0$ ) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

*Table 8-6: IDLIMAGETILE Structure (Continued)*

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these

tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 8-2: Interaction Between Image Level and Zoom with Equal Tile Sizes

---

### Note

See “[Image Tiling](#)” in Chapter 4 of the *Object Programming* manual for more information on creating an image pyramid and for tiling examples.

---

## Arguments

### View

An object reference to the `IDLgrView` object used to render the image object. This is required so the visible tiles can be determined.

### Image

An object reference to the tiled `IDLgrImage` object that will be tested to determine which of its tiles are required.

## Keywords

### COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

### ALL\_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

## Version History

6.2	Introduced
-----	------------

## IDLgrClipboard:: SetProperty

The IDLgrClipboard::SetProperty procedure method sets the value of a property or group of properties for the clipboard buffer.

### Syntax

*Obj*->[IDLgrClipboard::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrClipboard Properties” on page 3973 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced
-----	------------

# IDLgrColorbar

The IDLgrColorbar object consists of a color-ramp with an optional framing box and annotation axis. The object can be horizontal or vertical.

An IDLgrColorbar object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrcolorbar__define.pro` in the `lib` subdirectory of the IDL distribution.

## Superclasses

[IDLgrModel](#)

[IDLitComponent](#)

## Creation

See “[IDLgrColorbar::Init](#)” on page 4021.

## Properties

Objects of this class have the following properties. See “[IDLgrColorbar Properties](#)” on page 4005 for details on individual properties.

- [ALL](#)
- [BLUE\\_VALUES](#)
- [COLOR](#)
- [DIMENSIONS](#)
- [GREEN\\_VALUES](#)
- [HIDE](#)
- [MAJOR](#)
- [MINOR](#)
- [PALETTE](#)
- [PARENT](#)

- RED\_VALUES
- SHOW\_AXIS
- SHOW\_OUTLINE
- SUBTICKLEN
- THICK
- THREED
- TICKFORMAT
- TICKFRMTDATA
- TICKLEN
- TICKTEXT
- TICKVALUES
- TITLE
- XCOORD\_CONV
- XRANGE
- YCOORD\_CONV
- YRANGE
- ZCOORD\_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- `IDLgrColorbar::Cleanup`
- `IDLgrColorbar::ComputeDimensions`
- `IDLgrColorbar::GetProperty`
- `IDLgrColorbar::Init`
- `IDLgrColorbar::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLgrModel](#)
- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

---

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## BLUE\_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the `aBlue` argument to the `IDLgrColorbar::Init` method.

<b>Property Type</b>	Byte vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

The color to be used as the foreground color for the axis and outline box. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

<b>Property Type</b>	Color		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIMENSIONS

A two element integer vector [*dx*, *dy*] that specifies the size of the ramp display (not the axis) in pixels. If  $dx > dy$ , the colorbar is drawn horizontally with the axis placed below or above the ramp box depending on the value of the `SHOW_AXIS` property. If  $dx < dy$ , the colorbar is drawn vertically with the axis placed to the right or left of the ramp box depending on the value of the `SHOW_AXIS` property. The default value is [16,256].

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GREEN\_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the `IDLgrColorbar::Init` method.

<b>Property Type</b>	Byte vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MAJOR

An integer that represents the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PALETTE

An object reference to an instance of the IDLgrPalette object class. If this property is a valid object reference, the colors within the IDLgrPalette are used to specify the colors for the colorbar.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PARENT

An object reference to the object that contains this colorbar.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## RED\_VALUES

A byte vector that contains the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrColorbar::Init method.

<b>Property Type</b>	Byte vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHOW\_AXIS

An integer value that indicates whether the axis should be drawn:

- 0 = Do not display axis (the default)
- 1 = Display axis on left side or below the color ramp
- 2 = Display axis on right side or above the color ramp

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHOW\_OUTLINE

A Boolean value indicating whether the colorbar bounds should be outlined:

- 0 = Do not display outline (the default)
- 1 = Display outline

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness used to draw the axis and box outline, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THREED

A Boolean value that determines whether to create the colorbar as a graphic object that can be fully transformed in three dimensions on initialization. By default, the colorbar always faces the viewer and is drawn at  $z=0$ .

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TICKFORMAT

Either a standard IDL format string (see “*Format Codes*” in Chapter 18 of the *Building IDL Applications* manual for details on format codes) or a string containing the name of a user-supplied function that returns a string to be used to format the axis tick mark labels. The function should accept integer arguments for the direction of the axis, the index of the tick mark, and the value of the tick mark, and should return a string to be used as the tick mark’s label. The function may optionally accept a keyword called DATA, which will be automatically set to the TICKFRMTDATA value. The default TICKFORMAT is "", the null string, which indicates that IDL will determine the appropriate format for each value.

### Note

If the user-defined function’s name does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified. For more information, see “[XYZ]TICKFORMAT” on page 4790.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TICKFRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT property, if any. By default, this value is undefined, indicating that the DATA property will be undefined (and furthermore, need not be supported by the user-supplied function). Note that TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrColorbar::GetProperty method.

<b>Property Type</b>	Scalar of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TICKTEXT

An object reference to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (each with a single string) that specifies the annotations to be assigned to the tick marks. By default, TICKTEXT is set to the NULL object, which indicates that IDL will

compute tick annotations based upon the major tick values. The positions and orientation of the provided text object(s) may be overwritten by the colorbar.

<b>Property Type</b>	Object reference or object reference vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TICKVALUES

A floating-point vector of data values that represent the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element double-precision floating-point vector of the form [ $x_{min}$ ,  $x_{max}$ ] specifying the range of the  $x$  data coordinates covered by the colorbar.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector, [ $s_0$ ,  $s_1$ ], of scaling factors that converts Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element double-precision floating-point vector of the form  $[ymin, ymax]$  that specifies the range of the  $Y$  data coordinates covered by the colorbar.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that converts  $Z$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element double-precision floating-point vector of the form  $[zmin, zmax]$  specifying the range of the  $Z$  data coordinates covered by the colorbar.

### Note

Until the colorbar is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the `ComputedDimensions` method on the colorbar object to get the data dimensions of the colorbar prior to a draw operation.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrColorbar::Cleanup

The IDLgrColorbar::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrColorbar::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrColorbar::ComputeDimensions

The IDLgrColorbar::ComputeDimensions function method retrieves the dimensions of a colorbar object for the given destination object. The result is a three-element double-precision floating-point vector  $[xDim, yDim, zDim]$  representing the dimensions of the colorbar object measured in data units.

### Syntax

```
Result = Obj->[IDLgrColorbar::]ComputeDimensions( DestinationObj  
[, PATH=objref(s)] )
```

### Return Value

Returns the dimensions of a colorbar object for the given destination object.

### Arguments

#### DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the colorbar are being requested.

### Keywords

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrColorbar::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

#### Note

---

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

---

## Version History

5.1	Introduced
-----	------------

## IDLgrColorbar::GetProperty

The IDLgrColorbar::GetProperty procedure method retrieves the value of a property or group of properties for the colorbar.

### Syntax

*Obj*->[IDLgrColorbar:]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 4005 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrColorbar::Init

The IDLgrColorbar::Init function method initializes the colorbar object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW( 'IDLgrColorbar' [, aRed, aGreen, aBlue] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrColorbar::]Init([aRed, aGreen, aBlue] [, PROPERTY=value])  
(In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### aRed

A vector containing the red values for the color palette. These values should be within the range of  $0 < Value < 255$ . The number of elements comprising the *aRed* vector must not exceed 256.

### aGreen

A vector containing the green values for the color palette. These values should be within the range of  $0 < Value < 255$ . The number of elements comprising the *aGreen* vector must not exceed 256.

## aBlue

A vector containing the blue values for the color palette. These values should be within the range of  $0 < Value < 255$ . The number of elements comprising the *aBlue* vector must not exceed 256.

If *aRed*, *aGreen*, and *aBlue* are not provided, the color palette will default to a 256 entry greyscale ramp.

## Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 4005 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrColorbar:: SetProperty

The IDLgrColorbar:: SetProperty procedure method sets the value of a property or group of properties for the colorbar.

### Syntax

*Obj*->[IDLgrColorbar:]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrColorbar Properties” on page 4005 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced

# IDLgrContour

The IDLgrContour object draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created.

An IDLgrContour object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

The object stores the following argument or property in double-precision if the DOUBLE\_DATA property is specified, and in single-precision otherwise.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrContour::Init](#)” on page 4062.

## Properties

Objects of this class have the following properties. See “[IDLgrContour Properties](#)” on page 4027 for details on individual properties.

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrContour::AdjustLabelOffsets
- IDLgrContour::Cleanup
- IDLgrContour::GetCTM
- IDLgrContour::GetLabelInfo
- IDLgrContour::GetProperty
- IDLgrContour::Init
- IDLgrContour::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.1	Introduced
5.6	Added AM_PM, C_LABEL_INTERVAL, CLIP_PLANES, C_LABEL_OBJECTS, C_LABEL_NOGAPS, C_LABEL_SHOW, C_USE_LABEL_COLOR, C_USE_LABEL_ORIENTATION, DAYS_OF_WEEK, LABEL_FONT, LABEL_FORMAT, LABEL_FRMATDATA, LABEL_UNITS, MONTHS, and USE_TEXT_ALIGNMENTS properties
6.1	Added ALPHA_CHANNEL property

- IDLitComponent

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object except DATA\_VALUES and GEOM.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the contour. The default value of 1.0 causes IDL to draw the contours completely opaque. If the value of this property is less than 1.0, then the pixels of the contours are blended with the pixels already on the screen, where the color of the contour is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color mode. If contour colors (C\_COLOR property) are supplied, then the value of this

property is used for the contour alpha if the C\_COLOR property does not contain alpha values (3-channel RGB colors). If the C\_COLOR property does contain alpha values (4-channel RGBA colors), then the alpha from each contour color is used. When contour labels (either text or symbols) are used and a label's corresponding value in the C\_USE\_LABEL\_COLOR property is zero, the value of this property is used for the label alpha if contour colors are not provided or if the contour colors are provided and do not contain alpha values. If the alpha values are supplied in the C\_COLOR property, then each label uses the alpha from its corresponding C\_COLOR contour color. When contour labels (either text or symbols) are used and a label's corresponding value in the C\_USE\_LABEL\_COLOR property is non-zero, then the value of the label object's ALPHA\_CHANNEL property is used to draw the label. In other words, C\_USE\_LABEL\_COLOR also implies using the label object's alpha as well as its color.

### Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## AM\_PM

A string vector of two values indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL\_FORMAT property.

<b>Property Type</b>	String vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ANISOTROPY

A three-element floating-point vector  $[x, y, z]$  that represents the multipliers to be applied to the internally computed correction factors along each axis that account for

anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range [*xmin*, *ymin*, *zmin*] to [*xmax*, *ymax*, *zmax*], then the default correction factors are computed as follows:

```

dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
    xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
    ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
    zcorrection = maxRange / dz

```

This internally computed correction is then multiplied by the corresponding [*x*, *y*, *z*] values of the ANISOTROPY property. The default value for this property is [1,1,1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Anistrophy		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## C\_COLOR

A vector of colors to be used to specify the color of each contour level. The vector may be of the form [*n*] where each entry is a color index, or of the form [3,*n*] where each 3-element row is an RGB color, or of the form [4,*n*] where each 4-element row is an RGBA color. To remove contour colors after they have been set, set C\_COLOR to a scalar.

If C\_COLOR is not specified, the entire contour plot is drawn in the single color provided by the COLOR property, which is the default action. If there are no contour colors, GetProperty returns a value of -1 for this property.

If there are more contour levels than elements in C\_COLOR, the elements of C\_COLOR are cyclically repeated.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Colors		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## C\_FILL\_PATTERN

An array of IDLgrPattern objects that represent the patterns to be applied at each contour level if the FILL property is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this property is set to any scalar value, all contour levels are filled with a solid color (this is the default). If there are no fill pattern objects stored in this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Fill patterns		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## C\_LABEL\_INTERVAL

A floating-point vector that indicates the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C\_LABEL\_INTERVAL values will be repeated cyclically. The default is 0.4.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## C\_LABEL\_NOGAPS

An integer vector that indicates whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the C\_LABEL\_NOGAPS values will be repeated cyclically.

By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## C\_LABEL\_OBJECTS

An array of object references that provides examples of labels to be drawn for each contour level. The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C\_LABEL\_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values. Note that the objects specified via this property are used as descriptors only. The actual objects drawn as labels are generated by IDL, and may be accessed via the IDLgrContour::GetLabelInfo method. The contour labels will have the same color as the corresponding contour level (see C\_COLOR) unless the C\_USE\_LABEL\_COLOR property is specified. The orientation of the label will be automatically computed unless the C\_USE\_LABEL\_ORIENTATION property is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE\_TEXT\_ALIGNMENTS property is specified.

### Note

---

The object(s) set via this property will not be destroyed automatically when the contour is destroyed.

---

<b>Property Type</b>	Object reference array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## C\_LABEL\_SHOW

An integer vector that indicates whether labels are shown. For each contour value, if the corresponding value in the C\_LABEL\_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements in this vector, the C\_LABEL\_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## C\_LINestyle

An integer array of linestyles that represent the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this property is set to any scalar value, all levels are drawn as solid lines (this is the default). If there are no linestyles specified for this property, GetProperty will return a value of -1.

To use a pre-defined line style, set the C\_LINestyle property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Linestyles		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## C\_THICK

A floating-point array of line thicknesses that represent the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this property is set to any scalar value, all contour levels are drawn with a line thickness of 1.0 points (this is the default). If there are no thicknesses specified for this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Thicknesses		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## C\_USE\_LABEL\_COLOR

An integer vector that indicates whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C\_USE\_LABEL\_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C\_COLOR property for the contour object will be used instead.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

### Note

When user-defined IDLgrSymbol objects are used for labels in an IDLgrContour object and C\_USE\_LABEL\_COLORS is set to non-zero values, all properties including the color are defined by the object composing the user-defined symbol, and not from the values set on the symbol object itself. For example, a green bow tie-shaped IDLgrPolyline is assigned to the symbol object, and this symbol object is assigned to the C\_LABEL\_OBJECTS property. If C\_USE\_LABEL\_COLOR is set, there will be green bow tie shaped labels on the contour lines. If C\_USE\_LABEL\_COLOR is not set, the bow tie color is defined by C\_COLOR. Properties defined on the symbol object itself are ignored in all cases.

## C\_USE\_LABEL\_ORIENTATION

An integer vector that indicates whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the `BASELINE` and `UPDIR` property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the `C_USE_LABEL_ORIENTATION` values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## C\_VALUE

A floating-point value or a floating-point vector for which contour values are to be drawn. Setting **ONLY** a scalar value of 0 will cause the default action of even sampling of contour levels across the `DATA_VALUES`, using the value of the `N_LEVELS` property to determine the number of samples. IDL will convert any other scalar value to a single element vector containing that value and will then use it as if the user had supplied it as a vector. If there are no values specified for this property, `GetProperty` will return a value of -1. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Level values		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CLIP\_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**COLOR**

The color to be used to draw the contours. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0,0,0]. This value will be ignored if the C\_COLOR property is set to a vector.

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**DATA\_VALUES**

A floating-point vector or two-dimensional array that specifies the values to be contoured. The property is the same as the *Values* argument described in “IDLgrContour::Init” on page 4062. IDL converts and stores this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE\_DATA property is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

<b>Property Type</b>	Floating-point vector or array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DAYS\_OF\_WEEK

A string vector of 7 values that indicates the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the LABEL\_FORMAT property.

<b>Property Type</b>	String vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH\_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

### Note

---

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH\_OFFSET values. It is safest to use only a DEPTH\_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH\_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH\_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH\_OFFSET.

---

**Note**

---

DEPTH\_OFFSET has no effect unless the FILL property is set.

---

<b>Property Type</b>	Integer		
<b>Name String</b>	Depth offset		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**DEPTH\_TEST\_DISABLE**

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

**Note**

---

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH\_TEST\_FUNCTION and DEPTH\_WRITE\_DISABLE properties are effectively ignored.

---

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**DEPTH\_TEST\_FUNCTION**

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the

depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE\_DATA

A Boolean value that indicates whether the object is to store data provided by either the *Values* argument or the DATA\_VALUES property parameter in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any value data already stored in the object to the requested precision, if necessary.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE\_GEOM

A Boolean value that indicates whether the object is to store data provided by any of the GEOMX, GEOMY, or GEOMZ property parameters in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any geometry data already stored in the object to the requested precision, if necessary.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOWNHILL

A Boolean value that indicates whether downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

- 0 = Do not render downhill tick marks.
- 1 = Render downhill tick marks

In a property sheet, this property appears as an enumerated list with the following options:

- Hide
- Show

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Downhill ticks		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## FILL

A Boolean value that indicates whether the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contour may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Fill contours		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## GEOM

A floating-point array that contains the geometry associated with the contour. IDL returns this data in single-precision floating-point by default or in double-precision floating-point if the `DOUBLE_GEOM` property is set in the `IDLgrContour::Init` method.

The shape of the data contained in `GEOM` depends on the value of the `GEOMZ` property (and potentially the `GEOMX` and `GEOMY` properties). The following rules apply:

- If `GEOMZ` is a vector of `Z` values  $[z_0, z_1, z_2, \dots]$  (in which case it is presumed that `GEOMX` and `GEOMY` were also set as vectors), `GEOM` will contain a  $3 \times N$  array of `XYZ` values:  $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$ .
- If `GEOMZ` is a  $3 \times N$  array of `XYZ` values  $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$ , `GEOM` will contain a  $3 \times N$  array of `XYZ` values:  $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$ .
- If `GEOMZ` is an  $N \times M$  array of `Z` values  $[[z_0, z_1, z_2, \dots], [z_N, z_{N+1}, z_{N+2}, \dots], \dots]$  (in which case it is presumed that `GEOMX` and `GEOMY` were also set as  $N \times M$  arrays), `GEOM` will contain a  $3 \times N \times M$  array of `XYZ` values:  $[[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots], [[x_N, y_N, z_N], \dots], \dots]$
- If `GEOMZ` is a scalar and the `PLANAR` property contains a `True` value (in which case it is presumed that `DATA_VALUES` was set as an  $N \times M$  array), `GEOM` will contain a  $3 \times N \times M$  array of `XYZ` values:  $[[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots], [[x_N, y_N, z_N], \dots], \dots]$
- If `GEOMZ` is a scalar and the `PLANAR` property contains a `False` value, `GEOM` will be undefined.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## GEOMX

A floating-point vector or two-dimensional array that specifies the `X` coordinates of the geometry with which the contour values correspond. If `X` is a vector, it must match the number of elements in the `Values` argument or `DATA_VALUES` property value, or it must match the first of the two dimensions of the `Values` argument or `DATA_VALUES` property value (in which case, the `X` coordinates will be repeated for each row of data values). IDL converts and maintains this data as double-precision

floating-point if the parameter is of type `DOUBLE` or if the `DOUBLE_GEOM` property is non-zero. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

<b>Property Type</b>	Floating-point vector or array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GEOMY

A floating-point vector or two-dimensional array specifying the Y coordinates of the geometry with which the contour values correspond. If Y is a vector, it must match the number of elements in the *Values* argument or `DATA_VALUES` property value, or it must match the second of the two dimensions of the *Values* argument or `DATA_VALUES` property value (in which case, the Y coordinates will be repeated for each column of data values). IDL converts and maintains this data as double precision floating point if the parameter is of type `DOUBLE` or if the `DOUBLE_GEOM` property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

<b>Property Type</b>	Floating-point vector or array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GEOMZ

A floating-point scalar, a vector, or a two-dimensional array specifying the Z coordinates of the geometry with which the contour values correspond.

- If `GEOMZ` is a scalar and the `PLANAR` property contains a True value, the resulting contour geometry will be projected onto the plane `Z=GEOMZ`. If `GEOMZ` is a scalar, and the `PLANAR` property is not set, any geometry associated with the contour will be freed.
- If `GEOMZ` is a vector of Z coordinates, the number of elements in the vector should be the same as the number of elements in `DATA_VALUES`.
- If `GEOMZ` is an array and the leading dimension is 3, then the data is treated as a list or array of 3-D vertices. The product of the array dimensions following the 3 should equal the number of `DATA_VALUES`.

- If GEOMZ is an array and the leading dimension is not 3, then the data is treated as a list or array of single Z coordinates. If the number of dimensions is 2, then the data is treated as a 2-D array of Z values. Otherwise, it is treated as a vector of Z values. In either case, the total number of elements in the array should be the same as the number of DATA\_VALUES.
- If GEOMZ is not set, the geometry will be derived from the DATA\_VALUES property (if it is set to a two-dimensional array). In this case, the connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE\_GEOM property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

<b>Property Type</b>	Floating-point scalar, vector, or array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LABEL\_FONT

An object reference to an IDLgrFont object that describes the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if C\_LABEL\_SHOW is set but the corresponding C\_LABEL\_OBJECTS text object is not provided), or for any text label objects provided via C\_LABEL\_OBJECTS that do not already have the font property set. The default value for this property is a NULL object reference, indicating that 12 pt. Helvetica will be used.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LABEL\_FORMAT

A string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: Axis, Index, and Value, where:

- Axis is simply the value 2 to indicate that values along the Z axis are being formatted. (This allows a single callback routine to be used for both axis labeling and contour labeling.)
- Index is the contour level index (indices start at 0).
- Value is the data value of the current contour level.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LABEL\_FRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the LABEL\_FORMAT property, if any. By default,

this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

---

**Note**

LABEL\_FRMTDATA will not be included in the structure returned via the ALL property to the IDLgrContour::GetProperty method.

---

<b>Property Type</b>	Scalar of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## LABEL\_UNITS

A string that indicates the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

---

**Note**

The singular form of each of the time unit strings is also acceptable (for example, LEVEL\_UNITS='Day' is equivalent to LEVEL\_UNITS='Days').

---

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MAX\_VALUE

A floating point value that indicates the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Maximum value		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MONTHS

A string vector of 12 values indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C\_LABEL\_FORMAT keyword.

<b>Property Type</b>	String vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MIN\_VALUE

A floating-point value that indicates the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Minimum value		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## N\_LEVELS

An integer value that indicates the number of contour levels to generate. This property is ignored if the C\_VALUE property is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this property to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

<b>Property Type</b>	INTEGER		
<b>Name String</b>	Number of levels		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this contour.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## PLANAR

A Boolean value that indicates whether the contoured data is to be projected onto a plane. This property is ignored if GEOMZ is not a scalar. The default is non-planar (i.e., to display the contoured data at the Z locations provided by the GEOMZ property).

In a property sheet, this property appears as an enumerated list with the following options:

- Planar (the default)
- Three-D

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Projection		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## POLYGONS

An integer array of polygon descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument or the DATA\_VALUES property). A polygon description is an integer or long word array of the form:  $[n, i0, i1, \dots, in-1]$ , where  $n$  is the number of vertices that define the polygon, and  $i0..in-1$  are indices into the X, Y, and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count,  $n$ , to 0. To end the drawing list, even if additional array space is available, set  $n$  to -1. If this property is not specified, a single polygon will be generated.

### Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADE\_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADING

An integer that indicates the type of shading to use:

- 0 = Flat (default): The color has a constant intensity for each face of the contour, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat (the default)
- Gouraud

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Shading		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKINTERVAL

A floating-point value that indicates the distance between downhill tickmarks, in data units. If TICKINTERVAL is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Downhill tick interval		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TICKLEN

A floating-point value that indicates the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Downhill tick length		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## USE\_TEXT\_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the C\_LABEL\_OBJECTS property), the ALIGNMENT and VERTICAL\_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL\_ALIGNMENT properties of the label

IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element double-precision floating-point vector of the form  $[xmin, xmax]$  specifying the range of the X data coordinates covered by the contour.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the contour.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector, [*s*<sub>0</sub>, *s*<sub>1</sub>], of scaling factors that converts *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element double-precision floating-point vector of the form  $[zmin, zmax]$  that specifies the range of the  $Z$  data coordinates covered by the contour.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrContour::AdjustLabelOffsets

The IDLgrContour::AdjustLabelOffsets procedure method adjusts the offsets at which contour labels are positioned.

### Syntax

*Obj*->[IDLgrContour::]AdjustLabelOffsets, *LevelIndex*, *LabelOffsets*

### Arguments

#### LevelIndex

The index of the contour level for which the label offsets are being adjusted. This value must be greater than or equal to zero and less than the number of levels (refer to the N\_LEVELS property in the IDLgrContour::Init method).

#### LabelOffsets

A scalar or vector of floating point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each contour line at which each label is to be positioned. The number of elements in this vector must exactly match the number of elements returned in the LABEL\_OFFSETS vector retrieved via the IDLgrContour::GetLabelInfo method for the same level.

### Keywords

None

### Version History

5.1	Introduced
-----	------------

## IDLgrContour::Cleanup

The IDLgrContour::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrContour::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrContour::GetCTM

The IDLgrContour::GetCTM method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrContour::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref] )
```

### Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrContour::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.1	Introduced
-----	------------

## IDLgrContour::GetLabelInfo

The IDLgrContour::GetLabelInfo procedure method retrieves information about the labels for a contour. The returned information is only valid until the next time the C\_LABEL\_INTERVAL or C\_LABEL\_OBJECTS property is modified using the IDLgrContour::SetProperty method, or the offsets are adjusted using the IDLgrContour::AdjustLabelOffsets method.

### Syntax

```
Obj->[IDLgrContour::]GetLabelInfo, Destination, LevelIndex  
    [, LABEL_OFFSETS=variable] [, LABEL_POLYLINES=variable]  
    [, LABEL_OBJECTS=variable]
```

### Arguments

#### Destination

A reference to a destination object (such as an IDLgrWindow or IDLgrBuffer object). The contour label information will be computed so that the requested font size is satisfied for this destination device.

#### LevelIndex

The index of the contour level for which the label information is being requested. This value must be greater than or equal to zero and less than the number of levels (refer to the N\_LEVELS keyword in the IDLgrContour::Init method).

### Keywords

#### LABEL\_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of floating point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each contour line at which the contour labels are positioned.

#### LABEL\_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of contour polyline indices, [P<sub>0</sub>, P<sub>1</sub>, ...], that indicate which contour lines are labeled. P<sub>i</sub> corresponds to the i<sup>th</sup> contour line.

Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL\_POLYLINES vector.

## LABEL\_OBJECTS

Set this keyword to a named variable that upon return will contain a vector of objects that represent the labels for each contour label.

## Version History

5.1	Introduced
-----	------------

## IDLgrContour::GetProperty

The IDLgrContour::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

### Syntax

*Obj*->[IDLgrContour::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrContour Properties” on page 4027 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrContour::Init

The IDLgrContour::Init function method initializes the contour object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrContour' [, *Values*] [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrContour::]Init([*Values*] [, *PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Values

A vector or two-dimensional array of values to be contoured. If no values are provided, the values will be derived from the GEOMZ keyword value (if set and the PLANAR keyword is not set). In this case, the values to be contoured will match the Z coordinates of the provided geometry. IDL converts and maintains this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE\_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

## Keywords

Any property listed under “[IDLgrContour Properties](#)” on page 4027 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrContour:: SetProperty

The IDLgrContour::SetProperty procedure method sets the value of a property or group of properties for the contour.

### Syntax

*Obj*->[IDLgrContour::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrContour Properties” on page 4027 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced
-----	------------

# IDLgrFont

A font object represents a typeface, style, weight, and point size that may be associated with text objects.

## Superclasses

None

## Creation

See “[IDLgrFont::Init](#)” on page 4072.

## Properties

Objects of this class have the following properties. See “[IDLgrFont Properties](#)” on page 4067 for details on individual properties.

- [ALL](#)
- [NAME](#)
- [SIZE](#)
- [SUBSTITUTE](#)
- [THICK](#)
- [UVALUE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrFont::Cleanup](#)
- [IDLgrFont::GetProperty](#)
- [IDLgrFont::Init](#)
- [IDLgrFont::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See “[Font Objects](#)” in Chapter 9 of the *Object Programming* manual for examples.

## Version History

5.0	Introduced
6.2	Added UVALUE property

## IDLgrFont Properties

IDLgrFont objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrFont::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrFont::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrFont::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [NAME](#)
- [SIZE](#)
- [SUBSTITUTE](#)
- [THICK](#)
- [UVALUE](#)

### ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

### Note

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

### NAME

A string containing the name of the font used. See [“Fontname”](#) on page 4072 for details on constructing font name strings.

**Note**

Setting this property in the Init method is equivalent to specifying the *FontName* argument.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**SIZE**

A floating-point value representing the point size of the font. The default is 12.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**SUBSTITUTE**

A string that indicates the font to use as a substitute if the specified *Fontname* is not available on the graphics destination. Valid values are only those fonts that are available on all destination objects (the fonts included with IDL). These are: 'Helvetica' (the default), 'Courier', 'Times', 'Symbol', or 'Hershey'.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0, indicating the line thickness (measured in points) to use for the Hershey vector fonts. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## UVALUE

A value of any type containing any information you wish.

### Note

---

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrFont object is destroyed.

---

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrFont::Cleanup

The IDLgrFont::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrFont::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrFont::GetProperty

The IDLgrFont::GetProperty procedure method retrieves the value of a property or group of properties for the font.

### Syntax

*Obj*->[IDLgrFont::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrFont Properties” on page 4067 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrFont::Init

The IDLgrFont::Init function method initializes the font object.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

### Note

See “[Font Objects](#)” in Chapter 9 of the *Object Programming* manual for information on creating an using font objects.

---

## Syntax

```
Obj = OBJ_NEW('IDLgrFont' [, Fontname] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrFont::]Init([Fontname] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Fontname

A string representing the name of the font to be used. This string should take the form 'fontname\*modifier1\*modifier2\*...\*modifierN'. All destination objects support the following fontnames: Helvetica, Courier, Times, Symbol, and Monospace Symbol. (These fonts are included with IDL; you may have other fonts installed on your system as well.)

Valid modifiers for each of these fonts (except Symbol and Monospace Symbol) are:

- *Font weight:* Bold
- *Font angle:* Italic

For example, 'Helvetica\*Bold\*Italic'.

To select a Hershey vector font, use a fontname of the form: 'Hershey\**fontnum*' where *fontnum* is the Hershey font's index number. See [“Hershey Vector Font Samples”](#) on page 4933 for descriptions of the Hershey vector fonts.

---

#### Note

Beginning with IDL version 5.1, only TrueType and Hershey fonts are supported in the Object Graphics system. See [“Fonts”](#) in Appendix H for details on these font systems.

---

## Keywords

Any property listed under [“IDLgrFont Properties”](#) on page 4067 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrFont:: SetProperty

The IDLgrFont::SetProperty procedure method sets the value of a property or group of properties for the font.

### Syntax

*Obj*->[IDLgrFont::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrFont Properties](#)” on page 4067 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrImage

An image object represents a mapping from a two-dimensional array of data values to a two dimensional array of pixel colors, resulting in a flat 2-D-scaled version of the image, drawn at  $Z = 0$ .

An IDLgrImage object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Beginning with IDL 6.2, IDLgrImage renders an image by default using a texture-mapped polygon on graphics devices using the RGB color model, for a significant increase in functionality and performance. IDL continues to use a 2D "bitmap" primitive to draw an image on devices using the indexed color model, since texture mapping is not available on such devices.

---

## Note

With the texture-mapping performance improvements of 6.2, interpolation results may differ slightly across graphics devices and from pre-6.2 results. See [INTERPOLATE](#) for details.

---

## Transformations of IDLgrImage Objects

By default, IDLgrImage objects are drawn at  $Z=0$  and are positioned and sized with respect to two points:

$$p1 = [\text{LOCATION}(0), \text{LOCATION}(1), 0]$$

$$p2 = [\text{LOCATION}(0) + \text{DIMENSION}(0), \text{LOCATION}(1) + \text{DIMENSION}(1), 0].$$

where LOCATION and DIMENSION are properties of the image object. These two points are transformed in three dimensions, and then projected onto the screen to form the opposite corners of a 2-D rectangle using screen space points designated as  $p1'$  and  $p2'$ :

$$[ [p1'[0], p1'[1]], [p2'[0], p1'[1]], \\ [p2'[0], p2'[1]], [p1'[0], p2'[1]] ]$$

The image data is drawn on the display as a 2-D image within this 2-D rectangle whose sides are parallel to the screen sides. The image data is *scaled* in two dimensions (not rotated) to fit into this projected rectangle and then drawn with  $Z$  buffering disabled.

To draw an image with the current full 3D transformation (the same way other objects such as polygons are transformed), set the IDLgrImage TRANSFORM\_MODE property to 1. See the IDLgrImage [TRANSFORM\\_MODE](#) property for details.

Objects are drawn to a destination device in the order that they are added (via the Add method) to the model, view, or scene that contains them. By default, image objects do not take into account the depth locations of other objects that may be included in the view object unless you enable depth testing (see “[DEPTH\\_TEST\\_DISABLE](#)” in the *IDL Reference Guide* manual for details).

This means that objects that are drawn to the destination object (window or printer) after the image is drawn will appear to be in front of the image, even if they are located behind the image object. Since the image is drawn by default with depth testing disabled, you can think of the image primitive as ‘painting’ the image onto the screen without regard for other objects that might already have been drawn there.

This behavior can be changed by enabling depth testing to make the image primitive behave like other primitives such as polygons when they are drawn with depth testing enabled.

See “[Displaying Multiple Images in Object Graphics](#)” in Chapter 4 of the *Object Programming* manual for an example using the LOCATION property.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrImage::Init](#)” on page 4107.

## Properties

Objects of this class have the following properties. See “[IDLgrImage Properties](#)” on page 4079 for details on individual properties.

- [ALL](#)
- [BLEND\\_FUNCTION](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_OFFSET](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DIMENSIONS](#)
- [HIDE](#)

- RESET\_DATA
- SUB\_RECT
- TILE\_CURRENT\_LEVEL
- TILE\_LEVEL\_MODE
- TILE\_SHOW\_BOUNDARIES
- TILING
- XCOORD\_CONV
- YCOORD\_CONV
- ZCOORD\_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- `IDLgrImage::Cleanup`
- `IDLgrImage::DeleteTileData`
- `IDLgrImage::GetCTM`
- `IDLgrImage::GetProperty`
- `IDLgrImage::Init`
- `IDLgrImage::SetProperty`
- `IDLgrImage::SetTileData`

In addition, this class inherits the methods of its superclasses (if any).

## Examples

For image object examples see [Chapter 4, “Working with Image Objects”](#) in the *Object Programming* manual. Also see [“Mapping an Image onto Elevation Data”](#) in Chapter 3 of the *Image Processing in IDL* manual for a texture mapping example.

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.2	Removed NO_COPY property and documented it as an IDLgrImage::Init keyword. Added ALPHA_CHANNEL, DEPTH_OFFSET, RENDER_METHOD, TILE_COLOR, TILE_CURRENT_LEVEL, TILE_DIMENSIONS, TILE_LEVEL_MODE, TILE_NUM_LEVELS, TILE_SHOW_BOUNDARIES, TILED_IMAGE_DIMENSIONS, TILING, and TRANSFORM_MODE properties Added DeleteTileData and SetTileData methods

## IDLgrImage Properties

IDLgrImage objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrImage::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrImage::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrImage::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties. See [“IDLgrImage Properties”](#) on page 4079 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [BLEND\\_FUNCTION](#)
- [CHANNEL](#)
- [CLIP\\_PLANES](#)

- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

The fields of this structure may change in subsequent releases of IDL.

### Note

This structure returns a COLOR property that is consistent with other graphic objects. However, as an image object's color depends on each sample of data, the concept of an overall COLOR is not meaningful for this object and is not used in rendering the object.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the image. The default value of 1.0 causes IDL to draw the image completely opaque. If the value of this property is less than 1.0, then the pixels of the image are blended with the pixels already on the screen, where the image is blended according to the values in the BLEND\_FUNCTION property.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color model.

If the image data contains an alpha channel, the effective alpha of each pixel is the pixel's alpha multiplied by the value in the ALPHA\_CHANNEL property.

Since the BLEND\_FUNCTION property contributes (along with the value of the ALPHA\_CHANNEL property) to the control of the blending, be sure to set the BLEND\_FUNCTION property to the desired value. Its default value is [0,0]. To obtain the same blending function used by other graphic objects using the ALPHA\_CHANNEL property, set the BLEND\_FUNCTION property to [3,4].

<b>Property Type</b>	Float-point value		
<b>Name String</b>	Opacity		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## BLEND\_FUNCTION

A two-element integer vector that controls how the alpha channel values will be interpreted. Set this property equal to a two-element vector [*src*, *dst*] specifying one of the functions listed below for each of the source and destination objects. These are only valid for RGB model destinations. If an alpha channel is not specified in an image, the image's alpha blend factor is assumed to be 1.0. The values of the blending function ( $V_{src}$  and  $V_{dst}$ ) are used in the following equation

$$C_d' = (V_{src} \cdot C_i) + (V_{dst} \cdot C_d)$$

where  $C_d$  is the initial color of a pixel on the destination device (the background color),  $C_i$  is the color of the pixel in the image, and  $C_d'$  is the resulting color of the pixel.

Setting *src* and *dst* in the BLEND\_FUNCTION vector to the following values determine how each term in the equation is calculated:

src or dst	$V_{src}$ or $V_{dst}$	What the function does
0	n/a	Alpha blending is disabled, which is the default setting. $C_d' = C_i$
1	1	The value of $V_{src}$ or $V_{dst}$ in the equation is one, thus the value of the term is the same as the color value.

Table 8-7: Values for *src* and *dst* in BLEND\_FUNCTION

src or dst	$V_{src}$ or $V_{dst}$	What the function does
2	0	The value of $V_{src}$ or $V_{dst}$ in the equation is zero, thus the value of the term is zero.
3	$Image_a$	The value of $V_{src}$ or $V_{dst}$ in the equation is the blend factor of the image's alpha channel.
4	$1-Image_a$	The value of $V_{src}$ or $V_{dst}$ in the equation is one minus the blend factor of the image's alpha channel.

*Table 8-7: Values for src and dst in BLEND\_FUNCTION (Continued)*

For example, setting `BLEND_FUNCTION = [3, 4]` creates an image in which you can see through the foreground image to the background to the extent defined by the alpha channel values of the foreground image.

Since the alpha blending operation is dependent on the values of pixels already drawn to the destination for some blending functions, the final result may depend more on the order of drawing the images, and not necessarily on their relative location along the Z axis. IDL draws images in the order that they are stored in the `IDLgrModel` object that contains them.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Blend function		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CHANNEL

A hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, `'ff0000'X` represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value `'ffffff'X`.

### Note

This property is ignored for CI destination objects.

This property is registered, but it is hidden by default.

<b>Property Type</b>	Integer		
<b>Name String</b>	Color channel		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CLIP\_PLANES

A 4-by- $N$  floating-point array of dimensions [4, $N$ ] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

### Note

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

### Note

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATA

A  $n \times m$ ,  $2 \times n \times m$ ,  $3 \times n \times m$ , or  $4 \times n \times m$  array (any type) of image data for the object. The  $n$  and  $m$  values may be in any position as specified by the INTERLEAVE property. This property is equivalent to the optional argument, *ImageData*.

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_OFFSET

This property only has an effect when the image is rendered with a texture-mapped polygon and depth testing is enabled.

Set this property to an integer value that specifies an offset in depth to be used when rendering images. This offset is applied along the viewing axis, with positive values moving the image away from the viewer.

The units are "Z-Buffer units," where a value of 1 is used to specify a distance that corresponds to a single step in the device's Z-Buffer.

Use DEPTH\_OFFSET to always cause an image to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of images at the same depth.

### Note

---

RSI suggests using this feature to remove stitching artifacts and not as a means for "layering" complex scenes with multiple DEPTH\_OFFSET values. It is safest to use only a DEPTH\_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH\_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH\_OFFSET values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH\_OFFSET. However, software rendering may reduce the rendering performance of images displayed as texture-mapped polygons.

---

<b>Property Type</b>	Integer		
<b>Name String</b>	Depth offset		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 (the default) to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

### Note

To preserve backward compatibility with previous versions of IDL the default value of this property is different from that of other graphic objects using this property.

### Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION`, `DEPTH_OFFSET`, and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value.

The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIMENSIONS

Set this property to a two-element integer vector of the form [*width, height*] specifying the dimensions of the rectangle in which the image is to be drawn on the device. The image will be resampled as necessary to fit within this rectangle. The default is derived from the dimensions of the given image data and is measured in pixels. IDL converts, maintains, and returns this data as double-precision floating-point.

Set this property to a scalar value to reset the image dimensions to the implicit dimensions of the data.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Draw dimensions		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## GREYSCALE

A Boolean value that determines whether the image is drawn through a palette.

0 = Use palette (the default).

1 = Do not use a palette.

This property only has an effect on single-band images. If this property is set to 1 and the destination color model is RGB, both the image palette (if present) and the destination device palette (if present) are bypassed, and the image is drawn in greyscale.

If the destination color model is Indexed, this property has no effect since the image pixels are copied directly to the device and are then translated to RGB by the device.

palette. The contents of the device palette determine the colors of the image on the display, which will be greyscale only if the device palette contains a grey ramp.

### Note

Since it is difficult or impossible to map a greyscale image into an arbitrary color palette, this property has no effect on devices using the indexed color model,

<b>Property Type</b>	Boolean		
<b>Name String</b>	Grayscale		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## INTERLEAVE

An integer value that indicates the dimension over which color is interleaved for images with more than one channel:

- 0 = Pixel interleaved: Images with dimensions  $(3, m, n)$
- 1 = Scan line interleaved (row interleaved): Images with dimensions  $(m, 3, n)$
- 2 = Planar interleaved: Images with dimensions  $(m, n, 3)$ .

**Note**

If an alpha channel is present, the 3s should be replaced by 4s. In a greyscale image with an alpha channel, the 3s should be replaced by 2s.

In a property sheet, this property appears as an enumerated list with the following options:

- Pixel
- Scanline
- Planar.

This property is registered, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Interleaving		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**INTERPOLATE**

An integer value to determine whether to display the `IDLgrImage` object using bilinear interpolation. The default is to use nearest neighbor interpolation.

- 0 = Nearest neighbor interpolation (the default)
- 1 = Bilinear interpolation

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Interpolation		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

See [“Interpolation Methods”](#) in Chapter 8 of the *Using IDL* manual for details.

**Note**

Prior to IDL 6.2, IDL performed image interpolation using its own algorithms in software, if requested with the INTERPOLATE property. With the 6.2 performance enhancements, this interpolation is now performed by any texture-mapping acceleration hardware or fallback software in the vendor-supplied hardware and software. Therefore, interpolation results may differ slightly across graphics devices and from pre-6.2 results. To preserve the exact, but slower interpolation results delivered before IDL 6.2, set the RENDER\_METHOD property to 1.

**LOCATION**

A two- or three-element floating-point vector  $[x, y]$  or  $[x, y, z]$  specifying the position of the lower lefthand corner of the image, measured in data units. If the vector is of the form  $[x, y]$ , then the  $z$  value is set equal to zero. The default is  $[0, 0, 0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

On devices using the RGB color model, IDLgrImage renders the image using a texture-mapped polygon, and this polygon is subject to clipping by the near/far clip planes, as defined in the IDLgrView object. To define an arbitrary rotation for an image, see [TRANSFORM\\_MODE](#).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Location		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

See “[Positioning Image Objects in a View](#)” in Chapter 4 of the *Object Programming* manual for an example using the LOCATION property.

**ORDER**

A Boolean value that determines whether to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

In a property sheet, this property appears as an enumerated list with the following options:

- Bottom-to-top
- Top-to-bottom

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Row order		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

### Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

See “[IDLgrPalette::Init](#)” on page 4211 for examples of creating a palette object and assigning it to an image object.

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RENDER\_METHOD

Set this property to 0 (the default) to cause the image to be rendered using a texture-mapped polygon whenever possible.

Set this property to 1 to cause the image to be rendered using a 2D pixel primitive. This is the mode used in versions of IDL prior to 6.2. When this method is used, the ALPHA\_CHANNEL property is ignored and the full 3D transform mode (TRANSFORM\_MODE property value 1) is not available.

The texture-mapped mode is more flexible and generally faster on devices with hardware texture mapping support.

This property has no effect on devices using the indexed color model, where the 2D pixel primitive method is always used.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Render method		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## RESET\_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects.

- 0 = Overwrite data that is shared by other objects (the default).
- 1 = Treat DATA as a new data set unique to this object.

There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE\_DATA

property is not in use). This property has no effect if no new data is provided via the DATA property.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHARE\_DATA

An object reference to an object with which data is to be shared by this image. An image may only share data with another image. The SHARE\_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SUB\_RECT

A four-element floating-point vector,  $[x, y, xdim, ydim]$ , specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle to display, in pixel coordinates.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_COLOR

Set this property to a three-element vector,  $[red, green, blue]$ , specifying the color to draw the tile if no data has been set using [IDLgrImage::SetTileData](#). If data has been

set for the tile being drawn, or data from another level can be substituted, this property is ignored. The default is [0,0,0] (black).

<b>Property Type</b>	USERDEF		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_CURRENT\_LEVEL

Set this property to an integer value that specifies the tile level that the destination object's QueryRequiredTiles method will request and use for drawing. The default is level 0, which is a tile from the full-resolution image. This property only applies when [TILE\\_LEVEL\\_MODE](#) is 0 (manual).

<b>Property Type</b>	INTEGER		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_DIMENSIONS

Set this property to a two-element integer vector specifying the dimensions of an image tile in the form of [*width, height*] in pixel units. The default value is [1024,1024]. Use this property to adjust the tile size to match your application's preferred tile size, if any. If the source of the tiled image data (e.g., image file or file server) has a default tile size, it will be most efficient to set this property to that tile size.

To determine the maximum allowable tile dimensions, use the `MAX_TILE_DIMENSIONS` keyword to the `GetDeviceInfo` method on the destination object (window, clipboard, or buffer object) to which the image will be drawn. If you set a `TILE_DIMENSIONS` value that exceeds the maximum tile dimension supported by the destination object, it will automatically be reduced to the maximum.

### Note

---

Tile dimensions that are a power of 2 (e.g., 256, 512, 1024) are more memory efficient.

---

<b>Property Type</b>	USERDEF		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_LEVEL\_MODE

Set this property to a scalar integer that defines the tile level selection mode. Use one of the following:

0	<p>Manual mode. The application is responsible for setting the level to be used with <a href="#">TILE_CURRENT_LEVEL</a>. The destination object's QueryRequiredTiles method always asks for and renders tiles at that specified level. This is the default.</p> <p>Use this mode if you <i>do not</i> have an image pyramid.</p>
1	<p>Automatic mode. The level to be requested and rendered is calculated by IDL based on image magnification or minification (the ratio of image pixels to screen pixels).</p> <p>Use this mode if you have an image pyramid and want images of different resolutions to be displayed based on zoom level.</p>

### Note

See [“Adding Tiling to Your Application”](#) in Chapter 4 of the *Object Programming* manual for additional information.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_NUM\_LEVELS

This property automatically calculates the number of image levels (resolution levels), or lets you set an integer value that specifies the number of levels in an image pyramid that can be requested by the destination object's `QueryRequiredTiles` method. This is calculated automatically or can be set manually as follows:

Automatically calculated	<p>This is automatically calculated when the image is created such that the lowest resolution level is just smaller than the tile size. For example, if the level 0, full-resolution image is 5000 by 5000 and the tile size is 1024 by 1024 pixels:</p> <ul style="list-style-type: none"> <li>• Level 1 will be 2500 by 2500</li> <li>• Level 2 will be 1250 by 1250</li> <li>• Level 3 will be 625 by 625</li> </ul> <p>Thus there are 4 levels (0 to 3), and level 3 is just smaller than the tile size. The default is to automatically calculate the number of levels based on <code>TILED_IMAGE_DIMENSIONS</code> and <code>TILE_DIMENSIONS</code> when the image is created.</p>
Manually set	<p>Set to an integer value specifying the number of levels. For example, setting 2 will result in <code>QueryRequiredTiles</code> requesting levels 0 and 1 as appropriate, and levels 0 and 1 being used for drawing as appropriate. This is useful if there are insufficient levels available in the image pyramid to match the calculated value of <code>TILE_NUM_LEVELS</code>.</p> <p>Set to 0 (zero) to use all available levels.</p>

### Note

If this property is set to a value higher than the calculated value, it will be ignored, and the calculated value will be used.

This property is only used when `TILE_LEVEL_MODE` is set to 1 (automatic).

<b>Property Type</b>	INTEGER		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_SHOW\_BOUNDARIES

Set this property equal to 1 to draw wireframe outlines around the tiles. This is useful while developing applications that use tiling to help visualize where the tiles are within the image. By default, this property is set equal to 0.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Show tile boundaries		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILED\_IMAGE\_DIMENSIONS

Set this property to a two-element integer vector [*width*, *height*] specifying the pixel size of the original, full-resolution image that will be tiled. This property must be set when the [TILING](#) property set to non-zero value; otherwise, IDL generates an error. The default value is [0,0].

<b>Property Type</b>	USERDEF		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILING

Set this property to 1 to enable tiling for this image object. The default value is 0 (no tiling). Use the destination object's `QueryRequiredTiles` method and the [IDLgrImage::SetTileData](#) method to determine tile visibility and load the appropriate data. Also, you must set [TILED\\_IMAGE\\_DIMENSIONS](#), changing the default value of [0,0] to the actual size of the image to be tiled to avoid generating an error.

### Note

A tiled image cannot be drawn on a destination device using the indexed color model. Also, tiling is not permitted when the image property [RENDER\\_METHOD=1](#).

<b>Property Type</b>	BOOLEAN		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**Note**

When tiling is activated, the object does not use any data stored in its [DATA](#) property. However, the data are available and will be used if `TILING` is set to zero.

See “[Image Tiling](#)” in Chapter 4 of the *Object Programming* manual for details on image tiling.

**TRANSFORM\_MODE**

Set this property to 0 (the default) to cause the image to be rendered into a rectangular region whose sides are always parallel to the window's sides. The rectangular region is defined by two points. The lower left point is specified by the `LOCATION` property. The upper right point is derived from the `LOCATION` property and either the `DIMENSIONS` property or the implicit image dimensions. These two points are transformed by the current model transform and are effectively projected onto a plane located at `LOCATION[2]` (default 0). The image is then drawn in this region. This is the mode used by versions of IDL prior to 6.2.

Set this property to 1 to cause the image to be rendered into an image rectangle where the entire image rectangle is transformed by the current full three-dimensional model transform. The image is rendered into the resulting rectangle, which may not be aligned with the window boundaries. This allows the image to be drawn with the full flexibility of the current model transform. For more information on transformations, see [Transformations of IDLgrImage Objects](#).

This property has no effect on devices using the indexed color model, where mode 0 is always used.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Transform mode		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**XCOORD\_CONV**

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element double-precision floating-point vector of the form [ $x_{min}$ ,  $x_{max}$ ] that specifies the range of  $x$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector, [ $s_0$ ,  $s_1$ ], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element double-precision floating-point vector of the form  $[ymin, ymax]$  that specifies the range of  $y$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Z$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

Two-element double-precision floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrImage::Cleanup

The IDLgrImage::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrImage::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrImage::DeleteTileData

The IDLgrImage::DeleteTileData procedure method removes tile data from the cache. This is useful to free up cache memory if the application knows a number of tiles will not be displayed again for some time. It could also be used if the image data changes and the old image data should be removed from the cache. If you remove a tile from the cache, a subsequent invocation of QueryRequiredTiles returns the tile if it is visible.

This method deletes tiles even if they were loaded with the NO\_FREE keyword set. An error is generated if the tile argument does not specify a valid tile or the level argument specifies an invalid level. If the tile being deleted doesn't have any tile data, no error will be generated.

### Syntax

*Obj*->[IDLgrImage::]DeleteTileData, *TileInfo* [, /ALL]

### Arguments

#### TileInfo

A named structure describing the tile or tiles for which the data is being deleted. This structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.

Table 8-8: IDLIMAGETILE Structure

Field	Data Type	Description
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of $n$ ( $n > 0$ ) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that is displaying the tiled IDLgrImage.

Table 8-8: IDLIMAGETILE Structure (Continued)

If a number of tiles are to be deleted by passing a region covering multiple tiles then X, Y, WIDTH and HEIGHT must be multiples of the tile size.

## Keywords

### ALL

Set this keyword to delete all tiles at all levels in the cache for this image. This is useful for clearing the cache when image data changes and new data will be loaded.

The new tile data may now have a different interleave format and number of channels than any tiles previously stored in the object. See [IDLgrImage::SetTileData](#).

### Note

The *TileInfo* structure must still be passed, and must contain a valid destination object reference in the DEST field. The other entries can be 0 in this case.

## Version History

6.2	Introduced
-----	------------

## IDLgrImage::GetCTM

The IDLgrImage::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrImage::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the image object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrImage::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrImage::GetProperty

The IDLgrImage::GetProperty procedure method retrieves the value of the property or group of properties for the image.

### Syntax

*Obj*->[IDLgrImage::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 4079 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrImage::Init

The IDLgrImage::Init function method initializes the image object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrImage' [, ImageData] [, PROPERTY=value] [, NO_COPY])
```

or

```
Result = Obj->[IDLgrImage::]Init([ImageData] [, PROPERTY=value]  
    [, NO_COPY]) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### ImageData

An array of data values to be displayed as an image. If this argument is not already of byte type, it is converted to byte type when the image object is created. Since IDL maintains the image data using the byte type, the input data values should range from 0 through 255. Image objects can have a single channel (one value per pixel—greyscale or color indexed), two channels (greyscale and alpha), three channels (red, green, and blue), or four channels (red, green, blue, and alpha). The alpha channel, if present, determines the transparency of the pixel. The BLEND\_FUNCTION property controls the interpretation of the alpha channel values. With channels, the data value of 0 specifies minimum intensity and the data value of 255 specifies maximum intensity. The alpha channel values are also specified in the image data in the range 0

through 255, with an image data value of 0 corresponding to an alpha blend factor of 0 and an image data value of 255 corresponding to an alpha blend factor of 1.0.

*ImageData* can be any of the following, where  $n$  is the width of the image, and  $m$  is the height:

- An  $n \times m$  array of color lookup table indices.
- An  $n \times m$  greyscale image, or a  $2 \times n \times m$ ,  $n \times 2 \times m$ , or  $n \times m \times 2$  greyscale image with an alpha channel. (The alpha channel is ignored if the destination device uses indexed color mode.)
- A  $3 \times n \times m$ ,  $n \times 3 \times m$ , or  $n \times m \times 3$  RGB image, or a  $4 \times n \times m$ ,  $n \times 4 \times m$ , or  $n \times m \times 4$  RGB image with an alpha channel.

If the array has more than one channel, the interleave is specified by the INTERLEAVE property.

## Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 4079 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

### NO\_COPY

If this keyword is set to a non-zero value, it relocates the image data from the input variable to the image object, leaving the input variable *ImageData* undefined. Only the *ImageData* argument is affected. The following example illustrates that the data is moved from the input variable.

```
imgdata = BYTSCL(DIST(300))
oImg = OBJ_NEW('IDLgrImage', imgData, /NO_COPY)
HELP, imgdata
; IDL prints IMGDATA UNDEFINED = <Undefined>
```

If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

## Version History

5.0	Introduced
6.2	Added NO_COPY keyword

## IDLgrImage:: SetProperty

The IDLgrImage::SetProperty procedure method sets the value of the property or group of properties for the image.

### Syntax

*Obj*->[IDLgrImage::]SetProperty[, *PROPERTY=*value] [, /NO\_COPY]

### Arguments

None

### Keywords

Any property listed under “IDLgrImage Properties” on page 4079 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

#### NO\_COPY

If this keyword is set to a non-zero value, and the [DATA](#) property is specified in the same invocation, it relocates the image data from the input variable to the image object, leaving the input DATA property variable undefined. Only the DATA property is affected. The following example illustrates that the data is moved from the input variable.

```
imgdata = BYTSCL(DIST(300))
oImg = OBJ_NEW('IDLgrImage')
oImg->SetProperty, DATA=imgdata, /NO_COPY
HELP, imgdata
; IDL prints IMGDATA UNDEFINED = <Undefined>
```

If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

### Version History

5.0	Introduced
6.2	Added NO_COPY keyword

## IDLgrImage::SetTileData

The IDLgrImage::SetTileData procedure method stores tile data in the IDLgrImage tile data cache. If a tile has data loaded but not for the required level, the data associated with the next highest available level will be used instead. Otherwise, IDLgrImage renders the tile using the solid color specified by TILE\_COLOR. An error is generated if any of the parameters are invalid. All units are in terms of pixels.

All image data tiles stored into the image object with SetTileData must be passed in arrays with consistent dimensions. That is, the number of channels and the interleave format must be the same for all tile data arrays. For example, if one tile is stored in an array with dimensions [3,200,340], then all other tile data arrays must have three dimensions where the first dimension value, the number of channels, is always 3. The other two dimension values, the width and height, can vary to express the tile size.

The first call to SetTileData after the object is created or after a call to DeleteTileData with the ALL keyword set determines the tile data array format to be used for all subsequent tiles. IDL generates an error if a tile data array is submitted with an inconsistent array format.

If data has already been set for the specified tile, it will be replaced by the data in the subsequent call to SetTileData.

---

### Note

When you call IDLgrImage::SetProperty after calling SetTileData, and then draw the tiles, the image data may not be displayed. If you set an image property with SetProperty, IDL may update the image data and delete any tiles that were previously stored with the SetTileData method. If this occurs, set image properties before using SetTileData, or set image properties and then call QueryRequiredTiles to reacquire the tiles before setting and drawing the tiles.

---

### Note

See “[Image Tiling](#)” in Chapter 4 of the *Object Programming* manual for information creating an application that uses tiling and code examples.

---

## Syntax

```
Obj->[IDLgrImage::]SetTileData, TileInfo, TileData [, NO_FREE=value]
```

## Arguments

### TileInfo

A named structure describing the tile or tiles for which the data is being set. The structures returned by the destination object's `QueryRequiredTiles` method can be passed directly (one at a time) to `SetTileData` along with the corresponding tile data.

This structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of $n$ ( $n > 0$ ) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that displays the tiled <code>IDLgrImage</code> .

*Table 8-9: IDLIMAGETILE Structure*

If a region of the image composed of multiple tiles is being set, `X`, `Y`, `WIDTH`, and `HEIGHT` must be multiples of the tile size (unless the region extends to the edge of the image in which case `Width` and `Height` do not need to be a multiple of the tile size).

### TileData

The data for the specified tile.

## Keywords

### NO\_FREE

Set this keyword if the tile data should remain loaded for the lifetime of the `IDLgrImage`, unless explicitly deleted by the `DeleteTileData` method. If the tile cache fills up, `IDLgrImage` might automatically delete the least recently used tile data from the cache to make room for new tile data. Setting this keyword prevents the `IDLgrImage` from automatically deleting this tile data in this situation.

## Version History

6.2	Introduced
-----	------------

# IDLgrLegend

The IDLgrLegend object provides a simple interface for displaying a legend. The legend itself consists of a (filled and/or framed) box around one or more legend items (arranged in a single column) and an optional title string. Each legend item consists of a glyph patch positioned to the left of a text string. The glyph patch is drawn in a square which is a fraction of the legend label font height. The glyph itself can be in one of two types (see the TYPE keyword). In line type, the glyph is a line segment with line style, thickness and color attributes and an optional symbol object drawn over it. In fill type, the glyph is a square patch drawn with color and optional pattern object attributes.

An IDLgrLegend object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrlegend__define.pro` in the `lib` subdirectory of the IDL distribution.

- [IDLgrModel](#)
- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## BORDER\_GAP

A floating-point value to indicate the amount of blank space to be placed around the outside of the glyphs and text items. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height).

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLUMNS

An integer value to indicate the number of columns the legend items should be displayed in. The default is one column.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## FILL\_COLOR

The color to be used to fill the legend background box. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [255,255,255].

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## FONT

An object reference to an instance of an IDLgrFont object class that describes the font to use to draw the legend labels. The default is 12 point Helvetica.

### Note

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a font object that will be destroyed when this legend object is destroyed, leaving a dangling object reference.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GAP

A floating-point value that indicates the amount of blank space to be placed vertically between each legend item. The units for this property are fractions of the legend label

font height. The default is 0.1 (10% of the label font height). The same gap is placed horizontally between the legend glyph and the legend text string.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GLYPH\_WIDTH

A floating-point value to indicate the width of the glyphs, measured as a fraction of the font height. The default is 0.8 (80% of the font height).

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ITEM\_COLOR

An array of colors defining the color of each item. The array defines  $M$  different colors, and should be either of the form  $[3,M]$  or  $[M]$ . In the first case, the three values

are used as an RGB triplet, in the second case, the single value is used as a color index value. The default color is [0,0,0].

<b>Property Type</b>	Color array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ITEM\_LINestyle

An integer array of integers defining the style of the line to be drawn if the TYPE property is set to zero. The array can be of the form [M] or [2,M]. The first form selects the linestyle for each legend item from the predefined defaults:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

The second form specifies the stippling pattern explicitly for each legend item (see the LINestyle property to [IDLgrPolyline::Init](#) for details).

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ITEM\_NAME

An string array representing the names of items in the legend. Specifying this property is the same as providing the *aName* argument for the `IDLgrLegend::Init` method.

<b>Property Type</b>	String array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ITEM\_OBJECT

An array of object references of type `IDLgrSymbol` or `IDLgrPattern` that represents the shapes of the items in the legend. A symbol object is drawn only if the `TYPE` property is set to zero. A pattern object is used when drawing the color patch if the `TYPE` property is set to one. The default object is the `NULL` object.

### Note

If one or more `IDLgrSymbol` object references are provided, the `SIZE` property of those objects may be modified by this legend to suit its layout needs.

<b>Property Type</b>	Object reference array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ITEM\_THICK

A floating-point array of floating-point values that define the thickness of each item line, in points, where each element is a value between 1.0 and 10.0. Out-of-range values are quietly clamped to the allowed range. This property is only used if the `TYPE` property is set to zero. The default is 1.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ITEM\_TYPE

An integer array that defines the type of glyph to be displayed for each item:

- 0 = line type (the default)
- 1 = filled box type

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## OUTLINE\_COLOR

The color to be used to draw the legend outline box. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0,0,0].

<b>Property Type</b>	Color		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## OUTLINE\_THICK

A floating-point value between 1.0 and 10.0 that defines the thickness of the outline frame, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PARENT

An object reference to the object that contains this legend.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## RECOMPUTE

A Boolean value that determines whether to recompute the legend dimensions when the legend is redrawn.

- 0 = Prevent IDL from recomputing legend dimensions (the default).
- 1 = Recompute the legend dimensions when the legend is redrawn.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> No	<b>Registered:</b> No

## SHOW\_FILL

A Boolean value that indicates whether the background should be filled with a color:

- 0 = Do not fill background (the default)
- 1 = Fill background

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHOW\_OUTLINE

A Boolean value indicating whether the outline box should be displayed:

- 0 = Do not display outline (the default)
- 1 = Display outline

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TEXT\_COLOR

The color to be used to draw the legend item text. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0,0,0].

<b>Property Type</b>	Color		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the legend. The default is the null object, specifying that no title is drawn. The title will be centered at the top of the legend, even if the text object itself has an associated location.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XCOORD\_CONV

A floating-point vector, [ $s_0, s_1$ ], of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element double-precision floating-point vector of the form  $[xmin, xmax]$  that specifies the range of the  $X$  data coordinates covered by the legend.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert  $Y$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element double-precision floating-point vector of the form  $[ymin, ymax]$  that specifies the range of the  $Y$  data coordinates covered by the legend.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert  $Z$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element double-precision floating-point vector of the form  $[zmin, zmax]$  that specifies the range of the  $Z$  data coordinates covered by the legend.

### Note

Until the legend is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the `ComputedDimensions` method on the legend object to get the data dimensions of the legend prior to a draw operation.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrLegend::Cleanup

The IDLgrLegend::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrLegend::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrLegend::ComputeDimensions

The IDLgrLegend::ComputeDimensions function method retrieves the dimensions of a legend object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the legend object measured in data units.

### Syntax

```
Result = Obj->[IDLgrLegend::]ComputeDimensions( DestinationObject  
[, PATH=objref(s)] )
```

### Return Value

Returns the dimensions of a legend object for the given destination object.

### Arguments

#### DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the legend are being requested.

### Keywords

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLegend::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

#### Note

---

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

---

## Version History

5.1	Introduced
-----	------------

## IDLgrLegend::GetProperty

The IDLgrLegend::GetProperty procedure method retrieves the value of a property or group of properties for the legend.

### Syntax

*Obj*->[IDLgrLegend::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrLegend Properties](#)” on page 4117 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrLegend::Init

The IDLgrLegend::Init function method initializes the legend object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrLegend' [, aItemNames] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrLegend::]Init([aItemNames] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### altemNames

An array of strings to be used as the displayed item label. The length of this array is used to determine the number of items to be displayed. Each item is defined by taking one element from the ITEM\_NAME, ITEM\_TYPE, ITEM\_LINestyle, ITEM\_THICK, ITEM\_COLOR, and ITEM\_OBJECT vectors. If the number of items (as defined by the ITEM\_NAME array) exceeds any of the attribute vectors, the attribute defaults will be used for any additional items.

## Keywords

Any property listed under [“IDLgrLegend Properties”](#) on page 4117 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrLegend:: SetProperty

The IDLgrLegend::SetProperty procedure method sets the value of a property or group of properties for the legend.

### Syntax

*Obj*->[IDLgrLegend::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrLegend Properties” on page 4117 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced
-----	------------

# IDLgrLight

A light object represents a source of illumination for three-dimensional graphic objects. Lights may be either ambient, positional, directional, or spotlights. A maximum of 8 lights per view are allowed. Lights are not required for objects displayed in two dimensions.

An IDLgrLight object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See [“IDLgrLight::Init”](#) on page 4150.

## Properties

Objects of this class have the following properties. See [“IDLgrLight Properties”](#) on page 4138 for details on individual properties.

- [ALL](#)
- [ATTENUATION](#)
- [COLOR](#)
- [CONEANGLE](#)
- [DIRECTION](#)
- [FOCUS](#)
- [HIDE](#)
- [INTENSITY](#)

- [IDLitComponent](#)

## ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

### Note

The fields of this structure may change in subsequent releases of IDL.

---

### Note

This structure returns ALPHA\_CHANNEL, CLIP\_PLANES, DEPTH\_TEST\_DISABLE, DEPTH\_TEST\_FUNCTION, DEPTH\_WRITE\_DISABLE, and [XYZ]RANGE properties that are consistent with other graphic objects. However, these properties are not used by the IDLgrLight object.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ATTENUATION

A 3-element floating-point vector of the form [constant, linear, quadratic] that describes the factor by which light intensity is to fall with respect to distance from the light source. ATTENUATION applies only to Positional and Spot lights, as specified by the TYPE property. The overall attenuation factor is computed as follows:

$$\text{attenuation} = 1 / (\text{constant} + \text{linear} * \text{distance} + \text{quadratic} * \text{distance}^2)$$

By default, the values are [1, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Attenuation		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## COLOR

A three-element byte vector specifying the RGB color of the light. The default is [255, 255, 255], which is a white light. The color of a light is ignored when graphics are sent to graphics destinations using the Indexed color model, in which case light intensities are scaled into the range of colors available on the graphics destination.

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CONEANGLE

A floating-point value that specifies the angle (measured in degrees) of coverage for a spotlight. The default is 60.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Spotlight cone angle		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DIRECTION

A three-element floating-point vector representing the direction in which a spotlight is to be pointed. The default is [0,0,-1].

### Note

---

For directional lights, the light's parallel rays follow a vector beginning at the position specified by LOCATION and ending at [0, 0, 0].

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Spotlight direction		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## FOCUS

A floating-point value that describes the attenuation of intensity for spotlights as the distance from the center of the cone of coverage increases. This factor is used as an exponent to the cosine of the angle between the direction of the spotlight and the direction from the light to the vertex being lighted. The default is 0.0.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Spotlight attenuation		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value that indicates whether this light should be enabled:

- 0 = Enable light (the default)
- 1 = Disable light

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

### Note

---

If no lights are present in the view (or if all lights in the view are hidden), an ambient light will be provided by default.

---

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## INTENSITY

A floating-point value between 0.0 (darkest) and 1.0 (brightest) that indicates the intensity of the light. The default is 1.0.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Intensity		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LOCATION

A floating-point vector of the form  $[x, y, z]$  describing the position of the light. By default, the position is  $[0, 0, 0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Location		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

### Note

---

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## TYPE

An integer that indicates the type of light. Valid values are:

- 0 = Ambient light. An ambient light is a universal light source, which has no direction or position. An ambient light illuminates every surface in the scene equally, which means that no edges are made visible by contrast. Ambient lights control the overall brightness and color of the entire scene. If no value is specified for the TYPE property, an ambient light is created.
- 1 = Positional light. A positional light supplies divergent light rays, and will make the edges of surfaces visible by contrast if properly positioned. A positional light source can be located anywhere in the scene.

- 2 = Directional light. A directional light supplies parallel light rays. The effect is that of a positional light source located at an infinite distance from scene.
- 3 = Spot light. A spot light illuminates only a specific area defined by the light's position, direction, and the cone angle, or angle which the spotlight covers.

In a property sheet, this property appears as an enumerated list with the following options:

- Ambient
- Positional
- Directional
- Spotlight

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Type		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Double-precision floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Double-precision floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Double-precision floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrLight::Cleanup

The IDLgrLight::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrLight::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrLight::GetCTM

The IDLgrLight::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrLight::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the light object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLight::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrLight::GetProperty

The IDLgrLight::GetProperty procedure method retrieves the value of a property or group of properties for the light.

### Syntax

*Obj*->[IDLgrLight::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrLight Properties” on page 4138 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrLight::Init

The IDLgrLight::Init function method initializes the light object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrLight' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrLight::]Init( [, PROPERTY=value] ) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLgrLight Properties](#)” on page 4138 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrLight:: SetProperty

The IDLgrLight::SetProperty procedure method sets the value of a property or group of properties for the light.

### Syntax

*Obj*->[IDLgrLight::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrLight Properties](#)” on page 4138 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrModel

A model object represents a graphical item or group of items that can be transformed (rotated, scaled, and/or translated). It serves as a container of other IDLgrModel objects or atomic graphic objects. IDLgrModel applies a transform to the current view tree.

## Superclasses

[IDL\\_Container](#)

[IDLitComponent](#)

## Creation

See “[IDLgrModel::Init](#)” on page 4171.

## Properties

Objects of this class have the following properties. See “[IDLgrModel Properties](#)” on page 4155 for details on individual properties.

- [ACTIVE\\_POSITION](#)
- [ALL](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [HIDE](#)
- [LIGHTING](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [RENDER\\_METHOD](#)
- [SELECT\\_TARGET](#)
- [TRANSFORM](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrModel::Add](#)
- [IDLgrModel::Cleanup](#)
- [IDLgrModel::Draw](#)
- [IDLgrModel::GetByName](#)
- [IDLgrModel::GetCTM](#)
- [IDLgrModel::GetProperty](#)
- [IDLgrModel::Init](#)
- [IDLgrModel::Reset](#)
- [IDLgrModel::Rotate](#)
- [IDLgrModel::Scale](#)
- [IDLgrModel::SetProperty](#)
- [IDLgrModel::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.2	Added ACTIVE_POSITION, RENDER_METHOD properties

## IDLgrModel Properties

IDLgrModel objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrModel::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrModel::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrModel::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ACTIVE\\_POSITION](#)
- [ALL](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [HIDE](#)
- [LIGHTING](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [RENDER\\_METHOD](#)
- [SELECT\\_TARGET](#)
- [TRANSFORM](#)

In addition, objects of this class inherit:

- [IDL\\_Container](#)
- [IDLitComponent](#)

## ACTIVE\_POSITION

This scalar integer property is a zero-based index into the model container. It indicates the container index of the object that is drawn by this model when the value of the RENDER\_METHOD property is 1.

This property is ignored when the value of the RENDER\_METHOD property is not 1.

The default value of this property is 0, indicating the first object in the container.

If this property specifies an index that does not refer to a valid container index, this model object draws nothing when the value of the RENDER\_METHOD property is 1. This can happen when the value of the ACTIVE\_POSITION property is less than zero, or greater than or equal to the number of objects currently in the container.

This property is registered as an integer, but it is hidden by default.

<b>Property Type</b>	INTEGER		
<b>Name String</b>	Active position		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ALL

An anonymous structure containing the values of all of the properties associated with this object.

### Note

The fields of this structure may change in subsequent releases of IDL.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## CLIP\_PLANES

An 4-by- $N$  floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ .

Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

---

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

---

**Note**

Note - Clipping planes are applied in the data space of the objects this model contains (prior to the application of this model's transform).

---

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Clipping planes		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Depth Test Disable		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Depth Test Enable		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Depth Write Disable		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw model and children (the default)
- 1 = Do not draw model or children

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

**Note**

HIDE only controls the display attributes of IDLgrModel children since the IDLgrModel object itself lacks geometry.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**LIGHTING**

An integer value that indicates whether lighting is to be enabled or disabled for all atomic graphic objects that have this model as a parent. IDLgrModel objects that have this model as a parent will not be effected, as they have their own value for this property. If this value is set to 0, any lights added as children of this model will be used to illuminate any other models in the view hierarchy that have lighting enabled.

- 0 = Disable lighting
- 1 = Enable single-sided lighting
- 2 = Enable double-sided lighting (the default)

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Lighting		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**PARENT**

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RENDER\_METHOD

This scalar integer property specifies how this model object renders the objects in its container.

If this property is set to a value of 0, the default, the model object draws all objects in its container.

If this property is set to a value of 1, the model object draws only the object specified by the ACTIVE\_POSITION property.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Render method		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

See [Chapter 10, “Animating Objects”](#) in the *Object Programming* manual for more information on how to create animation displays when this property is set to 1.

## SELECT\_TARGET

A Boolean value that tags the model object as the target object to be returned when any object contained by the model is selected via the `IDLgrWindow::Select` method.

- 0 = Do not tag the model object as the target object (default).
- 1 = Tag the model object as the target object.

By default, an IDLgrModel object cannot be returned as the target of a SELECT operation since it contains no geometry.

This property is registered as a Boolean property, but it is hidden by default.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Select target		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TRANSFORM

A 4-by-4 floating-point transformation matrix to be applied to the object. This matrix will be multiplied by its parent's transformation matrix (if the parent has one). The default is the identity matrix. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Model transform		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## IDLgrModel::Add

The IDLgrModel::Add procedure method adds a child to this Model.

### Syntax

*Obj*->[IDLgrModel::]Add, *Object* [, /ALIAS] [, POSITION=*index*]

### Arguments

#### Object

An instance of an atomic graphic object or another model object to be added to the model object.

### Keywords

#### ALIAS

Set this keyword to a nonzero value to indicate that an alias—rather than the object itself—is to be added to the model. With this keyword you can add the same object to multiple models without duplicating that object and its children. If this keyword is set, the PARENT keyword on the object being added will not change. Furthermore, if this keyword is set, the object being added will not be destroyed when the model is destroyed.

#### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

### Version History

5.0	Introduced
-----	------------

## IDLgrModel::Cleanup

The IDLgrModel::Cleanup procedure method performs all cleanup on the object.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrModel::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

---

5.0	Introduced
-----	------------

---

## IDLgrModel::Draw

The IDLgrModel::Draw procedure method draws the specified picture to the specified graphics destination. *This method is provided for purposes of sub-classing only, and is intended to be called only from the Draw method of a subclass of IDLgrModel.*

### Note

---

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

---

## Syntax

*Obj->*[IDLgrModel:]Draw, Destination, Picture

## Arguments

### Destination

The destination object ([IDLgrBuffer](#), [IDLgrClipboard](#), [IDLgrPrinter](#), or [IDLgrWindow](#)) to which the specified view object will be drawn.

### Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

## Keywords

None

## Version History

---

5.0	Introduced
-----	------------

---

## IDLgrModel::GetByName

The `IDLgrModel::GetByName` function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the `GetByName` function returns a null object reference.

---

**Note**

The `GetByName` function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

---

## Syntax

*Result* = *Obj*->[IDLgrModel::]GetByName(*Name*)

## Return Value

Returns the object reference to the named object or a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX file system. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the `GetByName` method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrModel::GetCTM

The IDLgrModel::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrModel::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the model object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrModel::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrModel::GetProperty

The IDLgrModel::GetProperty procedure method retrieves the value of a property or group of properties for the model.

### Syntax

*Obj*->[IDLgrModel:]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrModel Properties](#)” on page 4155 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrModel::Init

The IDLgrModel::Init procedure method initializes the model object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrModel' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrModel::]Init( [, PROPERTY=value)  (In a lifecycle method  
only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrModel Properties” on page 4155 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrModel::Reset

The IDLgrModel::Reset procedure method sets the current transform matrix for the model object to the identity matrix.

**Note**

Using this method is functionally identical to the following statement:

```
Obj->[IDLgrModel::]SetProperty, TRANSFORM=IDENTITY(4)
```

## Syntax

*Obj*->[IDLgrModel::]Reset

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrModel::Rotate

The IDLgrModel::Rotate procedure method rotates the model about the specified axis by the specified angle. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

### Syntax

*Obj*->[IDLgrModel:]Rotate, *Axis*, *Angle* [, /PREMULTIPLY]

### Arguments

#### Axis

A three-element vector of the form  $[x, y, z]$  describing the axis about which the model is to be rotated.

#### Angle

The angle (measured in degrees) by which the rotation is to occur.

### Keywords

#### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

### Version History

5.0	Introduced
-----	------------

## IDLgrModel::Scale

The IDLgrModel::Scale procedure method scales the model by the specified scaling factors. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

### Syntax

*Obj*->[IDLgrModel::]Scale, *Sx*, *Sy*, *Sz* [, /PREMULTIPLY]

### Arguments

#### **Sx, Sy, Sz**

The scaling factors in the *x*, *y*, and *z* dimensions by which the model is to be scaled.

### Keywords

#### **PREMULTIPLY**

Set this keyword to cause the scaling matrix specified by *Sx*, *Sy*, *Sz* to be pre-multiplied to the model's transformation matrix. By default, the scaling matrix is post-multiplied.

### Version History

5.0	Introduced
-----	------------

## IDLgrModel:: SetProperty

The IDLgrModel::SetProperty procedure method sets the value of a property or group of properties for the model.

### Syntax

*Obj*->[IDLgrModel::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrModel Properties](#)” on page 4155 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

## IDLgrModel::Translate

The IDLgrModel::Translate procedure method translates the model about the specified axis by the specified translation offsets. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

### Syntax

*Obj*->[IDLgrModel::]Translate, *Tx*, *Ty*, *Tz* [, /PREMULTIPLY]

### Arguments

#### **Tx, Ty, Tz**

The offsets in X, Y, and Z, respectively, by which the model is to be translated.

### Keywords

#### **PREMULTIPLY**

Set this keyword to cause the translation matrix specified by *Tx*, *Ty*, *Tz* to be pre-multiplied to the model's transformation matrix. By default, the translation matrix is post-multiplied.

### Version History

5.0	Introduced
-----	------------

# IDLgrMPEG

An IDLgrMPEG object creates an MPEG movie file from an array of image frames.

---

**Note**

The MPEG standard does not allow movies with odd numbers of pixels to be created.

---

---

**Note**

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

---

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrMPEG::Init](#)” on page 4190.

## Properties

Objects of this class have the following properties. See “[IDLgrMPEG Properties](#)” on page 4181 for details on individual properties.

- [ALL](#)
- [BITRATE](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [FORMAT](#)
- [FRAME\\_RATE](#)
- [IFRAME\\_GAP](#)
- [INTERLACED](#)
- [MOTION\\_VEC\\_LENGTH](#)
- [QUALITY](#)
- [SCALE](#)

- [STATISTICS](#)
- [TEMP\\_DIRECTORY](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrMPEG::Cleanup](#)
- [IDLgrMPEG::GetProperty](#)
- [IDLgrMPEG::Init](#)
- [IDLgrMPEG::Put](#)
- [IDLgrMPEG::Save](#)
- [IDLgrMPEG::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

If you have a series of image objects (or simple image arrays), you can combine them into a single MPEG file using the `IDLgrMPEG` object. Suppose you have an array image array containing `IDLgrImage` objects that represent a time-series. You could use the following commands to create an MPEG file from the images.

First, create an MPEG object, and populate the file with frames from the *imagearray* array:

```
myMPEG = OBJ_NEW('IDLgrMPEG', FILENAME='mympeg.mpg')
FOR image = 0, N_ELEMENTS(imagearray) DO BEGIN
    myMPEG->Put, imagearray[image], image
ENDFOR
; Save the MPEG file:
myMPEG->Save
```

---

### Note

Note that `imagearray` can contain either `IDLgrImage` objects or simple two-dimensional image arrays. All of the arrays or image objects must have the same dimensions.

---

## Version History

5.1	Introduced
-----	------------

## IDLgrMPEG Properties

IDLgrMPEG objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrMPEG::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrMPEG::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrMPEG::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [BITRATE](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [FORMAT](#)
- [FRAME\\_RATE](#)
- [IFRAME\\_GAP](#)
- [INTERLACED](#)
- [MOTION\\_VEC\\_LENGTH](#)
- [QUALITY](#)
- [SCALE](#)
- [STATISTICS](#)
- [TEMP\\_DIRECTORY](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## BITRATE

A double-precision floating-point value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

*Table 8-10: BITRATE Value Range*

Set this property to 0.0 (the default setting) to indicate that IDL should compute the BITRATE value based upon the value you have specified for the QUALITY property. The value of BITRATE returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

### Note

Only use the BITRATE property if changing the QUALITY property value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIMENSIONS

A two-element integer array specifying the dimensions (in pixels) of each of the images to be used as frames for the movie. If this property is not specified, the dimensions of the first image loaded will be used. Once `IDLgrMPEG::Put` has been called, this property can no longer be set.

### Note

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth.

## FILENAME

A string that represents the name of the file in which the encoded MPEG sequence is to be stored. The default is 'idl.mpg'.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## FORMAT

A Boolean value that specifies the type of MPEG encoding to use:

- 0 = MPEG1 (the default)
- 1 = MPEG2

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## FRAME\_RATE

An integer value that specifies the frame rate used in creating the MPEG file:

Value	Descriptions
1	23.976 frames/sec: NTSC encapsulated film rate
2	24 frames/sec: Standard international film rate
3	25 frames/sec: PAL video frame rate
4	29.97 frames/sec: NTSC video frame rate
5	30 frames/sec: NTSC drop frame video frame rate (the default)
6	50 frames/sec: Double frame rate/progressive PAL
7	59.94 frames/sec: Double frame rate NTSC
8	60 frames/sec: Double frame rate NTSC drop frame video

Table 8-11: FRAME\_RATE Values

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IFRAME\_GAP

A positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

Set this property to 0 (the default setting) to indicate that IDL should compute the IFRAME\_GAP value based upon the value you have specified for the QUALITY property. The value of IFRAME\_GAP returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

### Note

Only use the IFRAME\_GAP property if changing the QUALITY property value does not produce the desired results.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## INTERLACED

A Boolean value that indicates whether frames in the encoded MPEG file should be interlaced.

- 0 = Non-interlaced (the default)
- 1 = Interlaced

When interlacing is set, the video data is written to the file by writing the odd-numbered scan lines first, followed by the even-numbered scan lines. This format is used to provide smoother screen refreshing on slower display devices. You may need to generate an interlaced file if the intended playback device requires interlaced video data. Most modern MPEG playback devices can handle non-interlaced (progressive scan) video.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## MOTION\_VEC\_LENGTH

An integer value that specifies the length of the motion vectors to be used to generate predictive frames. The following table describes the valid values:

Value	Description
1	Small motion vectors.
2	Medium motion vectors.
3	Large motion vectors.

Table 8-12: *MOTION\_VEC\_LENGTH* Values

0 (the default setting) indicates that IDL should compute the MOTION\_VEC\_LENGTH value based upon the value you have specified for the QUALITY property. The value of MOTION\_VEC\_LENGTH returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero value stored in this property.

---

**Note**

Only use the MOTION\_VEC\_LENGTH property if changing the QUALITY value does not produce the desired results.

---

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## QUALITY

An integer value between 0 (low quality) and 100 (high quality), inclusive, that specifies the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

---

**Note**

Since MPEG uses JPEG (lossy) compression, the original picture quality cannot be reproduced even when setting QUALITY to its highest setting.

---

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SCALE

A two-element floating-point vector, [*xscale*, *yscale*], indicating the scale factors to be stored with the MPEG file as hints for playback. The default is [1.0, 1.0],

indicating that the movie should be played back at the dimensions of the stored image frames.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## STATISTICS

A Boolean value that determines whether to save statistical information about MPEG encoding for the supplied image frames in a file when the `IDLgrMPEG::Save` method is called. The information will be saved in a file with a name that matches that specified by the `FILENAME` property, with the extension `".stat"`.

- 0 = Statistics are not saved (the default).
- 1 = Save statistics.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TEMP\_DIRECTORY

A string value that specifies the directory in which to place temporary files while creating the MPEG movie file. The default value is platform specific.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrMPEG::Cleanup

The IDLgrMPEG::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrMPEG::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrMPEG::GetProperty

The IDLgrMPEG::GetProperty procedure method retrieves the value of a property or group of properties for the MPEG object.

### Syntax

*Obj*->[IDLgrMPEG::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrMPEG Properties” on page 4181 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrMPEG::Init

The IDLgrMPEG::Init function method initializes the MPEG object.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

### Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

---

## Syntax

```
Obj = OBJ_NEW('IDLgrMPEG' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrMPEG::]Init( [, PROPERTY=value])  (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under [“IDLgrMPEG Properties”](#) on page 4181 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrMPEG::Put

The IDLgrMPEG::Put procedure method puts a given image into the MPEG sequence at the specified frame. Note that all images in a given MPEG movie must have matching dimensions. If no dimensions were explicitly specified when the MPEG object was initialized, the dimensions will be set according to the dimensions of the first image.

### Syntax

*Obj*->[IDLgrMPEG::]Put, *Image*[, *Frame*]

### Arguments

#### Image

An instance of an IDLgrImage object or a  $m \times n$  or  $3 \times m \times n$  array representing the image to be loaded at the given frame.

#### Frame

An integer specifying the index of the frame at which the image is to be added. Frame indices start at zero. If *Frame* is not supplied, the frame number used will be one more than the last frame that was put. Frame number need not be consecutive; in case of a gap in frame numbers, the frame before the gap is repeated to fill the space.

### Keywords

None

### Version History

5.1	Introduced
-----	------------

## IDLgrMPEG::Save

The IDLgrMPEG::Save procedure method encodes and saves the MPEG sequence to the specified filename.

---

**Note**

The MPEG standard does not allow movies with odd numbers of pixels to be created.

---

## Syntax

*Obj*->[IDLgrMPEG::]Save [, FILENAME=*string*]

## Arguments

None

## Keywords

### FILENAME

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is `idl.mpg`.

## Version History

5.1	Introduced
Pre 6.1	Deprecated CREATOR_TYPE keyword

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

## IDLgrMPEG:: SetProperty

The IDLgrMPEG::SetProperty procedure method sets the value of a property or group of properties for the MPEG object.

### Syntax

*Obj*->[IDLgrMPEG::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrMPEG Properties](#)” on page 4181 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced
-----	------------

# IDLgrPalette

A palette object represents a color lookup table that maps indices to red, green, and blue values.

## Superclasses

None

## Creation

See “[IDLgrPalette::Init](#)” on page 4211.

## Properties

Objects of this class have the following properties. See “[IDLgrPalette Properties](#)” on page 4204 for details on individual properties.

- [ALL](#)
- [BLUE\\_VALUES](#)
- [BOTTOM\\_STRETCH](#)
- [GAMMA](#)
- [GREEN\\_VALUES](#)
- [NAME](#)
- [N\\_COLORS](#)
- [RED\\_VALUES](#)
- [TOP\\_STRETCH](#)
- [UVALUE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has this following methods:

- [IDLgrPalette::Cleanup](#)
- [IDLgrPalette::GetRGB](#)

- [IDLgrPalette::GetProperty](#)
- [IDLgrPalette::Init](#)
- [IDLgrPalette::LoadCT](#)
- [IDLgrPalette::NearestColor](#)
- [IDLgrPalette::SetRGB](#)
- [IDLgrPalette::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

This section contains the following examples:

- [“Displaying Indexed Images with Object Graphics”](#) on page 4196 — accesses the palette associated with an indexed image and passes the palette data to an IDLgrPalette object
- [“Highlighting Features with Color in Object Graphics”](#) on page 4199 — loads a pre-defined color table into a palette object and then modifies this color table to highlight image features

## Displaying Indexed Images with Object Graphics

An indexed image contains up to 256 colors, typically defined by a color table associated with the image. The value of each pixel relates to a color within the associated color table. Combinations of the primary colors (red, green, and blue) make up the colors within the color table. Most indexed images are stored as byte and therefore do not require scaling prior to display.

The following example imports an indexed image from the `avhrr.png` image file. This indexed image is a satellite photograph of the world. Complete the following steps for a detailed description of the process.

### Example Code

---

See `displayindexedimage_object.pro` in the `examples/doc/objects` subdirectory of the IDL installation directory for code that duplicates this example.

---

1. Determine the path to the `avhrr.png` file:

```
file = FILEPATH('avhrr.png', $
SUBDIRECTORY = ['examples', 'data'])
```

- Use `QUERY_IMAGE` to query the file to determine image parameters:

```
queryStatus = QUERY_IMAGE(file, imageInfo)
```

- Output the results of the file query:

```
PRINT, 'Query Status = ', queryStatus
HELP, imageInfo, /STRUCTURE
```

The following text appears in the Output Log:

```
Query Status =          1
** Structure <141d0b0>, 7 tags, length=36, refs=1:
  CHANNELS      LONG      1
  DIMENSIONS    LONG      Array[2]
  HAS_PALETTE   INT       1
  IMAGE_INDEX   LONG      0
  NUM_IMAGES    LONG      1
  PIXEL_TYPE    INT       1
  TYPE          STRING    'PNG'
```

- Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

The `HAS_PALETTE` tag has a value of 1. Thus, the image has a palette (color table), which is also contained within the file. The color table is made up of its three primary components (the red component, the green component, and the blue component).

- Use `READ_IMAGE` to import the image and its associated color table from the file:

```
image = READ_IMAGE(file, red, green, blue)
```

- Initialize the display objects:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
  DIMENSIONS = imageSize, TITLE = 'An Indexed Image')
oView = OBJ_NEW('IDLgrView', $
  VIEWPLANE_RECT = [0., 0., imageSize])
oModel = OBJ_NEW('IDLgrModel')
```

- Initialize the image's palette object:

```
oPalette = OBJ_NEW('IDLgrPalette', red, green, blue)
```

- Initialize the image object with the resulting palette object:

```
oImage = OBJ_NEW('IDLgrImage', image, $
  PALETTE = oPalette)
```

9. Add the image object to the model, which is added to the view, then display the view in the window:

```
oModel -> Add, oImage
oView -> Add, oModel
oWindow -> Draw, oView
```

10. Use the colorbar object to display the associated color table in another window:

```
oCbWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [256, 48], $
    TITLE = 'Original Color Table')
oCbView = OBJ_NEW('IDLgrView', $
    VIEWPLANE_RECT = [0., 0., 256., 48.])
oCbModel = OBJ_NEW('IDLgrModel')
oColorbar = OBJ_NEW('IDLgrColorbar', PALETTE = oPalette, $
    DIMENSIONS = [256, 16], SHOW_AXIS = 1)
oCbModel -> Add, oColorbar
oCbView -> Add, oCbModel
oCbWindow -> Draw, oCbView
```

The following figure shows the resulting indexed image and its color table.

*Figure 8-3: Indexed Image and Associated Color Table in Object Graphics*

The data values within the image are indexed to specific colors within the table. You can change the color table associated with this image to show how an indexed image is dependent upon its related color tables.

11. Change the palette (color table) to the EOS B pre-defined color table:

```
oPalette -> LoadCT, 27
```

12. Redisplay the image in another window to show the palette change:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
  DIMENSIONS = imageSize, TITLE = 'An Indexed Image')
oWindow -> Draw, oView
```

13. Redisplay the colorbar in another window to show the palette change:

```
oCbWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
  DIMENSIONS = [256, 48], $
  TITLE = 'EOS B Color Table')
oCbWindow -> Draw, oCbView
```

The following figure shows the indexed image with the EOS B color table.

*Figure 8-4: Indexed Image and EOS B Color Table in Object Graphics*

14. Clean up the object references. When working with objects always remember to clean up any object references with the OBJ\_DESTROY routine. Since the view contains all the other objects, except for the window (which is destroyed by the user), you only need to use OBJ\_DESTROY on the view object.

```
OBJ_DESTROY, [oView, oCbView, oPalette]
```

## Highlighting Features with Color in Object Graphics

This example shows how to create a color table to highlight image features using Object Graphics. Complete the following steps for a detailed description of the process.

**Example Code**

See `highlightfeatures_object.pro` in the `examples/doc/objects` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `mineral.png` file:

```
mineralFile = FILEPATH('mineral.png', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image and its associated color table into IDL:

```
mineralImage = READ_PNG(mineralFile, red, green, blue)
```

3. Determine the size of the imported image:

```
mineralSize = SIZE(mineralImage, /DIMENSIONS)
```

4. Initialize objects necessary for a graphics display:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [mineralSize[0], mineralSize[1]], $
    TITLE = 'mineral.png')
oView = OBJ_NEW('IDLgrView', VIEWPLANE_RECT = [0., 0., $
    mineralSize[0], mineralSize[1]])
oModel = OBJ_NEW('IDLgrModel')
```

5. Initialize a palette object containing the image's associated color table and apply the palette to the image objects:

```
oPalette = OBJ_NEW('IDLgrPalette', red, green, blue)
oImage = OBJ_NEW('IDLgrImage', mineralImage, $
    PALETTE = oPalette)
```

The objects are then added to the view, which is displayed in the window.

6. Add the image to the model, then add the model to the view:

```
oModel -> Add, oImage
oView -> Add, oModel
```

Draw the view in the window:

```
oWindow -> Draw, oView
```

This scanning electron microscope image shows mineral deposits in a sample of polished granite and gneiss. The associated color table is a reverse grayscale.

The following figure shows that the associated color table highlights the gneiss very well, but the other features are not very clear. The other features can be defined with IDL's pre-defined color table, RAINBOW.

*Figure 8-5: Mineral Image and Default Color Table (Object Graphics)*

The palette can easily be modified to show the RAINBOW pre-defined color table in another instance of the window object.

7. Update palette with RAINBOW color table and then display the image with this color table in another instance window of the window object:

```
oPalette -> LoadCT, 13
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [mineralSize[0], mineralSize[1]], $
    TITLE = 'RAINBOW Color')
oWindow -> Draw, oView
```

The following figure shows that the yellow, cyan, and red sections are now apparent, but the cracks are no longer visible. Details within the yellow areas

and the green background are also difficult to distinguish. These features can be highlighted by designing your own color table.

*Figure 8-6: Mineral Image and RAINBOW Color Table (Object Graphics)*

The features within the image are at specific ranges in between 0 and 255. Instead of a progressive color table, specific colors can be defined to be constant over these ranges. Any contrasting colors can be used, but the easiest to derive are the additive and subtractive primary colors used in the previous section.

8. Define colors for a new color table:

```
colorLevel = [[0, 0, 0], $ ; black
              [255, 0, 0], $ ; red
              [255, 255, 0], $ ; yellow
              [0, 255, 0], $ ; green
              [0, 255, 255], $ ; cyan
              [0, 0, 255], $ ; blue
              [255, 0, 255], $ ; magenta
              [255, 255, 255]] ; white
```

9. Create a new color table that contains eight levels, including the highest end boundary by first deriving levels for each color in the new color table:

```
numberOfLevels = CEIL(!D.TABLE_SIZE/8.)
level = INDGEN(!D.TABLE_SIZE)/numberOfLevels
```

10. Place each color level into its appropriate range.

```
newRed = colorLevel[0, level]
newGreen = colorLevel[1, level]
newBlue = colorLevel[2, level]
```

11. Include the last color in the last level:

```
newRed[!D.TABLE_SIZE - 1] = 255
```

```
newGreen[!D.TABLE_SIZE - 1] = 255
newBlue[!D.TABLE_SIZE - 1] = 255
```

Apply the new color table to the palette object:

12. Display the image with this color table in another window:

```
oPalette -> SetProperty, RED_VALUES = newRed, $
GREEN_VALUES = newGreen, BLUE_VALUES = newBlue
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
DIMENSIONS = [mineralSize[0], mineralSize[1]], $
TITLE = 'Cube Corner Colors')
oWindow -> Draw, oView
```

The following figure shows that each image feature is readily distinguishable.

*Figure 8-7: Mineral Image and Derived Color Table (Object Graphics)*

13. Clean up object references. When working with objects always remember to clean up any object references with the OBJ\_DESTROY routine. Since the view contains all the other objects, except for the window (which is destroyed by the user), you only need to use OBJ\_DESTROY on the view and the palette object:

```
OBJ_DESTROY, [oView, oPalette]
```

## Version History

5.0	Introduced
6.2	Added UVALE and NAME properties

## IDLgrPalette Properties

IDLgrPalette objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPalette::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPalette::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPalette::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [BLUE\\_VALUES](#)
- [BOTTOM\\_STRETCH](#)
- [GAMMA](#)
- [GREEN\\_VALUES](#)
- [NAME](#)
- [N\\_COLORS](#)
- [RED\\_VALUES](#)
- [TOP\\_STRETCH](#)
- [UVALUE](#)

### ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

**Note**

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## BLUE\_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the `IDLgrPalette::Init` method.

<b>Property Type</b>	Byte vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## BOTTOM\_STRETCH

An integer value in the range of  $0 \leq \textit{Value} \leq 100$  to indicate what percentage of the palette entries at the bottom of the palette should be filled with the value of the first palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at this entry and ending at the entry specified by the value of the `TOP_STRETCH` property. The default is 0 (zero).

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GAMMA

A floating-point value that indicates the gamma value to be applied to the color palette. This value should be in the range of  $0.1 \leq \textit{Gamma} \leq 10.0$ . The default is 1.0.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GREEN\_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrPalette::Init method.

<b>Property Type</b>	Byte-vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## NAME

A string giving the human-readable name of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Name		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_COLORS

An integer value that determines the number of elements in the color palette.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## RED\_VALUES

A byte vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrPalette::Init method.

<b>Property Type</b>	Byte vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TOP\_STRETCH

A floating-point value in the range of  $0 \leq \textit{Value} \leq 100$  to indicate what percentage of the palette entries at the top of the palette should be filled with the value of the last palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at the entry specified by the value of the `BOTTOM_STRETCH` property and ending at this entry. The default is 0 (zero).

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## UVALUE

A value of any type containing any information you wish.

### Note

---

Object references or pointers contained in the `UVALUE` property are *not* automatically cleaned up when the `IDLgrPalette` object is destroyed.

---

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrPalette::Cleanup

The IDLgrPalette::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrPalette::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrPalette::GetRGB

The IDLgrPalette::GetRGB function method returns the RGB values contained in the palette at the given index. The returned value is a three-element vector of the form [red, green, blue].

### Syntax

*Result* = *Obj*->[IDLgrPalette::]GetRGB(*Index*)

### Return Value

Returns the RGB values contained in the palette at the given index.

### Arguments

#### Index

The index whose RGB values are desired. This value should be in the range of  $0 \leq \textit{Index} < \text{N\_COLORS}$ , where N\_COLORS is the number of elements in the color palette, as returned by the N\_COLORS keyword to the IDLgrPalette:GetProperty method.

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrPalette::GetProperty

The IDLgrPalette::GetProperty procedure method retrieves the value of a property or group of properties for the palette.

### Syntax

*Obj*->[IDLgrPalette::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 4204 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrPalette::Init

The IDLgrPalette::Init function method initializes a palette object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrPalette', aRed, aGreen, aBlue [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPalette::]Init([aRed, aGreen, aBlue] [, PROPERTY=value])  
(In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### aRed

A vector containing the red values for the color palette. These values should be within the range of  $0 \leq \text{Value} \leq 255$ . The number of elements comprising the *aRed* vector must not exceed 256.

### aGreen

A vector containing the green values for the color palette. These values should be within the range of  $0 \leq \text{Value} \leq 255$ . The number of elements comprising the *aGreen* vector must not exceed 256.

## aBlue

A vector containing the blue values for the color palette. These values should be within the range of  $0 \leq \text{Value} \leq 255$ . The number of elements comprising the *aBlue* vector must not exceed 256.

## Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 4204 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrPalette::LoadCT

The IDLgrPalette::LoadCT procedure method loads one of the IDL predefined color tables into an IDLgrPalette object.

### Syntax

*Obj*->[IDLgrPalette::]LoadCT, *TableNum* [, FILE=*colortable filename*]

### Arguments

#### TableNum

The number of the pre-defined IDL color table to load, from 0 to 40.

### Keywords

#### FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl` in the IDL distribution. The MODIFYCT procedure can be used to create and modify colortable files.

### Version History

5.0	Introduced
-----	------------

## IDLgrPalette::NearestColor

The IDLgrPalette::NearestColor function method returns the index of the color in the palette that best matches the given RGB values.

### Syntax

*Result* = *Obj*->[IDLgrPalette::]NearestColor(*Red*, *Green*, *Blue*)

### Return Value

Returns the index of the color in the palette that best matches the given RGB values.

### Arguments

#### Red

The red value of the color that should be matched. This value should be within the range of  $0 \leq \text{Value} \leq 255$ .

#### Green

The green value of the color that should be matched. This value should be within the range of  $0 \leq \text{Value} \leq 255$ .

#### Blue

The blue value of the color that should be matched. This value should be within the range of  $0 \leq \text{Value} \leq 255$ .

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrPalette::SetRGB

The IDLgrPalette::SetRGB procedure method sets the color values at a specified index in the palette to the specified Red, Green and Blue values.

### Syntax

*Obj*->[IDLgrPalette::]SetRGB, *Index*, *Red*, *Green*, *Blue*

### Arguments

#### Index

The index within the Palette object to be set. This value should be in the range of  $0 \leq \textit{Value} < \textit{N\_COLORS}$ .

#### Red

The red value to set in the color palette.

#### Green

The green value to set in the color palette.

#### Blue

The blue value to set in the color palette.

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrPalette:: SetProperty

The IDLgrPalette::SetProperty procedure method sets the value of a property or group of properties for the palette.

### Syntax

*Obj*->[IDLgrPalette::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrPalette Properties” on page 4204 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrPattern

A pattern object describes which pixels are filled and which are left blank when an area is filled. Pattern objects are used by setting the `FILL_PATTERN` property of a polygon object equal to the object reference of the pattern object.

## Superclasses

None

## Creation

See [“IDLgrPattern::Init”](#) on page 4225.

## Properties

Objects of this class have the following properties. See [“IDLgrPattern Properties”](#) on page 4219 for details on individual properties.

- [ALL](#)
- [NAME](#)
- [ORIENTATION](#)
- [PATTERN](#)
- [SPACING](#)
- [STYLE](#)
- [THICK](#)
- [UVALUE](#)

## Methods

This class has this following methods:

- [IDLgrPattern::Cleanup](#)
- [IDLgrPattern::GetProperty](#)
- [IDLgrPattern::Init](#)
- [IDLgrPattern::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
6.2	Added UVALUE and NAME properties

## IDLgrPattern Properties

IDLgrPattern objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPattern::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPattern::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPattern:SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [NAME](#)
- [ORIENTATION](#)
- [PATTERN](#)
- [SPACING](#)
- [STYLE](#)
- [THICK](#)
- [UVALUE](#)

### ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

### Note

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## NAME

A string giving the human-readable name of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Name		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ORIENTATION

An integer representing the angle (measured in degrees counterclockwise from the horizontal) of the lines used in a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to one.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PATTERN

A 32 x 32 bit array (bitmap) describing the pattern that will be tiled over a polygon when a pattern fill is used. The bitmap must be configured as a 4 x 32 “bitmap byte array” as created by the CVTTOBM function. Each bit that is a 1 is drawn, each bit that is 0 is not drawn. Each bit in this array represents a 1 point by 1 point square area of pixels on the destination device. This property is ignored unless the *Style* argument (or STYLE property) is set to 2.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SPACING

A floating-point value representing the distance (measured in points) between the lines used for a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to 1. The default is 2.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## STYLE

An integer value that specifies the type of pattern, as follows:

- 0 = Solid (default)
- 1 = Line Fill
- 2 = Pattern

This property is the same as the *Style* argument described in “IDLgrPattern::Init” on page 4225.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0 that specifies the line thickness to be used to draw the pattern lines for a Line Fill, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points. This property is ignored unless the *Style* argument or STYLE property is set to 1.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## UVALUE

A value of any type containing any information you wish.

### Note

---

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrPattern object is destroyed.

---

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrPattern::Cleanup

The IDLgrPattern::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrPattern::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrPattern::GetProperty

The IDLgrPattern::GetProperty procedure method retrieves the value of a property or group of properties for the pattern.

### Syntax

*Obj*->[IDLgrPattern::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 4219 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.0	Introduced
-----	------------

## IDLgrPattern::Init

The IDLgrPattern::Init function method initializes the pattern object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrPattern' [, Style] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPattern::]Init([Style] [, PROPERTY=value]) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Style

A integer value representing the type of pattern. Valid values are:

- 0 = Solid color (default)
- 1 = Line Fill
- 2 = Pattern

## Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 4219 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

5.0	Introduced
-----	------------

## IDLgrPattern:SetProperty

The IDLgrPattern::SetProperty procedure method sets the value of a property or group of properties for the pattern.

### Syntax

*Obj*->[IDLgrPattern::](#)SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 4219 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrPlot

A plot object creates a set of polylines connecting data points in two-dimensional space.

An IDLgrPlot object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

---

**Note**

See [IDLgrAxis](#) for information on configuring plot axes.

---

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrPlot::Init](#)” on page 4250.

## Properties

Objects of this class have the following properties. See “[IDLgrPlot Properties](#)” on page 4230 for details on individual properties.

- [ALL](#)
- [CLIP\\_PLANES](#)
- [DATA](#)
- [DATAY](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DOUBLE](#)
- [HISTOGRAM](#)
- [MAX\\_VALUE](#)
- [NSUM](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [ALPHA\\_CHANNEL](#)
- [COLOR](#)
- [DATAX](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [MIN\\_VALUE](#)
- [PALETTE](#)
- [POLAR](#)
- [RESET\\_DATA](#)

- [SHARE\\_DATA](#)
- [THICK](#)
- [VERT\\_COLORS](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)
- [SYMBOL](#)
- [USE\\_ZVALUE](#)
- [XCOORD\\_CONV](#)
- [YCOORD\\_CONV](#)
- [ZCOORD\\_CONV](#)
- [ZVALUE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrPlot::Cleanup](#)
- [IDLgrPlot::GetCTM](#)
- [IDLgrPlot::GetProperty](#)
- [IDLgrPlot::Init](#)
- [IDLgrPlot::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property

## IDLgrPlot Properties

IDLgrPlot objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPlot::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPlot::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPlot::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties. See [“IDLgrPlot Properties”](#) on page 4230 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DATA\\_X](#)
- [DATA\\_Y](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [HISTOGRAM](#)
- [LINESYLE](#)
- [MAX\\_VALUE](#)
- [MIN\\_VALUE](#)
- [NSUM](#)
- [PALETTE](#)
- [PARENT](#)
- [POLAR](#)
- [REGISTER\\_PROPERTIES](#)
- [RESET\\_DATA](#)
- [SHARE\\_DATA](#)
- [SYMBOL](#)
- [THICK](#)
- [USE\\_ZVALUE](#)
- [VERT\\_COLORS](#)
- [XCOORD\\_CONV](#)
- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)
- [ZVALUE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

---

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the plot. The default value of 1.0 causes IDL to draw the plot completely opaque. If the value of this property is less than 1.0, then the pixels of the plot are blended with the pixels already on the screen, where the color of the plot is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode. If 3-channel (RGB) VERT\_COLORS are supplied, then the value of this property is used for the alpha at each vertex when drawing the plot line. If 4-channel (RGBA) VERT\_COLORS are supplied, then the alpha from each vertex color is used for the alpha at each vertex when drawing the plot line.

When a plot is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT\_COLORS are supplied. If the VERT\_COLORS are RGB, then the alpha value of the symbol is used to draw the symbol. If the VERT\_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

**Note**

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**CLIP\_PLANES**

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

The color to be used as the foreground color for this plot. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DATA

The plot data of any type in a  $3 \times n$  array, [*DataX*, *DataY*, *DataZ*].

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DATA X

A vector of any type that specifies the X values to be plotted. This property is the same as the X argument.

<b>Property Type</b>	Vector of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATAY

A vector of any type that specifies the Y values to be plotted. This property is the same as the Y argument.

<b>Property Type</b>	Vector of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

### Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = `INHERIT` - use value from parent model or view.
- 1 = `NEVER` - never passes.
- 2 = `LESS` - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HISTOGRAM

A Boolean value that determines whether to use only horizontal and vertical lines to connect the plotted points.

- 0 = The points are connected using a single straight line (the default).
- 1 = Use only horizontal and vertical lines to connect the plotted points.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Histogram plot		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LINestyle

An integer value that indicates the line style to be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the `LINestyle` property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the

*bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq repeat \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

<b>Property Type</b>	Linestyle		
<b>Name String</b>	Line style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MAX\_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. When this property is set, data values greater than the value of `MAX_VALUE` are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Maximum value		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MIN\_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of `MIN_VALUE` are treated as missing data and are not plotted. Note that the IEEE floating-point value

NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Minimum value		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## NSUM

An integer value representing the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

<b>Property Type</b>	Integer		
<b>Name String</b>	Points to average		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## POLAR

A Boolean value that determines whether to create a polar plot. The *X* and *Y* arguments must both be present. The *X* argument represents the radius, and the *Y* argument represents the angle expressed in radians.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Polar plot		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESET\_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XY] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another

object (that is, if the `SHARE_DATA` property is not in use). This property has no effect if no new data is provided via a `DATA` property.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHARE\_DATA

An object reference to an object with which data is to be shared by this plot. A plot may only share data with another plot. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SYMBOL

An object reference vector containing instances of the [IDLgrSymbol](#) object class. Each symbol in the vector will be drawn at the corresponding plotted point. If there are more points than elements in `SYMBOL`, the elements of the `SYMBOL` vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a plot, set the `SYMBOL` property equal to a null object reference.

<b>Property Type</b>	Object reference vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

<b>Property Type</b>	Thickness		
<b>Name String</b>	Thickness		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## USE\_ZVALUE

A Boolean value that determines whether to use the current ZVALUE. The plot is considered three-dimensional if this property is set.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## VERT\_COLORS

A vector of colors to be used to specify the color of the plot segment between each vertex. The vector may be of the form [n] where each entry is a color index, or of the form [3,n] where each 3-element row is an RGB color, or of the form [4,n] where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT\_COLORS to a scalar.

If VERT\_COLORS is not specified, the entire plot is drawn in the single color provided by the COLOR property, which is the default action.

If there are more vertices than elements in VERT\_COLORS, the elements of VERT\_COLORS are cyclically repeated.

When VERT\_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Vertex colors		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[xmin, xmax]$  specifying the range of  $x$  data coordinates covered by the graphic object. The plot line is *clipped* to the XRANGE values specified, but data points that lie outside the specified range are not removed. (Set the [MAX\\_VALUE](#) and [MIN\\_VALUE](#) properties if data outside the range should be removed.) If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form  $[ymin, ymax]$  specifying the range of y data values covered by the graphic object. The plot line is *clipped* to the YRANGE values specified, but data points that lie outside the specified range are not removed. (Set the [MAX\\_VALUE](#) and [MIN\\_VALUE](#) properties if data outside the range should be removed.) If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] specifying the range of *z* data values covered by the graphic object. The plot line is *clipped* to the ZRANGE values specified, but data points that lie outside the specified range are not removed. (Set the [MAX\\_VALUE](#) and [MIN\\_VALUE](#) properties if data outside the range should be removed.) IDL maintains and returns this property in double-precision floating-point.

### Note

The XRANGE and YRANGE properties can also be retrieved via the GetProperty method; ZRANGE, however, can only be retrieved, not initialized (Init method) or set (SetProperty method).

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZVALUE

A floating-point value to be used as the Z coordinate for the entire plot. By default, 0.0 is used as the Z coordinate.

### Note

The USE\_ZVALUE property needs to be set in order for ZVALUE to take effect.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrPlot::Cleanup

The IDLgrPlot::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrPlot::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrPlot::GetCTM

The IDLgrPlot::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrPlot::]GetCTM( [, DESTINATION=objref] [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the plot object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPlot::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrPlot::GetProperty

The IDLgrPlot::GetProperty procedure method retrieves the value of the property or group of properties for the plot.

### Syntax

*Obj*->[IDLgrPlot::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrPlot Properties” on page 4230 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrPlot::Init

The IDLgrPlot::Init function method initializes the plot object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrPlot' [, [*X*,] *Y*] [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrPlot::]Init( [[*X*,] *Y*] [, *PROPERTY=value*] ) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector representing the abscissa values to be plotted. If *X* is provided, *Y* is plotted as a function of *X*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

### Y

Either a vector of two-element arrays [*x*, *y*] representing the points to be plotted, or a vector representing the ordinate values to be plotted. If *Y* is a vector of ordinate values and *X* is not specified, *Y* is plotted as a function of the vector index of *Y*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the

inputted value is of type `DOUBLE`. Otherwise it is converted to single-precision floating-point.

## Keywords

Any property listed under [“IDLgrPlot Properties”](#) on page 4230 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrPlot:: SetProperty

The IDLgrPlot::SetProperty procedure method sets the value of the property or group of properties for the plot.

### Syntax

*Obj*->[IDLgrPlot::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrPlot Properties” on page 4230 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

# IDLgrPolygon

A polygon object represents one or more polygons that share a given set of vertices and rendering attributes. All polygons must be convex—that is, a line connecting any pair of vertices on the polygon cannot fall outside the polygon. Concave polygons can be converted to a set of convex polygons using the [IDLgrTessellator](#) object.

An IDLgrPolygon object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrPolygon::Init](#)” on page 4282.

## Properties

Objects of this class have the following properties. See “[IDLgrPolygon Properties](#)” on page 4255 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DEPTH\\_OFFSET](#)
- [DEPTH\\_TEST\\_DISABLE](#)

- YRANGE
- ZERO\_OPACITY\_SKIP

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrPolygon::Cleanup
- IDLgrPolygon::GetCTM
- IDLgrPolygon::GetProperty
- IDLgrPolygon::Init
- IDLgrPolygon::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties

## IDLgrPolygon Properties

IDLgrPolygon objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPolygon::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPolygon::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPolygon::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DEPTH\\_OFFSET](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [DIFFUSE](#)
- [DOUBLE](#)
- [EMISSION](#)
- [FILL\\_PATTERN](#)
- [HIDDEN\\_LINES](#)
- [HIDE](#)
- [LINESTYLE](#)
- [NORMALS](#)
- [PALETTE](#)
- [PARENT](#)
- [POLYGONS](#)
- [REGISTER\\_PROPERTIES](#)
- [REJECT](#)
- [RESET\\_DATA](#)
- [SHADE\\_RANGE](#)
- [SHADING](#)
- [SHARE\\_DATA](#)
- [SHININESS](#)
- [SPECULAR](#)
- [STYLE](#)
- [TEXTURE\\_COORD](#)
- [TEXTURE\\_INTERP](#)
- [TEXTURE\\_MAP](#)
- [THICK](#)
- [VERT\\_COLORS](#)

- [XCOORD\\_CONV](#)
- [YCOORD\\_CONV](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZERO\\_OPACITY\\_SKIP](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

---

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the polygon. The default value of 1.0 causes IDL to draw the polygon completely opaque. If the value of this property is less than 1.0, then the pixels of the polygon are blended with the pixels already on the screen. The color of the polygon is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polygon object may contain many polygons, the ordering of the polygons within the object (POLYGONS property) must be considered as well.

This property has no effect on devices using indexed color mode.

If VERT\_COLORS are supplied, then the value of this property is used for the vertex color alpha if the VERT\_COLORS do not contain alpha values (3-channel RGB

colors). If the VERT\_COLORS do contain alpha values (4-channel RGBA colors), then the alpha for each vertex color is used.

When used with textures, the ALPHA\_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA\_CHANNEL property).

### Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## AMBIENT

Set this property to a three-element vector [*red, green, blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Ambient reflective color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## BOTTOM

A scalar or three-element vector [*red, green, blue*] specifying the color used for drawing the backs of the polygons. (The back of a polygon is the side opposite the normal direction). Set this property to a scalar to draw the backs of the polygons with the same color as the front. If set to a scalar, IDL returns the default value of -1 if the property is retrieved with GetProperty. Setting a bottom color is only supported when the destination device uses RGB color mode.

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Bottom color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CLIP\_PLANES

A 4-by- $N$  floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

### Note

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

### Note

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polygons. The default color is  $[0, 0, 0]$  (black). If the TEXTURE\_MAP property is used, the final color is modulated by the texture map pixel values. This property is ignored if the VERT\_COLORS property is provided.

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DATA

A 2-by- $n$  or a 3-by- $n$  array of any type which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the property variable is of type DOUBLE or if the DOUBLE property parameter is also specified, otherwise it is converted to single precision floating point.

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH\_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

### Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH\_OFFSET values. It is safest to use only a DEPTH\_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH\_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH\_OFFSET values may produce better results on one machine than on another. Using IDL’s software

renderer will help improve the cross-platform consistency of scenes that use DEPTH\_OFFSET.

---

**Note**

DEPTH\_OFFSET has no effect unless the value of the STYLE property is 2 (Filled).

---

<b>Property Type</b>	Integer		
<b>Name String</b>	Depth offset		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

---

**Note**

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH\_TEST\_FUNCTION and DEPTH\_WRITE\_DISABLE properties are effectively ignored.

---

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIFFUSE

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Diffuse reflective color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## EMISSION

Set this property to a three-element vector [*red, green, blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Emissive color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## FILL\_PATTERN

An object reference to an IDLgrPattern object (or an array of IDLgrPattern objects) that specifies the fill pattern to use for filling the polygons. By default, FILL\_PATTERN is set to a null object reference, specifying a solid fill.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDDEN\_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Remove hidden		
<b>Get:</b> No	<b>Set:</b> Nos	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LINestyle

An integer value that indicates the line style that should be used to draw the polygon. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the `LINestyle` property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq \textit{repeat} \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

<b>Property Type</b>	Linestyle		
<b>Name String</b>	Line style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## NORMALS

A 3-by- $n$  floating-point array of unit polygon normals at each vertex. If this property is not set, vertex normals are computed by averaging shared polygon normals at each vertex. Normals are computed using the Right Hand Rule; that is, if the polygon is facing the viewer, vertices are taken in counterclockwise order. To remove previously specified normals, set NORMALS to a scalar.

### Note

Computing normals is a computationally expensive operation. Rendering speed increases significantly if you supply the surface normals explicitly. You can compute the array of polygon normals used by this property automatically. See [“COMPUTE\\_MESH\\_NORMALS”](#) on page 308 for details.

Once you use the NORMALS property in a call to IDLgrPolygon::Init or IDLgrPolygon::SetProperty, you are responsible for that IDLgrPolygon’s normals from then on. IDL will not calculate that IDLgrPolygon’s normals for you automatically, even if you draw the IDLgrPolygon after vertices or connectivity have been changed.

If you do not use the NORMALS property, IDL calculates normals the first time it draws the IDLgrPolygon. IDL reuses those normals for subsequent draws unless it determines that a fresh recalculation of normals is required, such as if the vertices of the IDLgrPolygon are changed, or you supply new normals via the NORMALS property.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## POLYGONS

An integer array of polygon descriptions. A polygon description is an integer or long word array of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$ , where  $n$  is the number of vertices that define the polygon, and  $i_0..i_{n-1}$  are indices into the X, Y, and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count,  $n$ , to 0. To end the drawing list, even if additional array space is available, set  $n$  to -1. If this property is not specified, a single polygon will be generated.

### Note

Setting the POLYGONS property to a scalar value will reset the property to its initial, undefined state.

### Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## REJECT

An integer value to reject polygons as being hidden depending on the orientation of their normals. Select from one of the following values:

- 0 = No polygons are hidden
- 1 = Polygons whose normals point away from the viewer are hidden
- 2 = Polygons whose normals point toward the viewer are hidden

Set this property to zero to draw all polygons regardless of the direction of their normals.

In a property sheet, this property appears as an enumerated list with the following options:

- None
- Normals point away
- Normals point toward

### Note

The REJECT property has no effect on non-filled polygons (where **STYLE** is 0 or 1).

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Polygon rejection		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## RESET\_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE\_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADE\_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. The default is [0, 255]. This property is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADING

An integer that represents the type of shading to use:

- 0 = Flat (default): The color of the first vertex in each polygon is used to define the color for the entire polygon. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Shading		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SHARE\_DATA

An object reference to an object with which data is to be shared by this polygon(s). Polygons may only share data with another polygons object or a polyline. The SHARE\_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	<i>Shininess</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SPECULAR

Set this property to a three-element vector [*red, green, blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This

property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Specular highlight color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## STYLE

An integer value that specifies how the polygon should be drawn:

- 0 = Points: Only vertices are drawn, using either COLOR or VERT\_COLORS.
- 1 = Lines: Each polygon is outlined by connecting vertices.
- 2 = Filled (default): The polygon faces are shaded.

In a property sheet, this property appears as an enumerated list with the following options:

- Points
- Lines
- Filled

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TEXTURE\_COORD

A 2 by  $n$  array containing the texture map coordinates, where  $n$  is the number of polygon vertices. Each two-element entry in this array specifies the texture coordinates for the corresponding vertex in the vertex list. One texture coordinate pair should exist for each vertex. Use this property in conjunction with the TEXTURE\_MAP property to wrap images over 2-D and 3-D polygons. Default coordinates are not provided.

Texture coordinates are normalized. This means that the  $m \times n$  image object specified via the TEXTURE\_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If

texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via `TEXTURE_MAP` is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TEXTURE\_INTERP

A Boolean value that indicates whether bilinear sampling is to be used for texture mapping an image onto the polygon(s). The default is nearest neighbor sampling.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Texture interpolation		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TEXTURE\_MAP

An object reference to an `IDLgrImage` object to be texture mapped onto the polygons. The tiling or mapping of the texture is defined expressly by `TEXTURE_COORD`. If this property is omitted, polygons are filled with the color specified by the `COLOR` or `VERT_COLORS` property. If both `TEXTURE_MAP` and `COLORS` or `VERT_COLORS` properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the

COLOR property should be set equal to [255,255,255].) To remove a texture map, set TEXTURE\_MAP equal to a null object reference.

Setting TEXTURE\_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrPolygon object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function  $src=alpha$  and  $dst=1 - alpha$ , which corresponds to a BLEND\_FUNCTION of (3,4) as described for the IDLgrImage object.

If the width and/or height of the provided image is not an exact power of two, then the texture map will consist of the given image pixel values resampled to the nearest larger dimensions that are exact powers of two.

---

**Note**

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

---

---

**Note**

Texture mapping is applied to all styles that are set by the STYLE property.

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Texture map		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points or the thickness of the lines to be drawn when STYLE is set to either 0 (Points) or 1 (Lines), in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

---

**Note**

The value of this property is ignored if STYLE is set to 2 (Filled).

---

In a property sheet, this property appears as follows:

<b>Property Type</b>	Thickness		
<b>Name String</b>	Thickness		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VERT\_COLORS

A vector of colors to be used to specify the color of a polygon vertex. The vector may be of the form  $[n]$  where each entry is a color index, or of the form  $[3,n]$  where each 3-element row is an RGB color, or of the form  $[4,n]$  where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set `VERT_COLORS` to a scalar.

If `VERT_COLORS` is not specified, the entire polygon is drawn in the single color provided by the `COLOR` property, which is the default action.

If `SHADING` is set to 0 (Flat, the default) the color of a polygon is the color of the first vertex of that polygon. Color is interpolated between vertices if `SHADING` is set to 1 (Gouraud).

If there are more vertices than elements in `VERT_COLORS`, the elements of `VERT_COLORS` are cyclically repeated.

### Note

If the polygon object is being rendered on a destination device that uses the Indexed color model, and the view that contains the polygon also contains one or more light objects, the `VERT_COLORS` property is ignored and the `SHADE_RANGE` property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Vertex colors		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[xmin, xmax]$  that specifies the range of  $x$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating point vector, [*s*<sub>0</sub>, *s*<sub>1</sub>], of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZERO\_OPACITY\_SKIP

A Boolean value that makes it possible to gain finer control over the rendering of textured polygon pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity.

- 1 = Any texels are “skipped” and not rendered at all (the default).
- 0 = The Z-buffer is updated for these pixels and the display image is not affected as noted above.

By updating the Z-buffer without updating the display image, the polygon can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

---

**Note**

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

---

<b>Property Type</b>	Boolean		
<b>Name String</b>	Skip zero opacity		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ZRANGE

A two-element floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrPolygon::Cleanup

The IDLgrPolygon::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrPolygon::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrPolygon::GetCTM

The IDLgrPolygon::GetCTM The IDLgrPolygon::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrPolygon::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polygon object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolygon::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrPolygon::GetProperty

The IDLgrPolygon::GetProperty procedure method retrieves the value of the property or group of properties for the polygons.

### Syntax

*Obj*->[IDLgrPolygon::]GetProperty[, *PROPERTY=variable*]

### Arguments

There are no arguments for this methods.

### Keywords

Any property listed under “IDLgrPolygon Properties” on page 4255 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrPolygon::Init

The IDLgrPolygon::Init function method initializes the polygons object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrPolygon' [, X [, Y[, Z]]] [, PROPERTY=*value*])

or

*Result* = *Obj*->[IDLgrPolygon::]Init([X, [Y, [Z]]] [, PROPERTY=*value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector argument providing the X coordinates of the vertices. The vector must contain at least three elements. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,\*] or [3,\*]), in which case, X[0,\*] specifies the X values, X[1,\*] specifies the Y values, and X[2,\*] specifies the Z values.

This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

## Y

A vector argument providing the Y coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

## Z

A vector argument providing the Z coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

## Keywords

Any property listed under [“IDLgrPolygon Properties”](#) on page 4255 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Examples

See [“Mapping an Image onto a Sphere”](#) in Chapter 3 of the *Image Processing in IDL* manual and [Chapter 8, “Polygon and Polyline Objects”](#) in the *Object Programming* manual.

## Version History

5.0	Introduced
-----	------------

## IDLgrPolygon:: SetProperty

The IDLgrPolygon::SetProperty procedure method sets the value of the property or group of properties for the polygons.

### Syntax

*Obj*->[IDLgrPolygon::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrPolygon Properties” on page 4255 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced

# IDLgrPolyline

A polyline object represents one or more polylines that share a set of vertices and rendering attributes.

An IDLgrPolyline object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrPolyline::Init](#)” on page 4310.

## Properties

Objects of this class have the following properties. See “[IDLgrPolyline Properties](#)” on page 4287 for details on individual properties.

- [ALL](#)
- [CLIP\\_PLANES](#)
- [DATA](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DOUBLE](#)
- [LABEL\\_NOGAPS](#)
- [LABEL\\_OBJECTS](#)
- [LABEL\\_USE\\_VERTEX\\_COLOR](#)
- [PALETTE](#)
- [POLYLINES](#)
- [RESET\\_DATA](#)
- [SHARE\\_DATA](#)
- [THICK](#)
- [ALPHA\\_CHANNEL](#)
- [COLOR](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [HIDE](#)
- [LABEL\\_OFFSETS](#)
- [LABEL\\_POLYLINES](#)
- [LINESTYLE](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [SHADING](#)
- [SYMBOL](#)
- [USE\\_LABEL\\_COLOR](#)

- `USE_LABEL_ORIENTATION`
- `USE_TEXT_ALIGNMENTS`
- `VERT_COLORS`
- `XCOORD_CONV`
- `XRANGE`
- `YCOORD_CONV`
- `YRANGE`
- `ZCOORD_CONV`
- `ZRANGE`

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- `IDLgrPolyline::Cleanup`
- `IDLgrPolyline::GetCTM`
- `IDLgrPolyline::GetProperty`
- `IDLgrPolyline::Init`
- `IDLgrPolyline::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added <code>CLIP_PLANES</code> , <code>LABEL_NOGAPS</code> , <code>LABEL_POLYLINES</code> , <code>LABEL_OFFSETS</code> , <code>LABEL_OBJECTS</code> , <code>LABEL_USE_VERTEX_COLOR</code> , <code>USE_LABEL_COLOR</code> , <code>USE_LABEL_ORIENTATION</code> , <code>USE_TEXT_ALIGNMENTS</code> properties
6.1	Added <code>ALPHA_CHANNEL</code> property

## IDLgrPolyline Properties

IDLgrPolyline objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPolyline::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPolyline::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPolyline::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [LABEL\\_NOGAPS](#)
- [LABEL\\_OFFSETS](#)
- [LABEL\\_OBJECTS](#)
- [LABEL\\_POLYLINES](#)
- [LABEL\\_USE\\_VERTEX\\_COLOR](#)
- [LINESSTYLE](#)
- [PALETTE](#)
- [PARENT](#)
- [POLYLINES](#)

- [RESET\\_DATA](#)
- [SHADING](#)
- [SHARE\\_DATA](#)
- [SYMBOL](#)
- [THICK](#)
- [USE\\_LABEL\\_COLOR](#)
- [USE\\_LABEL\\_ORIENTATION](#)
- [USE\\_TEXT\\_ALIGNMENTS](#)
- [VERT\\_COLORS](#)
- [XCOORD\\_CONV](#)
- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

The fields of this structure may change in subsequent releases of IDL.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the polyline. The default value of 1.0 causes IDL to draw the line completely opaque. If the value of this property is less than 1.0, then the pixels of the polyline are blended with the pixels already on the screen, where the color of the polyline is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polyline object may contain many polylines, or because a line may draw in back or in front of itself, the ordering of the polylines within the object (POLYLINES property) must be considered as well.

This property has no effect on devices using indexed color mode.

If 3-channel (RGB) VERT\_COLORS are supplied, then the value of this property is used for the alpha at each vertex to draw the line. If 4-channel (RGBA) VERT\_COLORS are supplied, then the alpha from each vertex color is used for the alpha at each vertex to draw the line.

When a polyline is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT\_COLORS are supplied. If the VERT\_COLORS are RGB, then the alpha value of the symbol is used to draw the

symbol. If the VERT\_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

When used with labels, the value of this property is used as the alpha channel value for a label if its corresponding value in the USE\_LABEL\_COLOR property is zero and the value of LABEL\_USE\_VERTEX\_COLOR is zero.

If a label's corresponding value in the USE\_LABEL\_COLOR property is zero and the LABEL\_USE\_VERTEX\_COLOR property is non-zero, then the label is drawn with the alpha value from its corresponding vertex color, if the alpha values are included in the vertex colors. If the vertex colors do not include alpha values, the value of this property is used as the alpha value for the label.

If a label's corresponding value in the USE\_LABEL\_COLOR property is non-zero, then the value of the label object's ALPHA\_CHANNEL property is used to draw the label. In other words, USE\_LABEL\_COLOR also implies using the label object's alpha as well as its color.

---

### Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) in Chapter 2 of the *Object Programming* manual.

---

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CLIP\_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

---

### Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

---

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>			
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**COLOR**

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polylines. The default color is [0, 0, 0] (black). This property is ignored if the `VERT_COLORS` property is provided.

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**DATA**

A 2-by- $n$  or a 3-by- $n$  floating-point array which defines, respectively, the 2-D or 3-D vertex data. `DATA` is equivalent to the optional arguments, `X`, `Y`, and `Z`. This property is converted to double-precision floating-point values if the `DOUBLE` property is set. Otherwise, it is converted to single-precision floating-point.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

### Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = `INHERIT` - use value from parent model or view.
- 1 = `NEVER` - never passes.
- 2 = `LESS` - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LABEL\_NOGAPS

An integer vector of values indicating whether gaps should be computed for the corresponding label. A zero value indicates that a gap will be computed for the labels; a non-zero value indicates that no gap will be computed for the label. If the number of labels exceeds the number of elements in this vector, the LABEL\_NOGAPS values will be repeated cyclically. By default, gaps are computed for all labels (so that the polyline does not pass through the label).

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LABEL\_OFFSETS

A scalar or vector of floating-point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each polyline (specified via the LABEL\_POLYLINES property) at which each label (as specified via the LABEL\_OBJECTS property) would be positioned. If LABEL\_OFFSETS is set to a scalar less than zero, then the offsets will be automatically computed to be evenly distributed along the length of the polyline. If a scalar value greater than or equal to zero is provided, it is used for all labels. If a vector is provided, the number of offsets must match the number of labels provided via LABEL\_OBJECTS. By default, this property is set to the scalar, -1, indicating that the label offsets will be automatically computed.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LABEL\_OBJECTS

An object reference (or vector of object references) to specify the labels to be drawn along the polyline path(s). The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a label. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a label.

If one or more IDLgrText objects are provided, the LOCATION property of the provided text object(s) may be overwritten; position is determined according to the values provided via the LABEL\_OFFSETS property. The labels will have the same color as the corresponding polyline (see the COLOR property) unless the USE\_LABEL\_COLOR property is specified. The orientation of the label objects USE\_LABEL\_ORIENTATION property is specified. The horizontal and vertical alignment for any text labels will each default to 0.5 (i.e., centered) unless the USE\_TEXT\_ALIGNMENTS property is specified.

### Note

The objects provided via this property will not be destroyed automatically when this IDLgrPolyline is destroyed.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LABEL\_POLYLINES

An integer or integer vector of polyline indices, [P0, P1, ...], that indicate which polylines are to be labeled. Pi corresponds to the ith polyline specified via the POLYLINES property. This property is intended to be used in conjunction with the LABEL\_OBJECTS property. If a scalar is provided, all labels will be drawn along the single indicated polyline. If a vector is provided, the number of polyline indices must match the number of labels provided via LABEL\_OBJECTS.

By default, this property is set to the scalar, 0, indicating that only the first polyline will be labeled.

**Note**

If a given polyline has more than one label, then the corresponding polyline index may appear more than once in the LABEL\_POLYLINES vector.

<b>Property Type</b>	Integer or integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**LABEL\_USE\_VERTEX\_COLOR**

An integer value that indicates whether labels should be colored according to the vertex coloring (if the VERT\_COLORS property is set).

- A non-zero value = labels should be colored according to the vertex coloring
- Zero (the default) = the label will be drawn using the color specified via the COLOR property of the polyline object (unless the USE\_LABEL\_COLOR property is set).

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**LINestyle**

An integer or array value that indicates the line style to be used to draw the polyline. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINestyle property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot

- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq \textit{repeat} \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

<b>Property Type</b>	Linestyle		
<b>Name String</b>	Line style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the `IDLGrPalette` object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the `PALETTE` property on this object is not set, the destination object `PALETTE` property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## POLYLINES

An integer array of polyline descriptions. A polyline description is an integer or long word array of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$ , where  $n$  is the number of vertices that define the polyline, and  $i_0..i_{n-1}$  are indices into the  $X$ ,  $Y$ , and  $Z$  arguments that represent the vertices of the polyline(s). To ignore an entry in the POLYLINES array, set the vertex count,  $n$ , and all associated indices to 0. To end the drawing list, even if additional array space is available, set  $n$  to -1. If this property is not specified, a single connected polyline will be generated from the  $X$ ,  $Y$ , and  $Z$  arguments.

### Note

Setting the POLYLINES property to a scalar value will reset the property to its initial, undefined state.

### Note

The connectivity array described by POLYLINES allows an individual object to contain more than one polyline. Vertex, normal and color information can be shared by the multiple polylines. Consequently, the polyline object can represent an entire mesh and compute reasonable normal estimates in most cases.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESET\_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE\_DATA property is not in use). This property has no effect if no new data is provided via the DATA property. .

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADING

An integer representing the type of shading to use:

- 0 = Flat (default): The color of the second vertex in a line segment is used to define the color for the entire line segment. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Shading		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SHARE\_DATA

An object reference to an object whose data is to be shared by this polyline. A polyline may only share data with a polygon object or another polyline. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SYMBOL

An object reference vector containing one or more instances of the [IDLgrSymbol](#) object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in `SYMBOL`, the elements of the `SYMBOL` vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set `SYMBOL` to a scalar.

<b>Property Type</b>	Object reference vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

<b>Property Type</b>	Thickness		
<b>Name String</b>	Thickness		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## USE\_LABEL\_COLOR

An integer vector of values to indicate whether the COLOR property value for the corresponding label object is to be used to draw that label. If the number of labels exceeds the number of elements in this vector, the USE\_LABEL\_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR property of each label object will be ignored, and the COLOR property for the polyline object will be used instead.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## USE\_LABEL\_ORIENTATION

An integer vector of values to indicate whether the orientation of the corresponding label object is to be used to draw that label. For IDLgrText objects, this refers to the BASELINE and UPDIR property values. For IDLgrSymbol objects, this refers to the default (un-rotated) orientation of the symbol. If the number of labels exceeds the number of elements in this vector, the USE\_LABEL\_ORIENTATION values will be repeated cyclically. By default, USE\_LABEL\_ORIENTATION is zero, indicating

that the orientation will be automatically computed so that the baseline is parallel to the polyline, and the updir is perpendicular to the polyline.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## USE\_TEXT\_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the LABEL\_OBJECTS property), the ALIGNMENT and VERTICAL\_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw those labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL\_ALIGNMENT properties of the IDLgrText object(s) will be overwritten with default values (0.5 for each, indicating centered labels).

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## VERT\_COLORS

A vector of colors to be used to specify the color of the line segment between each vertex. The vector may be of the form  $[n]$  where each entry is a color index, or of the form  $[3,n]$  where each 3-element row is an RGB color, or of the form  $[4,n]$  where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT\_COLORS to a scalar.

If VERT\_COLORS is not specified, the entire polyline is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a line segment is the color of the second vertex of that line segment. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT\_COLORS, the elements of VERT\_COLORS are cyclically repeated.

When VERT\_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

When VERT\_COLORS is used with labels, the application of the color and alpha of the labels is controlled by the USE\_LABEL\_COLOR and LABEL\_USE\_VERTEX\_COLOR properties.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Vertex colors		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[xmin, xmax]$  that specifies the range of  $x$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form  $[ymin, ymax]$  that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrPolyline::Cleanup

The IDLgrPolyline::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrPolyline::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrPolyline::GetCTM

The IDLgrPolyline::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrPolyline::]GetCTM( [, DESTINATION=objref]  
    [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polyline object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolyline::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

-----	------------

## IDLgrPolyline::GetProperty

The IDLgrPolyline::GetProperty procedure method retrieves the value of a property or group of properties for the polylines.

### Syntax

*Obj*->[IDLgrPolyline::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrPolyline Properties” on page 4287 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrPolyline::Init

The IDLgrPolyline::Init function method initializes the polylines object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrPolyline' [, X [, Y[, Z]]] [, PROPERTY=*value*])

or

*Result* = *Obj*->[IDLgrPolyline::]Init([X, [Y, [Z]]] [, PROPERTY=*value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector providing the X components of the points to be connected. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,\*] or [3,\*]), in which case, X[0,\*] specifies the X values, X[1,\*] specifies the Y values, and X[2,\*] specifies the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

### Y

A vector providing the Y coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type

DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Z

A vector providing the Z coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Keywords

Any property listed under “[IDLgrPolyline Properties](#)” on page 4287 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrPolyline:: SetProperty

The IDLgrPolyline::SetProperty procedure method sets the value of a property or group of properties for the polylines.

### Syntax

*Obj*->[IDLgrPolyline::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrPolyline Properties](#)” on page 4287 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

# IDLgrPrinter

A printer object represents a hardcopy graphics destination. When a printer object is created, the printer device to which it refers is the default system printer. To change the printer, utilize the printer dialogs (see [“DIALOG\\_PRINTJOB”](#) on page 608 and [“DIALOG\\_PRINTERSETUP”](#) on page 606.)

---

**Note**

Objects or subclasses of this type can not be saved or restored.

---

## Superclasses

None

## Creation

See [“IDLgrPrinter::Init”](#) on page 4336.

## Properties

Objects of this class have the following properties. See [“IDLgrPrinter Properties”](#) on page 4317 for details on individual properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GAMMA](#)
- [GRAPHICS\\_TREE](#)
- [LANDSCAPE](#)
- [N\\_COLORS](#)
- [N\\_COPIES](#)
- [NAME](#)
- [PALETTE](#)
- [PRINT\\_QUALITY](#)
- [PRINTER\\_NAME](#)

- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [UNITS](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrPrinter::Cleanup](#)
- [IDLgrPrinter::Draw](#)
- [IDLgrPrinter::GetContiguousPixels](#)
- [IDLgrPrinter::GetFontnames](#)
- [IDLgrPrinter::GetProperty](#)
- [IDLgrPrinter::GetTextDimensions](#)
- [IDLgrPrinter::Init](#)
- [IDLgrPrinter::NewDocument](#)
- [IDLgrPrinter::NewPage](#)
- [IDLgrPrinter::QueryRequiredTiles](#)
- [IDLgrPrinter::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See [Chapter 12, “Displaying, Copying and Printing Objects”](#) in the *Object Programming* manual for information on the IDLgrPrinter object. See [“Positioning Objects Within a Page”](#) in Chapter 12 of the *Object Programming* manual for additional examples that define the locations of objects within the hardcopy page.

The following example demonstrates the process of printing the contents of an IDL graphics display object (a buffer or a window) to an IDLgrPrinter object. The resolution of the printed page is based on the resolution of the screen. The model object in the printer object must be scaled to maintain the same size as displayed on

the screen. The location of the view must also be changed to center the display on the page.

```

PRO PrintingAnImage

; Determine the path to the "convec.dat" file.
convecFile = FILEPATH('convec.dat', $
    SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the image with the file.

## IDLgrPrinter Properties

IDLgrPrinter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPrinter::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPrinter::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPrinter::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GAMMA](#)
- [GRAPHICS\\_TREE](#)
- [LANDSCAPE](#)
- [N\\_COLORS](#)
- [N\\_COPIES](#)
- [NAME](#)
- [PALETTE](#)
- [PRINT\\_QUALITY](#)
- [PRINTER\\_NAME](#)
- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [UNITS](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

The fields of this structure may change in subsequent releases of IDL.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR\_MODEL

An integer value that determines the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Color model		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DIMENSIONS

A two-element integer vector of the form *[width, height]* specifying the overall drawable area that may be printed on a page. By default, the dimensions are measured in device units (refer to the [UNITS](#) property).

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## GAMMA

An object reference to an IDLgrPalette object whose entries will be used as the gamma correction table for color printing. Gamma correction only applies if COLOR\_MODEL=1 (Indexed).

When the color palette (specified via the PALETTE property) is loaded for the printer, if a gamma correction table is provided, then each of the [R,G,B] entries in the color palette will be translated through the gamma correction table. For example, at color index *i*:

```
correctedRed[i] = gammaRed[paletteRed[i]]
correctedGreen[i] = gammaGreen[paletteGreen[i]]
correctedBlue[i] = gammaBlue[paletteBlue[i]]
```

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GRAPHICS\_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is

valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS\_TREE property is set equal to the null-object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## LANDSCAPE

A Boolean value that indicates whether to produce hardcopy output in landscape mode. The default value of zero indicates Portrait mode.

### Note

The printer driver may not support the LANDSCAPE option; in general, it is best to use the printer dialogs to set orientation.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_COLORS

An integer value that indicates the number of colors (between 2 and 256) to be used if the COLOR\_MODEL is set to Indexed (1). This property is ignored if the COLOR\_MODEL is set to RGB (0).

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of colors		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## N\_COPIES

An integer that determines the number of copies of print data to be generated. The default is 1 copy.

### Note

Your specific printer driver may not support the N\_COPIES option. You can also use the printer dialogs to set the number of copies.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## NAME

A string giving the human-readable name of this object. This property is initialized to the network name of the printer unless another value is set during initialization.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table if the Indexed color model is used.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PRINT\_QUALITY

An integer value indicating the print quality at which graphics are to be drawn to the printer. Note that the print quality is independent of the rendering quality (as set by the QUALITY property). Valid values are:

- 0 = Low
- 1 = Normal (this is the default)
- 2 = High

Generally, setting the print quality to a lower value will increase the speed of the printing job, but decrease the resolution; setting it to a higher value will cause the printing job to take more time, but will increase the resolution.

### Note

Some printer drivers may not be able to support different printing qualities. In these cases, the setting of the PRINT\_QUALITY property will be quietly ignored.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PRINTER\_NAME

A string containing the network name of the printer, (*e.g.*, '\\BORG\HpJet ').

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## QUALITY

An integer value that indicates the rendering quality at which graphics are to be drawn to this destination. Note that the rendering quality is independent of the print quality (as set by the PRINT\_QUALITY property). Valid values are:

- 0 = Low

- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Draw quality		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESOLUTION

A floating-point vector of the form [*xres*, *yres*] defining the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Resolution		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> Yes

## UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the drawable area on a page.

### Note

---

If you change the value of the UNITS property (using the SetProperty method), IDL will convert the current value of the DIMENSIONS property to the new units.

---

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrPrinter::Cleanup

The IDLgrPrinter::Cleanup procedure method performs all cleanup on the object. If a document is open (that is, if graphics have been draw to the printer), the document is closed and the pending graphics are sent to the current printer.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrPrinter::]Cleanup *(In a lifecycle method only.)*

## Arguments

None

## Keywords

None

## Version History

---

5.0	Introduced

## IDLgrPrinter::Draw

The IDLgrPrinter::Draw procedure method draws the given picture to this graphics destination.

### Printing in Bitmap or Vector Graphic Mode

The IDLgrPrinter::Draw method VECTOR keyword generates output in bitmap or vector format. The following table shows the keyword options and results for each platform.

Keyword Settings	Windows Printer Output	UNIX File Type
VECTOR = 0	Bitmap (BMP)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)
VECTOR = 1	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)

*Table 8-13: File Types Produced by IDLgrPrinter Draw Method*

Because Windows printer output is usually sent directly to the printer, EMF and BMP files are not viewable. On UNIX, the printer output is usually directed to a file named xprinter.eps by default.

#### Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them when VECT\_SORTING=0. Otherwise, objects are drawn to the destination device based on their average depth value. See “[Bitmap and Vector Graphic Output](#)” in Chapter 12 of the *Object Programming* manual for more information on bitmap and vector output.

## Syntax

```
Obj->[IDLgrPrinter::]Draw [, Picture] [, VECT_SORTING={ 0 | 1 } ]
    [, VECT_TEXT_RENDER_METHOD={ 0 | 1 } ] [, VECTOR={ 0 | 1 } ]
```

# Arguments

## Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

# Keywords

## VECT\_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. This causes the object primitives to appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.
- 1 = enable sorting (default). Objects are ordered from back to front based on each primitive object's average depth value.

### Note

---

Objects that intersect each other, [IDLgrImage](#) objects (which do not update the depth buffer), and objects contained within transparent views may not sort correctly. See [“Controlling What is Displayed in Vector Graphics”](#) in Chapter 12 of the *Object Programming* manual for details.

---

## VECT\_TEXT\_RENDER\_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). Use the output device's text primitives when rendering text.
- 1 = render text as primitives composed of triangles. Render text in the vector file as a series of filled triangles. This produces text that closely matches the text on the display device, but the output file size is larger.

**Note**

---

When using the IDLgrPrinter object under UNIX, the Xprinter output is regarded as write-only. As there is no support for 3-D text, IDL always generates filled triangles when rendering text in the Xprinter output. On Windows, the vector output is always Enhanced MetaFile (EMF) file format. Because printer output is usually sent directly to the printer the EMF file cannot be seen by the user.

---

**Note**

---

See “[Text Rendering in Vector Graphics](#)” in Chapter 12 of the *Object Programming* manual for more information.

---

## VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the printer in bitmap format. The bitmap retains the quality of the original image.
- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable to the printer. The vector representation, which is sent to the printer, does not retain all the attributes of the original image.

**Note**

---

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See “[Bitmap and Vector Graphic Output](#)” in Chapter 12 of the *Object Programming* manual for a complete discussion of when to output to bitmap or vector graphics based on picture content.

---

## Version History

5.0	Introduced
6.1	Added VECT_SORTING, VECT_TEXT_RENDER_METHOD keywords

## IDLgrPrinter::GetContiguousPixels

The `IDLgrPrinter::GetContiguousPixels` function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the `N_COLORS` property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the `SHADE_RANGE` property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

## Syntax

*Result* = *Obj*->[[IDLgrPrinter::](#)]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::GetFontnames

The `IDLgrPrinter::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

### Syntax

```
Result = Obj->[IDLgrPrinter::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

### Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

### Arguments

#### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “\*”.

### Keywords

#### IDL\_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

#### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “\*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::GetProperty

The IDLgrPrinter::GetProperty procedure method retrieves the value of a property or group of properties for the printer.

### Syntax

*Obj*->[IDLgrPrinter::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrPrinter Properties](#)” on page 4317 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::GetTextDimensions

The IDLgrPrinter::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

### Syntax

```
Result = Obj->[IDLgrPrinter::]GetTextDimensions( TextObj [, DESCENT=variable]  
[, PATH=objref(s)] )
```

### Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

### Arguments

#### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

### Keywords

#### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this

keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrPrinter::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

## Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::Init

The IDLgrPrinter::Init function method initializes the printer object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrPrinter' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPrinter::]Init( [, PROPERTY=value])  (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLgrPrinter Properties](#)” on page 4317 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::NewDocument

The IDLgrPrinter::NewDocument procedure method closes the current document (a page or group of pages), which causes any pending output to be sent to the printer, finishing the printer job.

### Syntax

*Obj*->[IDLgrPrinter::]NewDocument

### Arguments

None

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::NewPage

The IDLgrPrinter::NewPage procedure method issues a new page command to the printer.

### Syntax

*Obj*->[IDLgrPrinter::](#)NewPage

### Arguments

None

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrPrinter::QueryRequiredTiles

The IDLgrPrinter::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

### Note

Printer support of tiled images is not available in vector mode (when the IDLgrPrinter::Draw method VECTOR keyword is set to 1).

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

### Note

If the device is in Color Index mode (COLOR\_MODEL=1) or the image has [RENDER\\_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

## Syntax

```
Result = Obj->[IDLgrPrinter::]QueryRequiredTiles( View, Image
  [, COUNT=variable] [, ALL_VISIBLE=value] )
```

## Return Value

Returns an array of structures for required tiles or 0 (zero) if no tiles are required. Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.

Table 8-14: IDLIMAGETILE Structure

Field	Data Type	Description
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of $n$ ( $n > 0$ ) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

*Table 8-14: IDLIMAGETILE Structure (Continued)*

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these

tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 8-8: Interaction Between Image Level and Zoom with Equal Tile Sizes

---

### Note

See “[Image Tiling](#)” in Chapter 4 of the *Object Programming* manual for more information on creating an image pyramid and for tiling examples.

---

## Arguments

### View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

### Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

## Keywords

### COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

### ALL\_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

## Version History

6.2	Introduced
-----	------------

## IDLgrPrinter:: SetProperty

The IDLgrPrinter::SetProperty procedure method sets the value of a property or group of properties for the printer.

### Syntax

*Obj*->[IDLgrPrinter::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrPrinter Properties](#)” on page 4317 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrROI

The IDLgrROI object class is an object graphics representation of a region of interest.

## Superclasses

[IDLanROI](#)

[IDLitComponent](#)

## Creation

See “[IDLgrROI::Init](#)” on page 4361.

## Properties

Objects of this class have the following properties. See “[IDLgrROI Properties](#)” on page 4347 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [STYLE](#)
- [SYMBOL](#)
- [THICK](#)

- [XCOORD\\_CONV](#)
- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLgrROI object class has the following methods:

- [IDLgrROI::Cleanup](#)
- [IDLgrROI::GetProperty](#)
- [IDLgrROI::Init](#)
- [IDLgrROI::PickVertex](#)
- [IDLgrROI::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.3	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property

## IDLgrROI Properties

IDLgrROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrROI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrROI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrROI::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [STYLE](#)
- [SYMBOL](#)
- [THICK](#)
- [XCOORD\\_CONV](#)
- [XRANGE](#)

- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLanROI](#)
- [IDLitComponent](#)

## ALL

An anonymous structure with the values of all of the properties associated with the state of this object. State information about the object may include things like color, line style, etc., but not vertex data or user values.

### Note

---

The fields in this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the ROI. The default value of 1.0 causes IDL to draw the ROI completely opaque. If the value of this property is less than 1.0, then the pixels of the ROI are blended with the pixels already on the screen, where the color of the ROI is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

When the ROI is drawn with symbols, the symbol color and alpha values are always used to draw the symbols.

**Note**

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**CLIP\_PLANES**

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw the region. The default color is [0, 0, 0].

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

### Note

---

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

---

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always

sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value indicating whether this region should be drawn:

- 0 = draw the region (the default)
- 1 = do not draw the region

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LINestyle

An integer that indicates the line style to be used to draw the region. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern. The valid values for the pre-defined line styles are:

- 0 = solid (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that defines the color palette of this object. This property is only used for Object Graphics destinations using the RGB color model. In this case, if the color value for the region is specified as a color index value, this palette is used to look up the color for the region. If the PALETTE property is not set, the destination object PALETTE property is used, which defaults to a gray scale ramp.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## STYLE

An integer value that indicates the geometrical primitive to use to represent the region when displayed. Valid values include:

- 0 = points
- 1 = open polyline
- 2 = closed polyline (the default)

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SYMBOL

An object reference to an [IDLgrSymbol](#) object for the symbol used for display when `STYLE = 0` (points). By default, a dot is used.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points, or the thickness of the lines, measured in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

<b>Property Type</b>	THICKNESS		
<b>Name String</b>	Thickness		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A vector,  $[s_0, s_1]$ , of scaling factors used to convert  $X$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Double-precision floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[xmin, xmax]$  that specifies the range of  $x$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Y$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form  $[ymin, ymax]$  that specifies the range of  $y$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Z$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrROI::Cleanup

The IDLgrROI::Cleanup procedure method performs all cleanup for a region of interest object.

---

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrROI::]Cleanup    (*In a lifecycle method only.*)

## Arguments

None

## Keywords

None

## Version History

---

5.3	Introduced
-----	------------

---

## IDLgrROI::GetProperty

The IDLgrROI::GetProperty procedure method retrieves the value of a property or group of properties for the Object Graphics region.

### Syntax

*Obj*->[IDLgrROI::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrROI Properties” on page 4347 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.3	Introduced
-----	------------

## IDLgrROI::Init

The IDLgrROI::Init function method initializes an Object Graphics region of interest.

### Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW( 'IDLgrROI' [, X[, Y[, Z]]] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrROI::]Init([X[, Y[, Z]]] [, PROPERTY=value]) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2, \*] or [3, \*]), in which case, X[0, \*] represents the X values, X[1, \*] represents the Y values, and X[2, \*] represents the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

**Y**

A vector providing the Y components of the vertices. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

**Z**

A scalar or vector providing the Z components of the vertices. If not provided, Z values default to 0.0. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

**Keywords**

Any property listed under [“IDLgrROI Properties”](#) on page 4347 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

**Version History**

5.3	Introduced
-----	------------

## IDLgrROI::PickVertex

The IDLgrROI::PickVertex function method picks a vertex of the region which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

### Syntax

*Result* = *Obj*->[IDLgrROI::]PickVertex( *Dest*, *View*, *Point* [, **PATH**=*objref*] )

### Return Value

Returns the index of the nearest region vertex. If two or more vertices are equally nearest to the point, the smallest index of those vertices is returned.

### Arguments

#### Dest

An object reference to an [IDLgrWindow](#) or [IDLgrBuffer](#) for which the pick is to occur.

#### View

An object reference to the [IDLgrView](#) containing this region.

#### Point

A two-element vector, [x, y], representing the device location used for picking a nearest vertex.

### Keywords

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected vertex is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

## Version History

5.3	Introduced
-----	------------

## IDLgrROI:: SetProperty

The IDLgrROI::SetProperty procedure method sets the value of a property or group of properties for the Object Graphics region.

### Syntax

*Obj*->[IDLgrROI::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrROI Properties” on page 4347 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.3	Introduced
-----	------------

# IDLgrROIGroup

The IDLgrROIGroup object class is an Object Graphics representation of a group of regions of interest.

## Superclasses

[IDLAnROIGroup](#).

[IDLitComponent](#)

## Creation

See “[IDLgrROIGroup::Init](#)” on page 4378.

## Properties

Objects of this class have the following properties. See “[IDLgrROIGroup Properties](#)” on page 4368 for details on individual properties.

- [ALL](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [HIDE](#)
- [PARENT](#)
- [XCOORD\\_CONV](#)
- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLgrROIGroup class has the following methods:

- [IDLgrROIGroup::Add](#)
- [IDLgrROIGroup::Cleanup](#)
- [IDLgrROIGroup::GetProperty](#)
- [IDLgrROIGroup::Init](#)
- [IDLgrROIGroup::PickRegion](#)
- [IDLgrROIGroup::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.3	Introduced
5.6	Added CLIP_PLANES property

## IDLgrROIGroup Properties

IDLgrROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrROIGroup::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrROIGroup::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrROIGroup::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [HIDE](#)
- [PARENT](#)
- [XCOORD\\_CONV](#)
- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZCOORD\\_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLanROIGroup](#).
- [IDLitComponent](#)

## ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

---

### Note

The fields in this structure may change in subsequent releases of IDL.

---

---

### Note

This structure returns ALPHA\_CHANNEL and COLOR properties that are consistent with other graphic objects. However, neither property is used by the IDLgrROIGroup object.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## CLIP\_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

---

### Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

---

---

### Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

---

---

### Note

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

---

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

### Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

**Note**

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**HIDE**

A Boolean value indicating whether this region group should be drawn:

- 0 = draw the region group (the default)
- 1 = do not draw the region group.

<b>Property Type</b>	BOOLEAN		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**PARENT**

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

**XCOORD\_CONV**

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $X$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[x_{min}, x_{max}]$  that specifies the range of  $x$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Y$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form  $[ymin, ymax]$  that specifies the range of  $y$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Z$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrROIGroup::Add

The IDLgrROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLgrROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

### Syntax

*Obj*->[\[IDLgrROIGroup::\]Add](#), *ROI*

### Arguments

#### ROI

A reference to an instance of the IDLgrROI object class representing the region of interest to add to the group.

### Keywords

Accepts all keywords accepted by the [IDLanROIGroup::Add](#) method.

### Version History

5.3	Introduced
-----	------------

## IDLgrROIGroup::Cleanup

The IDLgrROIGroup::Cleanup procedure method performs all cleanup for an Object Graphics region of interest group object.

### Note

---

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrROIGroup:]Cleanup    (*In a lifecycle method only.*)

## Arguments

None

## Keywords

None

## Version History

---

5.3	Introduced
-----	------------

---

## IDLgrROIGroup::GetProperty

The IDLgrROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

### Syntax

*Obj*->[IDLgrROIGroup:]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrROIGroup Properties” on page 4368 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.3	Introduced
-----	------------

## IDLgrROIGroup::Init

The IDLgrROIGroup::Init function method initializes an Object Graphics region of interest group object.

---

### Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

*Obj* = OBJ\_NEW('IDLgrROIGroup' [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrROIGroup::]Init( [, *PROPERTY=value*]) *(In a lifecycle method only.)*

---

### Note

Keywords can be used in either form. They are omitted in the second form for brevity.

---

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrROIGroup Properties” on page 4368 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.3	Introduced
-----	------------

## IDLgrROIGroup::PickRegion

The IDLgrROIGroup::PickRegion function method picks a region within the group which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

### Syntax

*Result* = *Obj*->[IDLgrROIGroup::]PickRegion( *Dest*, *View*, *Point* [, *PATH*=*objref*] )

### Return Value

Returns the object reference of the nearest region. If two or more regions are equally nearest to the point, the one that was added to the region group first is returned.

### Arguments

#### Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

#### View

An object reference to the IDLgrView containing this region.

#### Point

A two-element vector, [x, y], representing the device location to use for picking a nearest region.

### Keywords

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected region is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

## Version History

5.3	Introduced
-----	------------

## IDLgrROIGroup:: SetProperty

The IDLgrROIGroup::Set Property procedure method sets the value of a property or group of properties for the region group.

### Syntax

*Obj*->[IDLgrROIGroup::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrROIGroup Properties” on page 4368 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.3	Introduced
-----	------------

# IDLgrScene

A scene object represents the entire scene to be drawn and serves as a container of [IDLgrView](#) or [IDLgrViewgroup](#) objects.

## Superclasses

[IDL\\_Container](#)

[IDLitComponent](#)

## Creation

See “[IDLgrScene::Init](#)” on page 4393.

## Properties

Objects of this class have the following properties. See “[IDLgrScene Properties](#)” on page 4385 for details on individual properties.

- [ALL](#)
- [COLOR](#)
- [HIDE](#)
- [REGISTER\\_PROPERTIES](#)
- [TRANSPARENT](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrScene::Add](#)
- [IDLgrScene::Cleanup](#)
- [IDLgrScene::GetByName](#)
- [IDLgrScene::GetProperty](#)
- [IDLgrScene::Init](#)
- [IDLgrScene::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

## IDLgrScene Properties

IDLgrScene objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrScene::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrScene::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrScene::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [COLOR](#)
- [HIDE](#)
- [REGISTER\\_PROPERTIES](#)
- [TRANSPARENT](#)

In addition, objects of this class inherit:

- [IDL\\_Container](#)
- [IDLitComponent](#)

### ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

### Note

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR

The color to which the scene should be erased before drawing. The color may be specified as a color lookup table index or a three-element vector [*red*, *green*, *blue*].

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Background color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

For IDLgrScene, the available properties (and their iTool data types) are:

- HIDE (Boolean)

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## TRANSPARENT

A Boolean value that determines whether to disable window clearing. If this property is not set, the destination object in use by the scene is automatically erased when the scene is initialized.

<b>Property Type</b>	BOOLEAN		
<b>Name String</b>	Transparent		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> No	<b>Registered:</b> Yes

## IDLgrScene::Add

The IDLgrScene::Add function method verifies that the added item is an instance of an [IDLgrView](#) or IDLgrViewgroup object. If it is, IDLgrScene:Add adds the view or viewgroup to the specified scene.

### Syntax

*Obj*->[IDLgrScene::]Add, *View* [, POSITION=*index*]

### Arguments

#### View

An instance of the [IDLgrView](#) or [IDLgrViewgroup](#) object class.

### Keywords

#### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

### Version History

5.0	Introduced
-----	------------

## IDLgrScene::Cleanup

The IDLgrScene::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrScene::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrScene::GetByName

The IDLgrScene::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

---

**Note**

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

---

## Syntax

*Result* = *Obj*->[IDLgrScene::]GetByName(*Name*)

## Return Value

Returns the object reference to the named object. If the named object is not found, returns a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the `GetByName` method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrScene::GetProperty

The IDLgrScene::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

### Syntax

*Obj*->[IDLgrScene::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrScene Properties](#)” on page 4385 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrScene::Init

The IDLgrScene::Init function method initializes the scene object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrScene' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrScene:]Init( [, PROPERTY=value)    (In a lifecycle method  
only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrScene Properties” on page 4385 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrScene:: SetProperty

The IDLgrScene::SetProperty procedure method sets the value of a property or group of properties for the buffer.

### Syntax

*Obj*->[IDLgrScene::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrScene Properties](#)” on page 4385 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced

# IDLgrSurface

A surface object represents a shaded or vector representation of a mesh grid.

An IDLgrSurface object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrSurface::Init](#)” on page 4430.

## Properties

Objects of this class have the following properties. See “[IDLgrSurface Properties](#)” on page 4399 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DATA\\_X](#)
- [DATA\\_Y](#)
- [DATA\\_Z](#)
- [DEPTH\\_OFFSET](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [DIFFUSE](#)
- [DOUBLE](#)
- [EMISSION](#)
- [EXTENDED\\_LEGOS](#)
- [HIDDEN\\_LINES](#)
- [HIDE](#)
- [LINESTYLE](#)
- [MAX\\_VALUE](#)
- [MIN\\_VALUE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [RESET\\_DATA](#)
- [SHADE\\_RANGE](#)

- SHADING
- SHININESS
- SKIRT
- STYLE
- TEXTURE\_HIGHRES
- TEXTURE\_MAP
- USE\_TRIANGLES
- XCOORD\_CONV
- YCOORD\_CONV
- ZCOORD\_CONV
- ZRANGE
- SHARE\_DATA
- SHOW\_SKIRT
- SPECULAR
- TEXTURE\_COORD
- TEXTURE\_INTERP
- THICK
- VERT\_COLORS
- XRANGE
- YRANGE
- ZERO\_OPACITY\_SKIP

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- `IDLgrSurface::Cleanup`
- `IDLgrSurface::GetCTM`
- `IDLgrSurface::GetProperty`
- `IDLgrSurface::Init`
- `IDLgrSurface::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See “[Mapping an Image onto Elevation Data](#)” in Chapter 3 of the *Image Processing in IDL* manual for a texture mapping example and [Chapter 6, “Working with Surface Objects”](#) in the *Object Programming* manual for additional examples.

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties

## IDLgrSurface Properties

IDLgrSurface objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrSurface::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrSurface::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrSurface::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP\\_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DATA\\_X](#)
- [DATA\\_Y](#)

- [VERT\\_COLORS](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZERO\\_OPACITY\\_SKIP](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

---

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the surface. The default value of 1.0 causes IDL to draw the surface completely opaque. If the value of this property is less than 1.0, then the pixels of the surface are blended with the pixels already on the screen. The color of the surface is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This also applies to the individual facets of the surface that IDL generates to represent the surface geometry. Since you do not have control over the rendering order of the facets that form the surface, there is little you can do to change

the ordering so that the facets draw in a back-to-front order. Therefore, using this property to draw semi-transparent surfaces is not recommended unless the surface geometry and orientation is such that the surface can be viewed without self-overlapping areas.

This property has no effect on devices using indexed color mode.

When used with textures, the ALPHA\_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA\_CHANNEL property).

### Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## AMBIENT

Set this property to a three-element vector [*red, green, blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Ambient reflective color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## BOTTOM

A scalar or three-element vector [*red, green, blue*] specifying the color used to draw the bottom of the surface. Set this property to a scalar to draw the bottom with the

same color as the top. If set to a scalar, IDL returns the default value of -1 if the property is retrieved with GetProperty. Setting a bottom color is only supported when the destination device uses RGB color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Bottom color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CLIP\_PLANES

A 4-by- $N$  floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

### Note

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

### Note

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

The color to be used as the foreground color for this model. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is  $[0, 0, 0]$ .

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DATA

An array of any type that specifies the surface data. The array format is based upon the following:

- If the DATAZ property (or Data argument) was set to an  $M \times N$  array (via the `::Init` or `::SetProperty` methods), then the value returned via the DATA property is a  $3 \times M \times N$  array, `[[[x,y,z],[x,y,z],...],[x,y,z],[x,y,z],...],...`.
- If the DATAZ keyword (or Data argument) was never set, then the value returned via the DATA property is an undefined variable.

The value of the DATA array represents the combination of the DATAZ, DATAY, and DATAZ values defined using `::SetProperty`. If DATAZ was set, and DATAZ and DATAY were not, the DATA value returned includes the implied X and Y grid locations.

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DATAX

A floating-point vector or a two-dimensional array specifying the X coordinates of the surface grid. This property is the same as the X argument described for [“IDLgrSurface::Init”](#) on page 4430. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

<b>Property Type</b>	Floating-point vector or array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATAY

A floating-point vector or a two-dimensional array specifying the Y coordinates of the surface grid. This property is the same as the Y argument described for “[IDLgrSurface::Init](#)” on page 4430. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

<b>Property Type</b>	Floating-point vector or array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATAZ

A two-dimensional floating-point array to display as a surface. This property is the same as the Z argument described for “[IDLgrSurface::Init](#)” on page 4430. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH\_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

**Note**

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH\_OFFSET values. It is safest to use only a DEPTH\_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH\_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH\_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH\_OFFSET.

**Note**

DEPTH\_OFFSET has no effect unless the value of the STYLE property is 2 or 6 (Filled or LegoFilled).

<b>Property Type</b>	INTEGER		
<b>Name String</b>	Depth offset		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**DEPTH\_TEST\_DISABLE**

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

**Note**

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH\_TEST\_FUNCTION and DEPTH\_WRITE\_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIFFUSE

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Diffuse reflective color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## EMISSION

Set this property to a three-element vector [*red, green, blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Emissive color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## EXTENDED\_LEGO

A Boolean value that determines whether to force the IDLgrSurface object to display the last row and column of data when lego display styles are selected.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Show last lego row/column		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDDEN\_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Remove hidden lines		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LINESTYLE

An integer value that indicates the line style to use to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq repeat \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

<b>Property Type</b>	Linestyle		
<b>Name String</b>	Line style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MAX\_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. If this property is present, data values greater than the value of MAX\_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Maximum value		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MIN\_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN\_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Minimum value		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESET\_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XYZ] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE\_DATA property is not in use). This property has no effect if no new data is provided via a DATA[XYZ] property. .

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADE\_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color element for the brightest pixel. This value is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHADING

An integer representing the type of shading to use if STYLE is set to 2 (Filled).

- 0 = Flat (default): The color has a constant intensity for each face of the surface, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Fill shading		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SHARE\_DATA

An object reference to an object whose data is to be shared by this surface. A surface may only share data with another surface. The SHARE\_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	<i>Shininess</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SHOW\_SKIRT

A Boolean value that determines whether to enable skirt drawing. The default is to disable skirt drawing. .

<b>Property Type</b>	Boolean		
<b>Name String</b>	Show skirt		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SKIRT

A floating-point value that determines the  $Z$  value at which a skirt is to be defined around the array. The  $Z$  value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given  $Z$  value, and the same  $X$  and  $Y$  values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see `SHOW_SKIRT` above). IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Skirt bottom height		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SPECULAR

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

<b>Property Type</b>	COLOR		
<b>Name String</b>	<i>Specular highlight color</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## STYLE

An integer value that indicates the style to be used to draw the surface. Valid values are:

- 0 = Points
- 1 = Wire mesh (the default)
- 2 = Filled
- 3 = RuledXZ
- 4 = RuledYZ
- 5 = Lego
- 6 = LegoFilled: for outline or shaded and stacked histogram-style plots.

---

### Note

Stitching effects may appear when combining an unfilled style (STYLE=0, 1, 3, 4, or 5) and hidden lines (HIDDEN\_LINES=1). In such a case, missing lines may be caused by depth buffer resolution, limited depth offset support of the graphics card, or invisible parts of a surface occluding line visibility.

---

In a property sheet, this property appears as an enumerated list with the following options:

- Points
- Wire mesh
- Filled
- Ruled XZ
- Ruled YZ
- Lego
- Lego filled

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Surface style		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TEXTURE\_COORD

A 2-by- $n$  floating-point array of texture map coordinate pairs that are internally mapped to surface vertex coordinates. The number of data points in the surface and the value of  $n$  in the 2-by- $n$  array should be equal.

Each texture map coordinate pair is mapped to a surface vertex coordinate pair in array order. For example, with a 2-by-9 element array, texture map coordinates will be mapped to a 3-by-3 surface as follows:

Figure 8-9: Mapping Texture Coordinates

Use this property in conjunction with the `TEXTURE_MAP` property to warp images over the surface. To stretch (or shrink) the texture map to cover the surface mesh completely, set `TEXTURE_COORD` to a scalar. By default, IDL stretches (or shrinks) the texture map to cover the surface mesh completely, and sets `TEXTURE_COORD` to a scalar (-1).

Texture coordinates are normalized. This means that the  $m \times n$  image object specified via the `TEXTURE_MAP` property is mapped into the range  $[0.0, 0.0]$  to  $[1.0, 1.0]$ . As the texture coordinates run from 0.0 to 1.0 across a texture, a texture coordinate of  $[0.5, 0.5]$  at a vertex specifies that the image pixel at the exact center of the image is mapped to the surface at that vertex. If texture coordinates outside the range  $[0.0, 0.0]$  to  $[1.0, 1.0]$  are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via `TEXTURE_MAP` is a  $256 \times 256$  array, and we want to map the image into a surface two units on each side. To completely fill the  $2 \times 2$  surface with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [0,1], [1,1]]
```

To fill the  $2 \times 2$  surface with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [0,2], [2,2]]
```

Because of the way in which high-resolution textures require modified texture coordinates, if the `TEXTURE_COORD` property is used, `TEXTURE_HIGHRES` will be disabled.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TEXTURE\_HIGHRES

An integer value that determines the type of texture tiling, if any, that will be used to maintain the full pixel resolution of the original texture image. Set this property to one of the following options:

- 0 = If the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to this resolution.
- 1 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. As a large image could easily consume all available video memory, this mode employs texture Level of Detail (LoD). Rather than loading the entire image into the texture tiles at the full resolution, the image tiles are downsampled based on the level of zoom. If the entire image is visible the texture tiles will contain highly downsampled data from the image to conserve video memory. As a portion of the image is zoomed in on, progressively higher resolution image data is loaded into the visible tiles, until the maximum resolution is reached. The tiles that are not visible during zooming are not loaded with high resolution data.

### Note

---

This mode is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic when `TEXTURE_HIGHRES=0`.

---

- 2 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. However, the highest resolution data is loaded into all tiles. LoD tiling is disabled. This mode should only be used if the video memory is sufficient for the image size.

If not set, and the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to the maximum resolution supported by the 3-D hardware on your system. The default value is 0.

**Note**

---

TEXTURE\_HIGHRES is supported only when `STYLE=2` (Filled).

---

**Note**

---

Because of the way in which high-resolution textures require modified texture coordinates, if you specify the TEXTURE\_COORD property, high resolution textures (TEXTURE\_HIGHRES) will be disabled.

---

In a property sheet, this property appears as an enumerated list with the following options:

- No tiling
- LOD tiling
- Tiling

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Texture hires		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**TEXTURE\_INTERP**

A Boolean value that indicates whether bilinear sampling is to be used with texture mapping. The default method is nearest-neighbor sampling.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Texture interpolation		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## TEXTURE\_MAP

An object reference to an instance of the `IDLgrImage` object class to be texture mapped onto the surface. If this property is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the `COLOR` or `VERT_COLORS` property. If both `TEXTURE_MAP` and `COLORS` or `VERT_COLORS` properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the `COLOR` property should be set equal to [255,255,255].) By default, the texture map will be stretched (or shrunk) to cover the surface mesh completely.

Setting `TEXTURE_MAP` to the object reference of an `IDLgrImage` that contains an alpha channel allows you to create a transparent `IDLgrSurface` object. If an alpha channel is present in the `IDLgrImage` object, IDL blends the texture using the blend function `src = alpha` and `dst = 1 - alpha`, which corresponds to a `BLEND_FUNCTION` of (3,4) as described for the `IDLgrImage` object.

If a texture is provided without texture coordinates, `IDLgrSurface` generates its own texture mapping coordinates to map the texture onto the surface without resampling artifacts, even if the provided texture image does not have dimensions that are an exact power of two. If texture coordinates are provided, the image is resampled to the nearest larger dimensions that are exact powers of two.

### Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

### Note

Texture mapping is applied to all styles that are set by the `STYLE` property except `Lego` and `LegoFilled`.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Texture map		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

<b>Property Type</b>	Thickness		
<b>Name String</b>	Line thickness		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## USE\_TRIANGLES

A Boolean value that determines whether to force the IDLgrSurface object to use triangles instead of quads to draw the surface and skirt.

In a property sheet, this property appears as an enumerated list with the following options:

- Quads
- Triangles

<b>Property Type</b>	Boolean		
<b>Name String</b>	Draw method		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VERT\_COLORS

A vector of colors to be used to specify the color of a surface vertex. The vector may be of the form  $[n]$  where each entry is a color index, or of the form  $[3,n]$  where each 3-element row is an RGB color, or of the form  $[4,n]$  where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT\_COLORS to a scalar.

If VERT\_COLORS is not specified, the entire surface is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a surface polygon is the color of the first vertex of that surface polygon. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT\_COLORS, the elements of VERT\_COLORS are cyclically repeated.

### Note

If the surface object is being rendered on a destination device that uses the Indexed color model, and the view that contains the surface also contains one or more light objects, the VERT\_COLORS property is ignored and the SHADE\_RANGE property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Vertex colors		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $X$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[xmin, xmax]$  that specifies the range of  $x$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Y$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form  $[ymin, ymax]$  that specifies the range of  $y$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert  $Z$  coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZERO\_OPACITY\_SKIP

A Boolean value that determines whether to gain finer control over the rendering of textured surface pixels (texels) by setting an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this property is set to 1, any texels are “skipped” and not rendered at all. If this property is set to zero, the  $Z$ -buffer is updated for these pixels and the display image is not affected as noted above. By updating the  $Z$ -buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

### Note

---

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

---

<b>Property Type</b>	Boolean		
<b>Name String</b>	Skip zero opacity		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ZRANGE

A two-element floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrSurface::Cleanup

The IDLgrSurface::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrSurface::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrSurface::GetCTM

The IDLgrSurface::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrSurface::]GetCTM( [, DESTINATION=objref]  
    [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrSurface::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrSurface::GetProperty

The IDLgrSurface::GetProperty procedure method retrieves the value of a property or group of properties for the surface.

### Syntax

*Obj*->[IDLgrSurface::](#)GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 4399 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrSurface::Init

The IDLgrSurface::Init function method initializes the surface object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrSurface' [, Z [, X, Y]] [, PROPERTY=*value*])

or

*Result* = *Obj*->[IDLgrSurface::]Init([Z [, X, Y]] [, PROPERTY=*value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinates for a column of Z (e.g., X[0] specifies the X coordinate for Z[0, \*]). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z ( $X_{ij}$  specifies the X coordinate of  $Z_{ij}$ ). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinates for a column of Z (e.g., Y[0] specifies the Y coordinate for Z[\* , 0]). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z ( $Y_{ij}$  specifies the Y coordinate of  $Z_{ij}$ ). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is defined as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array indices of each element of Z. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 4399 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrSurface::SetProperty

The IDLgrSurface::SetProperty procedure method sets the value of a property or group of properties for the surface.

### Syntax

*Obj*->[IDLgrSurface::](#)SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 4399 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

# IDLgrSymbol

A symbol object represents a graphical element that is plotted relative to a particular position.

**Note**

Seven predefined symbols are provided by IDL.

---

## Superclasses

None

## Creation

See [“IDLgrSymbol::Init”](#) on page 4442.

## Properties

Objects of this class have the following properties. See [“IDLgrSymbol Properties”](#) on page 4435 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [COLOR](#)
- [DATA](#)
- [NAME](#)
- [SIZE](#)
- [THICK](#)
- [UVALUE](#)

## Methods

This class has the following methods:

- [IDLgrSymbol::Cleanup](#)
- [IDLgrSymbol::GetProperty](#)
- [IDLgrSymbol::Init](#)

- [IDLgrSymbol:: SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
6.1	Added ALPHA_CHANNEL property
6.2	Added NAME and UVALUE properties

## IDLgrSymbol Properties

IDLgrSymbol objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrSymbol::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrSymbol::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrSymbol::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [COLOR](#)
- [DATA](#)
- [NAME](#)
- [SIZE](#)
- [THICK](#)
- [UVALUE](#)

### ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

### Note

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the symbol. The default value of 1.0 causes IDL to draw the symbol completely opaque. If the value of this property is less than 1.0, then the pixels of the symbol are blended with the pixels already on the screen, where the color of the symbol is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Some of the objects that use symbols have properties that control the alpha value that is ultimately used to render the symbol. This ultimate alpha value might come from the parent object's ALPHA\_CHANNEL property, an alpha value from a vertex color in the parent object, or the value of this property, depending on the settings of properties in the parent object. Refer to the reference guide for the parent properties for information on these controls.

### Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

The color used to draw the symbol. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default color is the color of the object for which this symbol is being used.

<b>Property Type</b>	Color		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATA

Either an integer value (from the following list), or an object reference to either an IDLgrModel object, or atomic graphic object. Setting this property is equivalent to setting the *Data* argument.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond
- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = “Greater-than” Arrow Head (>)
- 9 = “Less-than” Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

<b>Property Type</b>	Integer or object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## NAME

A string giving the human-readable name of this object.

<b>Property Type</b>	STRING		
<b>Name String</b>	Name		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SIZE

A one-, two-, or three-element floating-point vector describing the X, Y, and Z scaling factors to be applied to the symbol. The default is [1.0, 1.0, 1.0].

- If SIZE is specified as a scalar, then the X, Y, and Z scale factors are all equal to the scalar value.
- If SIZE is specified as a 2-element vector, then the X and Y scale factors are as specified by the vector, and the Z scale factor is 1.0.
- If SIZE is specified as a 3-element vector, then the X, Y, and Z scale factors are as specified by the vector.

IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to used to draw any lines that make up the symbol, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

<b>Property Type</b>	Floating-point		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## UVALUE

A value of any type containing any information you wish.

### Note

---

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrSymbol object is destroyed.

---

<b>Property Type</b>	User Defined		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrSymbol::Cleanup

The IDLgrSymbol::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrSymbol::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrSymbol::GetProperty

The IDLgrSymbol::GetProperty procedure method retrieves the value of a property or group of properties for the symbol.

### Syntax

*Obj*->[IDLgrSymbol::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrSymbol Properties” on page 4435 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.0	Introduced
-----	------------

## IDLgrSymbol::Init

The IDLgrSymbol::Init function method initializes the plot symbol.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrSymbol' [, *Data*] [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrSymbol::]Init([*Data*] [, *PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Data

Either an integer value from the list shown below, or an object reference to either an IDLgrModel object or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = “Greater-than” Arrow Head (>)
- 9 = “Less-than” Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

## Keywords

Any property listed under [“IDLgrSymbol Properties”](#) on page 4435 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

5.0	Introduced
5.6	Added <i>Data</i> argument

## IDLgrSymbol:: SetProperty

The IDLgrSymbol::SetProperty procedure method sets the value of a property or group of properties for the symbol.

### Syntax

*Obj*->[IDLgrSymbol::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrSymbol Properties” on page 4435 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrTessellator

A tessellator object decomposes a polygon description into a set of triangles. Use the tessellator object to convert complex and/or concave polygons into a form suitable for drawing with the IDLgrPolygon object. IDLgrPolygon can draw only convex polygons correctly.

The polygon contours may intersect each other and may be self-intersecting. The contours may be disjoint, overlapping, or contained within other contours. The contours may also be degenerate, may contain repeated points, and may or may not be closed. The order of the vertices may be either counter-clockwise or clockwise. For best results, the polygon contours should be coplanar.

The tessellator object uses the "odd-winding rule" to determine if a point is in the interior of the polygon and therefore contained in a triangle output by the tessellator. With this rule, a point is in the interior if it is circled an odd number of times as we travel around each of the contours.

---

**Note**

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

---

Specify polygon contours with calls to the [IDLgrTessellator::AddPolygon](#) method. After adding all the contours, use the [IDLgrTessellator::Tessellate](#) method to perform the tessellation and retrieve the resulting list of vertices and connectivity array.

If the polygon contours contain intersecting or self-intersecting contours, the tessellator may return vertices that were not in the original set of vertices specified with the [IDLgrTessellator::AddPolygon](#) method. These vertices are created by the intersecting contours.

If your vertex data also includes other information, such as a color for each vertex, then you may wish for this extra information to be created for any new vertices generated by the tessellator. Use the AUXDATA keywords for [IDLgrTessellator::AddPolygon](#) and [IDLgrTessellator::Tessellate](#) to pass in and retrieve your per-vertex data. The tessellator object interpolates the per-vertex data from neighboring vertices to create new per-vertex data for the new vertices it generates.

In the following example of handling per-vertex data with generated vertices, the polygon is a simple self-intersecting "bow-tie" polygon. It is submitted to the

tessellator with four vertices, but the tessellator returns a fifth at the point of self-intersection. Color data for the four original vertices is also supplied, and the tessellator returns a fifth color.

```

PRO tessaux
  oTess = OBJ_NEW('IDLgrTessellator')
  colors = [[0,255,0],[0,255,0],[0,64,0],[0,64,0]]
  oTess->AddPolygon, [0,1,0,1], [0,0,1,1], AUXDATA=colors
  result = oTess->Tessellate(v, c, AUXDATA=aux)
  PRINT, v[* ,4]
  PRINT, aux[* ,4]
  oPoly = OBJ_NEW('IDLgrPolygon', v, POLYGONS=c, $
VERT_COLORS=aux, SHADING=1)
  XOBJVIEW, oPoly, /BLOCK
  OBJ_DESTROY, [oTess, oPoly]
END

```

The generated output will be:

```

0.500000  0.500000
0  159  0

```

## Superclasses

None

## Creation

See “[IDLgrTessellator::Init](#)” on page 4452.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- [IDLgrTessellator::AddPolygon](#)
- [IDLgrTessellator::Cleanup](#)
- [IDLgrTessellator::Init](#)
- [IDLgrTessellator::Reset](#)
- [IDLgrTessellator::Tessellate](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
-----	------------

## IDLgrTessellator Properties

Objects of this class have no properties of their own.

## IDLgrTessellator::AddPolygon

The IDLgrTessellator::AddPolygon procedure method adds a polygon to the tessellator object.

### Syntax

*Obj*->[IDLgrTessellator::]AddPolygon, X [, Y[, Z]] [, **AUXDATA**=array of auxiliary data] [, **INTERIOR**] [, **POLYGON**=array of polygon descriptions]

### Arguments

#### X

A  $1 \times n$ ,  $2 \times n$ , or  $3 \times n$  array of polygon vertices.

#### Y

A vector of Y values. If X and Y are both specified, they must be one-dimensional vectors of the same length.

#### Z

A vector of Z values. If X, Y, and Z are all specified, they must all three be one-dimensional vectors of the same length. If no Z values are specified, the Z value for the polygon is set to 0.

### Keywords

#### AUXDATA

Set this keyword to an array of auxiliary per-vertex data. This array must have dimensions  $[m,n]$  where  $m$  is the number of auxiliary data items per vertex and  $n$  is the number of vertices specified in the X, Y, and Z arguments. If you specify AUXDATA in any invocation of the AddPolygon method, you must specify it on all invocations of the method for the polygons to be tessellated together with the Tessellate method. Further, the value of  $m$  in the dimensions must be the same for all polygons. That is, all polygons must have the same number of auxiliary data items for each vertex.

## INTERIOR

Set this keyword to set a polygon to be an interior polygon, which is treated as a hole in the exterior polygons.

### Note

---

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

---

## POLYGON

Set this keyword to an array of polygon descriptions. A polygon description is an integer or long word array of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$ , where  $n$  is the number of vertices that define the polygon, and  $i_0..i_{n-1}$  are indices into the X, Y, and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGON array, set the vertex count,  $n$ , to 0. To end the drawing list, even if additional array space is available, set  $n$  to -1. If this keyword is not specified, a single polygon will be generated.

### Note

---

The connectivity array described by POLYGONS allows you to add multiple polygons to the tessellator object with a single AddPolygon operation.

---

## Version History

5.0	Introduced
5.6	Added AUXDATA keyword

## IDLgrTessellator::Cleanup

The IDLgrTessellator::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrTessellator::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrTessellator::Init

The IDLgrTessellator::Init function method initializes the tessellator object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrTessellator')

or

*Result* = *Obj*->[IDLgrTessellator::]Init() *(In a lifecycle method only.)*

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrTessellator::Reset

The IDLgrTessellator::Reset procedure method resets the object's internal state. All previously added polygons are removed from memory and the object is prepared for a new tessellation task.

### Syntax

*Obj*->[IDLgrTessellator::]Reset

### Arguments

None

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrTessellator::Tessellate

The IDLgrTessellator::Tessellate function method performs the actual tessellation.

### Syntax

```
Result = Obj->[IDLgrTessellator:]Tessellate( Vertices, Poly
    [, AUXDATA=variable] [, /QUIET] )
```

### Return Value

Returns 1, and the contents of Vertices and Poly are set to the results of the tessellation. Returns 0 if tessellation fails.

### Arguments

If the tessellation succeeds, IDLgrTessellator::Tessellate returns 1 and the contents of Vertices and Poly are set to the results of the tessellation. If the tessellation fails, the function returns 0.

#### Vertices

A  $2 \times n$  array if all the input polygons were 2-D. A  $3 \times n$  array if all the input polygons were 3-D.

#### Poly

An array of polygon descriptions. A polygon description is an integer or long word array of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$ , where  $n$  is the number of vertices that define the polygon, and  $i_0..i_{n-1}$  are indices into the  $X$ ,  $Y$ , and  $Z$  arguments that represent the polygon vertices.

#### Note

---

On output, the *Vertices* array can be used as the value of the DATA property, and the *Poly* array can be used as the value of the POLYGON property, of an IDLgrPolygon object.

---

## Keywords

### AUXDATA

Set this keyword to a named variable that receives the auxiliary data associated with each vertex returned in the Vertices argument. The data is an  $[m, n]$  array where  $m$  is the number of per-vertex auxiliary data items specified in the call(s) to the AddPolygon method, and  $n$  is the number of vertices returned in the Vertices argument. The type of the returned auxiliary data is the same as the type of the data supplied with the AUXDATA keyword in the last call to AddPolygon.

### QUIET

Set this keyword to suppress warning and error message generation due to tessellation errors. !ERROR\_STATE is not updated in the case of the return value being '0' when the QUIET keyword is specified.

## Version History

5.0	Introduced
5.6	Added AUXDATA keyword

# IDLgrText

A text object represents one or more text strings that share common rendering attributes. An IDLgrText object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrText::Init](#)” on page 4478.

## Properties

Objects of this class have the following properties. See “[IDLgrText Properties](#)” on page 4458 for details on individual properties.

- [ALIGNMENT](#)
- [ALPHA\\_CHANNEL](#)
- [CHAR\\_DIMENSIONS](#)
- [COLOR](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [ENABLE\\_FORMATTING](#)
- [FILL\\_COLOR](#)
- [HIDE](#)
- [LOCATIONS](#)
- [PALETTE](#)
- [RECOMPUTE\\_DIMENSIONS](#)
- [RENDER\\_METHOD](#)
- [UPDIR](#)
- [XCOORD\\_CONV](#)
- [ALL](#)
- [BASELINE](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [FILL\\_BACKGROUND](#)
- [FONT](#)
- [KERNING](#)
- [ONGLASS](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [STRINGS](#)
- [VERTICAL\\_ALIGNMENT](#)
- [XRANGE](#)

- [YCOORD\\_CONV](#)
- [ZCOORD\\_CONV](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrText::Cleanup](#)
- [IDLgrText::GetCTM](#)
- [IDLgrText::GetProperty](#)
- [IDLgrText::Init](#)
- [IDLgrText::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added CLIP_PLANES property

## IDLgrText Properties

IDLgrText objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrText::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrText::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrText::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties:

- [ALIGNMENT](#)
- [ALPHA\\_CHANNEL](#)
- [CHAR\\_DIMENSIONS](#)
- [COLOR](#)
- [DEPTH\\_TEST\\_FUNCTION](#)
- [ENABLE\\_FORMATTING](#)
- [FILL\\_COLOR](#)
- [HIDE](#)
- [LOCATIONS](#)
- [PALETTE](#)
- [RECOMPUTE\\_DIMENSIONS](#)
- [RENDER\\_METHOD](#)
- [UPDIR](#)
- [XCOORD\\_CONV](#)
- [YCOORD\\_CONV](#)
- [ZCOORD\\_CONV](#)
- [ALL](#)
- [BASELINE](#)
- [CLIP\\_PLANES](#)
- [DEPTH\\_TEST\\_DISABLE](#)
- [DEPTH\\_WRITE\\_DISABLE](#)
- [FILL\\_BACKGROUND](#)
- [FONT](#)
- [KERNING](#)
- [ONGLASS](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [STRINGS](#)
- [VERTICAL\\_ALIGNMENT](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent Properties](#)

## ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested horizontal alignment of the text baseline. An alignment of 0.0 (the default) left-justifies the text at the given position; an alignment of 1.0 right-justifies the text, and an alignment of 0.5 centers the text over the given position.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Horizontal alignment		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

---

The fields of this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

A floating-point value that determines the opacity of the text with respect to the background. Set this property to a value in the range [0.0, 1.0] (1.0 is the default) to draw the text foreground and background with the specified blending factor. A value of 1.0 draws the text opaquely without blending the text with objects already drawn on the destination. Edges of the glyphs are always blended. A value of 0.0 draws no text at all. A value in the middle of the range draws the text semi-transparently, which provides a way of creating labels that are visible while allowing features blocked by the labels to still be seen. This property is used only when the `RENDER_METHOD` in effect is 0 (Texture).

**Note**

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**BASELINE**

A two- or three-element floating-point vector describing the direction in which the baseline is to be oriented. Use this property in conjunction with the UPDIR property to specify the plane on which the text lies. The default BASELINE is [1.0,0,0] (i.e., parallel to the x-axis).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Baseline direction		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**CHAR\_DIMENSIONS**

A two-element floating-point vector [*width*, *height*] indicating the dimensions (measured in data units) of a bounding box for each character, to be used when scaling text projected in three dimensions. If either *width* or *height* is zero, the text will be scaled such that if it were positioned halfway between the near and far clipping planes, it will appear at the point size associated with this text object’s font. The default value is [0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

**Note**

If you set the CHAR\_DIMENSIONS property to [0,0] (using the SetProperty method), indicating that IDL should calculate the text size, the value (returned by the GetProperty method) will not be updated to reflect the calculated size until you call either the Draw method or the GetTextDimensions method.

For example, if the VIEWPLANE\_RECT of the view the text object is being rendered in is set equal to [0,0,10,10] (that is, it spans ten data units in each of the X and Y directions), setting the CHAR\_DIMENSIONS property equal to [2, 3] will scale the text such that each character fills 20% of the X range and 30% of the Y range.

This property has no effect if the ONGLASS property is set equal to one.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## CLIP\_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

### Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

### Note

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR

The color to be used as the foreground color for the text. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_TEST\_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

### Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_TEST\_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DEPTH\_WRITE\_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

### Note

If depth testing (see DEPTH\_TEST\_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ENABLE\_FORMATTING

A Boolean value that determines whether the text object should honor embedded Hershey-style formatting codes within the strings. (Formatting codes are described in [Appendix H, “Fonts”](#).) The default is not to honor the formatting codes.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## FILL\_BACKGROUND

Set this property to zero (the default) to render the text with a transparent bitmap background, allowing graphics behind the text to show through between the glyphs. Set this property to non-zero to draw the text bitmap background with the color

specified by the `FILL_COLOR` property. This property can only be used when `RENDER_METHOD` is set to 0 (Texture).

<b>Property Type</b>	Boolean		
<b>Name String</b>	Fill background		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## FILL\_COLOR

An integer vector that determines whether to use a text background color other than the view color. Set this property to -1 (the default) to specify that the text background should be drawn using the view color. Set this property to a three-element vector [*red*, *green*, *blue*] or color index value to specify that the text bitmap background should be drawn using the specified color. This property is used only when the `FILL_BACKGROUND` property has a non-zero value and the `RENDER_METHOD` in effect is 0 (Texture).

In a property sheet, this property appears as a color property

<b>Property Type</b>	COLOR		
<b>Name String</b>	Fill background		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## FONT

An object reference to an instance of an `IDLgrFont` object class to describe the font to use to draw this string. The default is 12 point Helvetica. See [IDLgrFont](#) for details.

### Note

---

If the default font is in use, retrieving the value of the `FONT` property (using the `GetProperty` method) will return a null object.

---

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## KERNING

A Boolean value that determines whether to enable kerning while rendering characters. Kerning reduces the amount of space between glyphs if the shape of each glyph allows it, according to the font information stored in the font's file (e.g., AV). Set this property to a non-zero value (the default is zero) to enable kerning. Enabling kerning may not necessarily result in rendering glyphs more closely together because some fonts do not contain the required kerning information. This property is used only when the RENDER\_METHOD in effect is 0 (Texture).

<b>Property Type</b>	Boolean		
<b>Name String</b>	Kerning		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LOCATIONS

A floating-point array of one or more two- or three-element vectors specifying the coordinates (measured in data units) used to position the string(s). The default location for each string is [0,0,0]. Each vector is of the form [x, y] or [x, y, z]; if z is not provided, it is assumed to be zero. Each location corresponds to a string in the *String* argument; the number of locations should be equal the number of strings. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Text locations		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ONGLASS

A Boolean value that indicates whether the text should be displayed “on the glass”. Text that is drawn “on the glass” always faces the viewer, regardless of the 3-D orientation of the objects “underneath” the glass. The default is projected 3-D text.

<b>Property Type</b>	Boolean		
<b>Name String</b>	On glass		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## RECOMPUTE\_DIMENSIONS

An integer value that indicates when this text object's character dimensions (refer to the CHAR\_DIMENSIONS property) are to be recomputed automatically:

- 0 = The physical size of the text is affected by model and view transforms. The size of the text in terms of data units is obtained from CHAR\_DIMENSIONS. Since the character dimensions are specified in data units, the text will maintain the data space size specified by CHAR\_DIMENSIONS as the transforms change. In other words, the physical text size changes along with other primitives. If the value of this property is [0, 0], the text font's point size is used to compute the physical size of the text in terms of data units using the transforms in effect for the first draw. This setting is the default value for this property.
- 1 = The physical size of the text is only affected by model transforms. The CHAR\_DIMENSIONS property is ignored. The size of the text is computed from the font's point size the first time it is drawn, and IDL does not try to keep the size of the text constant with respect to changes in the model transforms.
- 2 = The physical size of the text is held constant, even as the model and view change. The CHAR\_DIMENSIONS property is ignored and the text is always drawn with a physical size equal to the text font's point size. IDL adjusts its internal text transforms to maintain the physical size of the text.

In a property sheet, this property appears as an enumerated list with the following options:

- Never
- Previous
- Always

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Recompute dimensions		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RENDER\_METHOD

A Boolean value that determines how the text object will be rendered. Set this property to one of the following values:

- 0 = TEXTURE. IDL renders the text by placing a bitmap representation of a glyph into a texture map and then rendering a polygon with the texture map. The `FILL_BACKGROUND`, `ALPHA_CHANNEL`, and `FILL_COLOR` properties control the drawing of the background portions of the texture map and how the entire texture map is blended into the scene. Leaving these three properties set to their default values produces a result that closely approximates the `TRIANGLES` rendering method. One important difference is that the glyph bitmaps are generated by the FreeType font rendering library, producing glyphs that are more accurately rendered and anti-aliased than those drawn with the `TRIANGLES` method. The `TEXTURE` method cannot be used on indexed color destinations. The text is rendered with the `TRIANGLES` method if the destination color model is indexed.
- 1 = TRIANGLES. IDL renders the text by tessellating the glyph outline into a set of small triangles that are then drawn to produce the solid glyph. IDL also draws a blended line around the edge of the glyph to approximate anti-aliasing. This setting forces IDL to use the process it used as the default before IDL 6.0.

In a property sheet, this property appears as an enumerated list with the following options:

- Texture
- Triangles

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Render method		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## STRINGS

The string (or vector of strings) associated with the text object. This property is the same as the *String* argument described for “IDLgrText::Init” on page 4478.

If the number of strings matches the number of locations (as specified by the LOCATIONS property), the existing locations are used.

### Note

If the number of strings *does not* match the number of locations, the number of locations is modified to match the number of strings, and the location value for each string is reset to [0,0,0].

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Text strings		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## UPDIR

A two- (or three-) element floating-point vector describing the vertical direction for the string. The *upward direction* is the direction defined by a vector pointing from the origin to the point specified. Use this property in conjunction with the BASELINE property to specify the plane on which the text lies; the direction specified by UPDIR should be orthogonal to the direction specified by BASELINE. The default UPDIR is [0.0, 1.0, 0.0] (i.e., parallel to the *Y* axis).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Up direction		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VERTICAL\_ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested vertical alignment of the text. An alignment of 0.0 (the default) bottom-justifies the text at the given location; an alignment of 1.0 top-justifies the text at the given location.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Vertical alignment		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element floating-point vector of the form  $[xmin, xmax]$  that specifies the range of  $x$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element floating-point vector of the form  $[ymin, ymax]$  that specifies the range of  $y$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is  $[0.0, 1.0]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZRANGE

A two-element floating-point vector of the form  $[zmin, zmax]$  that specifies the range of  $z$  data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

### Note

Until the text is drawn to the destination object, the [XYZ]RANGE properties will only report the locations of the text. Use the `GetTextDimensions` method of the destination object to get the data dimensions of the text prior to a draw operation.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrText::Cleanup

The IDLgrText::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrText::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrText::GetCTM

The IDLgrText::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrText::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the text object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrText::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrText::GetProperty

The IDLgrText::GetProperty procedure method retrieves the value of a property or group of properties for the text.

### Syntax

*Obj*->[IDLgrText::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrText Properties” on page 4458 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrText::Init

The IDLgrText::Init function method initializes the text object.

---

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

*Obj* = OBJ\_NEW('IDLgrText' [, *String or vector of strings*] [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrText::]Init([*String or vector of strings*] [, *PROPERTY=value*])  
(*In a lifecycle method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

---

**Note**

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

---

## Keywords

Any property listed under “[IDLgrText Properties](#)” on page 4458 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrText:: SetProperty

The IDLgrText::SetProperty procedure method sets the value of a property or group of properties for the text.

### Syntax

*Obj*->[IDLgrText::]SetProperty[, *PROPERTY*=*value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrText Properties” on page 4458 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrView

A view object represents a rectangular area in which graphics objects are drawn. It is a container for objects of the [IDLgrModel](#) class.

## Superclasses

[IDL\\_Container](#)

[IDLitComponent](#)

## Creation

See “[IDLgrView::Init](#)” on page 4496.

## Properties

Objects of this class have the following properties. See “[IDLgrView Properties](#)” on page 4483 for details on individual properties.

- [ALL](#)
- [COLOR](#)
- [DEPTH\\_CUE](#)
- [DIMENSIONS](#)
- [DOUBLE](#)
- [EYE](#)
- [HIDE](#)
- [LOCATION](#)
- [PARENT](#)
- [PROJECTION](#)
- [REGISTER\\_PROPERTIES](#)
- [TRANSPARENT](#)
- [UNITS](#)
- [VIEWPLANE\\_RECT](#)
- [ZCLIP](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrView::Add](#)
- [IDLgrView::Cleanup](#)
- [IDLgrView::GetByName](#)
- [IDLgrView::GetProperty](#)
- [IDLgrView::Init](#)
- [IDLgrView::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
-----	------------

## IDLgrView Properties

IDLgrView objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrView::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrView::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrView::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [COLOR](#)
- [DEPTH\\_CUE](#)
- [DIMENSIONS](#)
- [DOUBLE](#)
- [EYE](#)
- [HIDE](#)
- [LOCATION](#)
- [PARENT](#)
- [PROJECTION](#)
- [REGISTER\\_PROPERTIES](#)
- [TRANSPARENT](#)
- [UNITS](#)
- [VIEWPLANE\\_RECT](#)
- [ZCLIP](#)

In addition, objects of this class inherit:

- [IDL\\_Container](#)
- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

The fields of this structure may change in subsequent releases of IDL.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR

The color for the view. This is the color to which the view area will be erased before its contents are drawn. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [255, 255, 255] (white).

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DEPTH\_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color. Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH\_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between  $Z_{bright}$  and  $Z_{dim}$  determines the result of the rendering:

- $Z_{bright} < Z_{dim}$ : Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$ : Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$ : Disables depth cueing.

You can disable depth cueing by setting  $z_{bright} = z_{dim}$ . The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Depth cue		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the viewport (the rectangle in which models are displayed on a graphics destination). By default, the viewport dimensions are set to [0, 0], which indicates that it will match the dimensions of the graphics destination to which it is drawn. The dimensions are measured in the units specified by the UNITS property.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE

A Boolean value that controls the precision used for rendering the entire contents of the view. If set, IDL calculates the transformations used for the modeling and view transforms using double-precision floating-point arithmetic. This allows the values specified for the VIEWPLANE\_RECT, modeling transforms in IDLgrModel objects, and coordinate data in atomic graphic objects to be used as double-precision before mapping to device coordinates.

**Note**

If this property is set to 0, IDL uses single-precision floating-point arithmetic for these values, which can cause loss of significance and incorrect rendering of data. Setting this property to 1 may impact graphics performance and should only be used when handling data requiring double precision.

The default value is 0.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Double precision		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**EYE**

A floating-point value that specifies the distance from the eyepoint to the viewplane ( $Z=0$ ). The default is 4.0. The eyepoint is always centered within the viewplane rectangle. (That is, if the `VIEWPLANE_RECT` property is set equal to `[0,0,1,1]`, the eyepoint will be at  $X=0.5$ ,  $Y=0.5$ .) IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Eye distance		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**HIDE**

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LOCATION

A two-element floating-point vector of the form  $[x, y]$  specifying the position of the lower left corner of the view. The default is  $[0, 0]$ , measured in device units.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Viewport location		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## PROJECTION

An integer value indicating the type of projection to use within this view. All models displayed within this view will be projected using this type of projection. Valid values are described below.

- 1 = Orthogonal projection (default).
- 2 = Perspective: Indicates that all models are projected toward the eye (located at the origin), which is the apex of the viewing frustum. With a perspective projection, models that are farther away from the eye will appear smaller in the view than models that are nearer to the eye.

In a property sheet, this property appears as an enumerated list with the following options:

- None
- Orthogonal
- Perspective

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Projection		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## TRANSPARENT

A Boolean value that determines whether to disable the viewport erase, making the viewport transparent. If this value is false, the viewport is erased and the depth buffer initialized. If this value is true, the viewport is not erased and the depth buffer is not initialized.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Transparent		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## UNITS

An integer value that specifies the units of measure for this view. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the graphics destination's *rect*.

### Note

If you set the UNITS property (using the SetProperty method) of a view without also setting the LOCATION and DIMENSIONS properties, IDL will use the existing size and location values in the new units, *without conversion*. This means that if your view's location and dimensions were previously measured in centimeters, and you change the value of UNITS to 1 (measurement in inches), the actual size of the view object will change.

In a property sheet, this property appears as an enumerated list with the following options:

- Device
- Inches
- Centimeters
- Normalization

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Units		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VIEWPLANE\_RECT

A four-element floating-point vector of the form  $[x, y, width, height]$  to describe the bounds in  $x$  and  $y$  of the view volume. Objects within the view volume are projected into the viewport. These values are measured in normalized space. The default is  $[-1.0, -1.0, 2.0, 2.0]$  IDL converts, maintains, and returns this data as double-precision floating-point.

**Note**

The z bounds of the view volume are set via the ZCLIP property. The viewplane rectangle is always located at Z=0.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Viewplane rectangle		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**ZCLIP**

A two element floating-point vector representing the near and far clipping planes to be applied to the objects in this view. The vector should take the form [*near*, *far*]. By default, these values are [1, -1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Z clipping		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## IDLgrView::Add

The IDLgrView::Add procedure method adds a child to this view.

### Syntax

*Obj*->[IDLgrView::]Add, *Model* [, POSITION=*index*]

### Arguments

#### Model

An instance of the IDLgrModel object class.

### Keywords

#### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

### Version History

5.0	Introduced
-----	------------

## IDLgrView::Cleanup

The IDLgrView::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrView:]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrView::GetByName

The IDLgrView::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

---

### Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

---

## Syntax

*Result* = *Obj*->[IDLgrView::]GetByName(*Name*)

## Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrView::GetProperty

The `IDLgrView::GetProperty` procedure method retrieves the value of the property or group of properties for the view.

### Syntax

*Obj*->`[IDLgrView::]GetProperty[, PROPERTY=variable]`

### Arguments

None

### Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4483 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrView::Init

The IDLgrView::Init function method initializes the view object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrView' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrView::]Init( [, PROPERTY=value)  (In a lifecycle method  
only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrView Properties” on page 4483 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrView:: SetProperty

The IDLgrView::SetProperty procedure method sets the value of the property or group of properties for the view.

### Syntax

*Obj*->[IDLgrView::]SetProperty[, *PROPERTY=**value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4483 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

# IDLgrViewgroup

The IDLgrViewgroup object is a simple container object, very similar to the IDLgrScene object. It contains one or more IDLgrView objects and an IDLgrScene can contain one or more of these objects. This object is special in that it can also contain objects which do not have a Draw method (e.g. IDLgrPattern and IDLgrFont). An IDLgrViewgroup object cannot be returned by a call to the IDLgrWindow::Select method or the IDLgrBuffer::Select method.

## Superclasses

[IDL\\_Container](#)

[IDLitComponent](#)

## Creation

See “[IDLgrViewgroup::Init](#)” on page 4508.

## Properties

Objects of this class have the following properties. See “[IDLgrViewgroup Properties](#)” on page 4501 for details on individual properties.

- [ALL](#)
- [HIDE](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [IDLgrViewgroup::Add](#)
- [IDLgrViewgroup::Cleanup](#)
- [IDLgrViewgroup::GetByName](#)
- [IDLgrViewgroup::GetProperty](#)

- [IDLgrViewgroup::Init](#)
- [IDLgrViewgroup::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.1	Introduced
-----	------------

## IDLgrViewgroup Properties

IDLgrViewgroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrViewgroup::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrViewgroup::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrViewgroup::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [ALL](#)
- [HIDE](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)

In addition, objects of this class inherit:

- [IDL\\_Container](#)
- [IDLitComponent](#)

### ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

### HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PARENT

An object reference to the object that contains this viewgroup.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrViewgroup::Add

The IDLgrViewgroup::Add function method verifies that the added item is not an instance of the IDLgrScene or IDLgrViewgroup object. If it is not, IDLgrViewgroup:Add adds the object to the specified viewgroup.

### Syntax

*Obj*->[IDLgrViewgroup::]Add, *Object* [, POSITION=*index*]

### Arguments

#### Object

An instance of an object or a list of objects. Objects which subclass IDLgrScene or IDLgrViewgroup can not be added (avoiding circularity constraints). All other objects are allowed.

### Keywords

#### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

### Version History

5.1	Introduced
-----	------------

## IDLgrViewgroup::Cleanup

The IDLgrViewgroup::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY,Obj

or

Obj->[IDLgrViewgroup::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrViewgroup::GetByName

The IDLgrViewgroup::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

### Note

---

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

---

## Syntax

*Result* = *Obj*->[IDLgrViewgroup::]GetByName(*Name*)

## Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrViewgroup::GetProperty

The IDLgrViewgroup::GetProperty procedure method retrieves the value of a property or group of properties for the viewgroup object.

### Syntax

*Obj*->[IDLgrViewgroup::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrViewgroup Properties](#)” on page 4501 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrViewgroup::Init

The IDLgrViewgroup::Init function method initializes the viewgroup object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLgrViewgroup' [, *PROPERTY=value*])

or

*Result* = *Obj*->[IDLgrViewgroup::]Init([, *PROPERTY=value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrViewgroup Properties” on page 4501 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrViewgroup:: SetProperty

The IDLgrViewgroup::SetProperty procedure method sets the value of a property or group of properties for the viewgroup.

### Syntax

*Obj*->[IDLgrViewgroup::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrViewgroup Properties](#)” on page 4501 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced
-----	------------

# IDLgrVolume

A volume object represents a mapping from a three-dimensional array of data to a three-dimensional array of voxel colors, which, when drawn, are projected to two dimensions.

An IDLgrVolume object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrVolume::Init](#)” on page 4535.

## Properties

Objects of this class have the following properties. See “[IDLgrVolume Properties](#)” on page 4513 for details on individual properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [AMBIENT](#)
- [BOUNDS](#)
- [CLIP\\_PLANES](#)
- [COMPOSITE\\_FUNCTION](#)
- [DATA0](#)
- [DATA1](#)
- [DATA2](#)
- [DATA3](#)
- [DEPTH\\_CUE](#)
- [HIDE](#)
- [HINTS](#)
- [INTERPOLATE](#)
- [LIGHTING\\_MODEL](#)
- [OPACITY\\_TABLE0](#)
- [OPACITY\\_TABLE1](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [RENDER\\_STEP](#)
- [RGB\\_TABLE0](#)
- [RGB\\_TABLE1](#)
- [TWO\\_SIDED](#)
- [VALID\\_DATA](#)

- `VOLUME_SELECT`
- `XRANGE`
- `YRANGE`
- `ZCOORD_CONV`
- `XCOORD_CONV`
- `YCOORD_CONV`
- `ZBUFFER`
- `ZERO_OPACITY_SKIP`

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- `IDLgrVolume::Cleanup`
- `IDLgrVolume::ComputeBounds`
- `IDLgrVolume::GetCTM`
- `IDLgrVolume::GetProperty`
- `IDLgrVolume::Init`
- `IDLgrVolume::PickVoxel`
- `IDLgrVolume::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
5.6	Added <code>CLIP_PLANES</code> keyword
6.0	Deprecated <code>CUTTING_PLANES</code> property
6.1	Added <code>ALPHA_CHANNEL</code> property
6.2	Removed <code>NO_COPY</code> property and documented as a keyword on <code>IDLgrVolume::Init</code> and <code>IDLgrVolume::SetProperty</code>

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

## IDLgrVolume Properties

IDLgrVolume objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrVolume::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrVolume::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrVolume::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA\\_CHANNEL](#)
- [AMBIENT](#)
- [BOUNDS](#)
- [CLIP\\_PLANES](#)
- [COMPOSITE\\_FUNCTION](#)
- [DATA0](#)
- [DATA1](#)
- [DATA2](#)
- [DATA3](#)
- [DEPTH\\_CUE](#)
- [HIDE](#)
- [HINTS](#)
- [INTERPOLATE](#)
- [LIGHTING\\_MODEL](#)
- [OPACITY\\_TABLE0](#)
- [OPACITY\\_TABLE1](#)
- [PARENT](#)
- [REGISTER\\_PROPERTIES](#)
- [RENDER\\_STEP](#)
- [RGB\\_TABLE0](#)
- [RGB\\_TABLE1](#)
- [TWO\\_SIDED](#)
- [VALID\\_DATA](#)
- [VOLUME\\_SELECT](#)
- [XCOORD\\_CONV](#)
- [XRANGE](#)
- [YCOORD\\_CONV](#)
- [YRANGE](#)
- [ZBUFFER](#)
- [ZCOORD\\_CONV](#)
- [ZERO\\_OPACITY\\_SKIP](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

---

### Note

The fields of this structure may change in subsequent releases of IDL.

---

---

### Note

This structure returns COLOR, DEPTH\_TEST\_DISABLE, DEPTH\_TEST\_FUNCTION, and DEPTH\_WRITE\_DISABLE properties that are consistent with other graphic objects. However, these properties are not used by the IDLgrVolume object.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ALPHA\_CHANNEL

Apply to the volume only when the volume is rendered with a destination rendering quality setting of Low (0). In the case, the volume is rendered as a wireframe cube. Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the wireframe cube. The default value of 1.0 causes IDL to draw the wireframe cube completely opaque. If the value of this property is less than 1.0, then the pixels of the wireframe cube are blended with the pixels already on the screen, where the color of the wireframe cube is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

**Note**

For more detailed information on alpha channel support for IDL Object Graphics, see “Controlling Object Transparency” in Chapter 2 of the *Object Programming* manual.

<b>Property Type</b>	Float-point value		
<b>Name String</b>	<i>Transparency</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**AMBIENT**

The color and intensity of the volume’s base ambient lighting. Color is specified as a three-element vector [*red, green, blue*]. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING\_MODEL is set.

In a property sheet, this property appears as a color property.

<b>Property Type</b>	COLOR		
<b>Name String</b>	Ambient color		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**BOUNDS**

A six-element floating-point vector of the form [ $x_{min}$ ,  $y_{min}$ ,  $z_{min}$ ,  $x_{max}$ ,  $y_{max}$ ,  $z_{max}$ ], which represents the sub-volume to be rendered. .

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Subvolume bounds		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

**CLIP\_PLANES**

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half

space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

---

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

---

---

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any  $x$ ,  $y$ , or  $z$  coordinate conversion).

---

---

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX\_NUM\_CLIP\_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

---

---

**Note**

Clipping planes are equivalent to the obsolete cutting planes. If defined, CUTTING\_PLANES will be applied first, then the CLIP\_PLANES (until a maximum number of planes is reached).

---

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COMPOSITE\_FUNCTION

An integer value that determines the composite function to be used to measure the value of a pixel on the viewing plane by analyzing the voxels falling along the corresponding ray. Specify one of the following compositing functions:

- 0 = Alpha (default): Alpha-blending. The recursive equation  $dest' = src * srcalpha + dest * (1 - srcalpha)$  is used to compute the final pixel color.
- 1 = MIP: Maximum intensity projection. The color of each pixel on the viewing plane is determined by the voxel with the highest opacity value along the corresponding ray.

- 2 = Alpha sum: Alpha-blending. The recursive equation

$$\text{dest}' = \text{src} + \text{dest} * (1 - \text{srcalpha})$$

is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.

- 3 = Average: Average-intensity projection. The resulting image is the average of all voxels along the corresponding ray. Disables lighting and only works with grey scale palettes. Will not work with four-channel volumes.

In a property sheet, this property appears as an enumerated list with the following options:

- Alpha blending
- Maximum intensity projection
- Alpha sum
- Average intensity

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Composite function		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DATA0

A three-dimensional array of any type of the format  $(d_x, d_y, d_z)$ , which specifies a data volume. Setting this property is the same as including the *vol<sub>0</sub>* argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA1, DATA2, or DATA3, all existing data is removed from the object.

### Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATA1

A three-dimensional array of any type of the format  $(d_x, d_y, d_z)$ , which specifies a data volume. Setting this property is the same as including the  $vol_1$  argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA2, or DATA3, all existing data is removed from the object.

### Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATA2

A three-dimensional array of any type of the format  $(d_x, d_y, d_z)$ , which specifies a data volume. Setting this property is the same as including the  $vol_2$  argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA3, all existing data is removed from the object.

### Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATA3

A three-dimensional array of any type of the format  $(d_x, d_y, d_z)$ , which specifies a data volume. Setting this property is the same as including the  $vol_3$  argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA2, all existing data is removed from the object.

**Note**

---

DATA0, DATA1, DATA2, and DATA3 sizes are dynamic.

---

**Note**

---

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

---

<b>Property Type</b>	Array of any type		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**DEPTH\_CUE**

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH\_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between  $Z_{bright}$  and  $Z_{dim}$  determines the result of the rendering:

- $Z_{bright} < Z_{dim}$ : Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$ : Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$ : Disables depth cueing.

You can disable depth cueing by setting  $z_{bright} = z_{dim}$ . The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Depth cue range		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Show		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## HINTS

An integer value that specifies one of the following acceleration hints:

- 0 = Disables all acceleration hints (default).
- 1 = Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.

- 2 = Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
- 3 = Selects the two acceleration options described above.

In a property sheet, this property appears as an enumerated list with the following options:

- Disable
- Euclidean distance map (EDM)
- Multiple CPU
- EDM and Multiple CPU

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Acceleration hints		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## INTERPOLATE

A Boolean value that determines whether to use Trilinear interpolation to determine the data value for each step on a ray. Setting this property improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Trilinear

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Interpolation		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## LIGHTING\_MODEL

A Boolean value that determines whether to use the current lighting model during rendering in conjunction with a local gradient evaluation.

### Note

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Use lighting		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## OPACITY\_TABLE0

A 256-element byte array that specifies the opacity table for DATA0. The default table is the linear ramp.

<b>Property Type</b>	Byte array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## OPACITY\_TABLE1

A 256-element byte array that specifies the opacity table for DATA1. The default table is the linear ramp. This table is used only when VOLUME\_SELECT is set equal to 1.

<b>Property Type</b>	Byte array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PARENT

An object reference to the object that contains this object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RENDER\_STEP

A three-element floating-point vector of the form  $[x, y, z]$  that specifies the stepping factor through the voxel matrix.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	XYZ render step		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## RGB\_TABLE0

A 256 x 3-element byte array that specifies the RGB color table for DATA0. The default table is the linear ramp. .

<b>Property Type</b>	Byte array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## RGB\_TABLE1

A 256 x 3-element byte array that specifies the RGB color table for DATA1. The default table is the linear ramp. This table is used only when VOLUME\_SELECT is set equal to 1.

<b>Property Type</b>	Byte array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TWO\_SIDED

A Boolean value that determines whether the lighting model uses a two-sided voxel gradient. The two-sided gradient is different from the one-sided gradient (default) in that the absolute value of the inner product of the light direction and the surface gradient is used instead of clamping to 0.0 for negative values. .

In a property sheet, this property appears as an enumerated list with the following options:

- One-sided
- Two-sided

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Voxel gradient		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VALID\_DATA

An integer array (one per volume, DATA0, DATA1, etc.) which have the value 1 if volume data has been loaded for that volume and 0 if that volume data is currently undefined.

<b>Property Type</b>	Integer array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## VOLUME\_SELECT

An integer value that selects how the volume data (DATA0, DATA1, DATA2, DATA3) is combined to form the src and srcalpha parameters described in the COMPOSITE\_FUNCTION function property.

The volume data is always stored and treated as 8-bit indices into the RGB and opacity tables.

Set the RGB and/or opacity tables to linear ramps to use the volume data as direct color or opacity values. Accepted values are:

0	<p>Render single volume from DATA0. This is the default. The value at voxel [i,j,k] would be computed as:</p> <pre>srcRed[i,j,k] = RGB_TABLE0 [DATA0 [i,j,k], 0] srcGreen[i,j,k] = RGB_TABLE0 [DATA0 [i,j,k], 1] srcBlue[i,j,k] = RGB_TABLE0 [DATA0 [i,j,k], 2] srcAlpha[i,j,k] = OPACITY_TABLE0 [DATA0 [i,j,k]]</pre>
1	<p>Render dual volume from DATA0 and DATA1. The value at voxel [i,j,k] is modulated between the two data sets as follows:</p> <pre>srcRed[i,j,k] = (RGB_TABLE0 [DATA0 [i,j,k], 0] *                 RGB_TABLE1 [DATA1 [i,j,k], 0]) / 255 srcGreen[i,j,k] = (RGB_TABLE0 [DATA0 [i,j,k], 1] *                   RGB_TABLE1 [DATA1 [i,j,k], 1]) / 255 srcBlue[i,j,k] = (RGB_TABLE0 [DATA0 [i,j,k], 2] *                   RGB_TABLE1 [DATA1 [i,j,k], 2]) / 255 srcAlpha[i,j,k] = (OPACITY_TABLE0 [DATA0 [i,j,k]] *                   OPACITY_TABLE1 [DATA1 [i,j,k]]) / 255</pre>
2	<p>Render RGBA volume from DATA0 (red), DATA1 (green), DATA2 (blue), and DATA3 (alpha). The value at voxel [i,j,k] would be computed as:</p> <pre>srcRed[i,j,k] = RGB_TABLE0 [DATA0 [i,j,k], 0] srcGreen[i,j,k] = RGB_TABLE0 [DATA1 [i,j,k], 1] srcBlue[i,j,k] = RGB_TABLE0 [DATA2 [i,j,k], 2] srcAlpha[i,j,k] = OPACITY_TABLE0 [DATA3 [i,j,k]]</pre>

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## XRANGE

A two-element double-precision floating-point vector of the form  $[xmin, xmax]$  that specifies the range of  $x$  data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## YCOORD\_CONV

A floating-point vector,  $[s_0, s_1]$ , of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of y data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZBUFFER

A Boolean value that determines whether to clip the rendering to the current Z-buffer and then update the buffer. The default is to not modify the current Z-buffer.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Update Z buffer		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ZCOORD\_CONV

A floating-point vector, [*s*<sub>0</sub>, *s*<sub>1</sub>], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]IDL converts, maintains, and returns this data as double-precision floating-point.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZERO\_OPACITY\_SKIP

A Boolean value that determines whether to skip voxels with an opacity of 0. This property can increase the output contrast of MIP (MAXIMUM\_INTENSITY) projections by allowing the background to show through. If this property is set, voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the property) continues to render voxels with an opacity of zero.

<b>Property Type</b>	Boolean		
<b>Name String</b>	Skip zero opacity		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrVolume::Cleanup

The IDLgrVolume::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrVolume::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrVolume::ComputeBounds

The IDLgrVolume::ComputeBounds procedure method computes the smallest bounding box that contains all voxels whose opacity lookup is greater than a given opacity value. The BOUNDS property is updated to the computed bounding box.

### Syntax

```
Obj->[IDLgrVolume::]ComputeBounds [, OPACITY=value] [, /RESET]
      [, VOLUMES=int array]
```

### Arguments

None

### Keywords

#### OPACITY

Set this keyword to the opacity value to be used to determine which voxels are included within the bounding box. All voxels whose opacity lookup is greater than this value will be included. The default value is zero.

#### RESET

Set this keyword to cause the BOUNDS keyword of IDLgrVolume::Init to be reset to contain the entire volume.

#### VOLUMES

Set this keyword to an array of integers which select which volumes to consider when computing the bounding box. A non-zero value selects a volume to be searched. The default is to search all loaded volumes. For example: VOLUMES=[0,1] will cause ComputeBounds to search only the volume loaded in DATA1.

### Version History

5.0	Introduced
-----	------------

## IDLgrVolume::GetCTM

The IDLgrVolume::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Syntax

```
Result = Obj->[IDLgrVolume::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

### Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

### Arguments

None

### Keywords

#### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the volume object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVolume::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

**TOP**

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

**Version History**

5.0	Introduced
-----	------------

## IDLgrVolume::GetProperty

The IDLgrVolume::GetProperty procedure method retrieves the value of a property or group of properties for the volume.

### Syntax

*Obj*->[IDLgrVolume::]GetProperty[, *PROPERTY=variable*] [, /NO\_COPY]

### Arguments

None

### Keywords

Any property listed under “IDLgrVolume Properties” on page 4513 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### NO\_COPY

If this keyword is set to a non-zero value, and the [DATA0](#), [DATA1](#), [DATA2](#), or [DATA3](#) property is specified in the same invocation, the data is relocated from the volume object into the destination variable, removing the data from the object.

```
vol = BYTARR(30,30,30)
oVol = OBJ_NEW('IDLgrVolume')
oVol->SetProperty, DATA0=vol

oVol->GetProperty, DATA0=vol, /NO_COPY
HELP, vol
; IDL prints VOL BYTE = Array[30, 30, 30]

; Verify that the data has been removed from the object by
; repeating the call.
oVol->GetProperty, DATA0=vol2, /NO_COPY
HELP, vol2
; IDL prints VOL2 UNDEFINED = <Undefined>
```

There can be 1, 2, 3, or 4 volumes stored in an IDLgrVolume. Calling Get with NO\_COPY is a good way to remove the data associated with one of the volumes without destroying the object.

## Version History

5.0	Introduced
6.1	Added NO_COPY keyword

## IDLgrVolume::Init

The IDLgrVolume::Init function method initializes the volume object. At least one volume must be specified, via arguments or keywords.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

### Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

---

## Syntax

```
Obj = OBJ_NEW('IDLgrVolume' [, vol0 [, vol1 [, vol2 [, vol3]]]]
      [, PROPERTY=value] [, /NO_COPY])
```

or

```
Result = Obj->[IDLgrVolume::]Init([vol0 [, vol1 [, vol2 [, vol3]]]]
      [, PROPERTY=value] [, /NO_COPY]) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### vol<sub>0</sub>

A three-dimensional array ( $d_x$ ,  $d_y$ ,  $d_z$ ) which specifies a data volume.

**vol<sub>1</sub>**

A three-dimensional array ( $d_x, d_y, d_z$ ) which specifies a data volume.

**vol<sub>2</sub>**

A three-dimensional array ( $d_x, d_y, d_z$ ) which specifies a data volume.

**vol<sub>3</sub>**

A three-dimensional array ( $d_x, d_y, d_z$ ) which specifies a data volume.

**Note**

---

If two or more of the above arguments are specified, they must have matching dimensions.

---

## Keywords

Any property listed under “[IDLgrVolume Properties](#)” on page 4513 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

### NO\_COPY

If this keyword is set to a non-zero value, it relocates the volume data from the input variable to the volume object, leaving the input variable ( $vol_0, vol_1, vol_2, vol_3$ , or [DATA0](#), [DATA1](#), [DATA2](#), or [DATA3](#)) undefined. Only these data-related arguments and properties are affected by the NO\_COPY keyword.

```
vol = BYTARR(30,30,30)
oVol = OBJ_NEW('IDLgrVolume', vol, /NO_COPY)

; Verify the data no longer exists in the input variable.
HELP, vol
; IDL prints VOL UNDEFINED = <Undefined>
```

If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

## Version History

5.0	Introduced
6.2	Added NO_COPY keyword

## IDLgrVolume::PickVoxel

The IDLgrVolume::PickVoxel function method computes the coordinates of the voxel projected to a location specified by the 2-D device coordinates point,  $[x_i, y_i]$ , and the current Z-buffer. The function returns the volume indices as a vector of three long integers. If the selected point is not within the volume, this function returns  $[-1,-1,-1]$ .

### Syntax

*Result* = *Obj*->[IDLgrVolume::]PickVoxel ( *Win*, *View*, *Point* [, *PATH*=*objref(s)*] )

### Return Value

Returns the volume indices as a vector of three long integers. If the selected point is not within the volume, this function returns  $[-1,-1,-1]$ .

### Arguments

#### Win

The IDLgrWindow object from which the Z-buffer is to be used.

#### View

The IDLgrView object that contains the volume.

#### Point

The  $[x, y]$  viewport coordinates of the point chosen.

### Keywords

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a voxel coordinate. Each path object reference specified with this keyword must contain an alias. The voxel coordinate is computed for the version of the object falling within the specified path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

## Version History

5.0	Introduced
-----	------------

## IDLgrVolume:: SetProperty

The IDLgrVolume::SetProperty procedure method sets the value of a property or group of properties for the volume.

### Syntax

*Obj*->[IDLgrVolume::]SetProperty[, *PROPERTY=value*] [/NO\_COPY]

### Arguments

None

### Keywords

Any property listed under “IDLgrVolume Properties” on page 4513 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

#### NO\_COPY

If this keyword is set to a non-zero value, it relocates the volume data from the input variable to the volume object, leaving the input variable ([DATA0](#), [DATA1](#), [DATA2](#), or [DATA3](#)) undefined. Only these data-related arguments and properties are affected by the NO\_COPY keyword.

```
vol = BYTARR(30,30,30)
oVol = OBJ_NEW('IDLgrVolume')
oVol->SetProperty, Data0=vol, /NO_COPY

; Verify that the data has been removed from the variable.
HELP, vol
; IDL prints VOL UNDEFINED = <Undefined>
```

If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

### Version History

5.0	Introduced
-----	------------

6.2	Added NO_COPY keyword
-----	-----------------------

# IDLgrVRML

The IDLgrVRML object allows you to save the contents of an Object Graphics hierarchy into a VRML 2.0 format file. The graphics tree can only contain a single view due to limitations in the VRML specification. The resulting VRML file is interactive and allows you to explore the geometry interactively using a VRML browser.

---

**Note**

Objects or subclasses of this type can not be saved or restored.

---

Aspect ratios are difficult to duplicate as they can be browser dependent. The object is limited to the primitives supported by VRML. Texture maps (and images) will be inlined into the output file. While this will generate large VRML files, the files are fully self-contained.

Several entities cannot be translated perfectly. These include:

## IDLgrImage Objects

Rotation and Z buffer behavior are not completely supported. Image objects will be converted into texture mapped polygons. BLEND\_FUNCTION is not completely supported (only binary srcAlpha,1-srcAlpha) This function is applied automatically if an alpha channel is present. It is also very browser dependent. Channel masks are not supported.

## IDLgrPolygon and IDLgrSurface Objects

Hidden line/hidden point display, color and vertex color blending with texture colors, and bottom color are not supported. Shading may be browser dependent. Front face culling is not supported and back face culling is only supported at the browser's discretion.

---

**Note**

The AMBIENT material property is not supported.

---

## IDLgrLight Objects

Lighting scope and intensity may be browser dependent.

## IDLgrText Objects

Text using the ONGLASS property is only supported for the initial view.

## **IDLgrViewgroup, IDLgrScene, IDLgrVolume Objects**

These objects are not supported.

## **IDLgrPalette Objects**

Palette objects are simulated using an RGB color model.

## **IDLgrPattern Objects**

Only solid or clear patterns are supported.

## **IDLgrFont, IDLgrSymbol Objects**

The THICK property is not supported.

## **IDLgrPolyline, IDLgrSymbol, IDLgrSurface, IDLgrPolygon and IDLgrPlot Objects**

Line attributes (thickness, linestyle) are not supported.

## **IDLgrView Objects**

Z-clipping control, aspect ratio preservation, the LOCATION property, and orthographic projections are not supported.

## **Destination Objects**

The COLOR\_MODEL property is not fully supported in Indexed Color mode, when using a SHADER\_RANGE (an RGB model will be substituted instead). The QUALITY property is not supported.

## **Superclasses**

[IDLitComponent](#)

## **Creation**

See “[IDLgrVRML::Init](#)” on page 4561.

## **Properties**

Objects of this class have the following properties. See “[IDLgrVRML Properties](#)” on page 4546 for details on individual properties.

- ALL
- COLOR\_MODEL
- DIMENSIONS
- FILENAME
- GRAPHICS\_TREE
- N\_COLORS
- PALETTE
- QUALITY
- REGISTER\_PROPERTIES
- RESOLUTION
- SCREEN\_DIMENSIONS
- UNITS
- WORLDINFO
- WORLDTITLE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrVRML::Cleanup
- IDLgrVRML::Draw
- IDLgrVRML::GetDeviceInfo
- IDLgrVRML::GetFontnames
- IDLgrVRML::GetProperty
- IDLgrVRML::GetTextDimensions
- IDLgrVRML::Init
- IDLgrVRML::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.1	Introduced
-----	------------

## IDLgrVRML Properties

IDLgrVRML objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrVRML::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrVRML::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrVRML::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [GRAPHICS\\_TREE](#)
- [N\\_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN\\_DIMENSIONS](#)
- [UNITS](#)
- [WORLDINFO](#)
- [WORLDTITLE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR\_MODEL

An integer that determines whether to use the indexed color model for the buffer:

- 0 = RGB (the default)
- 1 = Color indexed.

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Color model		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the window in units specified by the UNITS property. The default is [640,480].

### Note

The only use of this property is to support the use of normalized coordinates for the dimensions of the IDLgrView object passed to the IDLgrVRML::Draw method.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## FILENAME

A string that specifies the name of a file into which the vector data will be saved. The default is `idl.wrl`.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## GRAPHICS\_TREE

An object reference of type `IDLgrView`. If this property is set to a valid object reference, calling the `Draw` method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the `GRAPHICS_TREE` property is set equal to the null-object. .

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_COLORS

An integer that specifies the number of colors (between 2 and 256) to be used if `COLOR_MODEL` is set to indexed.

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of colors		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0=Low
- 1=Medium
- 2=High (the default).
- In a property sheet, this property appears as an enumerated list with the following options:
- Low
- Medium
- High

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Quality		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RESOLUTION

A two-element floating-point vector of the form  $[xres, yres]$  specifying the device resolution in centimeters per pixel.

### Note

This property is used for text scaling and partial aspect ratio preservation only. The default value is  $[0.0352778, 0.0352778]$  (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Resolution		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SCREEN\_DIMENSIONS

A two-element integer vector of the form  $[width, height]$  specifying the dimensions of the overall screen dimensions for the screen with which this object associated. The screen dimensions are measured in device units.

<b>Property Type</b>	Integer vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## UNITS

An integer that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (the default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## WORLDINFO

A list of strings for the info field of the VRML WorldInfo node. The default is the null string, "".

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## WORLDTITLE

A string containing the title for the VRML WorldInfo node, TITLE field. The default is 'IDL VRML file'.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLgrVRML::Cleanup

The IDLgrVRML::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrVRML::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.1	Introduced
-----	------------

## IDLgrVRML::Draw

The IDLgrVRML::Draw procedure method draws the given picture to this graphics destination.

### Syntax

*Obj*->[IDLgrVRML::]Draw [, *Picture*]

### Arguments

#### Picture

The view (an instance of an [IDLgrView](#) object) to be drawn. If the view has a LOCATION property, it is ignored.

### Keywords

None

### Version History

5.1	Introduced
-----	------------

## IDLgrVRML::GetDeviceInfo

The IDLgrVRML::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

### Syntax

```
Obj->[IDLgrVRML::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

### Arguments

None

### Keywords

#### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

#### MAX\_NUM\_CLIP\_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

#### MAX\_TEXTURE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX\_TEXTURE\_DIMENSIONS* contains a two element integer array that specifies the maximum texture size supported by the device.

## MAX\_VIEWPORT\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX\_VIEWPORT\_DIMENSIONS* contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

## NAME

Set this keyword equal to a named variable. Upon return, *NAME* contains the name of the rendering device as a string.

## NUM\_CPUS

Set this keyword equal to a named variable. Upon return, *NUM\_CPUS* contains an integer that specifies the number of CPUs that are known to, and available to IDL.

### Note

The *NUM\_CPUS* keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

## VENDOR

Set this keyword equal to a named variable. Upon return, *VENDOR* contains the name of the rendering device creator as a string.

## VERSION

Set this keyword equal to a named variable. Upon return, *VERSION* contains the version of the rendering device driver as a string.

## Version History

5.1	Introduced
5.6	Added <i>MAX_NUM_CLIP_PLANES</i> keyword

## IDLgrVRML::GetFontnames

The IDLgrVRML::GetFontnames function method returns the list of available fonts that can be used in [IDLgrFont](#) objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

### Syntax

```
Result = Obj->[IDLgrVRML::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

### Return Value

Returns the list of available fonts that can be used in [IDLgrFont](#) objects.

### Arguments

#### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name, such as “Helvetica”. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “\*”.

### Keywords

#### IDL\_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL\_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

#### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “\*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

5.1	Introduced
-----	------------

## IDLgrVRML::GetProperty

The IDLgrVRML::GetProperty procedure method retrieves the value of a property or group of properties for the VRML object.

### Syntax

*Obj*->[IDLgrVRML::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLgrVRML Properties](#)” on page 4546 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.1	Introduced
-----	------------

## IDLgrVRML::GetTextDimensions

The `IDLgrVRML::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector  $[xDim, yDim, zDim]$  representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

### Syntax

```
Result = Obj->[IDLgrVRML::]GetTextDimensions( TextObj [, DESCENT=variable]  
[, PATH=objref(s)] )
```

### Return Value

Returns a 3-element double-precision floating-point vector  $[xDim, yDim, zDim]$  representing the dimensions of the text or axis object, measured in data units.

### Arguments

#### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

### Keywords

#### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values represent the distance to travel (parallel to the `UPDIR` vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if `TextObj` is an `IDLgrText` object.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this

keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVRML::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

---

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

---

## Version History

5.1	Introduced
-----	------------

## IDLgrVRML::Init

The IDLgrVRML::Init function method initializes the VRML object. This creates an object that will convert object hierarchies rendered to it into VRML format files.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDLgrVRML' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrVRML::]Init( [, PROPERTY=value]) (In a lifecycle method  
only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLgrVRML Properties” on page 4546 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.1	Introduced
-----	------------

## IDLgrVRML:: SetProperty

The IDLgrVRML::SetProperty procedure method sets the value of a property or group of properties for the VRML world.

### Syntax

*Obj*->[IDLgrVRML::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrVRML Properties” on page 4546 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.1	Introduced
-----	------------

# IDLgrWindow

A window object is a representation of an on-screen area on a display device that serves as a graphics destination.

---

**Note**

Objects or subclasses of this type can not be saved or restored.

---

## Note on Window Size Limits

The OpenGL libraries IDL uses impose limits on the maximum size of a drawable area. The limits are device-dependent — they depend both on your graphics hardware and the setting of the RENDERER property. Currently, the smallest maximum drawable area on any IDL platform is 1280 x 1024 pixels; the limit on your system may be larger.

## Superclasses

[IDLitComponent](#)

## Creation

See “[IDLgrWindow::Init](#)” on page 4596.

## Properties

Objects of this class have the following properties. See “[IDLgrWindow Properties](#)” on page 4567 for details on individual properties.

- [ALL](#)
- [CURRENT\\_ZOOM](#)
- [DISPLAY\\_NAME \(X Only\)](#)
- [IMAGE\\_DATA](#)
- [MINIMUM\\_VIRTUAL\\_DIMENSIONS](#)
- [PALETTE](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS\\_TREE](#)
- [LOCATION](#)
- [N\\_COLORS](#)
- [QUALITY](#)
- [RENDERER](#)
- [RETAIN](#)

- SCREEN\_DIMENSIONS
- UNITS
- VIRTUAL\_DIMENSIONS
- ZBUFFER\_DATA
- ZOOM\_NSTEP
- TITLE
- VIEWPORT\_DIMENSIONS
- VISIBLE\_LOCATION
- ZOOM\_BASE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrWindow::Cleanup
- IDLgrWindow::Draw
- IDLgrWindow::Erase
- IDLgrWindow::GetContiguousPixels
- IDLgrWindow::GetDeviceInfo
- IDLgrWindow::GetDimensions
- IDLgrWindow::GetFontnames
- IDLgrWindow::GetProperty
- IDLgrWindow::GetTextDimensions
- IDLgrWindow::Iconify
- IDLgrWindow::Init
- IDLgrWindow::PickData
- IDLgrWindow::QueryRequiredTiles
- IDLgrWindow::Read
- IDLgrWindow::Select
- IDLgrWindow::SetCurrentCursor
- IDLgrWindow::SetCurrentZoom
- IDLgrWindow::SetProperty
- IDLgrWindow::Show

- [IDLgrWindow::ZoomIn](#)
- [IDLgrWindow::ZoomOut](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
6.1	Added MINIMUM_VIRTUAL_DIMENSIONS, ZOOM_BASE, and ZOOM_NSTEP properties
6.2	Added QueryRequiredTiles method. Added VIEWPORT_DIMENSIONS property.

## IDLgrWindow Properties

IDLgrWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrWindow::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrWindow::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [CURRENT\\_ZOOM](#)
- [DISPLAY\\_NAME \(X Only\)](#)
- [IMAGE\\_DATA](#)
- [MINIMUM\\_VIRTUAL\\_DIMENSIONS](#)
- [PALETTE](#)
- [REGISTER\\_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN\\_DIMENSIONS](#)
- [UNITS](#)
- [VIRTUAL\\_DIMENSIONS](#)
- [ZBUFFER\\_DATA](#)
- [ZOOM\\_NSTEP](#)
- [COLOR\\_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS\\_TREE](#)
- [LOCATION](#)
- [N\\_COLORS](#)
- [QUALITY](#)
- [RENDERER](#)
- [RETAIN](#)
- [TITLE](#)
- [VIEWPORT\\_DIMENSIONS](#)
- [VISIBLE\\_LOCATION](#)
- [ZOOM\\_BASE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

### Note

The fields of this structure may change in subsequent releases of IDL.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COLOR\_MODEL

An integer value that determines whether to use indexed color as the color model for the window:

- 0 = RGB (default)
- 1 = Color Index

### Note

For some X11 display situations, IDL may not be able to support a color index model destination object in object graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations.

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed color

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Color model		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## CURRENT\_ZOOM

A floating-point value that represents the current zoom factor associated with this window.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Zoom factor		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> Yes

## DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the values of the [IDL\\_GR\\_WIN\\_HEIGHT](#) and [IDL\\_GR\\_WIN\\_WIDTH](#) preferences (under Microsoft Windows) or the values of the [IDL\\_GR\\_X\\_HEIGHT](#) and [IDL\\_GR\\_X\\_WIDTH](#) preferences (under UNIX). There are limits on the maximum size of an IDLgrWindow object; see “[Note on Window Size Limits](#)” on page 4564 for details.

### Note

---

Changing the DIMENSIONS property is merely a request to the windowing system and may be ignored.

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Dimensions		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## DISPLAY\_NAME (X Only)

A string that specifies the name of the X Windows display on which the window is to appear.

<b>Property Type</b>	STRING		
<b>Name String</b>	Display name		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> No	<b>Registered:</b> Yes

## GRAPHICS\_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView describing the graphics tree of this window object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS\_TREE property is set equal to the null-object.

<b>Property Type</b>	Object reference		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IMAGE\_DATA

A byte array representing the image that is currently displayed in the window. If the window object uses an RGB color model, the returned array will have dimensions (3, *winXSize*, *winYSize*), or (4, *winXSize*, *winYSize*) if an alpha channel is included. If the window object uses an Indexed color model, the returned array will have dimensions (*winXSize*, *winYSize*). See “IDLgrWindow::Read” on page 4604 for more information.

<b>Property Type</b>	Byte array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## LOCATION

A two-element floating-point vector of the form [x, y] to specify the location of the upper lefthand corner of the window relative to the display screen, in units specified by the UNITS property. By default, the window is positioned at one of four quadrants on the display screen, and the location is measured in device units.

### Note

---

Changing LOCATION properties is merely a request and may be ignored for various reasons. LOCATION may be adjusted to take into account window decorations.

---

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Location		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## MINIMUM\_VIRTUAL\_DIMENSIONS

A two-element vector, [*width*, *height*], specifying the minimum dimensions allowed for the virtual canvas of this window. The unit of measure is specified by the UNITS property. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default value of this property is [0, 0], a value indicating that the minimum virtual dimensions should match the current virtual dimensions.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_COLORS

An integer value that specifies the number of colors (between 2 and 256) to be used if COLOR\_MODEL is set to Indexed (1). This property is ignored if COLOR\_MODEL is set to RGB (0).

### Note

If COLOR\_MODEL is set to Color Index (1), setting N\_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the [IDLgrWindow::GetProperty](#) method. The actual number of available colors depends on your system and also on how you have used IDL.

<b>Property Type</b>	Integer		
<b>Name String</b>	Number of colors		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table, applicable if the Indexed color model is used.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Color palette		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to this destination. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default).

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Draw quality		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## REGISTER\_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## RENDERER

An integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL’s software implementation

By default, IDL uses the value specified in the Graphics tab of the IDLDE Preferences dialog. If the preference is not explicitly set in the IDLDE and your platform has a native OpenGL implementation, IDL uses that implementation as the default. If your platform does not have a native OpenGL implementation, IDL uses its own software implementation regardless of the value of this property. See “[Hardware vs. Software Rendering](#)” in Chapter 12 of the *Object Programming* manual for details. Your choice of renderer may also affect the maximum size of an IDLgrWindow object; see “[Note on Window Size Limits](#)” on page 4564 for details.

In a property sheet, this property appears as an enumerated list with the following options:

- OpenGL
- Software.

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Renderer		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## RESOLUTION

A floating-point vector of the form  $[xres, yres]$  reporting the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

<b>Property Type</b>	FLOAT		
<b>Name String</b>	Resolution		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> Yes

## RETAIN

An integer value that specifies how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the “Backing Store” preference set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

- 0 = No backing store.
- 1 = The server or window system is requested to provide the backing store. Note that requesting backing store from the server is only a request; backing store may not be provided in all situations.
- 2 = Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN property of [IDLgrWindow::GetProperty](#). IDL may also alter the RENDERER property while attempting to provide backing store.

In IDL Object Graphics, it is almost always best to disable backing store (that is, set the RETAIN property equal to zero). This is because drawing to an off-screen pixmap (which is what happens when backing store is enabled) almost always bypasses any hardware graphics acceleration that may be available, causing all rendering to be done in software. To ensure that windows are redrawn properly, enable the generation of expose events on the WIDGET\_DRAW window and redraw the window explicitly when an expose event is received.

### Note

If you are using software rendering (that is, the RENDERER property is set equal to one), IDL will refresh the window automatically regardless of the setting of the RETAIN property.

In a property sheet, this property appears as an enumerated list with the following options:

- No backing
- Server/Window
- IDL

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Retain		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

## SCREEN\_DIMENSIONS

A two-element floating-point vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this window is associated. The screen dimensions are measured in device units.

### Note

---

The maximum screen dimension size depends on the graphics device.

---

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## TITLE

A string that represents the title of the window.

<b>Property Type</b>	STRING		
<b>Name String</b>	Title		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## UNITS

An integer value that indicates the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the screen.

### Note

---

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units.

---

In a property sheet, this property appears as an enumerated list with the following options:

- Device
- Inches
- Centimeters
- Normalized

<b>Property Type</b>	ENUMLIST		
<b>Name String</b>	Units		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VIEWPORT\_DIMENSIONS

A two-element floating-point vector of the form  $[width, height]$  specifying the dimensions of the *viewport* of the draw widget that contains this window. If the window is not within a draw widget, this property is equivalent to the DIMENSIONS property.

<b>Property Type</b>	Floating-point vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## VIRTUAL\_DIMENSIONS

A two-element integer vector,  $[width, height]$ , specifying the dimensions of the *virtual canvas* for this window. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default is  $[0,0]$ , indicating that the virtual canvas dimensions should match the visible dimensions (as specified via the DIMENSIONS property).

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Virtual dimensions		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## VISIBLE\_LOCATION

A two-element integer vector,  $[x,y]$ , specifying the lower left location of the visible portion of the canvas (relative to the virtual canvas). In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time.

This property is registered as a user-defined property, but it is hidden by default.

<b>Property Type</b>	USERDEF		
<b>Name String</b>	Visible location		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> Yes

## ZBUFFER\_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

<b>Property Type</b>	Floating-point array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ZOOM\_BASE

A floating point value representing the base value by which the window's current zoom factor will be multiplied or divided for zooming in or zooming out. Allowable values are those greater than 1.0. The default is 2.0.

<b>Property Type</b>	Float		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## ZOOM\_NSTEP

A named variable that, upon return, will contain an integer that indicates the number of times this window's ZOOM\_BASE property has been applied to achieve the current zoom factor. A positive value indicates that the current zoom factor represents the result of zooming in ZOOM\_NSTEP times. A negative value indicates that the current zoom factor represents the result of zooming out ZOOM\_NSTEP times.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLgrWindow::Cleanup

The IDLgrWindow::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLgrWindow::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::Draw

The IDLgrWindow::Draw procedure method draws the specified scene or view object to this graphics destination.

### Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

## Syntax

```
Obj->[IDLgrWindow::]Draw [, Picture] [, CREATE_INSTANCE={1 | 2}]  
[, DRAW_INSTANCE={1 | 2}]
```

## Arguments

### Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn. If *Picture* is not supplied, the graphics hierarchy specified by the [GRAPHICS\\_TREE](#) property of the IDLgrWindow object will be drawn, if it exists. If neither the *Picture* argument or the [GRAPHICS\\_TREE](#) property are specified, nothing is drawn.

## Keywords

### CREATE\_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

### DRAW\_INSTANCE

Set this keyword to specify that the instance, or unchanging part of the drawing, is drawn to the device first. IDL then draws the changing part of the drawing, indicated by the scene, view or viewgroup specified by the *Picture* argument.

If the value of this keyword is 1, IDL copies both the instance image (color buffer) and the instance depth buffer to the device.

If the value of this keyword is 2, IDL copies only the instance image to the device.

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::Erase

The IDLgrWindow::Erase procedure method erases the entire contents of the window and initializes the depth buffer.

### Syntax

*Obj*->[IDLgrWindow::]Erase [, COLOR=*index or RGB vector*]

### Arguments

None

### Keywords

#### COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default erase color is white.

### Version History

5.0	Introduced
-----	------------

## IDLgrWindow::GetContiguousPixels

The `IDLgrWindow::GetContiguousPixels` function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the `N_COLORS` property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the `SHADE_RANGE` property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

## Syntax

*Result* = *Obj*->[[IDLgrWindow::](#)]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::GetDeviceInfo

The IDLgrWindow::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=0 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

### Syntax

```
Obj->[IDLgrWindow::]GetDeviceInfo [, ALL=variable]
    [, MAX_NUM_CLIP_PLANES=variable]
    [, MAX_TEXTURE_DIMENSIONS=variable]
    [, MAX_TILE_DIMENSIONS=variable]
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

### Arguments

None

### Keywords

#### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

#### MAX\_NUM\_CLIP\_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

#### MAX\_TEXTURE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_TEXTURE\_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

## MAX\_TILE\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_TILE\_DIMENSIONS contains a two element integer array that specifies the maximum tile size supported by the device.

## MAX\_VIEWPORT\_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX\_VIEWPORT\_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

## NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

## NUM\_CPUS

Set this keyword equal to a named variable. Upon return, NUM\_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

### Note

---

The NUM\_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

---

## VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

## VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

## Version History

5.0	Introduced
-----	------------

5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

## IDLgrWindow::GetDimensions

The IDLgrWindow::GetDimensions function method returns a two-element vector, [*width*, *height*], representing the visible dimensions (in pixel units) of this window.

### Syntax

```
Result = Obj -> [IDLgrWindow::]GetDimensions  
    ( [, MINIMUM_VIRTUAL_DIMENSIONS=variable]  
      [, ORIGINAL_VIRTUAL_DIMENSIONS=variable]  
      [, VIRTUAL_DIMENSIONS=variable] [, VISIBLE_LOCATION=variable])
```

### Return Value

Returns the visible dimensions of the window (in pixel units) in a two-element vector [*width*, *height*].

### Arguments

None

### Keywords

#### MINIMUM\_VIRTUAL\_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the minimum allowed virtual dimensions for this window.

#### Note

---

Returning MINIMUM\_VIRTUAL\_DIMENSIONS using GetDimensions provides the width and height of the window in pixel units. The property, “[MINIMUM\\_VIRTUAL\\_DIMENSIONS](#)” on page 4571, returns the dimensions of the window in units specified by the UNITS property.

---

#### ORIGINAL\_VIRTUAL\_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the virtual dimensions in pixels for this window if the current zoom factor was 1.0.

## VIRTUAL\_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the dimensions in pixels of the virtual canvas for this window.

## VISIBLE\_LOCATION

Set this keyword to a named variable that will contain a two-element vector, [*x*, *y*], representing the lower-left location of the visible portion of the window (relative to its virtual canvas).

## Version History

6.1	Introduced
-----	------------

## IDLgrWindow::GetFontnames

The `IDLgrWindow::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

### Syntax

```
Result = Obj->[IDLgrWindow::]GetFontnames(FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

### Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

### Arguments

#### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “\*”.

### Keywords

#### IDL\_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

#### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “\*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “\*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::GetProperty

The IDLgrWindow::GetProperty procedure method retrieves the value of a property or group of properties for the window.

### Syntax

*Obj*->[IDLgrWindow::]GetProperty[, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLgrWindow Properties” on page 4567 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

### Version History

5.0	Introduced
-----	------------

## IDLgrWindow::GetTextDimensions

The `IDLgrWindow::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector  $[xDim, yDim, zDim]$  representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

### Syntax

```
Result = Obj->[IDLgrWindow::]GetTextDimensions( TextObj  
    [, DESCENT=variable] [, PATH=objref(s)] )
```

### Return Value

Returns a 3-element double-precision floating-point vector  $[xDim, yDim, zDim]$  representing the dimensions of the text or axis object, measured in data units.

### Arguments

#### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

### Keywords

#### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values are the distance to travel (parallel to the `UPDIR` direction) from the baseline to reach the bottom of all the descenders for the string; the values will be negative or 0. This keyword is only valid if `TextObj` is of the class `IDLgrText`.

#### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the `PARENT` properties determine the path from the current

object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrWindow::GetTextDimensions` is called from within a Draw method and the `PATH` keyword is not set, the alias path used to find the object during the draw is used, rather than the `PARENT` path.

**Note**

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::Iconify

The IDLgrWindow::Iconify procedure method iconifies or de-iconifies the window.

### Note

Iconification under window systems is solely handled by the window manager; client applications, such as IDL, do not have the capability to manage icons. The Iconify method provides a hint to the window manager, which applies the information as it sees fit.

## Syntax

*Obj*->[IDLgrWindow::]Iconify, *IconFlag*

## Arguments

### IconFlag

Set *IconFlag* to 1 (one) to iconify the window or to 0 (zero) to restore the window. If the window is already restored, it is brought to the front of the window stack.

## Keywords

None

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::Init

The IDLgrWindow::Init function method initializes the window object.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

### Warning

When an IDLgrWindow object is created, its pixel values and depth buffer values are in an indeterminate state. This normally does not create a problem because most windows are completely covered by a non-transparent IDLgrView object, which causes the entire window to be painted with the view's background color and causes the depth buffer to be cleared before drawing the graphics.

However, if any area of the window is left uncovered by an IDLgrView, that area may contain random pixels after the window is drawn. In addition, if a transparent view covers an area of the window not also covered by a non-transparent view, there may be unwanted random pixels in the transparent view as well as random depth buffer values, which may cause some graphic primitives to not appear in the view at all.

Calling the [IDLgrWindow::Erase](#) method is useful for initializing the areas of a window not covered by a view (or which are “under” transparent views) to the desired color and for initializing the depth buffer for subsequent drawing in transparent views.

---

## Syntax

```
Obj = OBJ_NEW('IDLgrWindow' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrWindow::]Init([, PROPERTY=value]) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “[IDLgrWindow Properties](#)” on page 4567 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

5.0	Introduced
-----	------------

## IDLgrWindow::PickData

The IDLgrWindow::PickData function method maps a point in the two-dimensional device space of the window to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the window's device space "hits" a graphic object, or zero if no object was "hit". PickData returns -1 if the point selected falls outside of the specified view or window.

### Note

The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData. For example, you may use the DEPTH\_WRITE\_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn. This prevents the object from affecting the result returned by the PickData method.

## Syntax

```
Result = Obj->[IDLgrWindow::]PickData( View, Object, Location, XYZLocation
    [, DIMENSIONS=[w,h]] [, PATH=objref(s)] [, PICK_STATUS=variable])
```

## Return Value

Returns 1 if the specified location in the window's device space "hits" a graphic object, or 0 if no object was hit. Returns -1 if the point selected falls outside the specified view or window.

## Arguments

### View

The object reference of an IDLgrView object that contains the object being picked.

### Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

**Note**

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

**Location**

A two-element vector  $[x, y]$  specifying the location in the window's device space of the point to pick data from.

**XYZLocation**

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

**Note**

If the atomic graphic object specified as the target has been transformed using either the `LOCATION` or `DIMENSIONS` properties (this is only possible with `IDLgrAxis`, `IDLgrImage`, and `IDLgrText` objects), these transformations will *not* be included in the data coordinates returned by the `PickData` function. This means that you may need to re-apply the transformation accomplished by specifying `LOCATION` or `DIMENSIONS` once you have retrieved the data coordinates with `PickData`. This situation does not occur if you transform the axis, text, or image object using the `[XYZ]COORD_CONV` properties.

**Keywords****DIMENSIONS**

Set this keyword to a two-element array  $[w, h]$  to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates  $[x, y]$  specified in the *Location* argument, and will occupy the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions  $[3, w, h]$ .

## PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

### Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

## PICK\_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK\_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK\_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK\_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 8-15: PICK\_STATUS Keyword Values

## Version History

5.0	Introduced
5.6	Added PICK_STATUS keyword

## IDLgrWindow::QueryRequiredTiles

The `IDLgrWindow::QueryRequiredTiles` function method is used in conjunction with an `IDLgrImage` object that supports tiling. Initially, this type of `IDLgrImage` object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to `IDLgrImage::SetTileData` to load the required portion of the tiled image. When the `Draw` method is called, the destination object contains the image tiles that are the results of this method's query.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that `COUNT` is greater than 0 before accessing the returned array.

### Note

If the device is in Color Index mode (`COLOR_MODEL=1`) or the image has `RENDER_METHOD=1` set, then IDL will generate an error as tiling is not supported under these circumstances.

## Syntax

```
Result = Obj->[IDLgrWindow::]QueryRequiredTiles( View, Image
    [, COUNT=variable] [, ALL_VISIBLE=value] )
```

## Return Value

Returns an array of structures for required tiles or 0 (zero) if no tiles are required. Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.

Table 8-16: IDLIMAGETILE Structure

Field	Data Type	Description
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of $n$ ( $n > 0$ ) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

*Table 8-16: IDLIMAGETILE Structure (Continued)*

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

*Figure 8-10: Interaction Between Image Level and Zoom with Equal Tile Sizes*

**Note**

See “[Image Tiling](#)” in Chapter 4 of the *Object Programming* manual for more information on creating an image pyramid and for tiling examples.

## Arguments

### View

An object reference to the `IDLgrView` object used to render the image object. This is required so the visible tiles can be determined.

### Image

An object reference to the tiled `IDLgrImage` object that will be tested to determine which of its tiles are required.

## Keywords

### COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

### ALL\_VISIBLE

Set this keyword if `QueryRequiredTiles` should return all tiles that are visible even if they already have tile data loaded at the required level.

## Version History

6.2	Introduced
-----	------------

## IDLgrWindow::Read

The IDLgrWindow::Read function method reads an image from a window. The returned value is an instance of the [IDLgrImage](#) object class.

### Syntax

*Result* = *Obj*->[IDLgrWindow:]Read()

### Arguments

None

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrWindow::Select

The IDLgrWindow::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

### Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

## Syntax

```
Result = Obj->[IDLgrWindow::]Select( Picture, XY [, DIMENSIONS=[width,  
height]] [, /ORDER] [, SUB_SELECTION=variable] [, UNITS={0 | 1 | 2 | 3} ] )
```

## Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

## Arguments

### Picture

The view or scene (an instance of the [IDLgrView](#), [IDLgrViewgroup](#), or [IDLgrScene](#) class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT\_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

### XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels, as defined by the DIMENSIONS keyword.

## Keywords

### DIMENSIONS

Set this keyword to a two-element array  $[w, h]$  to specify that the selection box will have a width  $w$  and a height  $h$ , and will be centered about the coordinates  $[x, y]$  specified in the  $XY$  argument. The box occupies the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

Any object that intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

### ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If  $ORDER=0$  (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If  $ORDER=1$ , the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

#### Tip

---

If you are using  $DEPTH\_TEST\_FUNCTION=4$  (“less than or equal”) on your graphics objects, set  $ORDER=1$  to return objects at the same depth in the order in which they appear visually.

---

### SUB\_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes: all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)
- Select targets (IDLgrModel objects with the  $SELECT\_TARGET$  property set)
- Graphic objects displayed at the given  $XY$  location

## UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination

## Version History

5.0	Introduced
6.0	Added ORDER keyword
6.1	Added SUB_SELECTION keyword

## IDLgrWindow::SetCurrentCursor

The IDLgrWindow::SetCurrentCursor procedure method sets the current cursor image to be used while positioned over a drawing area.

### Syntax

*Obj*->[IDLgrWindow::]SetCurrentCursor [, *CursorName*] [, **IMAGE**=16 x 16  
bitmap] [, **MASK**=16 x 16 bitmap] [, **HOTSPOT**=[*x*, *y*]]

**Unix-Only Keywords:** [, **STANDARD**=*index*]

### Arguments

#### CursorName

A string that specifies which built-in cursor to use. This argument is ignored if any keywords to this routine are set. This string can either be a name provided to the REGISTER\_CURSOR routine or one of the following:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE\_NE
- SIZE\_NW
- SIZE\_SE
- SIZE\_SW
- SIZE\_NS
- SIZE\_EW
- UP\_ARROW

### Keywords

#### IMAGE

Set this keyword to a 16x16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the “hot spot” can be provided via the HOTSPOT keyword.

## MASK

When the IMAGE keyword is set, the MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are “masked out”.

## HOTSPOT

Set this keyword to a two-element vector specifying the  $[x, y]$  pixel offset of the cursor “hot spot”, the point which is considered to be the mouse position, from the upper left corner of the cursor image. This parameter is only applicable if IMAGE is provided. The cursor image is displayed top-down (the first row is displayed at the top).

## STANDARD

*This keyword is only available on UNIX platforms.*

Set this keyword to an X11 cursor font index to change the appearance of the cursor in the IDL graphics window to a glyph in this font. On non-X platforms, setting this keyword displays the crosshair cursor.

## Version History

5.0	Introduced
5.6	Added <i>CursorName</i> argument

## IDLgrWindow::SetCurrentZoom

The IDLgrWindow::SetCurrentZoom procedure method sets the current zoom factor for this window. The current zoom factor, the virtual canvas dimensions, and the location of the visible portion of the window are updated to reflect the new zoom factor.

### Syntax

*Obj*-> [IDLgrWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

### Arguments

#### ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 zoom out; values greater than 1.0 zoom in on the contents of the window.

### Keywords

#### RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

### Version History

6.1	Introduced
-----	------------

## IDLgrWindow:: SetProperty

The IDLgrWindow::SetProperty procedure method sets the value of a property or group of properties for the window.

### Syntax

*Obj*->[IDLgrWindow::]SetProperty[, *PROPERTY=value*]

### Arguments

None

### Keywords

Any property listed under “IDLgrWindow Properties” on page 4567 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

## IDLgrWindow::Show

The IDLgrWindow::Show procedure method exposes or hides a window.

### Syntax

*Obj->*[IDLgrWindow::]Show, *Position*

### Arguments

#### Position

Set this argument equal to a non-zero value to expose the window, or to 0 to hide the window.

### Keywords

None

### Version History

5.0	Introduced
-----	------------

## IDLgrWindow::ZoomIn

The IDLgrWindow::ZoomIn procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the window's [ZOOM\\_BASE](#) property). The current zoom factor, the virtual canvas dimensions, and the location of the visible portion of the window are updated to reflect the new zoom factor.

### Syntax

*Obj*->[IDLgrWindow::]ZoomIn

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLgrWindow::ZoomOut

The IDLgrWindow::ZoomIn procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the window's [ZOOM\\_BASE](#) property). The current zoom factor, the virtual canvas dimensions, and the location of the visible portion of the window are updated to reflect the new zoom factor.

### Syntax

*Obj*->[IDLgrWindow::](#)ZoomOut

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## Chapter 9

# Miscellaneous Object Classes

This chapter describes IDL's Container, COM, Java, and Trackball class libraries.

---

<a href="#">IDL_Container</a> .....	4616	<a href="#">IDLcomIDispatch</a> .....	4654
<a href="#">IDL_Savefile</a> .....	4628	<a href="#">IDLjavaObject</a> .....	4661
<a href="#">IDLcomActiveX</a> .....	4651	<a href="#">TrackBall</a> .....	4670

# IDL\_Container

An IDL\_Container object holds other objects. The IDL\_Container class, provides a way to group disparate IDL objects into single object, and allows you to easily move or destroy the objects within the container. Destroying an IDL\_Container object destroys any objects that have been added to the container via the Add method.

## Superclasses

None

## Creation

See “[IDL\\_Container::Init](#)” on page 4624.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- [IDL\\_Container::Add](#)
- [IDL\\_Container::Cleanup](#)
- [IDL\\_Container::Count](#)
- [IDL\\_Container::Get](#)
- [IDL\\_Container::Init](#)
- [IDL\\_Container::IsContained](#)
- [IDL\\_Container::Move](#)
- [IDL\\_Container::Remove](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
-----	------------

## **IDL\_Container Properties**

Objects of this class have no properties of their own.

## IDL\_Container::Add

The IDL\_Container::Add procedure method adds one or more child objects to the container.

### Syntax

*Obj*->[IDL\_Container::]Add, *Objects* [POSITION=*index*]

### Arguments

#### Objects

An object instance or array of object instances to be added to the container object.

### Keywords

#### POSITION

Set this keyword equal to a scalar or array of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within the container at which a new object should be placed. The default is to add new objects at the end of the list of contained items.

### Examples

If the container has three objects, a new object will be placed at the fourth position. Since positions begin at zero, this would be equivalent to setting POSITION=3.

### Version History

5.0	Introduced
-----	------------

## IDL\_Container::Cleanup

The IDL\_Container::Cleanup procedure method performs all cleanup on the object.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDL\_Container::]Cleanup (In a lifecycle method only.)

## Arguments

None.

## Keywords

None.

## Version History

---

5.0	Introduced
-----	------------

---

## IDL\_Container::Count

The IDL\_Container::Count function method returns the number of objects contained by the container object.

### Syntax

*Result* = *Obj*->[IDL\\_Container::](#)Count()

### Arguments

None.

### Keywords

None.

### Version History

5.0	Introduced
-----	------------

## IDL\_Container::Get

The IDL\_Container::Get function method returns an array of object references to objects in a container. Unless the ALL or POSITION keywords are specified, the first object in the container is returned. If no objects are found in the container, the Get function returns -1.

### Syntax

```
Result = Obj->[IDL_Container::]Get ([, /ALL [, ISA=class_name(s)] | ,  
    POSITION=index] [COUNT=variable] )
```

### Arguments

None.

### Keywords

#### ALL

Set this keyword to return an array of object references to all of the objects in the container.

#### COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function. If the ALL keyword is also specified, specifying this keyword is the same as calling the IDL\_Container::Count method.

#### ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

#### Note

---

This keyword is ignored if the ALL keyword is not provided.

---

## POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

## Version History

5.0	Introduced
-----	------------

## IDL\_Container::Init

The IDL\_Container::Init function method initializes the container object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Obj = OBJ_NEW('IDL_Container')
```

or

```
Result = Obj->[IDL_Container::]Init() (In a lifecycle method only.)
```

## Arguments

None.

## Keywords

None.

## Version History

5.0	Introduced
-----	------------

## IDL\_Container::IsContained

The IDL\_Container::IsContained function method returns true (1) if the specified object is in the container, or false (0) otherwise.

### Syntax

*Result* = *Obj*->[IDL\_Container::]IsContained( *Object* [, POSITION=*variable*] )

### Arguments

#### Object

The object reference or vector of object references of the object(s) to search for in the container.

### Keywords

#### POSITION

Set this keyword to a named variable that upon return will contain the position(s) at which (each of) the argument(s) is located within the container, or -1 if it is not contained.

### Version History

5.0	Introduced
-----	------------

## IDL\_Container::Move

The IDL\_Container::Move procedure method moves an object from one position in a container to a new position. The order of the other objects in the container remains unchanged.

Positioning within a container controls the rendering order of the contained objects. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later. Objects located “behind” other objects in three-dimensional space must be rendered before objects in front of them, even if the “front” objects are translucent.

### Syntax

*Obj->*[IDL\_Container::]Move, *Source*, *Destination*

### Arguments

#### Source

The zero-based index of the current location of the object to be moved.

#### Destination

The zero-based index of the location in the container where the object will reside after being moved.

### Keywords

None.

### Version History

5.0	Introduced
-----	------------

## IDL\_Container::Remove

The IDL\_Container::Remove procedure method removes an object from the container.

### Syntax

*Obj*->[IDL\_Container:]Remove [, *Child\_object*] [, POSITION=*index*] [, /ALL]

### Arguments

#### Child\_object

An object reference or array of object references for the objects to be removed from the container. If *Child\_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the container will be removed.

### Keywords

#### ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Child\_object* argument is not required.

#### POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child\_object* argument is supplied, this keyword is ignored.

### Version History

5.0	Introduced
-----	------------

# IDL\_Savefile

The IDL\_Savefile object provides complete query and restore capabilities for IDL SAVE files. IDL SAVE files are binary format files created with the SAVE procedure; they can contain data or IDL routines. Using IDL\_Savefile, you can retrieve information about the user, machine, and system that created the SAVE file, as well as the number and size of the various items contained in the file (variables, common blocks, routines, *etc*). You can also selectively restore individual items from the SAVE file.

Use IDL\_Savefile instead of the RESTORE procedure when you need to obtain detailed information on the items contained within a SAVE file without first restoring it, or when you wish to restore only selected items. Use RESTORE when you want to restore everything from the SAVE file using a simple interface.

## Superclasses

None

## Creation

See “[IDL\\_Savefile::Init](#)” on page 4636.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- [IDL\\_Savefile::Cleanup](#)
- [IDL\\_Savefile::Contents](#)
- [IDL\\_Savefile::Init](#)
- [IDL\\_Savefile::Names](#)
- [IDL\\_Savefile::Restore](#)
- [IDL\\_Savefile::Size](#)

In addition, this class inherits the methods of its superclasses (if any).

## Example

Use the `IDL_Savefile` object to query the contents of a SAVE file containing data and selectively restore variables.

Typically, `IDL_Savefile::Contents` is the first method called on a savefile object; the information retrieved indicates the number of different types of items contained in the file (variables, routines, *etc.*). Next, a call to `IDL_Savefile::Names` is used to obtain the names of items of a specific type. `IDL_Savefile::Size` can be used to determine the size of variables in the file, and `IDL_Savefile::Restore` can be used to restore items for use within the current IDL session.

```

; Select a SAVE file to restore. The file contains volume data.
savefile = FILEPATH('cduskcD1400.sav', $
    SUBDIRECTORY=['examples', 'data'])

; Create a savefile object.
sObj = OBJ_NEW('IDL_Savefile', savefile)

; Query the contents of the SAVE file to determine the number of
; regular variables contained therein.
sContents = sObj->Contents()
PRINT, sContents.N_VAR

; IDL Prints:
; 3

; Retrieve the names of the variables in the SAVE file.
sNames = sObj->Names()
PRINT, sNames

; IDL Prints:
; DENSITY MASSFLUX VELOCITY

; Determine the size of the DENSITY variable.
sDensitySize = sObj->Size('density')
PRINT, sDensitySize

; IDL Prints:
; 3          30          30          15          1          13500

; Restore the DENSITY variable.
sObj->Restore, 'density'

; Display the volume data.
IVOLUME, density

```

## Version History

6.1	Introduced
-----	------------

## See Also

[HEAP\\_NOSAVE](#), [HEAP\\_SAVE](#), [RESTORE](#), [SAVE](#)

## **IDL\_Savefile Properties**

Objects of this class have no properties of their own.

## IDL\_Savefile::Cleanup

The IDL\_Savefile::Cleanup procedure method performs all necessary cleanup when the savefile object is destroyed. The SAVE file associated with the object is closed. In addition, all in-memory data structures created by IDL when cataloging the SAVE file are released.

### Note

---

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

*or*

*Obj*->[IDL\_Savefile::]Cleanup *(In a lifecycle method only.)*

## Arguments

None.

## Keywords

None.

## Version History

6.1	Introduced
-----	------------

## IDL\_Savefile::Contents

The IDL\_Savefile::Contents function method returns a structure variable of type IDL\_SAVEFILE\_CONTENTS containing information about the associated SAVE file and its contents.

### Syntax

*Result* = *Obj*->[IDL\_Savefile::]Contents()

### Return Value

Returns a structure variable of type IDL\_SAVEFILE\_CONTENTS containing information about the associated SAVE file and its contents. The structure contains the following fields:

Field	Type	Description
FILENAME	String	The file path to the open SAVE file.
DESCRIPTION	String	A user-supplied description string for the SAVE file, as specified using the DESCRIPTION keyword to the SAVE procedure. If the SAVE file lacks a user supplied description, this field contains a null string.
FILETYPE	String	A description of SAVE file type. For a standard SAVE file, this field will contain the string "Portable (XDR)". For a compressed SAVE file, this field will contain "Portable (XDR) compressed".
USER	String	The user name of the user who issued the SAVE command that created the SAVE file.
HOST	String	The name of the computer on which the SAVE file was created.
DATE	String	The date on which the SAVE file was created.

*Table 9-1: Structure returned by IDL\_Savefile::Contents*

Field	Type	Description
ARCH	String	The value of the <code>!VERSION.ARCH</code> system variable field of the IDL installation that created the SAVE file.
OS	String	The value of the <code>!VERSION.OS</code> system variable field of the IDL installation that created the SAVE file.
RELEASE	String	The value of the <code>!VERSION.RELEASE</code> system variable field of the IDL installation that created the SAVE file.
N_COMMON	Integer	The number of main-level common blocks contained in the SAVE file.
N_VAR	Integer	The number of variables contained in the SAVE file.
N_SYSVAR	Integer	The number of system variables contained in the SAVE file.
N_PROCEDURE	Integer	The number of procedures contained in the SAVE file.
N_FUNCTION	Integer	The number of functions contained in the SAVE file.
N_OBJECT_HEAPVAR	Integer	The number of object heap variables contained in the SAVE file.
N_POINTER_HEAPVAR	Integer	The number of pointer heap variables contained in the SAVE file.
N_STRUCTDEF	Integer	The number of named structure definitions contained in the SAVE file. Named structure definitions are saved when a variable that references them is saved.

*Table 9-1: Structure returned by `IDL_Savefile::Contents` (Continued)*

## Arguments

None.

## Keywords

None.

## Example

See [“Example”](#) on page 4629.

## Version History

6.1	Introduced
-----	------------

## IDL\_Savefile::Init

The IDL\_Savefile::Init function method initializes the savefile object. The SAVE file associated with the object is opened and scanned to construct an internal data structure representing the contents. The SAVE file remains open until the savefile object is destroyed — the user is not allowed to use the CLOSE procedure to close the SAVE file.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Obj = OBJ_NEW('IDL_Savefile' [, Filename ] [, FILENAME=string]
             [, /RELAXED_STRUCTURE_ASSIGNMENT])
```

or

```
Result = Obj->[IDL_Savefile::]Init()    (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 (one) if initialization was successful, or 0 (zero) otherwise.

## Arguments

### Filename

A scalar string that contains the path name of the SAVE file from which information or data is to be recovered. If *Filename* is not present but the FILENAME keyword is specified, the keyword value is used. If neither the argument or the keyword is present, the file `idlsave.dat` in IDL's current working directory is used.

## Keywords

### FILENAME

Set this keyword equal to a scalar string that contains the path name of the SAVE file from which information or data is to be recovered.

#### Note

The FILENAME keyword duplicates the functionality of the *Filename* argument. If both are provided, the value specified by the *Filename* argument is used.

### RELAXED\_STRUCTURE\_ASSIGNMENT

Normally, the `IDL_Savefile::Restore` method is unable to restore a structure variable if the definition of its type has changed since the SAVE file was written. This commonly occurs when objects are saved and the class structures of the objects change before they are restored in another IDL session. In such cases, `IDL_Savefile::Restore` issues an error and does not restore the item.

Set the RELAXED\_STRUCTURE\_ASSIGNMENT keyword when creating a savefile object to cause the `IDL_Savefile::Restore` method to restore such incompatible values using “relaxed structure assignment,” in which all possible data are restored using a field-by-field copy.

See the description of the `STRUCT_ASSIGN` procedure for additional details. “Relaxed Structure Assignment” in Chapter 16 of the *Building IDL Applications* manual provides a more in-depth discussion of the structure-definition process.

## Version History

6.1	Introduced
-----	------------

## IDL\_Savefile::Names

The IDL\_Savefile::Names function method returns names, or heap variable identifiers, of items contained within the SAVE file. By default, this method returns the names of variables in the file; keywords can be used to obtain identifiers for other items.

### Syntax

```
Result = Obj->[IDL_Savefile:]Names( [, COUNT=variable]
    [, /COMMON_BLOCK | , COMMON_VARIABLE=string | , /FUNCTION |
    , /OBJECT_HEAPVAR | , /POINTER_HEAPVAR | , /PROCEDURE |
    , /STRUCTURE_DEFINITION | , /SYSTEM_VARIABLE] )
```

### Return Value

If the SAVE file contains one or more items of the specified type, the return value is a string array containing the names of the items. If no items of the specified type exist, the return value is a scalar null string.

---

**Note**

If either the OBJECT\_HEAPVAR or the POINTER\_HEAPVAR keyword is specified, the return value is an integer array containing integer values that can be used to recover the heap variables stored in the SAVE file. If no heap variables of the specified type exist, the return value is 0 (zero).

---

### Arguments

None.

### Keywords

---

**Note**

The Names method will only return the names of one type of item in a single call. With the exception of the COUNT keyword, specifying more than one keyword may cause the method to return unexpected results (most often a null string).

---

## COMMON\_BLOCK

Set this keyword to retrieve the names of any main-level COMMON blocks contained in the SAVE file. A main-level COMMON block item in a SAVE file consists of the name of the block and the names of the variables contained within it. (The values of the variables are saved separately, as normal variables.)

## COMMON\_VARIABLE

Set this keyword to a scalar string that contains the name of a main-level COMMON block. The value returned by the Names method will be a string array containing the names of the variables contained in the specified COMMON block.

## COUNT

Set this keyword equal to a named variable that will contain the number of identifiers returned. A value of 0 (zero) indicates that no identifiers of the specified type exist in the SAVE file, and that the result from the function is either a scalar null string or 0 (zero). A nonzero value indicates that the result is an array with that number of elements.

## FUNCTION

Set this keyword to return the names of the compiled functions contained in the SAVE file.

## OBJECT\_HEAPVAR

Set this keyword to return the integer heap identifiers for the object heap variables contained in the SAVE file.

### Note

---

It is rarely (if ever) necessary to restore heap variables directly; in almost all cases, restoring the regular variable that refers to the heap variable produces the desired effect. See [“Restoring Heap Variables Directly”](#) on page 4647 for a complete discussion of this topic.

---

Because the heap identifiers contained in the SAVE file being queried were assigned by the IDL session that saved the variables in the file, and not (in general) by the currently executing IDL session, the integers returned when OBJECT\_HEAPVAR is set are *not* valid heap identifiers within the current IDL session. Because of this, the values are returned as plain integer values, and not as object references. The returned integer values can be supplied to the [IDL\\_Savefile::Restore](#) method (using the OBJECT\_HEAPVAR keyword) to recover the object heap variables they reference.

**Warning**

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP\\_SAVE](#) for additional details on save attributes.

---

**POINTER\_HEAPVAR**

Set this keyword to return the integer heap identifiers for the pointer heap variables contained in the SAVE file.

**Note**

It is rarely (if ever) necessary to restore heap variables directly; in almost all cases, restoring the regular variable that refers to the heap variable produces the desired effect. See “[Restoring Heap Variables Directly](#)” on page 4647 for a complete discussion of this topic.

---

Because the heap identifiers contained in the SAVE file being queried were assigned by the IDL session that saved the variables in the file, and not (in general) by the currently executing IDL session, the integers returned when `POINTER_HEAPVAR` is set are *not* valid heap identifiers within the current IDL session. Because of this, the values are returned as plain integer values, and not as pointer references. The returned integer values can be supplied to the `IDL_Savefile::Restore` method (using the `POINTER_HEAPVAR` keyword) to recover the pointer heap variables they reference.

**Warning**

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP\\_SAVE](#) for additional details on save attributes.

---

**PROCEDURE**

Set this keyword to return the names of the compiled procedures contained in the SAVE file.

**STRUCTURE\_DEFINITION**

Structure definitions are saved by IDL as a side effect of saving structure variables that use the structure definition. Set this keyword to return the names of the structure definitions contained in the SAVE file.

**SYSTEM\_VARIABLE**

Set this keyword to return the names of system variables contained in the SAVE file.

## Example

See [“Example”](#) on page 4629.

## Version History

6.1	Introduced
-----	------------

## IDL\_Savefile::Restore

The `IDL_Savefile::Restore` procedure method selectively restores individual items from the associated SAVE file.

Given the *identifier* for an item within the SAVE file, this method restores the item along with any additional items (such as structure definitions or heap variables) upon which the specified item depends. Use the [IDL\\_Savefile::Names](#) method to retrieve valid item identifiers.

By default, this method restores variables from the SAVE file; keywords can be used to restore items of other types.

### Warning

---

There are several issues of which you should be aware when using this method to restore pointers or object references. See “[Notes on Restored Heap Variables](#)” on page 4644 for details.

---

## Syntax

```
Obj->[IDL_Savefile::]Restore, SaveItem [, /COMMON] [, /FUNCTION]
    [, /NEW_HEAPVAR=variable] [, /OBJECT_HEAPVAR]
    [, /POINTER_HEAPVAR] [, /PROCEDURE]
    [, /RESTORED_OBJECTS=variable] [, /STRUCTURE_DEFINITION]
    [, /VERBOSE]
```

## Arguments

### SaveItem

A scalar string or string array of identifiers for items to be restored from the SAVE file. Identifiers are retrieved from the SAVE file using the [IDL\\_Savefile::Names](#) method.

### Note

---

If either the `OBJECT_HEAPVAR` keyword or the `POINTER_HEAPVAR` keyword is specified, *SaveItem* must be an integer or integer array.

---

# Keywords

## COMMON

Set this keyword to restore the main-level COMMON block definitions specified by *SaveItem*.

---

**Note**

To restore both a COMMON block definition and the variables it references, restore the definition first, then restore the variables.

---

## FUNCTION

Set this keyword to restore the function(s) specified by *SaveItem*.

## NEW\_HEAPVAR

Set this keyword equal to a named variable that will contain valid references for heap variables.

---

**Note**

This keyword is only valid when either the OBJECT\_HEAPVAR or the POINTER\_HEAPVAR keyword is specified.

---

The returned variable will have the same structure as *SaveItem*, with each element in the returned array corresponding to the same element in the *SaveItem* array. If OBJECT\_HEAPVAR is specified, the returned variable will contain an array of object references; if POINTER\_HEAPVAR is specified, the returned variable will contain an array of pointers. See [“Notes on Restored Heap Variables”](#) on page 4644 for additional information on restoring heap variables.

## OBJECT\_HEAPVAR

Set this keyword to restore the object heap variable(s) specified by *SaveItem*. To obtain valid references to the newly restored heap variables, you must also specify the NEW\_HEAPVAR keyword. See [“Notes on Restored Heap Variables”](#) on page 4644 for additional information on restoring heap variables.

---

**Warning**

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP\\_SAVE](#) for additional details on save attributes.

---

## POINTER\_HEAPVAR

Set this keyword to restore the pointer heap variable(s) specified by *SaveItem*. To obtain valid references to the newly restored heap variables, you must also specify the `NEW_HEAPVAR` keyword. See “[Notes on Restored Heap Variables](#)” on page 4644 for additional information on restoring heap variables.

### Warning

---

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP\\_SAVE](#) for additional details on save attributes.

---

## PROCEDURE

Set this keyword to restore the procedure(s) specified by *SaveItem*.

## RESTORED\_OBJECTS

Set this keyword equal to a named variable that will contain an array of object references for any objects restored. The resulting list of objects is useful for programmatically calling the objects’ own restore methods (if any). If no objects are restored, the variable will contain a null object reference.

## STRUCTURE\_DEFINITION

Set this keyword to restore the named structure definition(s) specified by *SaveItem*. Named structure definitions are saved by IDL when a structure variable of that type is saved, and are restored when the variable is restored. The `STRUCTURE_DEFINITION` keyword allows you to restore just the definition, without the variable. This can be useful if you simply wish to create a new variable of the same type, and have no use for the saved variable data.

## VERBOSE

Set this keyword to print an informative message for each item restored.

### Note

---

Messages are only printed for top-level named variables. Heap variable references returned by the `NEW_HEAPVAR` keyword will not generate individual messages.

---

## Notes on Restored Heap Variables

IDL variables can contain object or pointer references to *heap variables*, and these heap variables can contain other such references, either to themselves or to other heap

variables. There is no limit to the number of references that can be made to a given heap variable. This flexible design allows the construction of arbitrary data structures. (See “[Heap Variables](#)” in Chapter 17 of the *Building IDL Applications* manual for a more complete discussion of heap variables.)

While the RESTORE procedure handles all details related to restoring heap variables in a way that is transparent to the IDL user, the IDL\_Savefile::Restore method provides greater flexibility and thus requires greater care. In particular, you should be aware of the following when using the IDL\_Savefile::Restore method to restore heap variables:

1. An IDL\_Savefile object will restore a given heap variable only once. This has implications for situations in which heap variables might be freed during the IDL\_Savefile object’s lifetime. See “[Caution Regarding Restored Heap Variables](#)” on page 4646 for a complete discussion of this issue.
2. The IDL\_Savefile object makes it possible to restore a heap variable independently of any regular IDL variable that might refer to it. This feature is described in detail in “[Restoring Heap Variables Directly](#)” on page 4647.

## Understanding How Heap Variables are Restored

When the SAVE procedure saves variables that contain object or pointer references, the referenced heap variables are also saved. Internally, heap variables are represented by unique integers called *heap identifiers*, which are not generally accessible (or useful) to the IDL user. The unique integers used to identify heap variables are assigned by IDL when the variables are created, and are therefore only unique within that IDL session. A given heap variable will typically have completely different identifiers in two different IDL sessions.

When RESTORE later restores variables containing object or pointer references, the heap variables are likewise restored. Note, however, that the unique identifiers for the restored heap variables will be different from the identifiers they had in the IDL session in which the SAVE file was created. RESTORE handles the mapping of the old identifiers to the new ones internally, in a manner that is completely transparent to the IDL user. This allows the user to save and restore very complex data structures using the simple interface provided by the SAVE and RESTORE procedures.

Notice that when using SAVE and RESTORE, the user always deals with regular named variables. Heap variables are never explicitly saved or restored; they are referenced only indirectly, through the regular variables that refer to them. Working with restored heap variables directly would be inconvenient, because heap variables lack mnemonic names that allow for easy identification, and because the original

integer identifiers assigned by IDL when the heap variables were created have no meaning in the IDL session into which the variables are restored.

The `IDL_Savefile::Restore` method duplicates the behavior of the `RESTORE` procedure with regard to heap variables. That is, when a regular IDL variable that refers to a pointer or object heap variable is restored, the heap variable is also restored automatically. In addition, although it is rarely (if ever) useful, the `IDL_Savefile::Restore` method provides the ability to restore heap variables *without* restoring the IDL variables that refer to them. To accomplish this, the `IDL_Savefile` object allows you to retrieve the integer heap identifiers stored in the `SAVE` file, using the `POINTER_HEAPVAR` and `OBJECT_HEAPVAR` keywords to the `Names` method. Note that it would be incorrect to treat these identifiers as object or pointer references, because they are not valid references in the restoring IDL session. For this reason, they are reported as simple integer values. They have no special meaning outside of that given to them by the `IDL_Savefile` object for a given object instance.

---

### Note

Restoring heap variables independently of regular variables is not recommended; the mechanism is provided only for completeness. See [“Restoring Heap Variables Directly”](#) on page 4647, for additional information.

---

## Caution Regarding Restored Heap Variables

A given instance of an `IDL_Savefile` object will never restore a given pointer or object heap variable more than once, regardless of the number of pointers or object references that refer to that heap variable. While this reflects the expected behavior of pointers and object references — references to the same underlying quantity should all point to the same heap variable — you must take care in situations in which heap variables can be destroyed during the lifetime of the `IDL_Savefile` object.

To make the implications of this behavior clear, consider an example in which a `SAVE` file contains two variables, `A` and `B`, each of which is a pointer reference to the same underlying pointer heap variable. After instantiating an `IDL_Savefile` object named `obj` that refers to the `SAVE` file, execute the following IDL statements:

```
obj->RESTORE, 'a'
PTR_FREE, a
obj->RESTORE, 'b'
```

The result is that both restored variables `A` and `B` are dangling references to a non-existent heap variable. IDL does not re-create the heap variable when `B` is restored, because the `IDL_Savefile` object knows that it already restored it once. The process of freeing the heap variable using the `PTR_FREE` procedure does not influence the behavior of the `IDL_Savefile` object — as far as the savefile object is concerned, the

heap variable referred to by the variable B has already been restored, and should not be restored again.

---

**Tip**

To force IDL to create multiple instances of a single saved heap variable, you can create multiple instances of the IDL\_Savefile object referring to the same SAVE file, and use each one to create a distinct and separate instance of the heap variable. We caution you that this sort of code can become confusing very quickly.

---

## Restoring Heap Variables Directly

The IDL\_Savefile object is designed to provide a way to query and restore *anything* contained within a SAVE file. As a result, the savefile object provides a mechanism for restoring heap variables independently of any regular IDL variables that may refer to them.

---

**Note**

The ability to directly restore heap variables independently of any referring regular variable is provided for completeness only. Restoring heap variables directly as described in this section is rarely (if ever) useful. The recommended way to restore a heap variable is to restore a regular IDL variable that refers to the heap variable.

---

To restore a heap variable independently of any regular variable, do the following:

1. Use either the POINTER\_HEAPVAR or the OBJECT\_HEAPVAR keyword (as appropriate) to the IDL\_Savefile::Names method to retrieve the integer heap identifier of the heap variable.
2. Use either the POINTER\_HEAPVAR or the OBJECT\_HEAPVAR keyword (as appropriate) and the NEW\_HEAPVAR keyword to the IDL\_Savefile::Restore method to associate the restored heap variable with a new regular variable.

The following IDL code provides an example of how this might look:

```
; First create a pointer
myPtr = PTR_NEW('99.00')

; Create a SAVE file containing the pointer reference
SAVE, myPtr, FILE='ptr.sav'

; Reset the IDL session
.FULL_RESET_SESSION

; Create a savefile object from the SAVE file
```

```
sObj = OBJ_NEW('IDL_Savefile', 'ptr.sav')

; Retrieve the heap identifier of the saved pointer heap variable
ptrName = sObj->Names(/POINTER_HEAPVAR)

; Restore the heap variable, associating it with a new regular
; variable. Note that ptrName is (in this case) a one-element
; array.
sObj->Restore, ptrName[0], /POINTER_HEAPVAR, NEW_HEAPVAR=myNewPtr

; Display the contents of the new variable
PRINT, *myNewPtr
```

IDL Prints:

```
99.00
```

### Tip

---

The above example is presented to depict the process of restoring a heap variable directly. It would have been much easier to simply restore the `myPtr` variable contained in the SAVE file.

---

## Example

See “[Example](#)” on page 4629 for an example that restores variable data.

## Version History

6.1	Introduced
-----	------------

## IDL\_Savefile::Size

The `IDL_Savefile::Size` function method returns the size and type information for the specified variable, system variable, or heap variable in the SAVE file associated with the savefile object, if no keywords are set. If a keyword is set, `IDL_Savefile::Size` returns only the specified quantity.

### Note

This method accepts the same keywords as the `SIZE` function, and returns the same information using the same formats. It differs only in that the argument is a string or integer identifier that specifies an item within a SAVE file, rather than an in-memory expression.

## Syntax

*Result* = *Obj*->[IDL\_Savefile:]Size(*SaveItem* [, *Keywords*])

## Return Value

If no keywords are set, the `Size` method returns a vector of integer type. The first element is equal to the number of dimensions of *SaveItem*. This value is 0 (zero) if *SaveItem* is scalar or undefined. The next elements contain the size of each dimension, one element per dimension (none if *SaveItem* is scalar or undefined). After the dimension sizes, the last two elements contain the type code (zero if undefined) and the number of elements in *SaveItem*, respectively.

See “[SIZE](#)” on page 2118 for a listing of IDL type codes.

If a keyword is set, the `Size` method returns the specified information.

## Arguments

### SaveItem

A scalar value that specifies the item within the SAVE file for which size information is requested. If *SaveItem* is a string, it is the name of a variable or system variable contained in the SAVE file. If *SaveItem* is an integer, it is the unique heap variable identifier for a heap variable contained in the SAVE file.

**Tip**

Use the [IDL\\_Savefile::Names](#) function method to obtain the names or heap variable identifiers contained within a SAVE file before calling this method.

## Keywords

IDL\_Savefile::Size method accepts all of the keywords accepted by the [SIZE](#) function. See “[SIZE](#)” on page 2118 for details.

## Example

See “[Example](#)” on page 4629.

## Version History

6.1	Introduced

## See Also

[SIZE](#)

# IDLcomActiveX

The IDLcomActiveX object class creates an IDL object that encapsulates an ActiveX control. IDL provides data type and other translation services, allowing IDL programs to access the ActiveX control's methods and properties using standard IDL syntax.

For detailed information on using the IDLcomActiveX object, see “[Using ActiveX Controls in IDL](#)” in Chapter 5 of the *External Development Guide* manual.

## Superclasses

[IDLcomIDispatch](#)

## Subclasses

When an ActiveX control is instantiated, IDL creates a dynamic subclass of the IDLcomActiveX class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See “[ActiveX Control Naming Scheme](#)” in Chapter 5 of the *External Development Guide* manual for details.

## Creation

IDLcomActiveX objects are always created automatically by IDL, as a result of a call to the [WIDGET\\_ACTIVEX](#) function. They should never be created manually.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

The IDLcomActiveX object class is a direct subclass of the IDLcomIDispatch class, and relies entirely on the superclass methods, providing none of its own.

## Version History

5.5	Introduced
-----	------------

## IDLcomActiveX Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLcomIDispatch](#)

# IDLcomIDispatch

The IDLcomIDispatch object class creates an IDL object that encapsulates a COM object. IDL provides data type and other translation services, allowing IDL programs to access the COM object's methods and properties using standard IDL syntax.

---

**Note**

COM objects encapsulated by IDLcomIDispatch objects must implement an IDispatch interface.

---

---

**Note**

You should be aware that COM, like C, stores array data in row-major format. IDL stores array data in column-major format. See “[Columns, Rows, and Array Majority](#)” in Chapter 15 of the *Building IDL Applications* manual for a detailed discussion of this issue and its implications for IDL application design.

---

For detailed information on using the IDLcomIDispatch object, see [Chapter 4](#), “[Using COM Objects in IDL](#)” in the *External Development Guide* manual.

## Superclasses

None

## Subclasses

When a COM object is instantiated, IDL creates a dynamic subclass of the IDLcomIDispatch class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See “[IDLcomIDispatch Object Naming Scheme](#)” in Chapter 4 of the *External Development Guide* manual for details.

ActiveX controls are instantiated within IDL as a special subclass of the IDLcomIDispatch class named IDLcomActiveX.

## Creation

See [IDLcomIDispatch::Init](#)

## Properties

Objects of this class have the following properties. See “[IDLcomIDispatch Properties](#)” on page 4656 for details on individual properties.

- *KEYWORD*

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

- [IDLcomIDispatch::Init](#)
- [IDLcomIDispatch::GetProperty](#)
- [IDLcomIDispatch::SetProperty](#)

In addition to these methods, you can call the underlying COM object’s methods directly. See “[Method Calls on IDLcomIDispatch Objects](#)” in Chapter 4 of the *External Development Guide* manual for details.

### Note

---

The IDL object system uses method names to identify and call object lifecycle methods (Init and Cleanup). If the COM object underlying an IDLcomIDispatch object implements Init or Cleanup methods, they will be overridden by IDL’s lifecycle methods — the COM object’s methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for the IDLcomIDispatch object, so any methods of the underlying COM object that use these names will be inaccessible from IDL.

---

## Version History

5.5	Introduced
-----	------------

## IDLcomIDispatch Properties

IDLcomIDispatch objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “[IDLcomIDispatch::GetProperty](#)” on page 4657. Properties with the word “Yes” in the “Init” column of the property table can be set via “[IDLcomIDispatch::Init](#)” on page 4658. Properties with the word “Yes” in the “Set” column in the property table can be set via “[IDLcomIDispatch::SetProperty](#)” on page 4660.

### **KEYWORD**

*KEYWORD* is a string containing the name of one of the underlying COM object’s properties, and *Variable* is the name of an IDL variable that will contain the retrieved property value. You can get multiple property values in a single statement by supplying multiple *KEYWORD=Variable* pairs.

### **Note**

---

*KEYWORD* must map exactly to the full name of the underlying COM object’s property method. The partial keyword name functionality provided by IDL is not valid with IDLcomIDispatch objects.

---

## IDLcomIDispatch::GetProperty

The IDLcomIDispatch::GetProperty function method is used to get properties from the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See “[Managing COM Object Properties](#)” in Chapter 4 of the *External Development Guide* manual.

### Syntax

*Obj*->[IDLcomIDispatch:]GetProperty, [, *PROPERTY=variable*] [, *arg0*, *arg1*, ...]

### Arguments

Because some of the underlying COM object's property methods may require arguments, the GetProperty method will accept optional arguments. The values of the arguments themselves will depend on the COM object that underlies the IDLcomIDispatch object.

#### Note

If arguments are required, you can only specify one property to retrieve in a given call to the GetProperty method.

### Keywords

Any property listed under “[IDLcomIDispatch Properties](#)” on page 4656 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.5	Introduced
-----	------------

## IDLcomIDDispatch::Init

The `IDLcomIDDispatch::Init` function method is used to initialize a given COM object and establish a link between the resulting IDL object and the `IDispatch` interface of the underlying COM object.

### Syntax

```
Obj = OBJ_NEW('IDLcomIDDispatch$ID_type$ID')
```

or

```
Result = Obj->[IDLcomIDDispatch$ID_type$ID::]Init( ) (In a lifecycle method only.)
```

where *ID\_type* is one of the following:

- `CLSID` if the object is identified by its COM class ID, or
- `PROGID` if the object is identified by its COM program ID,

and *ID* is the COM object's actual class or program identifier string. If the COM object's class identifier string is used to create the `IDLcomIDDispatch` object, the braces ( { } ) must be removed and the hyphens replaced by underscores. For details on constructing the class name, see “[IDLcomIDDispatch Object Naming Scheme](#)” in Chapter 4 of the *External Development Guide* manual for details.

#### Note

---

While COM objects incorporated into IDL are instances of the dynamic subclass created when the COM object is instantiated, they still expose the functionality of the class `IDLcomIDDispatch`, which is the direct superclass of the dynamic subclass. All `IDLcomIDDispatch` methods are available to the dynamic subclass.

---

### Arguments

None.

### Keywords

None.

## Version History

5.5	Introduced
-----	------------

## IDLcomIDispatch:: SetProperty

The IDLcomIDispatch::SetProperty function method is used to set properties for the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See “[Managing COM Object Properties](#)” in Chapter 4 of the *External Development Guide* manual for details.

### Syntax

*Obj*->[IDLcomIDispatch::]SetProperty [, *PROPERTY=value*]

### Arguments

None.

### Keywords

Any property listed under “[IDLcomIDispatch Properties](#)” on page 4656 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.5	Introduced
-----	------------

# IDLjavaObject

The IDLjavaObject class creates an IDL object that encapsulates a Java object. IDL provides data type and other translation services, allowing IDL programs to access the Java object's methods and properties using standard IDL syntax.

For detailed information on using the IDLjavaObject class, see [Chapter 8, “Using Java Objects in IDL”](#) in the *External Development Guide* manual.

## Superclasses

None

## Creation

See [“IDLjavaObject::Init”](#) on page 4666.

## Properties

The properties of this object depends on which Java object the IDLjavaObject class encapsulates. See [“IDLjavaObject Properties”](#) on page 4663 for more details.

## Methods

This class has the following methods:

- [IDLjavaObject::GetProperty](#)
- [IDLjavaObject::Init](#)
- [IDLjavaObject::SetProperty](#)

In addition to these methods, you can call the underlying Java object's methods directly. See [“Method Calls on IDL-Java Objects”](#) in Chapter 8 of the *External Development Guide* manual for details.

### Note

---

The IDL object system uses method names to identify and call object *lifecycle methods* (Init and Cleanup). If the Java object underlying IDLjavaObject implements Init or Cleanup methods, they will be overridden by IDL's lifecycle methods — the Java object's methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for IDLjavaObject, so any methods of the underlying Java object that use these names will be inaccessible

from IDL. In Java, you can wrap these methods with different named methods to work around this limitation.

---

When a function, procedure, or Init method is called with an array as a parameter, the array is copied from IDL into Java space according to the data conversion rules (see “IDL-Java Bridge Data Type Mapping” in Chapter 8 of the *External Development Guide* manual). After the Java call returns, any Java arrays are copied back to IDL arrays. The IDL array type after the “back-copy” will be the same type as that of the IDL array before the call.

---

**Note**

The SetProperty method does *not* copy arrays back from Java.

---

Note that this back-copy could cause some downcasting. For example, if you have an array of IDL bytes, you can call a Java method that accepts an array of longs. When the data are back-copied, the array of longs is cast to an array of bytes. If the Java method has changed one of the longs to a value greater than 255 (the upper limit of a byte), the long will be cast to some unexpected value. To avoid downcasting issues, IDL-Java programmers should know their data and make sure types in IDL and Java match as closely as possible.

## Examples

See [Chapter 8, “Using Java Objects in IDL”](#) in the *External Development Guide* manual.

## Version History

---

6.0	Introduced
-----	------------

---

## IDLjavaObject Properties

The property name of an instance of `IDLjavaObject` is passed to the IDL Java subsystem and is used in conjunction with the Java reflection API to access the related data member on the underlying object. The data member (property) is identified through the arguments to the `IDLjavaObject::GetProperty` and `IDLjavaObject::SetProperty` methods.

## IDLjavaObject::GetProperty

The IDLjavaObject::GetProperty procedure method retrieves properties (known as data members in Java) from the Java object that underlies the IDLjavaObject. The Java object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See “[Managing IDL-Java Object Properties](#)” in Chapter 8 of the *External Development Guide* manual.

### Syntax

```
Obj->[IDLjavaObject::]GetProperty [, PROPERTY=variable]
```

### Arguments

None

### Keywords

#### ***PROPERTY***

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

---

#### **Note**

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

---

The *variable* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See “[IDL-Java Bridge Data Type Mapping](#)” in Chapter 8 of the *External Development Guide* manual for more information.

---

#### **Note**

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

---

## Version History

6.0	Introduced
-----	------------

## IDLjavaObject::Init

The IDLjavaObject::Init function method instantiates the given Java object and establishes a link between the resulting IDL object with the underlying Java object.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: the Init method can be called from within the Init method of a subclass.

---

## Syntax

*Obj* = OBJ\_NEW('IDLjavaObject\$JAVACLASSNAME', *JavaClassName*[, *Arg1*, ...])

where *JAVACLASSNAME* is a case-insensitive string representing the Java class to be instantiated, see “[IDL-Java Bridge Architecture](#)” in Chapter 8 of the *External Development Guide* manual for more information. All periods in *JAVACLASSNAME* must be converted to underscores.

## Return Value

Returns an object reference to the newly-created object if initialization is successful, or a null object if initialization fails.

## Arguments

### JavaClassName

A string representing the Java class to be instantiated. See “[Java Class Names in IDL](#)” in Chapter 8 of the *External Development Guide* manual for more details.

### Arg1, ...

Additional arguments as required by the constructor. These arguments are passed to the underlying Java constructor. Arguments may be IDL primitive types, IDL strings, IDLJavaObjects, and arrays of the previous types. See “[IDL-Java Bridge Data Type Mapping](#)” in Chapter 8 of the *External Development Guide* manual for more information.

## Keywords

None

## Version History

6.0	Introduced
-----	------------

## IDLjavaObject:: SetProperty

The IDLjavaObject::SetProperty procedure method sets properties (known as data members in Java) for the Java object that underlies an instance of IDLjavaObject. The Java object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See “[Managing IDL-Java Object Properties](#)” in Chapter 8 of the *External Development Guide* manual for more details.

### Syntax

```
Obj->[IDLjavaObject::]SetProperty [, PROPERTY=value]
```

### Arguments

None

### Keywords

#### **PROPERTY**

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

---

#### **Note**

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

---

The *value* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See “[IDL-Java Bridge Data Type Mapping](#)” in Chapter 8 of the *External Development Guide* manual for more information.

---

#### **Note**

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

---

## Version History

# TrackBall

A TrackBall object translates widget events from a draw widget (created with the WIDGET\_DRAW function) into transformations that emulate a virtual trackball (for transforming object graphics in three dimensions).

This object class is implemented in the IDL language. Its source code can be found in the file `trackball__define.pro` in the `lib` subdirectory of the IDL distribution.

## Superclasses

None

## Creation

See “[TrackBall::Init](#)” on page 4674.

## Properties

Objects of this class have the following properties. See “[TrackBall Properties](#)” on page 4672 for details on individual properties.

- [AXIS](#)
- [CONSTRAIN](#)
- [MOUSE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- [TrackBall::Init](#)
- [TrackBall::Reset](#)
- [TrackBall::Update](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

5.0	Introduced
-----	------------

## TrackBall Properties

TrackBall objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Init” column of the property table can be set via “[TrackBall::Init](#)” on page 4674.

---

### Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 2947.

---

Objects of this class have the following properties.

- [AXIS](#)
- [CONSTRAIN](#)
- [MOUSE](#)

### AXIS

An integer value that indicates the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.
- 2 = Rotate only around the *Z* axis (this is the default).

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## CONSTRAIN

A boolean value that indicates whether the trackball transformations are to be constrained about the axis specified by the **AXIS** keyword. The default is not to constrain the transformations.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## MOUSE

An integer value that indicates which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## TrackBall::Init

The TrackBall::Init function method initializes the TrackBall object.

### Syntax

*Obj* = OBJ\_NEW('TrackBall', *Center*, *Radius* [, *PROPERTY=**value*] )

or

*Result* = *Obj*->[TrackBall::]Init( *Center*, *Radius* ) (In a lifecycle method only.)

#### Note

---

Keywords can be used in either form. They are omitted in the second form for brevity.

---

### Arguments

#### Center

A two-element vector, [X, Y], specifying the center coordinates of the trackball. X and Y should be specified in device units.

#### Radius

The radius of the trackball, specified in device units.

### Keywords

Any property listed under “[TrackBall Properties](#)” on page 4672 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.0	Introduced
-----	------------

## TrackBall::Reset

The TrackBall::Reset procedure method resets the state of the TrackBall object.

### Syntax

```
Obj->[TrackBall::]Reset, Center, Radius [, AXIS={0 | 1 | 2}] [, /CONSTRAIN]  
[, MOUSE={1 | 2 | 4}]
```

### Arguments

#### Center

A two-element vector, [X, Y], specifying the center coordinates of the trackball. X and Y should be specified in device units.

#### Radius

The radius of the trackball, specified in device units.

### Keywords

#### AXIS

Set this keyword to an integer value to indicate the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the X axis.
- 1 = Rotate only around the Y axis.
- 2 = Rotate only around the Z axis (this is the default).

#### CONSTRAIN

Set this keyword to indicate that the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

#### MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)

- 2 = Middle mouse button
- 4 = Right mouse button

## Version History

-----	------------

## TrackBall::Update

The `TrackBall::Update` function method updates the state of the `TrackBall` object based on the information contained in the input widget event structure. The return value is nonzero if a transformation matrix is calculated as a result of the event, or zero otherwise.

### Syntax

```
Result = Obj->[TrackBall::]Update( sEvent [, MOUSE={1 | 2 | 4}]  
    [, TRANSFORM=variable] [, TRANSLATE] )
```

### Arguments

#### **sEvent**

The widget event structure.

### Keywords

#### **MOUSE**

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

#### **TRANSFORM**

Set this keyword to a named variable that will contain a 4 x 4 element floating-point array if a new transformations matrix is calculated as a result of the widget event.

#### **TRANSLATE**

Set this keyword to indicate that the trackball movement should be constrained to translation in the X-Y plane rather than rotation about an axis.

## Example

The example code below provides a skeleton for a widget-based application that uses the `TrackBall` object to interactively change the orientation of graphics.

Create a trackball centered on a 512x512 pixel drawable area, and a view containing the model to be manipulated:

```
xdim = 512
ydim = 512
wBase = WIDGET_BASE()
wDraw = WIDGET_DRAW(wBase, XSIZE=xdim, YSIZE=ydim, $
    GRAPHICS_LEVEL=2, /BUTTON_EVENTS, $
    /MOTION_EVENTS, /EXPOSE_EVENTS, RETAIN=0 )
WIDGET_CONTROL, wBase, /REALIZE
WIDGET_CONTROL, wDraw, GET_VALUE=oWindow

oTrackball = OBJ_NEW('Trackball', [xdim/2.,ydim/2.], xdim/2.)
oView = OBJ_NEW('IDLgrView')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
XMANAGER, 'TrackEx', wBase
```

You must handle the trackball updates in the widget event-handling code. As the trackball transformation changes, update the transformation for the model object, and redraw the view:

```
PRO TrackEx_Event, sEvent
...
bHaveXform = oTrackball->Update( sEvent, TRANSFORM=TrackXform )
IF (bHaveXform) THEN BEGIN
oModel->GetProperty, TRANSFORM=ModelXform
oModel->SetProperty, TRANSFORM=ModelXform # TrackXform
oWindow->Draw, oView
ENDIF
...
END
```

---

### Example Code

For a complete example, see the file `surf_track.pro`, located in the `examples/doc/objects` subdirectory of the IDL distribution.

---

The `SURF_TRACK` procedure uses IDL widgets to create a graphical user interface to an object tree, creates a surface object from user-specified data (or from default data, if none is specified), and places the surface object in an IDL draw widget. The

SURF\_TRACK interface allows the user to specify several attributes of the object hierarchy via pulldown menus.

## ***Part III: Appendices***

## Appendix A

# IDL Direct Graphics Devices

The following topics are covered in this appendix:

---

Supported Devices .....	4684	The PCL Device .....	4741
Devices with Scalable Pixels .....	4686	The Printer Device .....	4743
Keywords Accepted by the IDL Devices .....	4687	The PostScript Device .....	4744
Window Systems .....	4728	The Regis Terminal Device .....	4757
Printing Graphics Output Files .....	4731	The Tektronix Device .....	4758
The CGM Device .....	4734	The Microsoft Windows Device .....	4761
The HP-GL Device .....	4736	The X Windows Device .....	4762
The Metafile Display Device .....	4738	The Z-Buffer Device .....	4771
The Null Display Device .....	4740		

# Supported Devices

IDL Direct Graphics support graphic output to the devices listed below:

Device Name	Description
CGM	Computer Graphics Metafile
HP	Hewlett-Packard Graphics Language (HP-GL)
METAFILE	Windows Metafile Format (WMF)
NULL	No graphics output
PCL	Hewlett-Packard Printer Control Language (PCL)
PRINTER	System printer
PS	PostScript
REGIS	Regis graphics protocol (DEC systems only)
TEK	Tektronix compatible terminal
WIN	Microsoft Windows
X	X Window System
Z	Z-buffer pseudo device

*Table A-2: IDL Graphics Output Devices*

Each of these devices is described in a section of this chapter. The `SET_PLOT` procedure can be used to select the graphic device to which IDL directs its output. IDL Object Graphics does not rely on the concept of a current graphics device.

The `DEVICE` procedure controls the graphic device-specific functions. An attempt has been made to isolate all device-specific functions in this procedure. `DEVICE` controls the graphics device currently selected by `SET_PLOT`. When using `DEVICE`, it is important to make sure that the current graphics device is the one you intend to use. This is because most of the devices have different keywords—you will most likely get a “keyword ... not allowed in call to: Device” error if you call `DEVICE` when the wrong device is selected.

## Obsolete Graphics Devices and Device Keywords

The following graphics devices are obsolete:

- LJ
- MAC

For information on obsolete graphics devices, See [Appendix J, “Obsolete Features”](#).

The following graphics device keywords are obsolete:

- DEPTH
- FONT

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## Devices with Scalable Pixels

For most direct graphics display devices, pixels are of a fixed size and the number of pixels available depends on the display resolution of the device. For such devices, the array of pixels written to the screen will be the same size as the image array.

Some direct graphics devices have the ability to place an image with any number of pixels into an area of arbitrary size. Such devices are said to have scalable pixels, because there is no direct connection between the number of pixels in the image and the physical space it occupies in the displayed image. The Computer Graphics Metafile (CGM) and PostScript (PS) devices fall into this category.

When the current image device has scalable pixels, IDL sets the first bit of the `!D.FLAGS` system variable field. The following IDL statement can be used to determine if the current device has scalable pixels:

```
SP = !D.FLAGS AND 1
```

SP will be nonzero if the device has scalable pixels. When displaying an image on a device with scalable pixels, the default is to use the entire display surface for the image. The `XSIZE` and `YSIZE` keywords can be used to override this default and specify the width and height of the desired display area.

The `XSIZE` and `YSIZE` keywords should also be used when positioning images with the *Position* argument to the `TV` or `TVSCL` routines. The *Position* argument normally uses the size of the image in pixels to determine the placement of the image, but this is not possible for devices with scalable pixels. Instead, the default for such devices is to fill the entire available display area. However, if `XSIZE` and `YSIZE` are specified along with the *Position* argument, `TV` or `TVSCL` will use them to determine image placement.

# Keywords Accepted by the IDL Devices

The following table indicates which keywords are accepted by the DEVICE procedure. The NULL device is not listed as it accepts no keywords. Details of the various keywords (listed alphabetically) can be found in the following pages.

## Note

Most keywords to the DEVICE procedure are sticky — that is, once you set them, they remain in effect until you explicitly change them again, or end your IDL session. The exceptions are keywords used to return a value from the system (GET\_FONTNAMES, for example) and those that perform a one-time-only operation (CLOSE\_FILE, for example).

*Table A-3: Keywords accepted by the IDL devices (Continued)*

Keywords accepted by the DEVICE command are described below. A list of devices that accept the keyword is included in parentheses below the keyword name.

## AVANTGARDE

(PS)

Set this keyword to select the ITC Avant Garde PostScript font.

## **AVERAGE\_LINES**

(REGIS)

Controls the method of writing images to the VT240. If this keyword is set, (default setting), even and odd pairs of image lines are averaged and written to a single line. If clear, each image line is written to the screen. See the discussion below. This keyword has no effect when using a VT300 series terminal.

## **BINARY**

(CGM)

Set this keyword to set the encoding type for the CGM output file to binary.

## **BITS\_PER\_PIXEL**

(PS)

IDL is capable of producing PostScript images with 1, 2, 4, or 8 bits per pixel. Using more bits per pixel gives higher resolution at the cost of generating larger files.

`BITS_PER_PIXEL` is used to specify the number of bits to use. If you do not specify a value for `BITS_PER_PIXEL`, a default value of 4 is used.

It should be noted that many laser printers, including the original Apple Laserwriter are capable of only 32 different shades of gray (which can be represented by 5 bits).

Thus, specifying 8 bits per pixel does not give 256 apparent shades of grey as might be expected, only 32, at a cost of sending twice the number of bits to the printer.

Often, 4 bits (16 levels of gray) will give acceptable results with a large savings in file size.

## **BKMAN**

(PS)

Set this keyword to select the ITC Bookman PostScript font.

## **BOLD**

(PS)

Set this keyword to specify that the bold version of the current PostScript font should be used.

## **BOOK**

(PS)

Set this keyword to specify that the book version of the current PostScript font should be used.

## **BYPASS\_TRANSLATION**

(WIN, X)

Set this keyword to bypass the translation tables, allowing direct specification of color indices. See [“Color Translation”](#) on page 4766. Pixel values read via the TVRD function are not translated if this keyword is set, and the result contains the byte value of the actual pixel values present in the display.

By default, the color translation tables are bypassed if the visual type is TrueColor or the visual type is DirectColor with a private colormap.

This keyword is accepted by the WIN device (for compatibility with the X device), but has no effect when set.

## **CLOSE**

(Z)

Set this keyword to deallocate the memory used by the Z-buffer. The Z-buffer device is reinitialized if subsequent graphics operations are directed to the device.

## **CLOSE\_DOCUMENT**

(PRINTER)

Set this keyword to have IDL send any buffered output to the currently selected printer. This keyword is applicable only when the printer device is selected. See [“The Printer Device”](#) on page 4743 for details.

## **CLOSE\_FILE**

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Set this keyword to have IDL output any buffered commands and close the current graphics file.

Caution: If you close the output file and then cause IDL to produce more output (e.g., by executing a new PLOT command), IDL will open the file again, causing the contents of the recently closed file to be lost. To avoid this, use the FILENAME keyword to specify a different file name or use SET\_PLOT to disable the graphics driver, or be sure to print the closed output file before creating more output.

See the discussion of printing output files in [“Printing Graphics Output Files”](#) on page 4731.

## CMYK

(PS)

Set this keyword to generate PostScript output using the CMYK (cyan, magenta, yellow, and black) color model. The default PostScript color model is RGB (red, green, blue). PostScript CMYK files require a PostScript Language Level 2 interpreter. Therefore, when this keyword is set, the [LANGUAGE\\_LEVEL](#) keyword value is set to 2. See [“CMYK Output”](#) on page 4747 for additional information on CMYK output with a color PostScript device.

## COLOR

(PCL, PS)

Set this keyword to enable color PCL or PostScript output. See [“The PCL Device”](#) on page 4741 or [“The PostScript Device”](#) on page 4744.

## COLORS

(CGM, TEK)

This keyword specifies the maximum number of colors and the size of the color table used for output. The value of the system variable fields `!D.N_COLORS` and `!D.TABLE_SIZE` are set to this value and `!P.COLOR` is set to one less than this value.

### For Tektronix Terminals Only

This keyword sets the number of colors supported by a 4100 series terminal. For example, if your terminal has 4-bit planes, the number of colors is  $2^4 = 16$ :

```
DEVICE, COLORS = 16
```

Valid values of this parameter are: 2, 4, 8, 16, or 64; other values will cause problems. Some Tektronix terminals will not operate properly if this parameter does not exactly match the number of colors available in the terminal hardware.

This parameter sets the field `!D.N_COLORS`, which affects the loading of color tables, the scaling used by the `TVSCL` procedure, and the number of bits output by the `TV` procedure to the terminal. It also changes the default color, `!P.COLOR` to the number of colors minus one.

## COPY

(WIN, X)

Use this keyword to copy a rectangular area of pixels from one region of a window to another. `COPY` should be set a six or seven element array:  $[X_s, Y_s, N_x, N_y, X_d, Y_d, W]$ ,

where:  $(X_s, Y_s)$  is the lower left corner of the source rectangle,  $(N_x, N_y)$  are the number of columns and rows in the rectangle, and  $(X_d, Y_d)$  is the coordinate of the destination rectangle. Optionally,  $W$  is the index of the window *from which the pixels should be copied to the current* window. If it is not supplied, the current window is used as both the source and destination.

## **COURIER**

(PS)

Set this keyword to select the Courier PostScript font.

## **CURSOR\_CROSSHAIR**

(WIN, X)

Set this keyword to select the crosshair cursor type. This is the IDL default.

## **CURSOR\_IMAGE**

(WIN, X)

Specifies the cursor pattern. The value of this keyword must be a 16-line by 16-column bitmap, contained in a 16-element short integer vector. The offset from the upper left pixel to the point that is considered the hot spot can be provided via the `CURSOR_XY` keyword.

## **CURSOR\_MASK**

(WIN, X)

When the `CURSOR_IMAGE` keyword is used to specify a cursor bitmap, the `CURSOR_MASK` keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the `CURSOR_IMAGE` that should be seen and bits that are not set are masked out.

By default, the `CURSOR_IMAGE` bitmap is used for both the image and the mask. This can cause the cursor to be invisible on a black background (because only black pixels are allowed to be displayed).

## **CURSOR\_ORIGINAL**

(WIN, X)

Set this keyword to select the window system's default cursor. Under X Windows, it is the cursor in use by the root window when IDL starts. For the Microsoft Windows device, it is the arrow pointer.

## CURSOR\_STANDARD

(WIN, X)

This keyword can be used to change the cursor appearance in IDL graphics windows.

### For X Windows

This keyword selects one of the predefined cursors provided by the X Window system. The available cursors shapes are defined in the file `cursorfont.h` in the directory `/usr/include/X11`. In order to use one of these cursors, you select the number of the cursor and provide it as the value of the `CURSOR_STANDARD` keyword. For example, the file gives the value of `XC_CROSS` as being 30. In order to make that the current cursor, use the statement:

```
DEVICE, CURSOR_STANDARD=30
```

### For Microsoft Windows

The table below shows the values for `CURSOR_STANDARD` that result in different cursor shapes. For example, to change the cursor to an “I-beam” when the cursor is in an IDL graphics window, use the command:

```
DEVICE, CURSOR_STANDARD = 32513
```

Value	Cursor Shape
32512	Arrow
32513	I-Beam
32514	Hourglass
32515	Black Crosshair
32516	Up Arrow
32640	Size (Windows only)
32641	Icon (Windows only)
32642	Size NW-SE
32643	Size NE-SW
32644	Size E-W
32645	Size N-S

Table A-4: Values for the WIN device `CURSOR_STANDARD` Keyword

## CURSOR\_XY

(WIN, X)

A two element integer vector giving the (X, Y) pixel offset of the cursor hot spot, the point which is considered to be the mouse position, from the lower left corner of the cursor image. This parameter is only applicable if `CURSOR_IMAGE` is provided. The cursor image is displayed top-down—the first row is displayed at the top.

## DECOMPOSED

(WIN, X)

This keyword is used to control the way in which graphics color index values are interpreted when using displays with decomposed color (`TrueColor` or `DirectColor` visuals). This keyword has no effect with other types of visuals.

Set this keyword to 1 to cause color indices to be interpreted as 3, 8-bit color indices where the least-significant 8 bits contain the red value, the next 8 bits contain the green value, and the most-significant 8 bits contain the blue value. This is the way IDL has always interpreted pixels when using visual classes with decomposed color.

Set this keyword to 0 to cause the least-significant 8 bits of the color index value to be interpreted as a `PseudoColor` index. This setting allows users with `DirectColor` and `TrueColor` displays to use IDL programs written for standard, `PseudoColor` displays without modification.

In older versions of IDL, color index values higher than `!D.N_COLORS-1` were clipped to `!D.N_COLORS-1` in the higher level graphics routines. In some cases, this clipping caused the exclusive-OR graphics mode to malfunction with raster displays. This clipping has been removed. Programs that incorrectly specified color indices higher than `!D.N_COLORS-1` will now probably exhibit different behavior.

## DEMI

(PS)

Set this keyword to specify that the demi version of the current PostScript font should be used.

## DIRECT\_COLOR

(X)

Set this keyword to select the `DirectColor` visual. The value of the keyword represents the number of bits per pixel. This keyword has effect only if no windows have been

created. Visual classes are discussed in more detail in “[X Windows Visuals](#)” on page 4762.

## EJECT

(HP)

In order to perform an erase operation on a plotter, it is necessary to remove the current sheet of paper and load a fresh sheet. The ability of various plotters to do this varies, so the EJECT keyword allows you to specify what should be done. The following table describes the possible values.

Value	Meaning
0	Do nothing. Note that this is likely to cause one page to plot over the previous one, so you should limit yourself to one page of output per file. This is the default.
1	Use the sheet feeder to load the next page.
2	Put the plotter off-line at the beginning of each page after the first.

*Table A-5: Values for the HP-GL Eject Keyword*

Many HP-GL plotters lack a sheet feeder, and require the user to load the next page manually. Therefore, the default action is for IDL to not issue any page eject instructions. In this case, you must restrict yourself to generating only a single plot at a time. If your plotter has a sheet feeder, you will want to issue the command:

```
DEVICE, /EJECT
```

to tell IDL that it should use the sheet feeder instead of placing the plotter off-line.

If your plotter does not have a sheet feeder, but it does understand the HP-GL NR command, use the command:

```
DEVICE, EJECT=2
```

to place the plotter off-line at the start of every plot except the first one. This causes the plotter to wait between plots for the user to replace the paper. When the user puts the plotter back on-line, the graphics commands for the new page are executed by the plotter. Consult the programming manual for your plotter to determine if this instruction is provided.

## ENCAPSULATED

(PS)

Set this keyword to create an encapsulated PostScript file, suitable for importing into another document (e.g., a LaTeX or FrameMaker document).

---

**Note**

You must explicitly set this keyword to zero to create “regular” PostScript output after creating encapsulated output. (That is, like most keyword settings to the DEVICE procedure, the setting “sticks” until you change it, or until you quit IDL.)

---

---

**Note**

IDL uses the value of this keyword to determine what type of output to generate when it starts writing to a file. Changing this keyword has no effect until a new file is started.

---

Normally, IDL assumes that its PostScript-generated output will be sent directly to a printer. It therefore includes PostScript commands to position the plot on the page and to eject the page from the printer. These commands are undesirable if the output is going to be inserted into the middle of another PostScript document. If ENCAPSULATED is present and non-zero, IDL does not generate these commands.

IDL follows the standard PostScript convention for encapsulated files. It assumes the standard PostScript scaling is in effect (72 points per inch). In addition, it declares the size, or *bounding box* of the plotting region at the top of the output file. This size is determined when the output file is opened (when the first graphics command is given), by multiplying the size of the plotting region (as specified with the XSIZE and YSIZE keywords) by the current scale factor (as specified by the SCALE\_FACTOR keyword).

Changing the size of the plotting region or scale factor once graphics have been output will not be reflected in the declared bounding box, and will confuse programs that attempt to import the resulting graphics. Therefore, when generating encapsulated PostScript, do not change the plot region size or scaling factor once any graphics commands have been issued. If you need to change these parameters, use the FILENAME keyword to start a new file.

## ENCODING

(CGM)

Set this keyword to set the CGM encoding type for the output file. Valid values are:

Value	Description
1	Binary encoding - the default.
2	Text encoding.
3	NCAR binary encoding.

*Table A-6: CGM Encoding Values*

The encoding type can only be changed when no CGM file is open.

## FILENAME

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Normally, all generated output is sent to a file named `idl.xxx`, where `xxx` is the lowercase name of the device shown in the table under “[Supported Devices](#)” on page 4684. The `FILENAME` keyword can be used to change these defaults. If `FILENAME` is specified:

1. If the file is already open (as happens if plotting commands have been directed to the file since the call to `SET_PLOT`), then the file is completed and closed as if `CLOSE_FILE` had been specified.
2. The specified file is opened for subsequent graphics output.

### HP-GL Only

Under UNIX, if you wish to send HP-GL output directly to a plotter without generating an intermediate file, you should specify the device special file for the plotter as the argument to `FILENAME`. For example, if your plotter is connected to a serial input/output port known on your system as `/dev/ttya`, you would issue the command:

```
DEVICE, FILENAME='/dev/ttya'
```

All subsequent HP-GL output is sent directly to the plotter connected to serial port `/dev/ttya`.

## FLOYD

(PCL, X)

Set this keyword to select the Floyd-Steinberg method of dithering. This algorithm distributes the error, due to displaying intermediate shades in either black or white, to surrounding pixels. This method generally gives the most pleasing results but requires the most computer time.

## FONT\_INDEX

(PS)

An integer representing the font index to be mapped to the current PostScript font.

Normally the font specification keywords (AVANTGARDE, etc.) take effect immediately to change the current font. The FONT\_INDEX keyword alters this behavior. The current font is not changed. Instead, the specified font is mapped to the specified font index. This mapping can then be used within text strings to change the font in the middle of the string. See [“Using PostScript Fonts”](#) on page 4745

## FONT\_SIZE

(PS)

The default height used for displayed text. FONT\_SIZE is given in points (a common typesetting unit of measure). The default size is 12 point text.

## GET\_CURRENT\_FONT

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the name of the current font is returned as a scalar string. A null string is returned if the Windows font is the default font. If the current device is PRINTER or METAFILE, the current font is returned.

## GET\_DECOMPOSED

(WIN, X)

Set this keyword to a named variable in which is returned the current state of the decomposed flag in the current direct graphics device.

## GET\_FONTNAMES

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which a string array containing the names of available fonts is returned. If no fonts are found, a null scalar string is returned. This keyword must be used in conjunction with the SET\_FONT keyword. Set the SET\_FONT keyword to a scalar string containing the name of the desired font or to a wildcard. For example, the following command will return in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

## GET\_FONTNUM

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the number of fonts available to your installation is returned. This keyword must be used in conjunction with the SET\_FONT keyword. Set the SET\_FONT keyword to a scalar string containing the name of the desired font or a wildcard. For example, the following command will return in the variable `numfonts` the number of available fonts:

```
DEVICE, GET_FONTNUM=numfonts, SET_FONT='*'
```

## GET\_GRAPHICS\_FUNCTION

(WIN, X, Z)

Set this keyword to a named variable that returns the value of the current graphics function (which is set with the SET\_GRAPHICS\_FUNCTION keyword). This can be used to remember the current graphics function, change it temporarily, and then restore it. See [“SET\\_GRAPHICS\\_FUNCTION”](#) on page 4719 keyword for an example.

## GET\_PAGE\_SIZE

(PRINTER)

Set this keyword to a named variable in which to return a two-element vector that contains the width and height of the page size in pixels.

## GET\_SCREEN\_SIZE

(WIN, X)

Set this keyword to a named variable in which to return a two-word array that contains the width and height of the server's screen, in pixels.

## GET\_VISUAL\_DEPTH

(WIN, X)

Set this keyword to a named variable into which a long integer is returned containing the depth of the visual associated with this device. Under X, if the X server is not connected when you call the `DEVICE` procedure with this keyword set, a new connection is made.

## GET\_VISUAL\_NAME

(WIN, X)

Set this keyword equal to a named variable in which a string containing the name of the current visual class IDL is using is returned. Possible return values are:

- `StaticGray` (X only)
- `GrayScale` (X only)
- `StaticColor` (X only)
- `PseudoColor`
- `TrueColor`
- `DirectColor` (X only)

Under X, if no connection to the X server has been established when the `DEVICE` procedure is called with this keyword set, a new connection is made.

## GET\_WINDOW\_POSITION

(WIN, X)

Set this keyword to a named variable that returns a two-element array containing the (X,Y) position of the lower left corner of the current window on the screen. The origin is also in the lower left corner of the screen.

## GET\_WRITE\_MASK

(WIN, X)

Specifies the name of a variable to receive the current value of the write mask.

## GIN\_CHARS

(TEK)

The number of characters IDL is to read when accepting a GIN (Graphics INput) report. The default is 5. If your terminal is configured to send a carriage return at the end of each GIN report, set this parameter to 6. If the number of GIN characters is too large, the IDL CURSOR procedure will not respond until two or more keys are struck. If it is too small, the extra characters sent by the terminal will appear as input to the next IDL prompt.

## GLYPH\_CACHE

(METAFILE, PRINTER, PS, WIN, Z)

Set this keyword to a scalar specifying the maximum number of glyphs to cache at any given time. The first time a glyph from a TrueType font is used, it is tessellated into triangles. These triangles are cached so that the tessellation step is not repeated for each use of that glyph. If the glyph cache fills, the least used glyph will be released before a new glyph is generated and cached. The default is 256.

## HELVETICA

(PS)

Set this keyword to select the Helvetica PostScript font.

## INCHES

(HP, METAFILE, PCL, PRINTER, PS)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if INCHES is present and non-zero, they are taken to be in inches instead.

## INDEX\_COLOR

(METAFILE, PRINTER)

Set this keyword to place the printer or MetaFile device in index color mode. This is the default. This keyword is applicable only when the printer or MetaFile device is selected.

## ISOLATIN1

(PS)

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters.

## ITALIC

(PS)

Set this keyword to specify that the italic version of the current PostScript font should be used.

## LANDSCAPE

(HP, PCL, PRINTER, PS)

IDL normally generates plots with portrait orientation (the abscissa is along the short dimension of the page). If the LANDSCAPE keyword is set, landscape orientation (abscissa along the long dimension of the page) is used instead. Note that explicitly setting LANDSCAPE=0 is the same as setting the [PORTRAIT](#) keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to landscape layout is started.

---

**Note**

The ability to set a printer to landscape mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

---

## LANGUAGE\_LEVEL

(PS)

Set this keyword to indicate the language level of the PostScript output that is to be generated by the device. Valid values include 1 (the default) and 2 (required for some features, such as filled patterns for polygons).

## LIGHT

(PS)

Set this keyword to specify that the light version of the current PostScript font should be used.

## MEDIUM

(PS)

Set this keyword to specify that the medium version of the current PostScript font should be used.

## NARROW

(PS)

Set this keyword to specify that the narrow version of the current PostScript font should be used.

## NCAR

(CGM)

Set this keyword to set the encoding type for the CGM output file to NCAR binary.

### The NCAR Binary Encoding

The NCAR binary encoding is used exclusively by the NCAR graphics package. Version 3.01 of NCAR View (`ctrans`, `ictrans`, and `cgm2ncgm`) does not correctly handle the following graphic elements:

- Cell arrays (raster images) with an odd number of pixels in the X dimension. Solution: specify an even number of pixels for the X dimension or make the image one column wider and fill with zeros.
- Raster images drawn in top down order. Solution: invert the image prior to using TV or TVSCL and do not use the /ORDER keyword. For example:

```
TV, image
; Draw image top to bottom:
TV, ROTATE(image, 7)
```

## OBLIQUE

(PS)

Set this keyword to specify that the oblique version of the current PostScript font should be used.

## OPTIMIZE

(PCL)

It is desirable, though not always possible, to compress the size of the PCL output file. Such optimization reduces the size of the output file, and improves I/O speed to the printer. There are three levels of optimization:

Value	Description
0	No optimization is performed. This is the default because it will work with any PCL device. However, users of devices which can support optimization should use one of the other optimization levels.
1	Optimization is performed using PCL optimization primitives. This gives the best output compression and printing speed. Unfortunately, not all PCL devices support it. On those that can't, the result will be garbage printed on the page. Consult the programmers manual for your printer to determine if it supports the required escape sequences. The required sequences are: <ESC>*b0M (select full graphics mode), <ESC>*b1M (select compacted graphics mode 1), and <ESC>*b2M (select compacted graphics mode 2). The HP LaserJet II does not support this optimization level. The DeskJet PLUS does.
2	IDL attempts to optimize the output by explicitly moving the left margin and then outputting non-blank sections of the page. This is primarily intended for use with the LaserJet II, which does not support optimization level 1. Note: This optimization can be very slow on some devices (such as the DeskJet PLUS). On such devices, it is best to avoid this optimization level.

*Table A-7: PCL Optimization Values*

## ORDERED

(PCL, X)

Set this keyword to select the ordered dither method. This introduces a pseudo-random error into the display by using a 4 by 4 “dither” matrix, yielding 16 apparent intensities. This is the default method.

## OUTPUT

(HP, PS)

Specifies a scalar string that is sent directly to the graphics output file without any processing, allowing the user to send arbitrary commands to the file. Since IDL does not examine the string, it is the user's responsibility to ensure that the string is correct for the target device.

## PALATINO

(PS)

Set this keyword to select the Palatino PostScript font.

## PIXELS

(PCL)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if the PIXELS keyword is set, they are taken to be in pixels instead. Note that the selected resolution will determine how large a region is actually written on the page.

## PLOT\_TO

(REGIS, TEK)

Directs the Tektronix graphic output that would normally go to the user's terminal to the specified I/O unit. The logical unit specified should be open with write access to a device or file. Graphic output may be saved in files for later playback, redirected to other terminals, or to devices that can accept Tektronix graphic commands.

Do not use the interactive graphics cursor when graphic output is not directed to your terminal.

To direct the graphic data to both the terminal and the file, set the unit to the negative of the actual unit number. Alternatively, you can use the TTY keyword, described below.

If the specified unit number is zero then Tektronix output to the file is stopped.

## PLOTTER\_ON\_OFF

(HP)

There are some configurations in which a HP-GL plotter is connected between the computer and a terminal. In this mode (known as eavesdrop mode), the plotter

ignores everything it is sent and passes it through to the terminal—the plotter is logically off. This state continues until an escape sequence is sent that turns the plotter logically on. At this point the plotter interprets and executes all input as HP-GL commands. Another escape sequence is sent at the end of the HP-GL commands to return the plotter to the logically off state.

Most configurations do not use eavesdrop mode, and the plotter is always logically on. However, if you are using this style of connection, you must use `PLOTTER_ON_OFF` to instruct IDL to generate the necessary on/off commands. If present and non-zero, `PLOTTER_ON_OFF` causes each output page to be bracketed by device control commands that turn the plotter logically on and off. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

## POLYFILL

(HP)

Some plotters (e.g., HP7550A) can perform polygon filling in hardware, while others (e.g., HP7475) cannot. IDL therefore assumes that the plotter cannot, and generates all polygon operations in software using line drawing. Specifying a non-zero value for the `POLYFILL` keyword causes IDL to use the hardware polygon filling. Setting it to zero reverts to software filling.

Different implementations of HP-GL plotters may have different limits for the number of vertices that can be specified for a polygon region before the plotter runs out of internal memory. Since this limit can vary, the HP-GL driver cannot check for calls to `POLYFILL` that specify too many points. Therefore, it is possible for the user to produce HP-GL output that causes an error when sent to the plotter. To avoid this situation, minimize the number of points used. On the HP7550A, the limit is about 127 points. If you do generate output that exceeds the limit imposed by your plotter, you will have to break that polygon filling operation into multiple smaller operations.

## PORTRAIT

(HP, PCL, PRINTER, PS)

Set the `PORTRAIT` keyword to generate plots using portrait orientation. Portrait orientation is the default. Note that explicitly setting `PORTRAIT=0` is the same as setting the `LANDSCAPE` keyword.

If the current device is `PRINTER`, and a page is open in the printer, it is closed and a new page set to portrait layout is started.

**Note**

The ability to set a printer to portrait mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

**PRE\_DEPTH**

(PS)

Set this keyword to a value indicating the bit depth to be used for the preview in the PostScript file. Valid values are 1 (for black and white preview) and 8 (for 8-bit grayscale preview). This keyword applies only if the PREVIEW keyword is nonzero. The default depth is 8.

**PRE\_XSIZE**

(PS)

Set this keyword to the width to be used for the preview in the PostScript file. PRE\_XSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, [“A Note About Preview Dimensions”](#).

**PRE\_YSIZE**

(PS)

Set this keyword to the height to be used for the preview in the PostScript file. PRE\_YSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, [“A Note About Preview Dimensions”](#).

**PREVIEW**

(PS)

Set this keyword to 1 to add a platform-independent preview to the PostScript output file in encapsulated PostScript interchange format (EPSI). EPSI is an ASCII format. Set this keyword to 2 to write the EPS file in EPSF format, including an on-screen preview that is supported by many Windows applications, e.g. MSWord. The default (0) is to not include a preview.

**Note**

---

EPSF is not an ASCII format and cannot be sent directly to a Postscript printer, unlike the EPSI format. It must be imported into an application for printing.

---

**A Note About Preview Dimensions**

Different applications may utilize the information within a PostScript file in different ways when displaying a screen preview. Some applications will ignore the preview contents entirely, and simply use the primary PostScript contents to generate a screen preview. Other applications will use the preview data and its corresponding dimensions for screen display. Still others will use the preview data and stretch it to the dimensions of the primary PostScript contents. It is therefore recommended that the target application (into which the encapsulated PostScript file is to be loaded) be considered when selecting an appropriate XSIZE, YSIZE, PRE\_XSIZE, and PRE\_YSIZE.

**PRINT\_FILE**

(WIN)

Set this keyword to the name of a file (e.g., PostScript or PCL) to be sent to the currently-selected Windows printer. IDL performs no type checking on this file before sending it to the printer. Therefore, if you have a PostScript printer selected and you send a file that contains no valid PostScript information, you'll simply get text output.

To send the file `myfile.ps` to the currently-selected Windows printer, enter:

```
DEVICE, PRINT_FILE='myfile.ps'
```

**PSEUDO\_COLOR**

(X)

If this keyword is present, the PseudoColor visual is used. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 4762.

**RESET\_STRING**

(TEK)

The string used to place the terminal back into the normal interactive mode after drawing graphics. Use this parameter, in conjunction with the SET\_STRING keyword, to control the mode switching of your terminal.

For example, the GraphON 200 series terminals require the string `<ESC>2` to activate the alphanumeric window after drawing graphics. The call to set this is:

```
DEVICE, RESET = string(27b) + '2'
```

If the 4100 series mode switch is set, using the keyword `TEK4100`, the default mode resetting string is `<ESC>%!1`, which selects the ANSI code mode.

## RESOLUTION

(PCL)

### PCL Only

The resolution at which the PCL printer will work. PCL supports resolutions of 75, 100, 150, and 300 dots per inch. The default is 300 dpi. Lower resolution gives smaller output files, while higher resolution gives superior quality.

## RETAIN

(WIN, X)

Use this keyword to specify the default method used for backing store when creating new windows. This is the method used when the `RETAIN` keyword is not specified with the `WINDOW` procedure. Backing store is discussed in more detail under [“Backing Store”](#) on page 4728, along with the possible values for this keyword. If `RETAIN` is not used to specify the default method, method 1 (server-supplied backing store) is used.

The initial value of this parameter is taken from the [IDL\\_GR\\_WIN\\_RETAIN](#) preference (Microsoft Windows) or the [IDL\\_GR\\_X\\_RETAIN](#) preference (UNIX).

### A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (`RETAIN=1`), reading data from a window using `TVRD` may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (`RETAIN=2`) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for `TVRD`. See [“Unexpected Results Using TVRD with X Windows”](#) on page 2402.

## SCALE\_FACTOR

(PRINTER, PS)

Specifies a scale factor applied to the entire plot. The default value is 1.0, allowing output to appear at its normal size. `SCALE_FACTOR` is used to magnify or shrink the resulting output.

The `SCALE_FACTOR` keyword behaves slightly differently in the context of the `PRINTER` device than it does in the context of the `PS` device.

When the current device is `PRINTER`, the `SCALE_FACTOR` keyword is designed to emulate a scalable resolution setting on the printer. For example, if you have a 300 x 300 pixel image—stored in the variable *image*—the following IDL commands will print *image* in a 0.5 inch square on a 600 dpi printer:

```
SET_PLOT, 'printer'
TV, image
```

Setting `SCALE_FACTOR` to 2 will scale the image to a 1 inch square on the same 600 dpi printer:

```
SET_PLOT, 'printer'
DEVICE, SCALE_FACTOR=2
TV, image
```

The output of IDL's Direct Graphics routines (`CONTOUR`, `PLOT`, `SURFACE`, etc.) is automatically scaled to fill the available drawing area. As a result, the following IDL commands will produce two identical copies of the same output on any printer:

```
SET_PLOT, 'printer'
PLOT, data
DEVICE, SCALE_FACTOR=2
PLOT, data
```

## SCHOOLBOOK

(PS)

Set this keyword to select the New Century Schoolbook PostScript font.

## SET\_CHARACTER\_SIZE

(CGM, HP, METAFILE, PCL, PRINTER, PS, REGIS, TEK, WIN, X, Z)

Set this keyword equal to a two-element vector to specify the font size and line spacing (leading) of vector and TrueType fonts, and the line spacing of device fonts. The way that the value of this vector determines character size is not completely intuitive.

The vector specified to the `SET_CHARACTER_SIZE` keyword sets the values of the `X_CH_SIZE` and `Y_CH_SIZE` fields in the `!D` structure. These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width fits in the specified rectangle. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines (baseline to baseline) is determined explicitly by the height of the rectangle.

For device fonts, the character size is fixed. When the device font system is in use, the first element of the vector specified to `SET_CHARACTER_SIZE` is silently ignored, and only the line-spacing value is used.

---

### Note

Changing between font systems (and sometimes changing from one font to another within the same font system) can also change the `!D` structure, so do not assume that the character size you have set is preserved when you change fonts.

---

## SET\_COLORMAP

(PCL)

Set this keyword to a 14,739 ( $= 3 \cdot 17^3$ ) element byte vector containing the RGB-to-printer color translation table for a color PCL printer. The default table is for an HP Deskjet 500C printer.

The translation table is divided into red, green, and blue planes of 4913 ( $=17^3$ ) elements each. For a given RGB triple, the offset into each plane is calculated as follows:

$$\text{Offset} = (\text{Red}/16) * 289 + (\text{Green}/16) * 17 + (\text{Blue}/16)$$

Thus, if the RGB triple is [16,32,160], the offset into each plane is 333. The printer will use the value at element 332 of the translation table as the red value, the value at element 5245 ( $=4913+332$ ) as the green value, and the value at element 10158 ( $=9826+332$ ) as the blue value.

The following example shows how to scale an existing colortable for use by a PCL printer.

```

; Set the plot window to the X device:
SET_PLOT, 'X'
; Create a window:
WINDOW, 0, XS=300, YS=300
; Load a color table:
LOADCT, 13
; Read color table values into variables:
TVLCT, r, g, b, /GET
; Re-size color table variables:
r2=CONGRID(r, 4913)
g2=CONGRID(g, 4913)
b2=CONGRID(b, 4913)
; Create 14,739-element color map:
colormap=[r2, g2, b2]
; Change to the PCL device:
SET_PLOT, 'PCL'
; Set file name, resolution, color, and color map:
DEVICE, FILE = 'pcl.pcl', RESOLUTION = 300, $
    /COLOR, SET_COLORMAP = colormap
; Display an image:
TVSCL, DIST(900)
; Close the device:
DEVICE, /CLOSE

```

**Note**

---

The color table used need not be one of IDL's predefined tables.

---

**SET\_COLORS**

(Z)

Sets the number of pixel values, !D.N\_COLORS and !D.TABLE\_SIZE. This value is used by a number of IDL routines to determine the scaling of pixel data and the default drawing index. Allowable values range from 2 to 256, and the default value is 256. Use this parameter to make the Z-buffer device compatible with devices with fewer than 256 colors indices.

**SET\_FONT**

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to a scalar string specifying the name of the font used when a hardware or TrueType font is selected. Note that hardware fonts cannot be rotated, scaled, or projected, and that the “!” commands for formatting may not work. When generating three-dimensional plots, it is best to use the vector-drawn or TrueType characters.

---

**Note**

On some platforms, GET\_FONT returns an empty string. When SET\_FONT is passed an empty string, the first font that can be successfully loaded will be used. This is the first available font found in the user's resource file (\$HOME/.Xdefaults) or the app-defaults file (\$IDL\_DIR/resource/X11/lib/app-defaults/Idl).

---

**Note on the FONT Keyword**

The SET\_FONT keyword was introduced with IDL version 5.1 and replaces the FONT and USER\_FONT keywords used in previous versions.

**Using TrueType Fonts**

For TrueType fonts, the specified font name must exactly match one of the names in the first column of the `ttfont.map` file in the `resource/fonts/tt` directory or (on Windows platforms) the name of an installed font. See [“About TrueType Fonts”](#) on page 4906 for details on the `ttfont.map` file and for a listing of TrueType fonts distributed with IDL. Note that you must include the TT\_FONT keyword to indicate that the font specified is a TrueType font. For example, the following sets the font to the font to the TrueType font Helvetica Bold Italic:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

---

**Note**

You can append additional TrueType fonts to the `ttfont.map` file if desired; on Windows platforms, additional fonts can also be added via the normal font installation procedures for your system. RSI cannot guarantee that TrueType fonts you add will be satisfactorily tessellated or displayed. See [“About TrueType Fonts”](#) on page 4906 for details.

---

**Using Hardware Fonts**

Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

**UNIX**

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. X Windows users can use the `xlsfonts` command to list available X Windows fonts.

On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

## Microsoft Windows

The SET\_FONT keyword should be set to a string with the following form:

```
DEVICE, SET_FONT='font*modifier1*modifier2*...modifiern'
```

where the asterisk (\*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = 'GARAMOND*ITALIC*24'
PLOT, FINDGEN(10), TITLE = 'IDL Plot'
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

---

### Note

If you set the output device to PostScript (SET\_PLOT, 'PS'), attempting to use the (\*) delimiter with SET\_PLOT will cause an error. You must use SET\_PLOT with specific PostScript font strings as described in [“Fonts and the PostScript Device”](#) on page 4912.

---

## SET\_GRAPHICS\_FUNCTION

(WIN, X, Z)

Most window systems allow applications to specify the graphics function. This is a logical function which specifies how the source pixel values generated by a graphics operation are combined with the pixel values already present on the screen. The complete list of possible values is given in the following table:

Logical Function	Code	Definition
GXclear	0	0
GXand	1	source AND destination
GXandReverse	2	source AND (NOT destination)
GXcopy	3	source
GXandInverted	4	(NOT source) AND destination
GXnoop	5	destination
GXxor	6	source XOR destination
GXor	7	source OR destination
GXnor	8	(NOT source) AND (NOT destination)
GXequiv	9	(NOT source) XOR destination
GXinvert	10	(NOT destination)
GXorReverse	11	source OR (NOT destination)
GXcopyInverted	12	(NOT source)
GXorInverted	13	(NOT source) OR destination
GXnand	14	(NOT source) OR (NOT destination)
GXset	15	1

*Table A-8: Graphic Function Codes*

The default graphics function is GXcopy, which causes new pixels to completely overwrite any previous pixels. Not all functions are available on all window systems.

For example, the following code segment inverts the bottom bit in the rectangle defined by its diagonal corners  $(x_0, y_0)$  and  $(x_1, y_1)$ :

```

; Set graphics function to exclusive or (GXor), and save the
; old function:
DEVICE, GET_GRAPHICS_FUNCTION = oldg, SET_GRAPHICS_FUNCTION = 6
; Use POLYFILL to select the area to be inverted. The source
; pixel value is 1:
POLYFILL, [[x0,y0], [x0,y1], [x1,y1], [x1,y0]], $
    /DEVICE, COLOR=1
; Restore the previous graphics function:
DEVICE, SET_GRAPHICS_FUNCTION=oldg

```

## SET\_RESOLUTION

(Z)

Set this keyword to a two-element vector that specifies the width and height of the Z-buffers. The default size is 640 by 480. If this size is not the same as the existing buffers, the current buffers are destroyed and the device is reinitialized.

## SET\_STRING

(TEK)

The string used to place the terminal into the graphics mode from the normal interactive terminal mode. If the 4100 series mode switch is set, using the keyword TEK4100, the default graphic mode setting string is `<ESC>%!0`, which selects the Tektronix code mode.

## SET\_TRANSLATION

(X)

This keyword can be used to allow multiple, simultaneous IDL sessions to use the same colors from a shared colormap. Use this keyword before the X connection is established (i.e., before a window is created), IDL will use the shared color map without allocating any additional colors, and will not load a grayscale ramp as is usually done when the X server starts up. The following example shows two cooperating IDL processes sharing the same colormap:

Execute the following commands in the first IDL session:

```

WINDOW, GET_X_ID = a
DEVICE, TRANSLATION = t
OPENW, 1, 'junk.dat'
WRITEU, 1, a, !D.N_COLORS, t[0:!D.N_COLORS-1]
CLOSE, 1

```

```
LOADCT, 3
```

Execute the following commands in the second IDL session:

```
OPENR, 1, 'junk.dat'
a=0L
n=0L
READU, 1, a, n
t = BYTARR(n)
READU, 1, t
CLOSE, 1
DEVICE, SET_TRANSLATION = t
WINDOW, COLORS=n, SET_X_ID=a
TV, DIST(256)
```

## SET\_WRITE\_MASK

(X, Z)

Sets the write mask to the specified value. For an  $n$ -bit system, the write mask can range from 0 to  $2^n-1$ .

## STATIC\_COLOR

(X)

Use this keyword to select the X Windows StaticColor visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 4762.

## STATIC\_GRAY

(X)

Use this keyword to select the X Windows StaticGray visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 4762.

## SYMBOL

(PS)

Set this keyword to select the Symbol PostScript font.

## TEK4014

(TEK)

Set this keyword to specify that coordinates are to be output with full 12-bit resolution. If this keyword is not present or is zero, 10-bit coordinates are output. Normally, IDL sends 10-bit coordinates. 12-bit coordinates are compatible with most terminals, even those without the full resolution, but require more characters to send.

---

### Note

The 4014 and the 4100 modes can be used together. The coordinate system IDL uses for the Tektronix is 0 to 4095 in the X direction and 0 to 3120 in the Y direction, even when not in the 4014 mode. In the 10-bit case the internal coordinates are divided by 4 prior to output.

---

## TEK4100

(TEK)

Set this keyword to indicate that the terminal is a 4100 or 4200 series terminal. The use of color, ANSI and Tektronix mode switching, hardware line styles, and pixel output with the TV procedure is supported with these terminals. Also, text is output differently.

## TEXT

(CGM)

Set this keyword to set the encoding type for the CGM output file to text.

## THRESHOLD

(PCL, X)

Set this keyword to select the threshold algorithm—the simplest dithering method. The value of this keyword is the threshold to be used. This algorithm simply compares each pixel against the given threshold, usually 128. If the pixel equals or exceeds the threshold the display pixel is set to white, otherwise it is black.

## TIMES

(PS)

Set this keyword to select the Times-Roman PostScript font.

## TRANSLATION

(WIN, X)

As discussed in “[Shared Colormaps](#)” on page 4765, using the shared colormap (normally recommended) causes IDL to translate between IDL color indices (which always start with zero and are contiguous) and the pixel values actually present in the display. The TRANSLATION keyword specifies the name of a variable to receive the translation vector. To read the translation table, use the command:

```
DEVICE, TRANSLATION=TRANSARR
```

where TRANSARR is a named variable into which the translation array is stored. The result is a 256-element byte vector. Element zero of the vector contains the pixel value allocated for the first color in the IDL colormap, and so forth.

### Microsoft Windows Only

This keyword is accepted by the WIN device, for compatibility with the X Windows driver, but simply returns a 256-element vector where each element has the value of its subscript (0 to 255).

## TRUE\_COLOR

(METAFILE, PRINTER, X)

Use this keyword to select TrueColor visuals. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in “[X Windows Visuals](#)” on page 4762. If the current device is PRINTER or METAFILE, the printer is placed in RGB or TrueColor mode if the value of the TRUE\_COLOR keyword is greater than zero (the number of bits per pixel specified is ignored.)

## TT\_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to indicate that the font set via the [SET\\_FONT](#) keyword (either to set the fontname or to retrieve fontnames in conjunction with the [GET\\_FONTNAMES](#) or [GET\\_FONTNUM](#) keywords) should be treated as a TrueType font.

## TTY

(REGIS, TEK)

Set this keyword to specify that output should be sent to the terminal at the same time that it is being sent to a file due to the `FILENAME` or `PLOT_TO` keywords. A zero value causes output to go only to the file. If no output file is in use, this keyword has no effect.

## USER\_FONT

(PS)

*This keyword is now obsolete and has been replaced by the [SET\\_FONT](#) keyword. Code that uses the `USER_FONT` keyword will continue to function as before, but we suggest that all new code use `SET_FONT`.*

## VT240

## VT241

(REGIS)

Set this keyword to configure the REGIS device for VT240 series terminals.

## VT340

## VT341

(REGIS)

Set this keyword to configure the REGIS device for VT340 series terminals.

## WINDOW\_STATE

(WIN, X)

Set this keyword to a named variable that returns an array containing one element for each possible window. Array element  $i$  contains a 1 if window  $i$  is open, otherwise it contains a 0.

## XOFFSET

(HP, PCL, PRINTER, PS)

Specifies the X position, on the page, of the lower left corner of output generated by IDL. `XOFFSET` is specified in centimeters, unless `INCHES` is specified. See [“Positioning Graphics Output”](#) on page 4733.

**PostScript Only**

SCALE does not affect the value of XOFFSET.

**XON\_XOFF**

(HP)

If present and non-zero, XON\_XOFF causes each output page to start with device control commands that instruct the plotter to obey xon/xoff (^S/^Q) style flow control. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

Such handshaking is the default. To turn it off, use the command

```
DEVICE, XON_XOFF=0
```

Often, it is not necessary to tell the plotter to obey flow control because the printing facilities on the system handle such details for you, but it is usually harmless.

**XSIZE**

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the width of output generated by IDL. XSIZE is specified in centimeters, unless INCHES is specified.

**Note**

---

For PCL and PS devices, this keyword's value is effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

---

**PostScript Only**

SCALE modifies the value of XSIZE. Hence, the following statement:

```
DEVICE, /INCHES, XSIZE=7.0, SCALE_FACTOR=0.5
```

results in a real width of 3.5 inches.

Also see [“A Note About Preview Dimensions”](#) on page 4712.

**YOFFSET**

(HP, PCL, PRINTER, PS)

Specifies the Y position, on the page, of the lower left corner of output generated by IDL. YOFFSET is specified in centimeters, unless INCHES is specified. See [“Positioning Graphics Output”](#) on page 4733.

**Note**

---

The corner of the page from which the Y offset is measured (lower or upper left) differs on various devices. Read the device specific information in the following sections to determine how this is handled for your device.

---

**PostScript Only**

SCALE does not affect the value of YOFFSET.

**YSIZE**

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the height of output generated by IDL. YSIZE is specified in centimeters, unless INCHES is specified.

**Note**

---

For PCL and PS devices, this keyword's value is effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

---

**PostScript Only**

SCALE modifies the value of YSIZE. Hence, the following statement:

```
DEVICE, /INCHES, YSIZE=5.0, SCALE_FACTOR=0.5
```

results in a real width of 2.5 inches.

Also see [“A Note About Preview Dimensions”](#) on page 4712.

**ZAPFCHANCERY**

(PS)

Set this keyword to select the ITC Zapf Chancery PostScript font.

**ZAPFDINGBATS**

(PS)

Set this keyword to select the ITC Zapf Dingbats PostScript font.

## Z\_BUFFERING

(Z)

This keyword enables and disables the Z-buffering. If this keyword is specified with a zero value, the driver operates as a standard 2-D device, the Z-buffering is disabled, and the Z-buffer (if any) is deallocated. Setting this keyword to one (the default value), enables the Z-buffering.

To disable Z-buffering enter:

```
DEVICE, Z_BUFFERING = 0
```

# Window Systems

The different window systems supported by IDL have many features in common. This section describes those features. See the individual descriptions of each system later in this chapter for additional information about each one.

IDL utilizes the window system by creating and using one or more largely independent windows, each of which can be used for the display of graphics and/or images. One color map table is shared among all these windows. Multiple windows can be active simultaneously. Windows are referenced using their index which is a non-negative integer.

“Dithering” or halftoning techniques are used to display images with multiple shades of gray on monochrome displays—displays that can only display white or black. This topic is discussed in [“Image Display On Monochrome Devices”](#) on page 4730.

Graphic and image output is always directed to the current window. When a window system is selected as the current IDL graphics device, the index number of the current window is found in the `!D.WINDOW` system variable. This variable contains -1 if no window is open or selected. The `WSET` procedure is used to change the current window. `WSHOW` hides, displays, and iconifies windows. `WDELETE` deletes a window.

The `WINDOW` procedure creates a new window with a given index. If a window already exists with the same index, it is first deleted. The size, position, title, and number of colors, may also be specified. If you access the display before creating the first window, IDL automatically creates a window with an index number of 0 and with the default attributes.

## Backing Store

One of the features that distinguishes various window systems is how they handle the issue of backing store. When part of a window that was previously not visible is exposed, there are two basic approaches that a window system can take. Some keep track of the current contents of all windows and automatically repair any damage to their visible regions (retained windows). This saved information is known as the backing store. Others simply report the damage to the program that created the

window and leave repairing the visible region to the program (non-retained windows).

Value	Description
0	No backing store.
1	Request the server or window system to perform backing store.
2	Make IDL perform backing store.

*Table A-9: Allowed Values for the RETAIN Keyword*

There are convincing arguments for and against both approaches. It is generally more convenient for IDL if the window system handles this problem automatically, but this often comes at a performance penalty. The actual cost of retained windows varies between systems and depends partially on the application.

The X Window system does not by default keep track of window contents. Therefore, when a window on the display is obscured by another window, the contents of its obscured portion is lost. Re-exposing the window causes the X server to fill the missing data with the default background color for that window, and request the application to redraw the missing data. Applications can request a backing store for their windows, but servers are not required to provide it. Many X servers do not provide backing store, and even those that do cannot necessarily provide it for all requesting windows. Therefore, requesting backing store from the server might help, but there is no certainty.

The IDL window system drivers allow you to control the issue of backing store using the RETAIN keyword to the DEVICE and WINDOW procedures. Using it with DEVICE allows you to set the default action for all windows, while using it with WINDOW lets you override the default for the new window. The possible values for this keyword are summarized under “[Backing Store](#)” on page 4728, and are described below:

- Setting the RETAIN keyword to 0 specifies that no backing store is kept. In this case, exposing a previously obscured window leaves the missing portion of the window blank. Although this behavior can be inconvenient, it usually has the highest performance because there is no need to keep a copy of the window contents.
- Setting the RETAIN keyword to 1 causes IDL to request that a backing store be maintained. If the window system decides to accept the request, it will automatically repair the missing portions when the window is exposed. X

Windows may or may not provide backing store when requested, depending on the capabilities of the server and the resources available to it.

- Setting the RETAIN keyword to 2 specifies that IDL should keep a backing store for the window itself, and repair any window damage when the window system requests it. This option exists for X Windows. In this case, a pixmap (off-screen display memory) the same size as the window is created at the same time the window is created, and all graphics operations sent to the window are also sent to the pixmap. When the server requests IDL to repair freshly exposed windows, this pixmap is used to fill in the missing contents. Pixmap is a precious resource in the X server, so backing pixmaps should only be requested for windows with contents that must absolutely be preserved.

If the type of backing store to use is not explicitly specified using the RETAIN keyword, IDL assumes option 1 and requests the window system to keep a backing store.

## A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See [“Unexpected Results Using TVRD with X Windows”](#) on page 2402.

## Image Display On Monochrome Devices

Images are automatically dithered when sent to some monochrome devices. Dithering is a technique which increases the number of apparent brightness levels at the expense of spatial resolution. Images with 256 gray levels are displayed on a display with only two colors, black and white, using halftoning techniques. PostScript handles dithering directly. IDL supports dithering for other devices if their DEVICE procedures accept the FLOYD, ORDERED, or THRESHOLD keywords.

# Printing Graphics Output Files

For Direct Graphics printer and plotter devices (e.g., PCL, PostScript, and HP-GL), IDL creates a file containing output commands. This file can be sent to the printer via the normal methods provided by the local operating system. When attempting to output the file before exiting IDL, the user must be sure that the graphics output file is complete. For example, the following IDL commands (executed under UNIX) will not produce the desired result:

```
SET_PLOT, 'PS'
PLOT, x, y
SPAWN, 'lpr idl.ps'
```

These commands fail because the attempt to print the file is premature—the file is still open within IDL and is not yet complete.

---

## Note

Use of SET\_PLOT and the direct graphics commands is not required when creating graphical output files or printing to a printer using the iTools or other object-graphics routines.

---

The following lines of code are an IDL procedure called OUTPUT\_PLOT which closes the current graphics file and sends it to the printer. This routine assumes that the graphics output file is named `idl.xxx`, where `xxx` represents the name of the graphics driver. For example, PostScript output file is assumed to be `idl.ps`. It also assumes that the graphics output to be printed is from the current graphics device, as selected with SET\_PLOT.

```
; Close the current graphics file, and print it. If the
; New_file parameter is present, rename the file to the given
; name so it won't be overwritten:
Pro OUTPUT_PLOT, New_file
; Close current graphics file:
DEVICE, /CLOSE
; Build the default output file name by using the idl name for
; the current device (!D.NAME):
file = 'idl.' + STRLOWCASE(!D.NAME)
; Build shell commands to send file to the printer.
; You will probably have to change this command in accordance
; with local usage:
cmd = 'lpr ' + file
; Concatenate rename command if new file specified:
IF N_ELEMENTS(New_file) GT 0 THEN $
    cmd = cmd + '; mv' + file + ' ' + New_file
; Issue shell commands to print/rename file:
```

```
SPAWN, cmd  
END
```

The call to `DEVICE` causes IDL to finish the file and close it, which makes it available for printing.

## Setting Up The Printer

In order for IDL generated output files to work properly with printers and plotters, it is necessary for the device to be configured properly. This usually involves configuring both the device hardware and the operating system printing software. When setting up your system, keep the following points in mind:

- The device and computer must use some form of flow control to prevent the computer from sending data faster than the printing device can handle it. The most common form of flow control is known as XON/XOFF, and involves the sending of Control-S (off) and Control-Q (on) characters from the device to the printer to manage the flow of data.

Many printers have a large buffer into which they store incoming data they haven't yet processed. This reduces the need to invoke flow control. When testing your configuration to ensure flow control is actually enabled, you must be sure to print a document long enough to fill any such buffer, or flow control may never occur, giving a false impression that the setup is correct. A common source of problems stem from attempting to print long IDL generated output files without proper flow control.

- Some devices (such as PCL) require an eight-bit data path, while others (such as PostScript) do not. For devices that do, it is important to ensure that the printer port and system printing software provide such a connection.

If you are having problems printing on a PostScript printer, the `ehandler.ps` file in the `resource/fonts/ps` subdirectory of the IDL distribution can help you to debug your problem. Sending this file to your PostScript Printer causes it to print any subsequent errors it encounters on a sheet of paper and eject it. The effect of this file lasts until the printer is reset.

## Setting Up Printers Under UNIX

Printers are configured in the `/etc/printcap` file. This file describes to the system which printers are connected to it, the characteristics of each printer, and how the printer port should be configured. Managing the `printcap` file is usually discussed in the system management documentation supplied with the system by the manufacturer. See “[IDL Printer Setup in UNIX or Mac OS X](#)” in Chapter 2 of the *Using IDL* manual for information on configuring a UNIX printer.

## Positioning Graphics Output

The difference between the XOFFSET and YOFFSET keywords to the DEVICE procedure, and the higher level plot positioning keywords and system variables (discussed in [Appendix B, “Graphics Keywords”](#)) can lead to confusion. A common misunderstanding is to attempt to use the DEVICE procedure “offset” and “size” keywords multiple times in an attempt to produce multiple plots on a single output page.

The DEVICE keywords are intended to specify the size and position of the entire output area on the page, not to move the plotting region for multiple plots. The driver does not monitor their values continuously, but only when initializing a new page or ejecting the current one.

The proper way to produce multiple plots is to use the high level positioning abilities. The !P.MULTI, !P.POSITION, and !P.REGION system variables can be used to position individual plots on the page. The plotting routines also accept the POSITION, MARGIN and REGION keywords.

## Image Background Color

Graphical output that is displayed with a black background on a monitor frequently look better if the background is changed to white when printed on white paper. This is easily done using the **BACKGROUND** graphics keyword or (if the only values displayed in black are in the background) with a statement like:

```
a (WHERE (a EQ 0B)) = 255B
```

# The CGM Device

## Device Keywords Accepted by the CGM Device:

[BINARY](#), [CLOSE\\_FILE](#), [COLORS](#), [ENCODING](#), [FILENAME](#), [NCAR](#),  
[SET\\_CHARACTER\\_SIZE](#), [TEXT](#)

The CGM, Computer Graphics Metafile, standard describes a device independent file format used for the exchange of graphic information. The IDL CGM driver produces CGM files encoded in one of three methods: *Text*, *Binary* or *NCAR Binary*. To direct graphics output to a CGM file, issue the command:

```
SET_PLOT, 'CGM'
```

This causes IDL to use the CGM driver for producing graphical output. Once the CGM driver is selected, the `DEVICE` procedure controls its actions, as described below. Typing `HELP, /DEVICE` displays the current state of the CGM driver. The CGM driver defaults to the binary encoding using 256 colors.

## Abilities and Limitations

This section describes details specific to IDL's CGM implementation:

- IDL uses the CGM default integer encoding for graphic primitives. Coordinate values range from 0 to 32767. It is advisable to use the values stored in `!D.X_SIZE` and `!D.Y_SIZE` instead of assuming a fixed coordinate range.
- Color information is output with a resolution of 8 bits (color indices and intensity values range from 0 to 255).
- The definition of background color in the CGM standard is somewhat ambiguous. According to the standard, color index 0 and the background color are the same. Because background color is specified in the metafile as a color value (RGB triple), not an index, it is possible to have the background color not correspond with the color value of index 0.
- The CGM `BACKGROUND_COLOUR` attribute is explicitly set by IDL only during an erase operation: changing the value of the color map at index 0 does not cause IDL to generate a `BACKGROUND_COLOUR` attribute until the next `ERASE` occurs. An `ERASE` command sets the background color to the value in the color map at index 0. The command `ERASE, INDEX` (where `INDEX` is not 0) generates the message "value of background color is out of allowed range." For consistent results, modify the color table before any graphics are output.

- The CGM standard uses scalable (variable size) pixels for raster images. By default, the TV and TVSCL procedures output images, regardless of size, using the entire graphics output area. To output an image smaller than the graphics output area, specify the XSIZE and YSIZE keywords with the TV and TVSCL procedures. For example:

```
; Select the CGM driver:
SET_PLOT, 'CGM'
; Create a 64 x 64 element array:
X = DIST(64)
; Display the image (fills entire screen):
TVSCL, X
; Now display 4 images on the screen:
ERASE
XS = !D.X_SIZE / 2 ; Size of each image, X dimension
YS = !D.Y_SIZE / 2 ; Size of each image, Y dimension
TVSCL, X, 0, XSIZE=XS, YSIZE=YS ; Upper left
TVSCL, X, 1, XSIZE=XS, YSIZE=YS ; Upper right
TVSCL, X, 2, XSIZE=XS, YSIZE=YS ; Lower left
TVSCL, X, 3, XSIZE=XS, YSIZE=YS ; Lower right
```

# The HP-GL Device

## Device Keywords Accepted by the HP-GL Device:

`CLOSE_FILE`, `EJECT`, `FILENAME`, `INCHES`, `LANDSCAPE`, `OUTPUT`, `PLOTTER_ON_OFF`, `POLYFILL`, `PORTRAIT`, `SET_CHARACTER_SIZE`, `XOFFSET`, `XON_XOFF`, `XSIZE`, `YOFFSET`, `YSIZE`

HP-GL (Hewlett-Packard Graphics Language) is a plotter control language used to produce graphics on a wide family of pen plotters. To use HP-GL as the current graphics device, issue the IDL command:

```
SET_PLOT, 'HP'
```

This causes IDL to use HP-GL for producing graphical output. Once the HP-GL driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, as described below. The default settings for the HP-GL driver are shown in the following table. Use the statement:

```
HELP, /DEVICE
```

to view the current state of the HP-GL driver.

Feature	Value
File	idl.hp
Orientation	Portrait
Erase	No action
Polygon filling	Software
Turn plotter logically on/off	No
Specify xon/xoff flow control	Yes
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.

*Table A-10: Default HP-GL Driver Settings*

## Abilities And Limitations

IDL is able to produce a wide variety of graphical output using HP-GL. The following is a list of what is and is not supported:

- All types of vector graphics can be generated, including line plots, contours, surfaces, etc.
- HP-GL plotters can draw lines in different colors selected from the pen carousel. It should be noted that color tables are not used with HP-GL. Instead, each color index refers directly to one of the pens in the carousel.
- Some HP-GL plotters can do polygon filling in hardware. Others can rely on the software polygon filling provided by IDL.
- It is possible to generate graphics using the hardware generated text characters, although such characters do not give much improvement over the standard vector fonts. To use hardware characters, set the !P.FONT system variable to zero, or set the FONT keyword to the plotting routines to zero.
- Since HP-GL is designed to drive pen plotters, it does not support the output of raster images. Therefore, TV and TVSCL do not work with HP-GL.
- Since pen plotters are not interactive devices, they cannot support such operations as cursors and windows.

## HP-GL Linestyles

The LINSTYLE graphics keyword allows specifying any of 6 linestyles. HP-GL does not support all of these linestyles, and styles 3 and 4 differ from the definition in [Appendix B, “Graphics Keywords”](#). The following table summarizes the differences:

Index	Normal Line Style	HP-GL Line Style
0	Solid	same
1	Dotted	same
2	Dashed	same
3	Dash Dot	Relative size of dash and dot are different.
4	Dash Dot Dot Dot	Dash Dot Dot
5	Long Dashes	same

*Table A-11: Linestyles for the HP-GL Device*

# The Metafile Display Device

## Device Keywords Accepted by the Metafile Device:

`CLOSE_FILE`, `FILENAME`, `GET_CURRENT_FONT`, `GET_FONTNAMES`, `GET_FONTNUM`, `GLYPH_CACHE`, `INCHES`, `INDEX_COLOR`, `SET_CHARACTER_SIZE`, `SET_FONT`, `TRUE_COLOR`, `TT_FONT`, `XSIZE`, `YSIZE`

The Windows Metafile Format (WMF) is used by Windows to store vector graphics in order to exchange graphics information between applications. This format is only available on the Windows platforms. To direct graphics to a file in the WMF format, use the `SET_PLOT` procedure:

```
SET_PLOT, 'METAFILE'
```

This causes IDL to use the Metafile driver for producing graphical output. Once the Metafile driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions. The default settings are given in the following table:

Feature	Value
File	idl.emf
Mode	N/A
Horizontal offset	N/A
Vertical offset	N/A
Width	7 in.
Height	5 in.
Resolution	Screen

*Table A-12: Default Metafile Driver Settings*

For example, the following will create a WMF file for a simple plot:

```
;Create X and Y Axis data
x=findgen(10)
y=findgen(10)

;Save current device name
mydevice=!D.NAME
```

```
;Set the device to Metafile
SET_PLOT, 'METAFILE'

;Name the file to be created
DEVICE, FILE='test.emf'

;Create the plot
PLOT, x, y

;Close the device which creates the Metafile
DEVICE, /CLOSE

;Set the device back to the original
SET_PLOT, mydevice
```

# The Null Display Device

## Device Keywords Accepted by the Null Device:

No keywords are accepted by the `DEVICE` procedure when the `NULL` device is selected.

To suppress graphics output entirely, use the null device:

```
SET_PLOT, 'NULL'
```

# The PCL Device

## Device Keywords Accepted by the PCL Device:

`CLOSE_FILE`, `COLOR`, `FILENAME`, `FLOYD`, `INCHES`, `LANDSCAPE`, `OPTIMIZE`, `ORDERED`, `PIXELS`, `PORTRAIT`, `RESOLUTION`, `SET_CHARACTER_SIZE`, `SET_COLORMAP`, `THRESHOLD`, `XOFFSET`, `XSIZE`, `YOFFSET`, `YSIZE`

PCL (Printer Control Language) is used by Hewlett-Packard laser and ink jet printers to produce graphics output. To direct graphics output to a PCL file, issue the command:

```
SET_PLOT, 'PCL'
```

This causes IDL to use the PCL driver for producing graphical output. Once the PCL driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, as described below. The default settings for the PCL driver are listed in the following table:

Feature	Value
File	idl.pcl
Mode	Portrait
Optimization level	0 (None)
Dither method	Floyd-Steinberg
Resolution	300 dpi
Horizontal offset	1/2 in.
Vertical offset	1 in.
Width	7 in.
Height	5 in.

*Table A-13: Default PCL Driver Settings*

The PCL device draws into a memory buffer of the specified size (or the default size, if the `XSIZE` and `YSIZE` keywords to `DEVICE` are not specified). Anything drawn outside this buffer will be silently discarded.

**Note**

Unlike monitors where white is the most visible color, PCL writes black on white paper. Setting the output color index to 0, the default when PCL output is selected, writes in black. A color index of 255 writes white which is invisible on white paper.

Color tables are not used with PCL unless the color mode has been enabled using the **COLOR** keyword to the **DEVICE** procedure. For images, color dithering produces realistic color image output even though PCL printers only produce eight output colors. In most cases, simply choosing an appropriate color table (using **LOADCT** or **XLOADCT**), or creating a color table from an image (via **TVLCT**) will work fine. If you need finer control over the colors used, see the **SET\_COLORMAP** keyword for additional information. For vector graphics, only eight colors are supported—no line dithering is implemented. Any RGB component that is not zero is treated as 255. The correct RGB definitions for each color are shown in the following table. Use the **HELP, /DEVICE** command to view the current options for PCL output.

Color	Red Value	Green Value	Blue Value
Red	255	0	0
Green	0	255	0
Blue	0	0	255
Cyan	0	255	255
Magenta	255	0	255
Yellow	255	255	0
Black	0	0	0
White	255	255	255

*Table A-14: PCL RGB Color Definitions*

**Note**

The values of **XSIZE** and **YSIZE** for this device are effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

# The Printer Device

## Device Keywords Accepted by the PRINTER Device:

`CLOSE_DOCUMENT`, `GET_CURRENT_FONT`, `GET_FONTNAMES`,  
`GET_FONTNUM`, `GET_PAGE_SIZE`, `INDEX_COLOR`, `PORTRAIT`,  
`SCALE_FACTOR`, `SET_CHARACTER_SIZE`, `TRUE_COLOR`, `XOFFSET`,  
`XSIZE`, `YOFFSET`, `YSIZE`

The PRINTER device allows IDL Direct Graphics to be output to a system printer. To direct graphics output to a printer, issue the command:

```
SET_PLOT, 'printer'
```

This causes IDL to use a printer driver to produce graphical output. By default, the default system printer is used for output. Use the `DIALOG_PRINTERSETUP` function to define the printing parameters for the printer device. Use the `DIALOG_PRINTJOB` function to control the print job itself.

Note that the printer device is an IDL Direct Graphics device. Like other Direct Graphics devices, you must change to the new device and then issue the IDL commands that send output to that device. With the printer device, you must use the `CLOSE_DOCUMENT` keyword to the `DEVICE` routine to actually initiate the print job and make something come out of your printer.

# The PostScript Device

## Device Keywords Accepted by the PS Device:

AVANTGARDE, BITS\_PER\_PIXEL, BKMAN, BOLD, BOOK, CLOSE\_FILE, CMYK, COLOR, COURIER, DEMI, ENCAPSULATED, FILENAME, FONT\_INDEX, FONT\_SIZE, HELVETICA, INCHES, ISOLATIN1, ITALIC, LANDSCAPE, LIGHT, MEDIUM, NARROW, OBLIQUE, OUTPUT, PALATINO, PORTRAIT, PRE\_DEPTH, PRE\_XSIZE, PRE\_YSIZE, PREVIEW, SCALE\_FACTOR, SCHOOLBOOK, SET\_CHARACTER\_SIZE, SET\_FONT, SYMBOL, TIMES, TT\_FONT, XOFFSET, XSIZE, YOFFSET, YSIZE, ZAPFCHANCERY, ZAPFDINGBATS

PostScript is a programming language designed to convey a description of a page containing text and graphics. Many laser printers and high-resolution, high-quality photo typesetters support PostScript. Color output or direct color separations can be produced with color PostScript. To direct graphics output to a PostScript file, issue the command:

```
SET_PLOT, 'PS'
```

This causes IDL to use the PostScript driver for producing graphical output. Once the PostScript driver is enabled via SET\_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings are given in the following table:

Feature	Value
File	idl.ps
Mode	Portrait, non-encapsulated, no color
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.
Scale factor	1.0
Font size	12 points
Font	Helvetica

*Table A-15: Default PostScript Driver Settings*

Feature	Value
# Bits / Image Pixel	4

Table A-15: Default PostScript Driver Settings (Continued)

### Note

Unlike monitors where white is the most visible color, PostScript writes black on white paper. Setting the output color index to 0, the default when PostScript output is selected, writes black. A color index of 255 writes white which is invisible on white paper. Color tables are not used with PostScript unless the color mode has been enabled using the DEVICE procedure. See “Color Images” on page 4746

To obtain adequate resolution, the device coordinate system used for PostScript output is expressed in units of 0.001 centimeter (i.e., 1000 pixels/cm).

Use the HELP, /DEVICE call to view the current font, file, and other options set for PostScript output.

## Using PostScript Fonts

Information necessary for rendering a set of 35 standard PostScript fonts are included with IDL. (The standard 35 fonts are the fonts found on the Apple Laserwriter II PostScript printer; the same fonts are found on almost any PostScript printer made in the time since the LaserWriter II appeared.) Use of PostScript fonts is discussed in detail in “About Device Fonts” on page 4910.

## Color PostScript

If you have a color PostScript device you can enable the use of color with the statement:

```
DEVICE, /COLOR
```

Enabling color also enables the color tables. Text and graphic color indices are translated to RGB by dividing the red, green and blue color table values by 255. As with most display devices, color indices range from 0 to 255. Zero is normally black and white is normally represented by an index of 255. For example, to create and load a color table with four elements, black, red, green and blue:

```
TVLCT, [0,255,0,0], [0,0,255,0], [0,0,0,255]
```

Drawing text or graphics with a color index of 0 results in black, 1 in red, 2 in green, and 3 in blue.

## Color Images

As with black and white PostScript, images may be output with 1, 2, 4, or 8 bits, yielding 1, 2, 16, or 256 possible colors. In addition, images are either pseudo-color or TrueColor. A pseudo-color image is a two dimensional image, each pixel of which is used to index the color table, thereby obtaining an RGB value for each possible pixel value. Pseudo-color images are similar to those displayed using the workstation monitor.

### Note

In the case of pseudo-color images of fewer than 8 bits, the number of columns in the image should be an exact multiple of the number of pixels per byte (i.e., when displaying 4 bit images the number of columns should be even, and 2 bit images should have a column size that is a multiple of 4). If the image column size is not an exact multiple, extra pixels with a value of 255 are output at the end of each row. This causes no problems if the color white is loaded into the last color table entry, otherwise a stripe of the last (index 255) color is drawn to the right of the image.

## TrueColor Images

A TrueColor image consists of an array with three dimensions, one of which has a size of three, containing the three color components. It may be considered as three two dimensional images, one each for the red, green and blue components. Use the TRUE keyword to the TV and TVSCL procedures to indicate that the image is a TrueColor image and to specify the dimension over which color is interleaved. RGB data can be interleaved by pixel, by line, or by image. Use the TRUE parameter to specify the method of interleaving. A  $c$  column by  $l$  line TrueColor image is dimensioned as follows:

TRUE Value	Dimensions	Interleaving
1	$(3, c, l)$	Pixel
2	$(c, 3, 1)$	Line or Row
3	$(c, l, 3)$	Image

Table A-16: Values for the TRUE Keyword

The following example writes a 24-bit image, interleaved over the third dimension, to a PostScript file:

```
SET_PLOT, 'PS'
;Set the PostScript device to *8* bits per color, not 24.
```

```

DEVICE, FILE='24bit.ps', /COLOR, BITS=8
TV, [[[r]], [[g]], [[b]]], TRUE=3
DEVICE, /CLOSE
; Return plotting to X windows:
SET_PLOT, 'X'

```

---

### Note

Currently, the PostScript device does not support TrueColor plots. Only TrueColor images are supported.

---

TrueColor images are also routed through the color tables. The red color table array contains the intensity translation table for the red image, and so forth. Assuming that the color tables have been loaded with the vectors  $R$ ,  $G$ , and  $B$ , a pixel with a color value of  $(r, g, b)$  is displayed with a color of  $(R_r, G_g, B_b)$ . As with other devices, a color table value of 255 represents maximum intensity, while 0 indicates an absence of the color. To pass the RGB pixel values without change, load the red, green and blue color tables with a ramp with a slope of 1.0:

```
TVLCT, INDGEN(256), INDGEN(256), INDGEN(256)
```

or with the LOADCT procedure:

```

; Load standard black/white table:
LOADCT, 0

```

## Image Background Color

Images that are displayed with a black background on a monitor frequently look better if the background is changed to white when displayed with PostScript. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

## CMYK Output

When the CMYK keyword is set, IDL converts the PostScript output to the CMYK color model as a final step. The indexed or RGB data is mapped to the cyan, magenta, yellow, and black color model just prior to output.

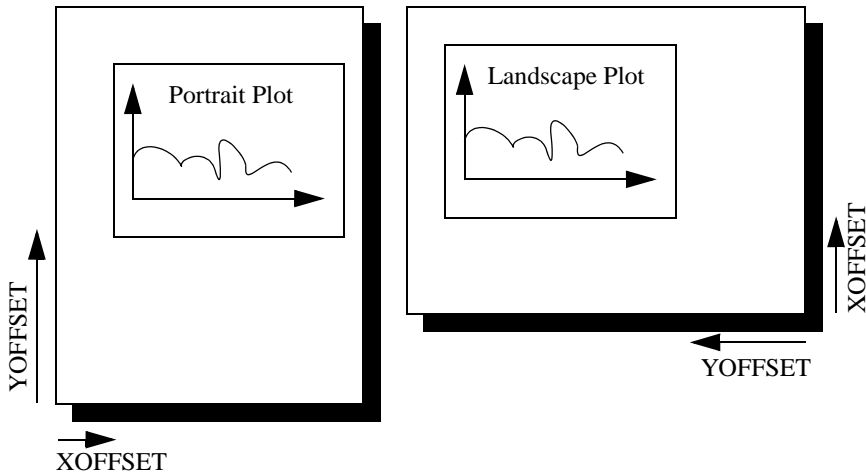

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

# PostScript Positioning

## Using the XOFFSET and YOFFSET Keywords

Often, IDL users are confused by the use of the XOFFSET and YOFFSET keywords to the PostScript DEVICE routine. These keywords control the position of IDL plots on the page. XOFFSET specifies the “X” position of the lower left corner of the output generated by IDL. This offset is always taken relative to the lower left-hand corner of the page when viewed in portrait orientation. YOFFSET specifies the “Y” position of the lower left corner of the output generated by IDL. This offset is also taken relative to the lower left-hand corner of the page when viewed in portrait orientation.

The following figure shows how the XOFFSET and YOFFSET keywords are interpreted by the PostScript device in the Portrait (left) and Landscape (right) modes. Note that the landscape plot uses the same origin for determining the effect of the XOFFSET and YOFFSET keywords, but that the output is rotated 270 degrees clockwise.

*Figure A-1: Interpretation of the XOFFSET and YOFFSET Keywords*

The page on the left shows an IDL plot printed in “portrait” orientation. Note that the X and Y offsets work just as we expect them to—increasing the XOFFSET moves the plot to the right and increasing the YOFFSET moves the plot up the page. The page on the right shows an IDL plot printed in “landscape” orientation. Here, the X and Y offsets are still taken relative to the same points even though the orientation of the

plot has changed. This happens because IDL moves the origin of the plot *before* rotating the PostScript coordinate system 270 degrees clockwise for the landscape plot.

---

**Note**

The XOFFSET and YOFFSET keywords have no effect when you generate ENCAPSULATED PostScript output.

---

## Encapsulated PostScript Output

Another form of PostScript output is Encapsulated PostScript. This is the format used to import PostScript files into page layout and desktop publishing programs. An Encapsulated PostScript (EPS) file is similar to a regular PostScript file except that it contains only one page of PostScript output contained in a “bounding box” that is used to tell other programs about the size and aspect ratio of the encapsulated image.

Most of the time, output from IDL to an EPS file is properly scaled into the EPS bounding box because commands such as PLOT take full advantage of the plotting area made available to them. Sometimes, however, the default bounding box is inappropriate for the image being displayed.

As an example, suppose you have an image that is narrow and tall that, when TV’ed to an IDL window, fills only a small portion of the plotting window. Similarly, when output to an EPS file, this image will only fill a small portion of the bounding box. When the resulting EPS file is brought into a desktop publishing program, it becomes very hard to properly scale the image since the aspect ratio of the bounding box bears no relation to the aspect ratio of the image itself.

To solve this problem, use the XSIZE and YSIZE keywords to the DEVICE procedure to make the bounding box just large enough to contain the image. Since IDL uses a resolution of 1000 dots per centimeter with the PostScript device, the correct XSIZE and YSIZE (in centimeters) can be computed as:

- $XSIZE = \text{Width of image in pixels} / 1000.0 \text{ pixels per cm}$
- $YSIZE = \text{Height of image in pixels} / 1000.0 \text{ pixels per cm}$

---

**Note**

The values of XSIZE and YSIZE for this device are effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

---

The following IDL procedure demonstrates this technique. This procedure reads an X Windows Dump file and writes it back out as a properly-sized, 8-bit-color Encapsulated PostScript file:

```

PRO XWDTOEPS, filename
; Read the XWD file. Pixel intensity information is stored
; in the variable 'array'. Values to reconstruct the color
; table are stored in 'r', 'g', and 'b':
array = READ_XWD(filename, r, g, b)
; Reconstruct the color table:
TVLCT, r,g,b
; Display the image in an IDL window:
TV, array
; Find the size of the picture. The width of the picture
; (in pixels) is stored in s[1]. The height of the picture
; is stored in s[2]:
s = SIZE(array)
; Take the 'xwd' (for X Windows Dump) extension off of
; the old filename and replace it with 'eps':
fl = STRLEN(filename)
filename = STRMID(filename, 0, fl-4)
filename = filename + '.eps'
PRINT, 'Making file: ', filename
PRINT, s
; Set the plotting device to PostScript:
SET_PLOT, 'ps'
; Use the DEVICE procedure to make the output encapsulated,
; 8 bits, color, and only as wide and high as it needs to
; be to contain the XWD image:
DEVICE, /ENCAPSUL, BITS_PER_PIXEL=8, /COLOR, $
      FILENAME=filename, XSIZE=S[1]/1000., $
      YSIZE=S[2]/1000.
; Write the image to the file:
TV, array
; Close the file:
DEVICE, /CLOSE
; Return plotting to X Windows:
SET_PLOT, 'x'
END

```

## Multiple Plots on the Same Page

To put multiple plots on the same PostScript page, use the !P.MULTI system variable (described in more detail in “!P” on page 4828). !P.MULTI is a 5-element integer array that controls the number of rows and columns of plots to make on a page or in a graphics window.

The first element of !P.MULTI is a counter that reports how many plots remain on the page. The second element of !P.MULTI is the number of columns per page. The third element is the number of rows per page.

For example, the following lines of code create a PostScript file, `multi.ps`, with 6 different plots arranged as 2 columns and 3 rows:

```
; Set plotting to PostScript:
SET_PLOT, 'PS'
; Set the filename:
DEVICE, FILENAME='multi.ps'
; Make IDL's plotting area hold 2 columns and 3 rows of plots:
!P.MULTI = [0, 2, 3]
; Create a simple dataset:
A = FINDGEN(10)
; Make 6 different plots:
PLOT, A
PLOT, SIN(A)
PLOT, COS(A)
PLOT, TAN(A)
PLOT, TANH(A)
PLOT, SINH(A)
; Close the file:
DEVICE, /CLOSE
; Return plotting to Windows:
SET_PLOT, 'win'
; Reset plotting to 1 plot per page:
!P.MULTI = 0
```

The resulting file produces a set of plots as shown in the following figure:

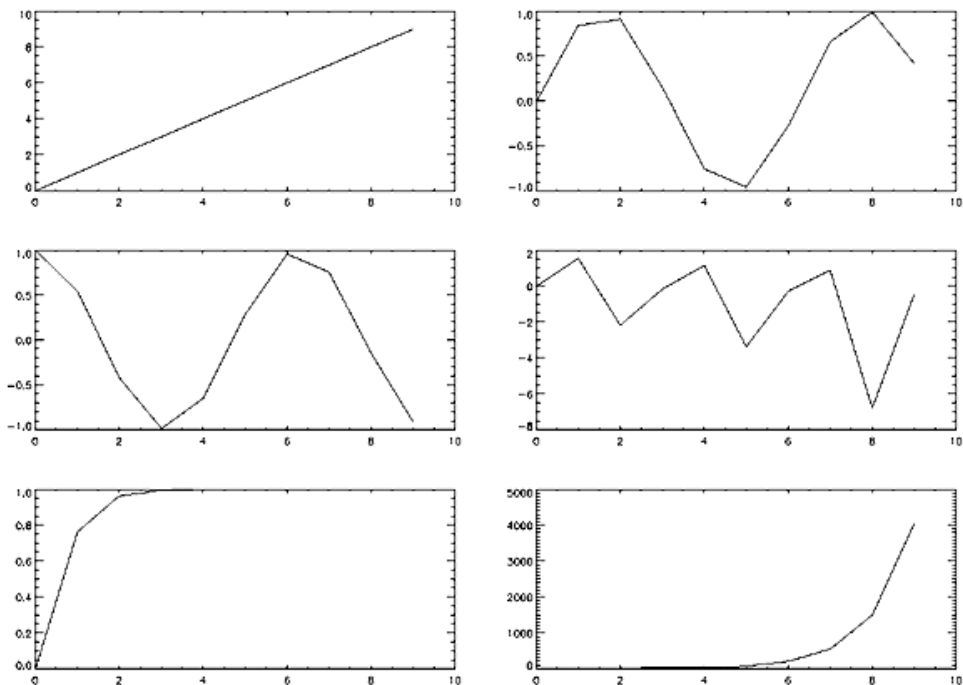

Figure A-2: Multiple plots on a single page produced by setting the `!P.MULTI` system variable.

## Importing IDL Plots into Other Documents

This section shows how to generate IDL PostScript graphics so that they can be inserted into other documents. It also provides several examples of how the PostScript graphics device is used. Simply omit the `ENCAPSULATED` keyword from the calls to `DEVICE` if you wish to produce plots that can be printed directly. The following figure is an encapsulated PostScript file suitable for inclusion in other documents. The figure was produced with the following IDL statements. Note the use of the `ENCAPSULATED` keyword in the call to `DEVICE`:

```

; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic1.ps'
x = FINDGEN(200)

```

```

; Plot the sine wave:
PLOT, 10000 * SIN(x/5) / EXP(x/100), $
      LINESTYLE = 2, TITLE = 'IDL PostScript Plot', $
      XTITLE = 'Point Number', YTITLE='Y Axis Title', $
      FONT = 0
; Add the cosine:
OPLOT, 10000 * COS(x/5) / EXP(x/100), LINESTYLE = 4
; Annotate the plot:
XYOUTS, 100, -6000, 'Sine', FONT = 0
OPLOT, [120, 180], [-6000, -6000], LINESTYLE = 2
XYOUTS, 100, -8000, 'Cosine', FONT = 0
OPLOT, [120, 180], [-8000, -8000], LINESTYLE = 4

```

Figure A-3: Sample PostScript plot using Helvetica font.

The following figure is a more complicated plot. It demonstrates some of the three-dimensional plotting capabilities of IDL. It was produced with the following IDL statements:

```

; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic2.ps'
; Access the data:
OPENR, 1, FILEPATH('abnorm.dat', SUBDIR=['examples', 'data'])
aa = ASSOC(1, BYTARR(64, 64))
; Get a smoothed version:
a = SMOOTH(aa[0], 3)

```

```

; Generate the surface:
SURFACE, a, /SAVE, ZAXIS = 1, XSTYLE = 1, YSTYLE = 1
; Add the contour:
CONTOUR, a, /T3D, /NOERASE, ZVALUE = 1, $
    XSTYLE = 1, YSTYLE = 1, C_LINestyle = [0,1,2], $
    TITLE = 'IDL PostScript Plot'
CLOSE, 1

```

*Figure A-4: Three-Dimensional Plot with Vector-Drawn Characters*

The following figure illustrates polygon filling. It was produced with the following IDL statements:

```

SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic3.ps'
x = FINDGEN(200)
; Upper sine wave:
a = 10000 * sin(x / 5) / exp(x / 100)
PLOT, a, /NODATA, TITLE = 'IDL PostScript Plot', $
    XTITLE='Point Number', YTITLE='Y Axis Title', $
    FONT = 0
; Vector of X vertices for polygon filling. Note that the
; ROTATE(V,2) function call returns the vector V in reverse order:
C = [X, ROTATE(X, 2)]

```

```

; Vector of Y vertices for polygon filling:
D = [A, ROTATE(A-2000, 2)]
; Fill the region using an intensity of about 75% white:
POLYFILL, C, D, COLOR=192

```

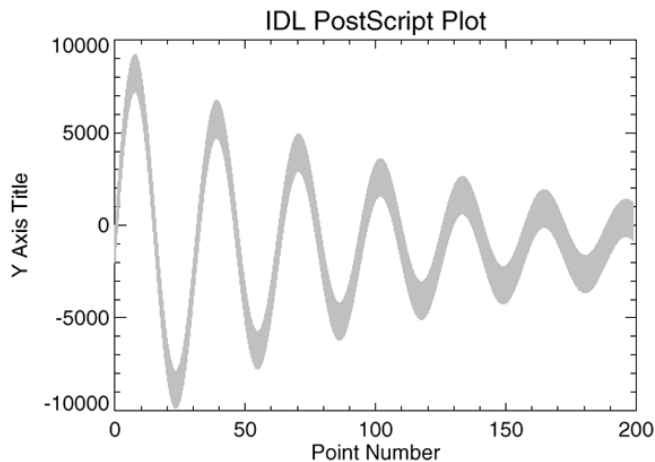

Figure A-5: Polygon Filling Example

The following figure illustrates IDL PostScript images. In this case, the same image is reproduced four times. In each case, a different number of bits are used per image pixel. It was produced with the following IDL statements:

```

SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic4.ps'
; Open image file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
; Variable to hold image:
a = BYTARR(192, 192, /NOZERO)
; Input the image:
READU, 1, a
; Done with the file:
CLOSE, 1
; Add a color table ramp to the bottom of the image:
A[0,0] = BYTSCL(INDGEN(192))#REPLICATE(1,16)
; Output the image four times:
FOR i = 0,3 DO BEGIN
    ; Use 1, 2, 4, and 8 bits per pixel:
    DEVICE, BITS_PER_PIXEL=2^i

```

```
    ; Output using TV with position numbers 0, 1, 2, and 3:  
    TV, a, i, XSIZE=2.5, YSIZE=2.5, /INCHES  
ENDFOR
```

*Figure A-6: 1, 2, 4, and 8-bit PostScript Images*

# The Regis Terminal Device

## Device Keywords Accepted by the REGIS Device:

[AVERAGE\\_LINES](#), [CLOSE\\_FILE](#), [FILENAME](#), [PLOTTER\\_ON\\_OFF](#),  
[SET\\_CHARACTER\\_SIZE](#), [TTY](#), [VT240](#), [VT340](#)

IDL provides Regis graphics output for the DEC VT240, VT330, and VT340 series of terminals. To output graphics to such terminals, issue the IDL command:

```
SET_PLOT, 'REGIS'
```

This causes IDL to use the Regis driver for producing graphical output.

## Defaults for Regis Devices

The default setting for Regis output is: VT340, 16 colors, 4 bits per pixel.

## Regis Limitations

- Four colors are available with VT240 and VT241 terminals, sixteen colors are available with the VT330 and VT340.
- Thick lines are emulated by filling polygons. There may be a difference in linestyle appearance between thick and normal lines.
- Image output is slow and is of poor quality, especially on the VT240 series. The VT240 is only able to write pixels on even numbered screen lines. IDL offers two methods of writing images to the 240:
  - Even and odd pairs of rows are averaged and written to the screen. An  $n, m$  image will occupy  $n$  columns and  $m$  screen rows. If this method is selected, graphics and image coordinates coincide. This method is the default (`AVERAGE_LINES = 1`). Routines that rely on a uniform graphics and image coordinate system, such as `SHADE_SURF`, work only in this mode.
  - Each line of the image is written to the screen, displaying every image pixel. An  $n, m$  image occupies  $2m$  lines on the screen. (`AVERAGE_LINES = 0`). Graphics and image coordinates coincide only at the lower left corner of the image.
- Pixel values cannot be read back from the terminal, rendering the `TVRD` function inoperable.

# The Tektronix Device

## Device Keywords Accepted by the REGIS Device:

`CLOSE_FILE`, `COLORS`, `FILENAME`, `GIN_CHARS`, `PLOT_TO`,  
`RESET_STRING`, `SET_CHARACTER_SIZE`, `SET_STRING`, `TEK4014`, `TEK4100`,  
`TTY`

The Tektronix 4000 (4010, 4014, etc.), 4100 and 4200 series of graphics terminals (and the multitude of terminals and microcomputers that emulate them) are among the most common graphics devices available. To use IDL graphics with such terminals, issue the command:

```
SET_PLOT, 'TEK'
```

This causes IDL to use the Tektronix driver for producing graphical output. Once the Tektronix driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, and to configure IDL for the specific features of your terminal. If you never call the `DEVICE` procedure, IDL assumes a plain vanilla Tektronix 4000 series compatible terminal. The 4200 series is upwardly compatible with the 4100 series; all references to the 4100 series also include the 4200 series. To set up IDL for use with a 4100 series compatible terminal with  $n$  colors, enter the following commands:

```
SET_PLOT, 'TEK'  
DEVICE, /TEK4100, COLORS = n
```

The number of colors should be set to  $2^B$  where  $B$  is the number of bit planes in your terminal. If you use a Tektronix compatible terminal that requires calling the `DEVICE` procedure for configuration, you should probably create and use a start-up procedure that calls the `DEVICE` procedure, as described in “[Startup Files](#)” in Chapter 1 of the *Using IDL* manual. Because of the tremendous variation among the requirements and abilities of these terminals, it is crucial that you configure IDL properly for your terminal. In particular, the mode switching character sequences, set by the keyword parameters `SET_STRING` and `RESET_STRING` must be set correctly.

## The DEVICE Procedure For Tektronix Terminals

The default setting for Tektronix output is: 10-bit coordinates, 4000 series terminals, and no use of color. The `DEVICE` keywords can be used to modify these defaults.

## Tektronix Limitations

- The line drawing procedures work with all models. Line style and color capabilities vary greatly among terminal models and/or emulation programs.
- Color and the display of images (albeit very slowly and frequently of a poor quality because of the small number of colors) is usable only with 4100 series terminals. Hardware polygon fill and thick lines do not work with the 4000 series.
- The image coordinate system does not match the graphics coordinate system. The graphics coordinates range from 0 to 3071 in Y, and from 0 to 4095 in X. Image coordinates vary according to terminal model. A typical range is from 0 to 479 in Y, and 0 to 639 in X. Because of this, the SHADE\_SURF procedure does not work with Tektronix terminals.

### Warning

---

Not all 4100 series terminals are capable of displaying images—the Tektronix pixel operations option is required. Many terminal emulators do not emulate this option. The Tektronix commands used to output images are: RU, begin pixel operations, RS, set pixel viewport, and RP, raster write. If your terminal or emulator does not accept these commands, you will not be able to display images.

---

- The Tektronix graphics protocol does not allow the specification of line thickness. Lines with a thickness more than 1.0 are drawn using polygon filling in the case of 4100 series terminals. With 4000 series terminals, thick lines are emulated by drawing multiple thin lines. This scheme will produce artifacts on some Tektronix emulating devices because of differing resolutions, normal line thicknesses and inexact coordinate conversions.

## Tektronix Device Limitations

Usage of Tektronix and Tektronix-compatible terminals with IDL has the following limitations:

- Image coordinates do not match the coordinates used by the rest of the graphic procedures. This is because no two models of Tektronix terminals are compatible. The graphics procedures utilize the default coordinate system of 1024 by 780, or 4096 by 3120 in the 12-bit mode. The size of the pixel memory and coordinate system vary widely between models. The *Position* parameter of the TV and TVSCL procedures does not work.

- The cursor can not be positioned from the computer meaning that the TVCRS procedure cannot be used with the Tektronix driver.
- Pixel values may not be read back from the terminal, rendering the TVRD function inoperable.

# The Microsoft Windows Device

## Device Keywords Accepted by the WIN Device:

BYPASS\_TRANSLATION, COPY, CURSOR\_CROSSHAIR,  
CURSOR\_ORIGINAL, CURSOR\_STANDARD, DECOMPOSED,  
GET\_CURRENT\_FONT, GET\_FONTNAMES, GET\_FONTNUM,  
GET\_GRAPHICS\_FUNCTION, GET\_SCREEN\_SIZE,  
GET\_WINDOW\_POSITION, PRINT\_FILE, RETAIN, SET\_CHARACTER\_SIZE,  
SET\_FONT, SET\_GRAPHICS\_FUNCTION, TRANSLATION, WINDOW\_STATE

The Microsoft Windows version of IDL uses the “WIN” device by default. This device is similar to the X Windows device described below. The “WIN” device is only available in IDL for Windows.

To set plotting to the Microsoft Windows device, use the command:

```
SET_PLOT, 'WIN'
```

# The X Windows Device

## Device Keywords Accepted by the X Device:

BYPASS\_TRANSLATION, COPY, CURSOR\_CROSSHAIR, CURSOR\_IMAGE, CURSOR\_MASK, CURSOR\_ORIGINAL, CURSOR\_STANDARD, CURSOR\_XY, DECOMPOSED, DIRECT\_COLOR, FLOYD, GET\_CURRENT\_FONT, GET\_FONTNAMES, GET\_FONTNUM, GET\_GRAPHICS\_FUNCTION, GET\_SCREEN\_SIZE, GET\_VISUAL\_NAME, GET\_WINDOW\_POSITION, GET\_WRITE\_MASK, ORDERED, PSEUDO\_COLOR, RETAIN, SET\_CHARACTER\_SIZE, SET\_FONT, SET\_GRAPHICS\_FUNCTION, SET\_TRANSLATION, SET\_WRITE\_MASK, STATIC\_COLOR, STATIC\_GRAY, THRESHOLD, TRUE\_COLOR, TTY, WINDOW\_STATE

X Windows is a network-based windowing system developed by MIT's project Athena. IDL uses the X System (often referred to simply as "X"), to provide an environment in which the user can create one or more independent windows, each of which can be used for the display of graphics and/or images.

In the X system, there are two basic cooperating processes: *clients* and *servers*. A server consists of a display, keyboard, and pointer (such as a mouse) as well as the software that controls them. Client processes (such as IDL) display graphics and text on the screen of a server by sending X protocol requests across the network to the server. Although in the most common case, the server and client reside on the same machine, this network based design allows much more elaborate configurations.

To use X Windows as the current graphics device, issue the IDL command:

```
SET_PLOT, 'X'
```

This causes IDL to use the X Window System for producing graphical output. Once the X driver is enabled via SET\_PLOT, the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the X Windows driver.

## X Windows Visuals

Visuals specify how the hardware deals with color. The X Window server (your display) may provide colors or only gray scale (black and white), or both. The color

tables may be changeable from within IDL (read-write), or may be fixed (read-only). The value of each pixel value may be mapped to any color (Un-decomposed Colormap), or certain bits of each pixel are dedicated to the red, green, and blue primary colors (Decomposed Colormap).

There are six X Windows visual classes—read-write and read-only visuals for three types of displays: Gray Scale, Pseudo Color, and Decomposed Color. The names of the visuals are shown in the following table:

Visual Name	Writable	Description
StaticGray	no	Gray scale
GrayScale	yes	Gray scale
StaticColor	no	Undecomposed color
PseudoColor	yes	Undecomposed color
TrueColor	no	Decomposed color
DirectColor	yes	Decomposed color

*Table A-17: X Windows Visual Classes*

IDL supports all six types of visuals, although not at all possible depths. UNIX X Window System users can use the command `xdpypinfo` to determine which visuals are supported by their systems.

Each X Window server has a default visual class. Many servers may provide multiple visual classes. For example, a server with display hardware that supports an 8-bit-deep, un-decomposed, writable color map (PseudoColor), may also easily provide StaticColor, StaticGray, and GrayScale visuals.

You can select the visual used by IDL using the DEVICE procedure before a window is created, or by including the resource `idl.gr_visual` in your X defaults file, as explained in [“Setting the X Window Defaults”](#) on page 4770.

## How IDL Selects a Visual Class

When opening the display, IDL asks the display for the following visuals, in order, until a supported visual class is found:

1. TrueColor, 24-bit, then 16-bit, then 15-bit
2. PseudoColor, 8-bit, then 4-bit
3. DirectColor, 24-bit

4. StaticColor, 8-bit, then 4-bit
5. GrayScale, any depth
6. StaticGray, any depth

You can override this behavior by using the `DEVICE` routine to specify the desired visual class and depth before you create a window. For example, if you are using a display that supports both the TrueColor, 24-bit-deep visual, and an 8-bit-deep PseudoColor visual, IDL will select the 24-bit-deep TrueColor visual. To instead use PseudoColor, issue the following command before creating a window:

```
DEVICE, PSEUDO_COLOR = 8
```

The colormap/visual class combination is chosen when IDL first connects with the X Window server. Note that if you connect with the X server by creating a window or using the `DEVICE` keyword to the `HELP` procedure, the visual class will be set; it then cannot be changed until IDL is restarted. If you wish to use a visual class other than the default, be sure to set it with a call to the `DEVICE` procedure *before* creating windows or otherwise connecting with the X Window server.

Windows are created in two ways:

1. Using the `WINDOW` procedure. `WINDOW` allows you to explicitly control many aspects of how the window is created.
2. If no windows exist and a graphics operation requiring a window is executed, IDL implicitly creates window 0 with the default characteristics.

Once the visual class is selected, all subsequently-created windows share the same class and colormap. The number of simultaneous colors available is stored in the system variable `!D.N_COLORS`. The visual class and number of colors, once initialized, cannot be changed without first exiting IDL.

## How IDL Obtains a Colormap

IDL chooses the type of colormap in the following manner:

- By default, the shared colormap is used whenever possible (i.e., whenever IDL is using the default visual for the system). All available colors from the shared colormap are allocated for use by IDL. This is what happens when no window currently exists and a graphics operation causes IDL to implicitly create one.
- If the number of colors to use is explicitly specified using the `COLORS` keyword with the `WINDOW` procedure, IDL attempts to allocate the number of colors specified from the shared colormap using the default visual of the screen. If there aren't enough colors available, a private colormap with that number of colors is used instead.

- Specifying a negative value for the `COLORS` keyword to the `WINDOW` procedure causes IDL to attempt to use the shared colormap, allocating all but the specified number of colors. For example:

```
WINDOW, COLORS = -8
```

allocates all but 8 of the currently available colors. This allows other applications that might need their own colors to run in tandem with IDL.

- If a visual type and depth is specified, via the `DEVICE` procedure, which does not match the default visual of the screen, a new, private, colormap is created.

## Using Color Under X

Colormaps define the mapping from color index to screen color. Two attributes of colormaps are important to the IDL user: they may be *private* or *shared*; and they may be *static* or *writable*. These different types of colormaps are described below.

### Shared Colormaps

The window manager creates a colormap when it is started. This is known as the default colormap, and can be shared by most applications using the display. When each application requires a colormap entry (i.e., a mapping from a color index to a color), it allocates one from this shared table. Advantages and disadvantages of shared colormaps include:

- Using the shared colormap ensures that all applications share the available colors without conflict. A given application will not change a color that is allocated to a different application. In the case of IDL it means that IDL can change the colors it has allocated without changing the colors in use by the window manager or other applications.
- The window system interface routines must translate between the actual and allocated pixel values, significantly slowing the transfer of images.
- The shared colormap might not have enough colors available to perform the desired operations with IDL.
- The number of available colors in the shared colormap depends on the window manager in use and the demands of other applications. Thus, the number of available colors can vary.
- The allocated colors in a shared colormap do not generally start at zero and they are not necessarily contiguous. This makes it difficult to use the write mask for certain operations.

## Private Colormaps

An application can create its own private color map. Most hardware can only display a single colormap at a time, so these private colormaps are called virtual color maps, and only one at a time is actually in use and visible. When the window manager gives the color focus to a window with a private colormap, the X window system loads its virtual colormap into the hardware colormap.

- Every color index supported by the hardware is available to IDL, improving the quality of images.
- Allocated colors always start at zero and are contiguous. This simplifies using the write mask.
- No translation between internal pixel values and the values required by the server is required, making the transfer of images more efficient.
- When the IDL colormap is loaded, other applications are displayed using the wrong colors. Furthermore, colors from the shared colormap are usually allocated from the lower end of the map first. These are the colors allocated by the window manager for such things as window borders, the color of text, and so forth. Since most IDL colormaps have very dark colors in the lower entries, the end effect with the IDL colormap loaded is that the non-IDL portions of the screen go blank.

## Static Colormaps

As mentioned above, the contents of static colormaps are determined outside of IDL and cannot be changed. When using a static colormap, the TVLCT procedure simulates writable colormaps by finding the closest RGB color entry in the colormap to the requested color. The colormap translation table is then set to map IDL color indices to those of the closest colors in the colormap.

The colors present in the colormap may, and probably will, *not* match the requested colors exactly. For example, with a typical static color map, loading the IDL standard color table number 0, which consists of 256 intensities of gray, results in only 8 or 16 distinct intensities.

With static colormaps, loading a new color table does not affect the appearance of previously written objects. The internal translation tables are modified, which only affects objects that are subsequently written.

## Color Translation

As mentioned above, colors from the shared colormap do not necessarily start from index zero, and are not necessarily contiguous. IDL preserves the illusion of a zero

based contiguous colormap by maintaining a translation table between user color indices, which range from 0 to !D.TABLE\_SIZE, and the actual pixel values allocated from the X server. Normally, the user need not be concerned with this translation table, but it is available using the statement:

```
DEVICE, TRANSLATION=T
```

This statement stores the current translation table, a 256 element byte vector, in the variable T. Element zero of the vector contains the value pixel allocated for the zeroth color in the IDL colormap, and so forth. In the case of a private colormap, each element of the translation vector contains it's own index value, because private colormaps start at zero and are contiguous.

The translation table may be bypassed, allowing direct access to the display's color indices, by setting the BYPASS\_TRANSLATION keyword in the DEVICE procedure.

```
DEVICE, /BYPASS_TRANSLATION
```

Translation can be reestablished by setting the keyword to zero:

```
DEVICE, BYPASS_TRANSLATION=0
```

By default, the color translation tables are bypassed if the visual type is TrueColor or the visual type is DirectColor with a private colormap.

## Using Pixmaps

X Windows can direct graphics to *windows* or *pixmaps*. Windows are the usual windows that appear on the screen and contain graphics. Pixmaps are invisible graphics memory contained in the server. Drawing to a window produces a viewable result, while drawing to a pixmap simply updates the pixmap memory.

Pixmaps are useful because it is possible to write graphics to a pixmap and then copy the contents of the pixmap to a window where it can be viewed. Furthermore, this copy operation is very fast because it happens entirely within the server. Provided enough pixmap memory is available, this technique works very well for animating a series of images by placing the images into pixmap memory and then sequentially copying them to a visible window.

To create a pixmap, use the PIXMAP keyword with the WINDOW procedure. For example, to create a square pixmap with 128 pixels per side as IDL window 1, use the command:

```
WINDOW, 1, /PIXMAP, XSIZE=128, YSIZE=128
```

Once they are created, pixmaps are treated just like normal windows, although some operations (WSHOW for instance) don't do anything useful when applied to a pixmap.

The following procedure shows how animation can be done using pixmap memory. It uses a series of 15 heart images taken from the file `abnorm.dat`. This file is supplied with all IDL distributions in the `examples/data` subdirectory of the main IDL directory. It creates a pixmap and writes the heart images to it. It then uses the COPY keyword of the DEVICE procedure to copy the images to a visible window. Pressing any key causes the display process to halt:

```

; Animate heart series:
PRO animate_heart
; Open the file containing the images:
OPENR, u, FILEPATH('abnorm.dat', SUBDIR = ['examples','data']), $
  /GET_LUN
; Associate a file variable with the file. Each heart image
; is 64x64 pixels:
frame = ASSOC(u, BYTARR(64,64))
; Window 0 is a pixmap which is 4 images tall and 4
; images wide. The images will be placed in this pixmap:
WINDOW, 0, /PIXMAP, XSIZE = 512, YSIZE = 512, /FREE
; Write each image to the pixmap. SMOOTH is used to improve
; the appearance of each image and REBIN is used to
; enlarge/shrink each image to the final display size:
FOR i=0, 15-1 DO TV, REBIN(SMOOTH(frame[i],3), 128, 128),i
; Close the image file and free the file unit:
FREE_LUN, u
; The visible window will be used to display the animated heart
; cycle:
WINDOW, XSIZE = 128, YSIZE=128, TITLE='Heart', /FREE
; Current frame number:
i = 0L
; Display frames until any key is pressed:
WHILE GET_KBRD(0) EQ '' DO BEGIN
; Compute x and y locations of pixmap image's lower left corner:
  x = (i mod 4) * 128 & y = 384 - (i/4) * 128
; Copy the next image from the pixmap to the visible window:
DEVICE, COPY = [x, y, 128, 128, 0, 0, 0]
; Keep track of total frame count:
i = (i + 1) MOD 15
ENDWHILE
END

```

Animation sequences with more and/or larger images can be made. See the documentation for the XANIMATE procedure, which is a more generalized embodiment of the above procedure.

**Note**

---

Some X Windows servers will refuse to create a pixmap that is larger than the physical screen in either dimension.

---

**Note**

---

Excessive pixmap allocation can exhaust virtual storage, causing some X Windows servers to become unresponsive.

---

## How Color is Interpreted for a TrueColor Visual

How a color (such as !P.COLOR) is interpreted by IDL (when a TrueColor visual is being utilized) depends in part upon the decomposed setting for the device.

To retrieve the decomposed setting:

```
DEVICE, GET_DECOMPOSED = currentDecomposed
```

To set the decomposed setting:

```
DEVICE, DECOMPOSED = newDecomposed
```

If the decomposed value is zero, colors (like !P.COLOR) are interpreted as indices into IDL's color table. A color should be in the range from 0 to !D.TABLE\_SIZE - 1. The IDL color table contains a red, green, and blue component at a given index; each of these components is in the range of 0 up to 255.

**Note**

---

IDL's color table does not map directly to a hardware color table for a TrueColor visual. If IDL's color table is modified, for example using the LOADCT or TVLCT routines, then the new color table will only take effect for graphics that are drawn after it has been modified.

---

If the decomposed value is non-zero, colors (like !P.COLOR) are interpreted as a combination of red, green, and blue settings. The least significant 8 bits contain the red component, the next 8 bits contain the green component, and the most significant 8 bits contain the blue component.

In either case, the most significant bits of each of the resulting red, green, and blue components are utilized. The number of bits utilized per component depends upon the red, green, and blue masks for the visual. On UNIX systems, a new field (Bits Per RGB) has been added to the output from HELP, /DEVICE. This Bits Per RGB field indicates the amount of bits utilized for each component.

**Tip**

---

The UNIX command `xdpinfo` also provides information about each of the visuals.

---

## Setting the X Window Defaults

You can set the initial default value of the following parameters by setting resources in the file `.Xdefaults` file in your home directory as follows:

Resource Name	Description
<code>idl.colors</code>	The number of colors used by IDL.
<code>idl.gr_depth</code>	The depth, in bits, of the visual used by IDL.
<code>idl.retain</code>	The default setting for the <code>retain</code> parameter: 0=none, 1= by server, 2=by IDL.
<code>idl.gr_visual</code>	The type of visual: StaticGray, GrayScale, StaticColor, PseudoColor, TrueColor, or DirectColor.

*Table A-18: IDL/ X Window Defaults*

For example, to set the default visual to PseudoColor, and to allocate 100 colors, insert the following lines in your defaults file:

```
idl.gr_visual: PseudoColor
idl.colors: 100
```

# The Z-Buffer Device

## Device Keywords Accepted by the Z Device:

`CLOSE`, `GET_GRAPHICS_FUNCTION`, `GET_WRITE_MASK`,  
`SET_CHARACTER_SIZE`, `SET_COLORS`, `SET_FONT`,  
`SET_GRAPHICS_FUNCTION`, `SET_RESOLUTION`, `Z_BUFFERING`

The IDL Z-buffer device is a pseudo device that draws 2-D or 3-D graphics in a buffer contained in memory. This driver implements the classic Z buffer algorithm for hidden surface removal. Although primarily used for 3-D graphics, the Z-buffer driver can be used to create 2-D objects in a frame buffer in memory. The resolution of this device can be set by the user.

All of the IDL plotting and graphics routines work with the Z-buffer device driver. In addition, the `POLYFILL` procedure has a few keyword parameters, allowing Gouraud shading and warping images over 3-D polygons, that are only effective when used with the Z-buffer.

When used for 3-D graphics, two buffers are present: an 8-bit-deep frame buffer that contains the picture; and a 16-bit-deep Z-buffer of the same resolution, containing the z-value of the visible surface of each pixel. The Z-buffer is initialized to the depth at the back of the viewing volume. When objects are drawn, the z-value of each pixel is compared with the value at the same location in the Z-buffer, and if the z-value is greater (closer to the viewer), the new pixel is written in the frame buffer and the Z-buffer is updated with the new z-value.

The Z-buffer device is a “pseudo device” in that drawing commands update buffers in memory rather than sending commands to a physical device or file. The `TVRD` function reads the contents of either buffer to an IDL array. This array may then be further processed, written to a file, or output to a raster-based graphics output device.

The Z-buffer driver can be used for 2-D graphics by disabling the depth computations.

To use the Z-buffer as the current graphics device, issue the IDL command:

```
SET_PLOT, 'Z'
```

Once the Z-buffer driver is enabled the `DEVICE` procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the Z-buffer driver and the amount of memory used for the buffers.

## Reading and Writing Buffers

The contents of both buffers are directly accessed by the TV and TVRD routines. The frame buffer that contains the picture is 8 bits deep and is accessed as channel 0. The Z depth buffer contains 16 bit integers and is accessed as channel 1. Always use CHANNEL=1 and set the keyword WORDS when reading or writing the depth buffer.

The normal procedure is to set the graphics device to “Z”, draw the objects, read the frame buffer, and then select another graphics device and write the image. For example, to create an image with the Z-buffer driver and then display it on an X-Window display:

```

; Select Z-buffer device:
SET_PLOT, 'Z'
; Write objects to the frame buffer using normal graphics
; routines, e.g. PLOT, SURFACE, POLYFILL
... ..
; Read back the entire frame buffer:
a=TVRD()
; Select X Windows:
SET_PLOT, 'X'
; Display the contents of the frame buffer:
TV, a

```

To read the depth values in the Z-buffer, use the command:

```
a = TVRD(CHANNEL=1, /WORDS)
```

To write the depth values, use the command:

```
TV, a, /WORDS, CHANNEL=1
```

The TV, TVSCL, and TVRD routines write or read pixels directly to a rectangular area of the designated buffer without affecting the other buffer.

## Z-Axis Scaling

The values in the depth buffer are short integers, scaled from -32765 to +32765, corresponding to normalized Z-coordinate values of 0.0 to 1.0.

## Polyfill Procedure

The following POLYFILL keywords are active only with the Z-buffer device: IMAGE\_COORDINATES, IMAGE\_INTERPOLATE, and TRANSPARENT. These

parameters allow images, specified via the PATTERN keyword, to be warped over 2-D and 3-D polygons.

The IMAGE\_COORDINATES keyword contains a 2 by  $N$  array containing the image space coordinates that correspond to each of the  $N$  vertices of the polygon. The IMAGE\_INTERPOLATE keyword indicates that bilinear interpolation is to be used, rather than the default nearest neighbor sampling. Pixels less than the value of TRANSPARENT are not drawn, simulating transparency. For Gouraud shading of polygons, the COLOR keyword can contain an array specifying the color index for each polygon vertex.

## Examples Using the Z-Buffer

This example forms a Bessel function, draws its shaded surface and overlays its contour, using the Z-buffer as shown in the following figure. The final output is directed to PostScript.

```

; Select the Z-buffer:
SET_PLOT, 'Z'
n = 50 ; Size of array for Bessel
; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)
; Draw the surface, label axes in black, background in white:
SHADE_SURF, a, /SAVE, COLOR=1, BACKGROUND=255
nlev = 8 ; Number of contour levels
; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
    LEVELS= FINDGEN(nlev)*1.5/nlev-.5, COLOR=1
; Read image:
b=TVRD()
; Select PostScript output:
SET_PLOT, 'PS'
; Output the image:
TV, b
; Close the new PostScript file:
DEVICE, /CLOSE

```

Figure A-7: Combined Shaded Surface and Contour Plot

The following example warps an image to a cube as shown in the figure below. The lower two quadrants of the image are warped to the front two faces of the cube. The upper-right quadrant is warped to the top face of the cube. The image is held in the array `a`, with dimensions `nx` by `ny`. The image is then output to PostScript as in the previous example.

```

; Select the Z-buffer:
SET_PLOT, 'Z'
; Make a white background for final output to PostScript:
ERASE, 255
; Establish 3-D scaling as (0,1) cube:
SCALE3, XRANGE=[0,1], YRANGE=[0,1], ZRANGE=[0,1]
; Define vertices of cube. Vertices 0-3 are bottom, 4-7 are top:
verts = [[0,0,0], [1,0,0], [1,1,0], [0,1,0], $
         [0,0,1], [1,0,1], [1,1,1], [0,1,1]]
; Fill lower left face:
POLYFILL, verts[*], [3,0,4,7]], /T3D, PATTERN=a, $
         IMAGE_COORD=[0,0], [nx/2,0], [nx/2,ny/2], [0,ny/2]]
; Fill lower right face:
POLYFILL, verts[*], [0,1,5,4]], /T3D, PATTERN=a, $
         IMAGE_COORD=[nx/2,0], [nx-1,0], $
         [nx-1,ny/2], [nx/2,ny/2]]
; Fill top face:
POLYFILL, verts[*], [4,5,6,7]], /T3D, PATTERN=a, $
         IMAGE_COORD = [[nx/2,ny/2], [nx-1,ny/2], $
         [nx-1,ny-1], [nx/2,ny-1]]
; Draw edges of cube in black:
PLOTS, verts[*], [0,4]], /T3D, COLOR=0

```

```
; Edges of top face:  
PLOTS, verts[*], [4,5,6,7,4]], /T3D, COLOR=0
```

*Figure A-8: Image Warped to a Cube Using the Z-Buffer*

## Appendix B

# Graphics Keywords

The IDL Direct Graphics routines, `CURSOR`, `ERASE`, `PLOTS`, `POLYFILL`, `TV` (and `TVSCL`), `TVCRS`, `TVRD`, and `XYOUTS`, and the plotting procedures, `AXIS`, `CONTOUR`, `PLOT`, `OPLOT`, `SHADE_SURF`, and `SURFACE`, accept a number of common keywords. Therefore, instead of describing each keyword along with the description of each routine, this section contains a brief summary of each graphics keyword. Routine-specific keywords are documented in the description of the routine. The graphics keywords are described below. The name of each keyword is followed by a list of routines that accept that keyword. Keywords that have a direct correspondence to fields in a system variable (usually `!P`) are also indicated.

The keywords that control the plot axes are prefixed with the character ‘X’, ‘Y’, or ‘Z’ depending on the axis in question. These keywords correspond to fields in the axis system variables: `!X`, `!Y`, and `!Z`, and are described in more detail in [“Graphics System Variables”](#) on page 4823. The axis keywords are shown in the form `[XYZ]NAME`. For example, `[XYZ]CHARSIZE` refers to the three keywords `XCHARSIZE`, `YCHARSIZE`, and `ZCHARSIZE`, which control the size of the characters annotating the three axes.

The system variable fields that control this are !X.CHAR.SIZE, !Y.CHAR.SIZE, and !Z.CHAR.SIZE.

The following graphics keywords are discussed in this appendix:

BACKGROUND	ORIENTATION	[XYZ]STYLE
CHANNEL	POSITION	[XYZ]THICK
CHARSIZE	PSYM	[XYZ]TICK_GET
CHARTHICK	SUBTITLE	[XYZ]TICKFORMAT
CLIP	SYMSIZE	[XYZ]TICKINTERVAL
COLOR	T3D	[XYZ]TICKLAYOUT
DATA	THICK	[XYZ]TICKLEN
DEVICE	TICKLEN	[XYZ]TICKNAME
FONT	TITLE	[XYZ]TICKS
LINESTYLE	[XYZ]CHARSIZE	[XYZ]TICKUNITS
NOCLIP	[XYZ]GRIDSTYLE	[XYZ]TICKV
NODATA	[XYZ]MARGIN	[XYZ]TITLE
NOERASE	[XYZ]MINOR	Z
NORMAL	[XYZ]RANGE	ZVALUE

## BACKGROUND

Accepted by: **CONTOUR**, **PLOT**, **SURFACE**.

System variable equivalent: !P.**BACKGROUND**.

The background color index to which all pixels are set when erasing the screen or page. The default is 0 (black). Not all devices support erasing the background to a specified color index.

For example, to produce a black plot with a white background on a color display:

```
PLOT, Y, BACKGROUND = 255, COLOR = 0
```

---

### Warning

If the **NOERASE** keyword (or !P.**NOERASE**) is set, the value of the **BACKGROUND** keyword (or !P.**BACKGROUND**) is ignored.

---

## CHANNEL

Accepted by: [ERASE](#), [TV](#), [TVRD](#). System variable equivalent: `!P.CHANNEL`.

This keyword specifies the memory channel for the operation. This parameter is ignored on display systems that have only one memory channel. When using a “decomposed” display system, the red channel is 1, the green channel is 2, and the blue channel is 3. Channel 0 indicates all channels. If omitted, `!P.CHANNEL` contains the default channel value.

---

### Note

`CONTOUR`, `PLOT`, `SHADE_SURF`, and `SURFACE` also accept the `CHANNEL` keyword, but simply pass it to `ERASE`.

---

## TrueColor Images

Images can be transferred to and from the display in either 8-bit or 24-bit mode. The `CHANNEL` parameter specifies the source or destination channel number for 8-bit images, and the `TRUE` keyword (see “[TrueColor Images](#)” on page 4746) indicates for 24-bit images the method of channel interleaving. If neither keyword parameter is present, the 8-bit image is written to all three-color channels, yielding the same effect as if the channel parameter is specified as 0.

For example, to transfer three 8-bit images contained in the arrays `R`, `G`, and `B` to their respective channels, use the following statements:

```
;Load red in channel 1:
TV, R, 0, 0, 1
;Load green in channel 2:
TV, G, 0, 0, 2
;Load blue in channel 3:
TV, B, 0, 0, 3
```

The position parameters (0, 0 above) can be altered to write to any location in the window.

## CHARSIZE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: `!P.CHARSIZE`.

The overall character size for the annotation when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. A `CHARSIZE` of 1.0 is normal. The size of the annotation on the axes may be set,

relative to CHAR.SIZE, with  $x$ CHAR.SIZE, where  $x$  is X, Y, or Z. The main title is written with a character size of 1.25 times this parameter.

## CHARTHICK

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#), [XYOUTS](#).  
System variable equivalent: !P.CHARTHICK.

An integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

## CLIP

Accepted by: [CONTOUR](#), [DRAW\\_ROI](#), [OPLLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: !P.CLIP.

The coordinates of a rectangle used to clip the graphics output. The rectangle is specified as a vector of the form  $[X_0, Y_0, X_1, Y_1]$ , giving coordinates of the lower left and upper right corners, respectively. The default clipping rectangle is the plot window, the area enclosed within the axes of the most recent plot. Coordinates are specified in data units unless an overriding coordinate unit specification keyword is present (i.e., NORMAL or DEVICE). If the clipping is provided in data or normalized units, the actual clipping rectangle is computed by converting those values to device units. The clipping itself always occurs in device space.

### Note

---

The default is not to clip the output of PLOTS and XYOUTS. To enable clipping include the keyword parameter NOCLIP = 0. With PLOTS, POLYFILL, and XYOUTS, this keyword controls the clipping of vectors and vector-drawn text.

---

For example, to draw a vector using normalized coordinates with its contents clipped within a rectangle covering the upper left quadrant of the display:

```
PLOTS, X, Y, CLIP=[0.,.5,.5,1.0], /NORM, NOCLIP=0
```

## COLOR

Accepted by: [AXIS](#), [CONTOUR](#), [DRAW\\_ROI](#), [ERASE](#), [OPLLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE\\_SURF](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: !P.COLOR.

The color index of the data, text, line, or solid polygon fill to be drawn. If this keyword is omitted, !P.COLOR specifies the color index.

When used with the PLOTS, POLYFILL, or XYOUTS procedure, this keyword parameter can be set to a vector to specify multiple color indices.

Gouraud shading of polygons is performed with the Z-buffer graphics output device and POLYFILL procedure when COLOR contains an array of color indices, one for each vertex.

## DATA

Accepted by: [AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW\\_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE\\_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the data coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

## DEVICE

[AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW\\_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE\\_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the device coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

For example, the following code displays an image contained in the variable A and then draws a contour plot of pixels [100:499, 100:399] over the correct section of the image:

```
;Display the image.
TV,A

;Draw the contour plot, specify the coordinates of the plot, in
;device coordinates, do not erase, set the X and Y axis styles to
;EXACT.
CONTOUR, A[100:499, 100:399], $
      POS = [100,100, 499,399], /DEVICE, $
      /NOERASE, XSTYLE=1, YSTYLE=1
```

Note that in the above example, the keyword specification /DEVICE is equivalent to DEVICE = 1.

## FONT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#), [XYOUTS](#).  
System variable equivalent: !P.FONT.

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to select the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See [Appendix H, “Fonts”](#) for a complete description of IDL’s font systems.

## LINestyle

Accepted by: [DRAW\\_ROI](#), [OPLot](#), [PLOT](#), [PLOTS](#), [SURFACE](#). System variable equivalent: `!P.LINestyle`.

This keyword indicates the line style used to draw lines; it indicates the line style of the lines used to connect the data points. This keyword should be set to the appropriate index for the desired linestyle as described in the following table.

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

*Table B-19: IDL Linestyles*

## NOCLIP

Accepted by: [CONTOUR](#), [DRAW\\_ROI](#), [OPLot](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: `!P.NOCLIP`.

Set this keyword to suppress clipping of the plot. The clipping rectangle is contained in `!P.CLIP`. By default, the plot is clipped within the plotting window.

### Note

The default value is clipping-disabled for `PLOTS`, `POLYFILL`, and `XYOUTS`. For all other routines, the default is to enable clipping.

With `PLOTS`, `POLYFILL`, and `XYOUTS`, this keyword controls the clipping of vectors and vector-drawn text. The default is to disable clipping, so to enable clipping

include the parameter `NOCLIP = 0`. To explicitly disable clipping set this parameter to one.

## NODATA

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#).

If this keyword is set, only the axes, titles, and annotation are drawn. No data points are plotted.

For example, to draw an empty set of axes between some given values:

```
PLOT, [XMIN, XMAX], [YMIN, YMAX], /NODATA
```

## NOERASE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SURFACE](#). System variable equivalent: `!P.NOERASE`.

Specifies that the screen or page is not to be erased. By default, the screen is erased, or a new page is begun, before a plot is produced.

### Warning

---

If the `NOERASE` keyword (or `!P.NOERASE`) is set, the value of the [BACKGROUND](#) keyword (or `!P.BACKGROUND`) is ignored.

---

## NORMAL

Accepted by: [AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW\\_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE\\_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the normalized coordinate system, and range from 0.0 to 1.0. The default coordinate system is `DATA` if no other coordinate-system specifications are present.

## ORIENTATION

Accepted by: [DRAW\\_ROI](#), [POLYFILL](#), [XYOUTS](#).

Specifies the counterclockwise angle in degrees from horizontal of the text baseline and the lines used to fill polygons. When used with the `POLYFILL` procedure, this keyword forces the “linestyle” type of fill, rather than solid or patterned fill.

## POSITION

Accepted by: [CONTOUR](#), [MAP\\_SET](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `!P.POSITION`.

Allows direct specification of the plot window. `POSITION` is a 4-element vector giving, in order, the coordinates  $[(X_0, Y_0), (X_1, Y_1)]$ , of the lower left and upper right corners of the data window. Coordinates are expressed in normalized units ranging from 0.0 to 1.0, unless the `DEVICE` keyword is present, in which case they are in actual device units. The value of `POSITION` is never specified in data units, even if the `DATA` keyword is present.

When setting the position of the window, be sure to allow space for the annotation, which resides outside the window. IDL outputs the message “% Warning: Plot truncated.” if the plot region is larger than the screen or page size. The plot region is the rectangle enclosing the plot window and the annotation.

When plotting in three dimensions, the `POSITION` keyword is a 6-element vector with the first four elements describing, as above, the XY position, and with the last two elements giving the minimum and maximum Z coordinates. The Z specification is always in normalized coordinate units.

When making more than one plot per page it is more convenient to set `!P.MULTI` than to manipulate the position of the plot directly with the `POSITION` keyword.

For example, the following statement produces a contour plot with data plotted in only the upper left quarter of the screen:

```
CONTOUR, Z, POS=[0., 0.5, 0.5, 1.0]
```

Because no space on the left or top edges was allowed for the axes or their annotation, the above described warning message results.

See “[Specifying the Location of the Plot](#)” on page 1677 for more information.

## PSYM

Accepted by: [DRAW\\_ROI](#), [OPLLOT](#), [PLOT](#), [PLOTS](#). System variable equivalent: `!P.PSYM`.

The symbol used to mark each data point. Normally, `PSYM` is 0, data points are connected by lines, and no symbols are drawn to mark the points. Set this keyword, or the system variable `!P.PSYM`, to the symbol index as shown in the table below to

mark data points with symbols. The keyword SYMSIZE is used to set the size of the symbols.

PSYM Value	Plotting Symbol
1	Plus sign (+)
2	Asterisk (*)
3	Period (.)
4	Diamond
5	Triangle
6	Square
7	X
8	User-defined. See <a href="#">USERSYM</a> procedure.
9	Undefined
10	Histogram mode. Horizontal and vertical lines connect the plotted points, as opposed to the normal method of connecting points with straight lines. See <a href="#">“Histogram Mode”</a> on page 4786 for an example.

*Table B-20: Values for the PSYM Keyword*

Negative values of PSYM cause the symbol designated by PSYM to be plotted at each point with solid lines connecting the symbols. For example, a value of -5 plots triangles at each data point and connects the points with lines. Histogram mode is the exception to this rule; since the points are already connected when PSYM=10, specifying the value -10 is meaningless, and will result in an error.

The following IDL code plots an array using points, and then overplots the smoothed array, connecting the points with lines:

```
;Plot using points.
PLOT, A, PSYM=3

;Overplot smoothed data.
OPLOT, SMOOTH(A,7)
```

See [“Plotting Symbols”](#) on page 1669 for another example.

## Histogram Mode

Using the keyword PSYM=10 with the PLOT routines draws graphs in the histogram mode, connecting points with vertical and horizontal lines. This next figure illustrates the comparison between the distribution of the IDL normally distributed random number function (RANDOMN) to the theoretical normal distribution.

*Figure B-9: Histogram Mode*

The plot was produced by the following IDL commands:

```

; Two-hundred values ranging from -5 to 4.95:
X = FINDGEN(200) / 20. - 5.
; Theoretical normal distribution, scale so integral is one:
Y = 1/SQRT(2.*!PI) * EXP(-X^2/2) * (10./200)
; Approximate normal distribution with RANDOMN,
; then form the histogram.
H = HISTOGRAM(RANDOMN(SEED, 2000), $
BINSIZE = 0.4, MIN = -5., MAX = 5.)/2000.
; Plot the approximation using "histogram mode."
PLOT,FINDGEN(26) * 0.4 - 4.8, H, PSYM = 10
; Overplot the actual distribution:
OPLLOT, X, Y * 8.

```

## SUBTITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `!P.SUBTITLE`.

A text string to be used as a subtitle for the plot. Subtitles appear below the X axis.

## SYMSIZE

Accepted by: [DRAW\\_ROI](#), [OPLOTT](#), [PLOT](#), [PLOTS](#).

Specifies the size of the symbols drawn when PSYM is set. The default size of 1.0 produces symbols approximately the same size as a character.

## T3D

Accepted by: [AXIS](#), [CONTOUR](#), [DRAW\\_ROI](#), [MAP\\_SET](#), [OPLOTT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE\\_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#). System variable equivalent: `!P.T3D`.

Set this keyword to indicate that the generalized transformation matrix in `!P.T` is to be used. If not present, the user-supplied coordinates are simply scaled to screen coordinates. See the examples in the description of the `SAVE` keyword.

### Note

---

Since T3D uses the transformation matrix in `!P.T`, it is important that `!P.T` contain a valid transformation matrix. This can be achieved in several ways:

---

- Use the `SAVE` keyword to save the transformation matrix from an earlier graphics operation.
- Establish a transformation matrix using the `T3D`, `SURFR`, or, `SCALE3` procedures.
- Set the value of `!P.T` directly.

## THICK

Accepted by: [AXIS](#), [DRAW\\_ROI](#), [OPLOTT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `!P.THICK`.

Indicates the line thickness. `THICK` overrides the setting of `!P.THICK`.

## TICKLEN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `!P.TICKLEN`.

Controls the length of the axis tick marks, expressed as a fraction of the window size. The default value is 0.02. `TICKLEN` of 1.0 produces a grid, while a negative `TICKLEN` makes tick marks that extend outside the window, rather than inwards. A value of -0.02 makes tick marks that extend away from the plot. Individual axis ticks can be controlled with the `[XYZ]TICKLEN` keyword.

For example, to produce outward-going tick marks of the normal length:

```
PLOT, X, Y, TICKLEN = -0.02
```

To provide a new default tick length, set `!P.TICKLEN`.

## TITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `!P.TITLE`.

Produces a main title centered above the plot window. The text size of this main title is larger than the other text by a factor of 1.25. For example:

```
PLOT, X, Y, TITLE = 'Final Results'
```

## [XYZ]CHARSIZE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalents: `![XYZ].CHARSIZE`.

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor set by `!P.CHARSIZE` or the keyword `CHARSIZE`.

## [XYZ]GRIDSTYLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#)

The index of the linestyle to be used for plot tickmarks and grids (i.e., when `[XYZ]TICKLEN` is set to 1.0). See [LINESTYLE](#) for a list of linestyles.

## [XYZ]MARGIN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].MARGIN`.

A 2-element array specifying the margin on the left and right sides (XMARGIN) or the top and bottom (YMARGIN) of the plot window, in units of character size. Default margins are 10 and 3 for the  $x$ -axis, and 4 and 2 for the  $y$ -axis. The ZMARGIN keyword is present for consistency and is currently ignored.

## [XYZ]MINOR

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].MINOR`.

The number of minor tick mark intervals. If set to zero, the default, IDL automatically determines the number of minor ticks in each major tick-mark interval. Setting this parameter to 1 suppresses the minor ticks, and setting it to a positive, nonzero number,  $n$ , produces  $n$  minor-tick intervals, and  $n-1$  minor-tick marks.

## [XYZ]RANGE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].RANGE`.

The desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. IDL will frequently round this range. This override can be defeated using the [XYZ]STYLE keywords.

See “[Range Keyword](#)” on page 1667 for an example.

## [XYZ]STYLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].STYLE`.

This keyword allows specification of axis options such as rounding of tick values and selection of a box axis. Each option is described in the following table:

Value	Description
1	Force exact axis range.

Table B-21: Values for the [XYZ]STYLE Keyword

Value	Description
2	Extend axis range.
4	Suppress entire axis
8	Suppress box style axis (i.e., draw axis on only one side of plot)
16	Inhibit setting the Y axis minimum value to 0 (Y axis only)

*Table B-21: Values for the [XYZ]STYLE Keyword*

Note that this keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the XAXIS keyword to 1+8, or 9.

## [XYZ]THICK

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].**THICK**.

This keyword controls the thickness of the lines forming the *x*, *y*, or *z* axes and their tick marks. A value of 1.0 is the default.

## [XYZ]TICK\_GET

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#).

A named variable in which to return the values of the tick marks for the designated axis. The result is a double precision floating-point array with the same number of elements as ticks.

For example, to retrieve in the variable *V* the values of the tick marks selected by IDL for the *Y* axis:

```
PLOT, X, Y, YTICK_GET = V
```

## [XYZ]TICKFORMAT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].**TICKFORMAT**.

Set this keyword to a string or a vector of strings. The string can be a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels. If a vector is provided, each string corresponds to a level of the axis. The [\[XYZ\]TICKUNITS](#) keyword determines the number of levels for an axis.

Each string is one of the following:

### A format code:

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual for more information on format codes.

**Example 1:** Display the X axis tick values using a format of F6.2 (six characters, with 2 places after the decimal point):

```
PLOT, X, Y, XTICKFORMAT='(F6.2)'
```

**Example 2:** Display the Y tick values using the “dollars and cents” format \$*dddd.dd*:

```
PLOT, X, Y, YTICKFORMAT='("$", F7.2)'
```

### The string 'LABEL\_DATE' :

Set [XYZ]TICKFORMAT to the string 'LABEL\_DATE' to create axes with date labels. The formatting of the labels is specified by first calling LABEL\_DATE with the DATE\_FORMAT keyword. See [LABEL\\_DATE](#) for more information.

**Example:** Use the LABEL\_DATE function as the callback function to display the X tick values in a date/time format:

```
dummy = LABEL_DATE(DATE_FORMAT='%M %Z')
mytimes = TIMEGEN(12, UNITS='MONTHS', START=JULDAY(1,1,2000))
y = FINDGEN(12)
PLOT, mytimes, y, XTICKUNITS='Time', XTICKFORMAT='LABEL_DATE'
```

See the “Examples” section of [LABEL\\_DATE](#) for more extensive examples.

### The name of a user-defined function:

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [XYZ]TICKUNITS is specified:

If [XYZ]TICKUNITS is *not* specified, the callback function is called with three parameters, *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis.
- *Index* is the tick mark index (indices start at 0).
- *Value* is the data value at the tick mark (a double-precision floating point value).

**Note**

*Value* is a double-precision floating-point value that represents the Julian date. The Julian date follows the astronomical convention, where Julian date 0.0d corresponds to 1 Jan 4713 B.C.E. at 12 pm.

If [XYZ]TICKUNITS is specified, the callback function is called with four parameters, *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled (level indices start at 0).

**Example 1:** Use a callback function to display the Y tick values as a percentage of a fixed value. Note that because we don't specify [XYZ]TICKUNITS, we do not include the *Level* parameter in our function definition:

```
FUNCTION YTICKS, axis, index, value
    fixvalue = 389.0d
    pvalue = (value/fixvalue) * 100.0d
    RETURN, STRING(pvalue, FORMAT='(D5.2, "%")')
END

PRO use_callback
    Y = FINDGEN(10)
    PLOT, Y, YTICKFORMAT='YTICKS'
END
```

**Example 2:** Create a two-level X axis. Display the X tick values in a customized date/time format that shows the number of days open for business for each month on one level, and marks leap years with an asterisk on another level:

```
FUNCTION XTICKS, axis, index, value, level

CASE level OF
    0: BEGIN ; months
        ; Number of days open for business in given month:
        CALDAT, value, month
        open = [18,19,23,20,22,22,19,10,20,21,22,14]
        nbdays = open[month]
        ; Return a string containing the month name plus
        ; the number of business days in parentheses:
        RETURN, STRING(value, nbdays, $
            FORMAT='(C(CMoA), "(, I2, ")")')
    END
    1: BEGIN ; years
        ; Generate a string for the year.
        yrStr = STRING(value, FORMAT='(C(CYI))')
```

```

; Determine if a leap year.  If so,
; append an asterisk to the string.
CALDAT, value, mo, da, yr
IF (yr MOD 4 EQ 0) THEN BEGIN
  IF (yr MOD 100 EQ 0) THEN $
    isLeap = (yr MOD 400) EQ 0 $
  ELSE $
    isLeap = 1b
ENDIF ELSE $
isLeap = 0b
IF (isLeap NE 0b) THEN $
  yrStr = yrStr + '*'
RETURN, yrStr
END
ENDCASE

END

PRO plot_sales

myDates = TIMEGEN(12, UNITS='Months', START=JULDAY(1,1,2000))
sales = [180,190,230,200,220,220,190,100,200,210,220,140]
PLOT, myDates, sales, XTICKUNITS=['Months', 'Years'], $
  XTICKFORMAT='XTICKS', XTITLE = 'Date (* = Leap Year)', $
  YTITLE='Sales (units)', POSITION = [0.2, 0.2, 0.9, 0.9]

END

```

## [XYZ]TICKINTERVAL

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#)

variable equivalent: ![XYZ].[TICKINTERVAL](#)

Set this keyword to a scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis range ([XYZ]RANGE) and the number of major tick intervals ([XYZ]TICKS). This keyword takes precedence over [XYZ]TICKS.

For example, if TICKUNITS=["Seconds", "Hours", "Days"], and XTICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

## [XYZ]TICKLAYOUT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].[TICKLAYOUT](#).

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

---

**Note**

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

## [XYZ]TICKLEN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKLEN`.

This keyword controls the lengths of tick marks (expressed in normal coordinates) for the individual axes. This keyword, if nonzero, overrides the global tick length specified in `!P.TICKLEN`, and/or the [TICKLEN](#) keyword parameter, which is expressed as a fraction of the window size in the tick mark's direction.

## [XYZ]TICKNAME

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKNAME`.

A string array of up to 30 elements that controls the annotation of each tick mark. If omitted or if a given string element contains the null string, IDL labels the tick mark with its value. To suppress the tick labels, supply a string array of one-character long, blank strings, i.e., `REPLICATE(' ', N)`. Null strings force IDL to number the tick mark with its value.

**Note**

---

If there are  $n$  tick-mark intervals, there are  $n + 1$  tick marks and labels.

---

## [XYZ]TICKS

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKS`.

The number of major tick *intervals* to draw for the axis. If this keyword is set to zero or omitted, IDL selects from three to six tick intervals. Setting this field to  $n$ , where  $n > 1$ , produces exactly  $n$  tick intervals, and  $n+1$  tick marks. Setting this field equal to 1 suppresses tick marks.

## [XYZ]TICKUNITS

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKUNITS`.

Set this keyword to a string or a vector of strings indicating the units to be used for axis tick labeling. If a vector of strings is provided, the axis will be drawn in multiple levels, where each string represents one level in the specified units.

**Note**

---

When creating multiple-level axes, you may need to adjust the plot positioning using the [POSITION](#) or [\[XYZ\]MARGIN](#) keywords in order to ensure that axis labels and titles are visible in the plot window.

---

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- 'Numeric'
- 'Years'
- 'Months'
- 'Days'
- 'Hours'
- 'Minutes'
- 'Seconds'

- 'Time' - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- '' - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the 'Numeric' unit. This is the default setting.

If any of the time units are utilized, the tick values are interpreted as Julian date/time values.

Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

---

#### Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

---

## [XYZ]TICKV

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKV`.

The data values for each tick mark, an array of up to 60 elements. You can directly specify these values, producing graphs with arbitrary tick marks. If you do this, IDL scales the axis from the first tick value to the last unless you directly specify a range.

---

#### Note

To specify the number of ticks and their values exactly, set `[XYZ]TICKS=N` (where  $N > 1$ ) and `[XYZ]TICKV=Values`, where *Values* has  $N+1$  elements.

---

## [XYZ]TITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TITLE`.

A string that contains a title for the specified axis.

## Z

Accepted by: [PLOTS](#), [POLYFILL](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Provides the Z coordinate if a Z parameter is not present in the call. This is of use only if the three-dimensional transformation is in effect (i.e., the T3D keyword is set).

## ZVALUE

Accepted by: [AXIS](#), [CONTOUR](#), [MAP\\_SET](#), [OPLOT](#), [PLOT](#), [SHADE\\_SURF](#), [SURFACE](#).

Sets the Z coordinate, in normalized coordinates in the range of 0 to 1, of the axis and data output from PLOT, OPLOT, and CONTOUR.

This keyword has effect only if !P.T3D is set and the three-dimensional to two-dimensional transformation is stored in !P.T. If ZVALUE is not specified, CONTOUR will output each contour at its Z coordinate, and the axes and title at a Z coordinate of 0.0.

## Appendix C

# Thread Pool Keywords

Many of the system routines documented in this manual make use of the IDL thread pool. The thread pool is discussed in detail in [Chapter 11, “Multithreading in IDL”](#) in the *Building IDL Applications* manual. System-wide use of the thread pool can be controlled with the [CPU](#) procedure, and the current system settings are visible via the [!CPU](#) system variable.

All system routines that use the thread pool accept the following keywords, which can be used to modify the default behavior for the duration of a single call. This allows you to modify the settings for a particular computation without affecting the global default settings of the IDL session.

## Thread Pool Keywords

### **TPOOL\_MAX\_ELTS**

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number you specify, IDL will not use the thread pool for the

computation. Setting this value to 0 removes any limit on the maximum number of elements, and any computation with at least `TPOOL_MIN_ELTS` will use the thread pool.

This keyword overrides the default value, given by `!CPU.TPOOL_MAX_ELTS`. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 11 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a maximum number of elements.

## **TPOOL\_MIN\_ELTS**

Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number you specify, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

This keyword overrides the default value, given by `!CPU.TPOOL_MIN_ELTS`. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 11 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a minimum number of elements.

## **TPOOL\_NOTHREAD**

Set this keyword to explicitly prevent IDL from using the thread pool for the current computation. If this keyword is set, IDL will use the non-threaded implementation of the routine even if the current settings of the `!CPU` system variable would allow use of the threaded implementation.

This keyword overrides the default value, given by `!CPU.TPOOL_NTHREADS`. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 11 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to disable use of the thread pool entirely.

# Appendix D

# System Variables

The following topics are included in this appendix:

---

What Are System Variables? . . . . .	4802	IDL Environment System Variables . . . .	4812
Constant System Variables . . . . .	4804	Graphics System Variables . . . . .	4823
Error Handling System Variables . . . . .	4806		

# What Are System Variables?

System variables are a special class of predefined variables available to all program units. Their names always begin with the exclamation mark character (!). System variables are used to set the options for plotting, to set various internal modes, to return error status, etc.

System variables have a predefined type and structure that cannot be changed. When an expression is stored into a system variable, it is converted to the variable type, if necessary and possible.

## Changing the Value of a System Variable

Some system variables are *read-only*: they contain values that are static and cannot or should not be changed by the user. For example, the value of the system variable !PI always contains the single-precision value of pi ( $\pi$ ), which is not available for redefinition.

You can change most system variables, however, simply by assigning a new value to the variable. For example, to change the current value of the !PROMPT system variable, which contains the text string used by IDL to prompt the user for input, simply assign a new string:

```
!PROMPT = "My IDL: "
```

This change will persist for the duration of the IDL session or until you make a new assignment.

Some system variables take their values from a *preference*. Changing the value of the associated preference changes the value of the system variable (although in some cases the change will not take effect until IDL is restarted). Preference values persist between IDL sessions; your change will stay in effect until you either change the preference value or assign a new value to the system variable directly. For additional information on preferences, see [Appendix E, "IDL Preferences"](#).

Finally, you can define new system variables using the [DEFSYSV](#) procedure.

## Default Values of System Variables

Each system variable takes its default value from one of the following sources:

- IDL's internal defaults. You cannot modify the default values of these system variables. The values of these system variables are either fixed (the value of `!PI`, for example) or must be generated by IDL depending on the current state (like the value of `!ERROR_STATE`).
- A user or system preference. You can modify the default values of these system variables by modifying the value of its associated preference. System variables with associated preferences are noted in the following sections.

# Constant System Variables

The following system variables contain predefined constants or values for use by IDL routines. System variables can be used just like other variables. For example, the command:

```
PRINT, ACOS(A) * !RADEG
```

converts a result expressed in radians to one expressed in degrees.

## !DPI

A read-only variable containing the double-precision value of pi ( $\pi$ ).

## !DTOR

A read-only variable containing the floating-point value used to convert degrees to radians ( $\pi/180 \cong 0.01745$ ).

## !MAP

An array variable containing the information needed to effect coordinate conversions between points of latitude and longitude and map coordinates. The values in this array are established by the MAP\_SET procedure; the user should not change them directly.

## !PI

A read-only variable containing the single-precision value of pi ( $\pi$ ).

## !RADEG

A read-only variable containing the floating-point value used to convert radians to degrees ( $180/\pi \cong 57.2958$ ).

## !VALUES

A read-only variable containing the IEEE single- and double-precision floating-point values *Infinity* and *NaN* (Not A Number). !VALUES is a structure variable with the following fields:

```
** Structure !VALUES, 4 tags, length=24:
   F_INFINITY      FLOAT      Infinity
   F_NAN           FLOAT      NaN
   D_INFINITY      DOUBLE     Infinity
   D_NAN           DOUBLE     NaN
```

where the meaning of the fields as follows:

### F\_INFINITY

The single-precision floating point value *Infinity*.

### F\_NAN

The single-precision floating point value *NaN* (Not a Number).

### D\_INFINITY

The double-precision floating point value *Infinity*.

### D\_NAN

The double-precision floating point value *NaN* (Not a Number).

For more information on these special floating-point values, see [“Special Floating-Point Values”](#) in Chapter 8 of the *Building IDL Applications* manual.

# Error Handling System Variables

The following system variables are either set by IDL when an error condition occurs or used by IDL when displaying information about errors.

## !ERR

*This system variable is now obsolete and has been replaced by the [!ERROR\\_STATE](#) system variable. Code that uses the `!ERR` system variable will continue to function as before, but all new code should use `!ERROR_STATE.CODE`.*

## !ERROR\_STATE

A structure variable which contains the status of the last error message. Whenever an error occurs, IDL sets the fields in this system variable according to the nature of the field. An IDL error is always comprised of an IDL-generated component, and may also contain an operating system-generated component. `!ERROR_STATE` includes the following fields:

```

** Structure !ERROR_STATE, 8 tags, length=112, data length=108:
  NAME           STRING      'IDL_M_SUCCESS'
  BLOCK          STRING      'IDL_MBLK_CORE'
  CODE           LONG         0
  SYS_CODE       LONG         Array[2]
  SYS_CODE_TYPE  STRING      ''
  MSG            STRING      ''
  SYS_MSG        STRING      ''
  MSG_PREFIX     STRING      '% '

```

where the meaning of the fields as follows:

### NAME

A read-only string variable containing the error name of the IDL-generated component of the last error message. Although the error code—as defined below in `CODE`—may change between IDL sessions, the name will always remain the same. If an error has not occurred in the current IDL session, this field is set to `IDL_M_SUCCESS`.

### BLOCK

A read-only string variable containing the name of the message block for the IDL-generated component of the last error message. If an error has not occurred in the current IDL session, this field is set to `IDL_MBLK_CORE`.

**Note**

---

See the *External Development Guide* for more information about blocks.

---

**CODE**

The error code of the IDL-generated component of the last error in IDL. Whenever an error occurs, IDL sets this system variable to the error code (a negative integer number) of the error. Although the error code may change between IDL sessions, the name—as defined above in `NAME`—will always remain the same. If an error has not occurred in the current IDL session, this field is set to 0.

**SYS\_CODE**

A long-integer variable containing the error code of the last error's operating system-generated component, if it exists.

For historical reasons, `SYS_CODE` is a two-element longword array. The first element of the array (that is, `SYS_CODE[0]`) contains the OS-defined error code. The second element of the array is not used, and always contains zero. Either `!ERROR_STATE.SYS_CODE` or `!ERROR_STATE.SYS_CODE[0]` will return the relevant error code.

**SYS\_CODE\_TYPE**

A string describing the type of system code contained in `SYS_CODE`. A null string in this field indicates that there is no system code corresponding to the current error. The possible non-NULL values are:

Value	Meaning
errno	Unix/Posix system error
win32	Microsoft Windows Win32 system error
winsock	Microsoft Windows sockets library error

*Table D-22: SYS\_CODE\_TYPE Values*

**MSG**

A read-only string variable containing the text of the last IDL-generated error message. Whenever an error occurs, IDL sets this field to the error message (a scalar string) that corresponds to the error code. If an error has not occurred in the current IDL session, this field is set to the null string, ''.

## SYS\_MSG

A read-only string variable containing the text of the last error's operating system-generated component, if it exists. When an operating system error occurs, IDL sets this field to the OS-defined error message string. If an error has not occurred in the current IDL session, this field is set to the null string, ''.

## MSG\_PREFIX

A string variable containing the prefix string used for the IDL-generated component of error messages. This field takes its default value from a *preference*. See “[IDL\\_MSG\\_PREFIX](#)” on page 4853 for details.

This system variable replaces !ERROR, !ERR\_STRING, !MSG\_PREFIX, !SYSERR\_STRING, and !SYSERROR, and includes two new fields: error name and block name.

## Using !ERROR\_STATE

At the beginning of an IDL session, !ERROR\_STATE contains default information. To see this information, you can either view !ERROR\_STATE from the System field of the Variable Watch Window (see “[The Variable Watch Window](#)” in Chapter 8 of the *Building IDL Applications* manual) or you can enter PRINT, !ERROR\_STATE at the Command Line. After an error has occurred, all of the fields of !ERROR\_STATE display their updated status.

You can use MESSAGE, /RESET to reset all the fields in !ERROR\_STATE to their default values.

## !ERROR

*This system variable is now obsolete and has been replaced by the [!ERROR\\_STATE](#) system variable. Code that uses the !ERROR system variable will continue to function as before, but we suggest that all new code use !ERROR\_STATE.CODE.*

## !ERR\_STRING

*This system variable is now obsolete and has been replaced by the [!ERROR\\_STATE](#) system variable. Code that uses the !ERR\_STRING system variable will continue to function as before, but we suggest that all new code use !ERROR\_STATE.MSG.*

## !EXCEPT

An integer variable that controls when IDL checks for invalid mathematical computations (exceptions), such as division by zero. The three allowed values are:

0	Never report exceptions.
1	Report exceptions when the interpreter is returning to an interactive prompt (the default).
2	Report exceptions at the end of each IDL statement. Note that this slows IDL by roughly 5% compared to setting <code>!EXCEPT=1</code> .

For more information on invalid mathematical computations and error reporting, see “[Math Errors](#)” in Chapter 8 of the *Building IDL Applications* manual.

The value of `!EXCEPT` is used by the `CHECK_MATH` function to determine when to return errors. See “[CHECK\\_MATH](#)” on page 243 for details.

### Note

In versions of IDL up to and including IDL 4.0.1, the default exception handling was functionally identical to setting `!EXCEPT=2`.

`!EXCEPT` takes its default value from a *preference*. See “[IDL\\_EXCEPT](#)” on page 4852 for details.

## !MOUSE

A structure variable that contains the status from the last cursor read operation. `!MOUSE` has the following fields:

```
** Structure !MOUSE, 4 tags, length=16:
X                LONG                511
Y                LONG                252
BUTTON           LONG                4
TIME             LONG                1428829775
```

where the meaning of the fields are described in the following sections.

## X

Contains the X location (in device coordinates) of the cursor when the mouse button was pressed.

## Y

Contains the Y location (in device coordinates) of the cursor when the mouse button was pressed.

## BUTTON

Contains:

- 1 (one) if the left mouse button was pressed,
- 2 (two) if the middle mouse button was pressed
- 4 (four) if the right mouse button was pressed.

## TIME

Contains the number of milliseconds since a base time.

See “[CURSOR](#)” on page 404 for details on reading the cursor position.

## !MSG\_PREFIX

*This system variable is now obsolete and has been replaced by the [!ERROR\\_STATE](#) system variable. Code that uses the [!MSG\\_PREFIX](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR\\_STATE.MSG\\_PREFIX](#).*

## !SYSERROR

*This system variable is now obsolete and has been replaced by the [!ERROR\\_STATE](#) system variable. Code that uses the [!SYSERROR](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR\\_STATE.SYS\\_CODE](#).*

## !SYSERR\_STRING

*This system variable is now obsolete and has been replaced by the [!ERROR\\_STATE](#) system variable. Code that uses the [!SYSERR\\_STRING](#) system variable will*

*continue to function as before, but we suggest that all new code use !ERROR\_STATE.SYS\_MSG.*

## **!WARN**

A structure variable that causes IDL to print warnings to the console or command log when obsolete IDL features are found at compile time. !WARN has the following fields:

```
** Structure !WARN, 3 tags, length=3:
   OBS_ROUTINES      BYTE      0
   OBS_SYSVARS       BYTE      0
   PARENS            BYTE      0
```

where the meaning of the fields as follows:

### **OBS\_ROUTINES**

If this field is set to 1 (one), IDL generates warnings when it encounters references to obsolete internal or library routines.

### **OBS\_SYSVARS**

If this field is set to 1 (one), IDL generates warnings when it encounters references to obsolete system variables.

### **PARENS**

If this field is set to 1 (one), IDL generates warnings when it encounters a use of parentheses to specify an index into an array.

#### **Note**

---

No warnings are generated when the fields of the !WARN structure are set equal to zero (the default).

---

# IDL Environment System Variables

The following system variables contain information about IDL's configuration.

## !CPU

IDL can use multiple system processors to perform some computations in parallel. See [Chapter 11, "Multithreading in IDL"](#) in the *Building IDL Applications* manual for additional information.

The !CPU system variable supplies information about the state of the system processor, and of IDL's use of it. !CPU is readonly, and cannot be modified directly. Use the CPU procedure to modify values contained in !CPU.

The !CPU structure is defined as follows:

```
{ !CPU, HW_VECTOR:0L, VECTOR_ENABLE:0L, HW_NCPU:0L,
  TPOOL_NTHREADS:0L, TPOOL_MIN_ELTS:0L, TPOOL_MAX_ELTS:0L }
```

where the meaning of the fields as follows:

### HW\_VECTOR

True (1) if the system supports a vector unit (e.g., Macintosh Altivec/Velocity Engine). False (0) otherwise.

#### Note

---

This value is currently always 0 (False) on platforms other than Macintosh.

---

### VECTOR\_ENABLE

True (1) if IDL will use a vector unit, if such a unit is available on the current system, and False (0) otherwise.

#### Note

---

This value is currently always 0 (False) on platforms other than Macintosh.

---

### HW\_NCPU

The number of CPUs contained in the system on which IDL is currently running.

## TPOOL\_NTHREADS

The number of threads that IDL will use in thread pool computations. The default is to use `HW_NCPU` threads, so that each thread will have the potential to run in parallel with the others. For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to using fewer CPUs.

If the `IDL_CPU_TPOOL_NTHREADS` preference has been set, then `TPOOL_NTHREADS` is initialized with this value at startup. On systems shared by multiple users, you may wish to set this preference so that IDL uses the specified number of threads instead of defaulting to the number of CPUs present in the underlying hardware. See [!CPU Settings Preferences](#) in [Appendix E, “IDL Preferences”](#) for details.

## TPOOL\_MIN\_ELTS

The number of elements in a computation that are necessary before IDL will use the thread pool to perform the work. For fewer than `TPOOL_MIN_ELTS`, the main IDL thread will simply perform the work without using the thread pool. It is important not to use the thread pool for small tasks because the overhead of threading will not be offset by the overhead incurred by operation of the pool, and the overall computation will go slower than if threading is not used.

## TPOOL\_MAX\_ELTS

The maximum number of elements in a computation for which IDL will use the thread pool. If this value is 0 (zero) (the default), then no limit is imposed and any computation with at least `TPOOL_MIN_ELTS` is a candidate for the thread pool. If your computation is too large for the physical memory available on the system, the virtual memory system of the operating system will begin paging. Under such conditions, the performance of the thread pool can be worse than that of a single threaded computation because the threads end up fighting each other for access to memory. `TPOOL_MAX_ELTS` can be used to prevent this.

---

### Note

The `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, `TPOOL_NTHREADS`, and `VECTOR_ENABLE` fields of this system variable take their default values from the [!CPU Settings Preferences](#). See [Appendix E, “IDL Preferences”](#) for details.

---

## !DIR

A string variable containing the path to the main IDL directory.

!DIR takes its default value from a *preference*. See “[IDL\\_DIR](#)” on page 4855 for details.

## !DLM\_PATH

Significant portions of IDL’s built in functionality are packaged in the form of Dynamically Loadable Modules (DLMs). DLMs correspond to UNIX sharable libraries or Windows DLLs, depending on the operating system in use. At startup, IDL searches for DLM definition files (which end in the `.d1m` suffix) and makes note of the routines supplied by each DLM. If such a routine is called, IDL loads the DLM that supplies it into memory. To see a list of the DLMs that IDL knows about, use `HELP, /DLM` (see “[HELP](#)” on page 932 for more information).

!DLM\_PATH takes its default value from a *preference*. See “[IDL\\_DLM\\_PATH](#)” on page 4855 for details.

If the `IDL_DLM_PATH` preference is not explicitly defined by the user, IDL supplies a default that contains the directory in the IDL distribution where the DLMs supplied by RSI reside. Once `!DLM_PATH` is expanded, IDL uses it as the list of places to look for DLM definition files.

Since all DLM searching happens once at startup time, it would be meaningless to change the value of `!DLM_PATH` afterwards. For this reason, it is a read-only system variable and cannot be assigned to. The value of `!DLM_PATH` is useful because it shows you where IDL looked for DLMs when it started.

### Using Path Definition Tokens to Load a DLM Path

Using the `<IDL_BIN_DIRNAME>` token in the `IDL_DLM_PATH` preference can be useful for distributing packages of DLMs with support for multiple operating system and hardware combinations. This token is described in “[The Path Definition String](#)” under [EXPAND\\_PATH](#).

For example, assume that you have your DLMs installed in `/usr/local/myd1m`, with support for each platform in a subdirectory using the same naming convention that IDL uses for the platform dependent subdirectories underneath the `bin` directory of the IDL distribution. Setting the `IDL_DLM_PATH` preference to the following:

```
"/usr/local/myd1m/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

adds the location of the proper DLM for your current system to IDL's `!DLM_PATH` at startup.

Similarly, the `<IDL_VERSION_DIRNAME>` token can be useful for distributing packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms. This token is described in “[The Path Definition String](#)” under [EXPAND\\_PATH](#).

For example, assume that you have your DLMs installed in `/usr/local/myd1m`. You create a subdirectory for each supported version of IDL within the `myd1m` directory. Within each of those subdirectories would be a subdirectory for each operating system and hardware combination supported by that version of IDL. Setting the `IDL_DLM_PATH` preference to the following:

```
"/usr/local/myd1m/<IDL_VERSION_DIRNAME>/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

adds the location of the proper DLM for your current system to IDL's `!DLM_PATH` at startup.

## !EDIT\_INPUT

An integer variable indicating whether keyboard line editing is enabled (when set to a non-zero value) or disabled (when set to zero). The default value for `!EDIT_INPUT` comes from the [IDL\\_EDIT\\_INPUT](#) preference. See [Appendix E, “IDL Preferences”](#) for details.

By default, IDL saves the last 20 command lines in a recall buffer. You can change the number of command lines saved in the recall buffer by setting the [IDL\\_RBUF\\_SIZE](#) preference to the desired number. To preserve backward compatibility with releases of IDL prior to version 6.2, you can also change the number of command lines saved in the recall buffer by setting `!EDIT_INPUT` equal to the number of lines you would like to save. In order for the change to take effect, IDL must be able to process the assignment statement before providing a command prompt. This means that you must put the assignment statement in the IDL startup file. (See “[Startup Files](#)” in Chapter 1 of the *Using IDL* manual for more information on startup files.)

To understand how IDL processes the request to change the recall buffer's size (either through `IDL_RBUF_SIZE` or through `!EDIT_INPUT`), see “[Support for Obsolete Preference Mechanisms](#)” on page 4887.

## !HELP\_PATH

A string variable listing the directories IDL will search for online help files. Help files must either be part of an IDL Assistant online help system (controlled by a `.adp`

file), Adobe Portable Document Format (.pdf) files, or HTML (.html or .htm) files. On Windows systems, help files can also be HTML Help (.chm) or Windows Help (.hlp) files. See [Chapter 23, “Providing Online Help For Your Application”](#) in the *Building IDL Applications* manual for additional information on creating IDL Assistant online help systems or other online help files.

!HELP\_PATH takes its default value from a *preference*. See [“IDL\\_HELP\\_PATH”](#) on page 4856 for details.

If the IDL\_HELP\_PATH preference is not explicitly defined by the user, IDL supplies a default that contains the directory in the IDL distribution where the help files supplied by RSI reside.

To change the value of !HELP\_PATH for the duration of an IDL session, simply set the variable equal to a new string containing the desired path. See [“Changing the Value of !PATH After IDL Starts”](#) on page 4819 for tips that also apply to setting the value of !HELP\_PATH.

## !JOURNAL

A read-only long-integer variable containing the logical unit number of the file used for journal output.

## !MAKE\_DLL

The MAKE\_DLL procedure and the CALL\_EXTERNAL function’s AUTO\_GLUE keyword use the standard system C compiler and linker to generate sharable libraries that can be used by IDL in various contexts (CALL\_EXTERNAL, DLMs, LINKIMAGE). There is a great deal of variation possible in the use of these tools between different platforms, operating system versions, and compiler releases. The !MAKE\_DLL system variable is used to configure how IDL uses them for the current platform.

The !MAKE\_DLL structure is defined as follows:

```
{ !MAKE_DLL, COMPILE_DIRECTORY:'', COMPILER_NAME:'', CC:'', LD:'' }
```

where the meaning of the fields as follows:

### COMPILE\_DIRECTORY

IDL requires a place to create the intermediate files necessary to build a sharable library, and possibly the final library itself. Unless told to use an explicit directory, it uses the directory given by the COMPILE\_DIRECTORY field of !MAKE\_DLL.

IDL takes the default value of this field from a *preference*. See “[IDL\\_MAKE\\_DLL\\_COMPILE\\_DIRECTORY](#)” on page 4856 for details.

## COMPILER\_NAME

A string containing the name of the C compiler used by RSI to build the currently running IDL. This field is not used by IDL, and exists solely for informational purposes and to help the end user decide which C compiler to install on their system.

## CC

A string used by IDL as a template to construct the command for using the C compiler. This template uses PRINTF style substitution codes, as described in the following table.

## LD

A string used by IDL as a template to construct the command for using the linker. This template uses PRINTF style substitution codes, as described in the following table.

When expanding !MAKE\_DLL.CC and !MAKE\_DLL.LD, IDL substitutes text in place of the PRINTF style codes described in [Table D-23](#). These codes are case-insensitive (they can be either upper or lower case).

### Note

It is possible to use C compilers other than the one assumed by RSI in !MAKE\_DLL to build sharable libraries. To do so, you can alter the contents of !MAKE\_DLL or use the CC and/or LD keyword to MAKE\_DLL and CALL\_EXTERNAL. Please understand that RSI cannot and does not maintain a list of all possible compilers and the necessary compiler options. This information is available in your compiler and system documentation. It is the programmer’s responsibility to understand the rules for the chosen compiler.

The following table describes the substitution codes for the CC and LD fields:

Code	Meaning
%B %b	The base name of a C file to compile. For example, if the C file is <code>moose.c</code> , then %B substitutes <code>moose</code> .
%C %c	The name of the C file.

*Table D-23: Description of CC and LD Field Codes*

Code	Meaning
%E %e	The name of the linker options file. This file, which is automatically generated by IDL as needed, is used to control the linker. Under UNIX, the system documentation refers to this as an export file, or a linker map file. Microsoft Windows calls it a <code>.DEF</code> file.
%F %f	This substitution code is no longer meaningful, and will be ignored.
%L %l	The name of the resulting sharable library. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform ( <code>.dll</code> , <code>.so</code> , <code>.sl</code> , <code>.exe</code> , <i>etc.</i> ).
%O %o	An object file name. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform ( <code>.o</code> , <code>.obj</code> ).
%X %x	When expanding <code>!MAKE_DLL.CC</code> , IDL inserts any text supplied via the <code>EXTRA_CFLAGS</code> keyword to <code>MAKE_DLL</code> or <code>CALL_EXTERNAL</code> in place of %X. IDL does not interpret this text. It is the user's responsibility to ensure that it is meaningful in the command. When expanding <code>!MAKE_DLL.LD</code> , the text from the <code>EXTRA_LFLAGS</code> keyword is substituted. The primary use for this code is to include necessary header include directories and link libraries.
%%	Replaced with a single % character.

Table D-23: Description of CC and LD Field Codes (Continued)

## !MORE

An integer variable indicating whether IDL should paginate help output sent to a tty device. Setting `!MORE` to zero (0) prevents IDL from paginating the output text. A non-zero value (the default) causes IDL to display output text one screen at a time.

`!MORE` takes its default value from a *preference*. See “[IDL\\_MORE](#)” on page 4852 for details.

## !PATH

A string variable listing the directories IDL will search for libraries and include files.

**Note**

The current directory is always searched before consulting !PATH.

!PATH takes its default value from a *preference*. See “[IDL\\_PATH](#)” on page 4857 for details.

## Note on Path Expansion

When IDL starts, it reads the value of the IDL\_PATH preference and builds a value to be stored in !PATH from the specified initialization value. While the initialization value can consist of a normal path string specifying all directories to be included in !PATH, it can also take advantage of several special values that IDL uses to dynamically create the value of !PATH. These values (the “+” symbol and the “<IDL\_\*>” strings) are described in detail in “[The Path Definition String](#)” under “[EXPAND\\_PATH](#)” in the *IDL Reference Guide* manual.

## Path Caching

By default, as IDL searches directories included in the !PATH system variable for .pro or .sav files to compile, it creates an in-memory list of *all* .pro and .sav files contained in each directory. When IDL later searches for a .pro or .sav file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process. If use of the patch cache causes problems, you can disable it either via a keyword to the PATH\_CACHE routine or via the [IDL\\_PATH\\_CACHE\\_DISABLE](#) preference.

See “[PATH\\_CACHE](#)” in the *IDL Reference Guide* manual for details.

## Changing the Value of !PATH After IDL Starts

Once IDL has started, you can alter the value of !PATH by setting it to a new string value. For example, on a UNIX system, to add a directory to !PATH for the duration of an IDL session, you would use a command like the following:

```
!PATH = '/usr2/project/idl_files:' + !PATH
```

Keep the following in mind when changing the value of !PATH by setting its value to a new string:

- Remember to use the proper platform-specific directory separator character in path specification strings.

- Remember to use the proper path string separator character for your platform. If you are writing a cross-platform application that changes `!PATH`, you may want to use code that looks something like this:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = 'new_path' + pathsep + !PATH
```

where *new\_path* is the path to the directory you want to add.

- You can use the `EXPAND_PATH` function to generate a path string. This method allows you to specify one or more directories and let IDL figure out whether those directories contain `.pro` or `.sav` files. It also allows you to use the “+” character path expansion technique. For example, the following commands add all directories below the *new\_path* directory that contain `.pro` or `.sav` files to `!PATH`:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = EXPAND_PATH('+new_path') + pathsep + !PATH
```

See “[EXPAND\\_PATH](#)” in the *IDL Reference Guide* manual for details.

- Setting the value of `!PATH` within an IDL session changes the value for that session only. If you want to change the value permanently, change the value of the `IDL_PATH` preference, using either the `PREF_SET` command or the Preferences dialog of the IDLDE.

## !PROMPT

A string variable containing the text string used by IDL to prompt the user for input. The default is `IDL>`.

`!PROMPT` takes its default value from a *preference*. See “[IDL\\_PROMPT](#)” on page 4853 for details.

## !QUIET

A long-integer variable indicating whether informational messages should be printed (0) or suppressed (nonzero). By default, `!QUIET` is set to zero.

`!QUIET` takes its default value from a *preference*. See “[IDL\\_QUIET](#)” on page 4853 for details.

## !VERSION

A structure variable containing information about the version of IDL in use. The structure is defined as follows:

```
{ !VERSION, ARCH:'', OS:'', OS_FAMILY:'', OS_NAME:'', $  
  RELEASE:'', BUILD_DATE:'', MEMORY_BITS:0, FILE_OFFSET_BITS:0 }
```

where the meaning of the fields as follows:

### ARCH

CPU hardware architecture of the system.

### OS

The vendor name of the operating system (for example: AIX, HP-UX, IRIX, linux, MacOS, OSF, sunos, Win32). This is the name of the underlying operating system kernel (not necessarily of the overall operating environment: see OS\_NAME). Once an OS name is assigned to a platform by RSI, it is not altered in subsequent releases. This makes it safe for use in IDL programs that need to distinguish between platforms. RSI recommends that you first consider using the OS\_FAMILY field before using the OS field, as most programs are mainly concerned with high level platform differences.

### OS\_FAMILY

The generic name of the operating system (UNIX, Windows). RSI recommends that whenever possible this field (rather than OS or OS\_NAME) be used in code that must distinguish between platforms.

### OS\_NAME

The vendor's name for the operating system environment, as used by the vendor for casual descriptive and promotional purposes. For example, on Sun workstations, the name of the operating system kernel (!VERSION.OS) is "sunos", whereas the name of the overall system (!VERSION.OS\_NAME) is "Solaris". Vendors change their descriptive environment names from time to time, and RSI updates the OS\_NAME field to reflect this. As a result, RSI recommends that IDL users restrict their use of this field to descriptive textual uses, and that the OS\_FAMILY or OS fields of !VERSION be used in code that must distinguish between platforms.

### RELEASE

IDL version number.

## BUILD\_DATE

The date the IDL executable was compiled, in the format dictated by ANSI C for the `__DATE__` macro.

## MEMORY\_BITS

The number of bits used to address memory. Possible values are 32 or 64. The number of bits used to address memory places a theoretical upper limit on the amount of memory available to IDL.

## FILE\_OFFSET\_BITS

The number of bits used to position file offsets. Possible values are 32 or 64. The number of bits used to position files places a theoretical upper limit on the largest file IDL can access.

### Note

---

If you need to differentiate between different IDL versions in your code, use `!VERSION.OS_FAMILY`. At present, two operating system families are supported: UNIX and Windows. For even more detail, you can use `!VERSION.OS`.

---

# Graphics System Variables

The following system variables control various IDL Direct Graphics functions. These system variables are structures that contain many tags. For example, the command

```
!P.TITLE = 'Cross Section'
```

sets the default plot title.

Many of the functions of the graphics keywords described in [Appendix B, “Graphics Keywords”](#), are also controlled by the system variables !P, !X, !Y, and !Z.

You can change the default style of plots, fonts, etc., by setting the corresponding field in the appropriate system variable. Also, some effects that persist longer than one call are controlled only by system variables. The field !P.MULTI is one example.

## Two-Dimensional Coordinate Conversion

The system variables !D, !P, !X, !Y, and !Z contain the information necessary to convert from one coordinate system to another. The relevant fields of these system variables are explained below, and formulae are given for conversions to and from each coordinate system. See “[Coordinates of 3-D Graphics](#)” in Chapter 8 of the *Using IDL* manual for a discussion of three-dimensional coordinates.

In the following discussion,  $D$  is a data coordinate,  $N$  is a normalized coordinate, and  $R$  is a raw device coordinate.

The fields !D.X\_VSIZE and !D.Y\_VSIZE always contain the size of the visible area of the currently selected display or drawing surface. Let  $V_x$  and  $V_y$  represent these two sizes.

The field !X.S is a two-element array that contains the parameters of the linear equation, converting data coordinates to normalized coordinates. !X.S[0] is the intercept, and !X.S[1] is the slope. !X.TYPE is 0 for a linear  $x$ -axis and 1 for a logarithmic  $x$ -axis. The  $y$ - and  $z$ -axes are handled in the same manner, using the system variables !Y and !Z.

Also, let  $D_x$  be the data coordinate,  $N_x$  the normalized coordinate,  $R_x$  the device coordinate,  $V_x$  the device X size (in device coordinates), and  $X_i = !X.S_i$  (the scaling parameter).

With the above variables defined, the linear two-dimensional coordinate conversions for the  $x$  coordinate can be written as follows:

Coordinate Conversion	Linear	Logarithmic
Data to normal	$N_x = X_0 + X_1 D_x$	$N_x = X_0 + X_1 \log D_x$
Data to device	$R_x = V_x (X_0 + X_1 D_x)$	$R_x = V_x (X_0 + X_1 \log D_x)$
Normal to device	$R_x = N_x V_x$	$R_x = N_x V_x$
Normal to data	$D_x = (N_x - X_0) / X_1$	$D_x = 10^{(N_x - X_0) / X_1}$
Device to data	$D_x = (R_x / V_x - X_0) / X_1$	$D_x = 10^{(R_x / V_x - X_0) / X_1}$
Device to normal	$N_x = R_x / V_x$	$N_x = R_x / V_x$

*Table D-24: Equations for X-axis Coordinate Conversion*

The  $y$ - and  $z$ -axis coordinates are converted in exactly the same manner, with the exception that there is no  $z$  device coordinate and that logarithmic  $z$ -axes are not permitted.

## !C

The cursor system variable. Currently, the only function of this system variable is to contain the subscript of the largest or smallest element found by the MAX and MIN functions. That information is better obtained through the optional output arguments to those routines. !C is included only for compatibility with old versions of IDL.

## !D

This system variable is a structure that contains information about the current graphics output device (or window, on a windowing system). Fields, in alphabetical order, are:

### FILL\_DIST

The line interval, in device coordinates, required to obtain a solid fill.

## FLAGS

A longword of flags that provide information about the current device. Each bit is a flag encoded as shown in the following table.

Bit	Value	Function
0	1	Device has scalable pixel size (e.g., PostScript).
1	2	Device can output text at an arbitrary angle using hardware.
2	4	Device can control line thickness with hardware.
3	8	Device can display images.
4	16	Device supports color.
5	32	Device supports polygon filling with hardware.
6	64	Device hardware characters are monospace.
7	128	Device can read pixels (i.e., it supports TVRD).
8	256	Device supports windows.
9	512	Device prints black on a white background (e.g., printers are plotters).
10	1024	Device has <i>no</i> hardware characters.
11	2048	Device does line-fill style polygon filling in hardware.
12	4096	Device will apply Hershey-style embedded formatting commands to device fonts.
13	8192	Device is a pen plotter.
14	16384	Device can transfer 16-bit pixels.
15	32768	Device supports Kanji characters.
16	65536	Device supports widgets.
17	131072	Device has Z-buffer.
18	262144	Device supports TrueType fonts.

Table D-25: !D.FLAGS Bit Definitions

To test whether a particular bit is set on your system, use an IDL command like the following:

```
IF (!D.FLAGS AND value) NE 0 THEN PRINT, 'Bit is set.'
```

where value is the value associated with the bit you wish to examine. For example, to check whether the device supports color, use:

```
IF (!D.FLAGS AND 16) NE 0 THEN PRINT, 'Bit is set.'
```

## N\_COLORS

The number of allowed color values. In the case of devices with windows, this field is set after the window system is initialized. For a monochrome system, !D.N\_COLORS is 2. For TrueColor displays, !D.N\_COLORS is  $2^{24}-1$  (roughly 16.7 million colors).

The low 8 bits, bits 0 to 7, of the color index are written to the red channel; bits 8 to 15 are written to the green; and bits 16 to 23 are written to the blue. For example, a given RGB, the index is  $R + 256(G + 256B)$ . To create a plot with a given color (assuming linear lookup tables), use the following statement:

```
PLOT, X, Y, COLOR = R + 256L * (G + 256L * B)
```

## NAME

A string containing the name of the device.

## ORIGIN

A two-element integer array containing the current pan/scroll offset. An offset of (0, 0) is normal. Positive offsets shift the display memory to the right and upwards. This field has relevance only with devices with hardware pan and scroll abilities.

## TABLE\_SIZE

The number of color table indices.

### Note

---

For TrueColor visuals, !D.TABLE\_SIZE will always be 256. If the visual depth is less than 24 bits, IDL emulates 256 entries.

---

## UNIT

The logical number of the file open for output by the current graphics device. This field only has meaning for devices that write to a file if the file is accessible to the user from IDL, and is 0 if no file is open.

For example, the PostScript driver fills this field with the unit number of the file open for PostScript output. In the case of Tektronix output to a file, !D.UNIT may be set to either + or – the logical unit number.

## **WINDOW**

The index of the currently open window. This field is set to -1 if no window is currently open. This field is used only with devices that support windows.

## **X\_CH\_SIZE**

## **Y\_CH\_SIZE**

The width and height of the rectangle that encloses the “average” character in the current font, in device units (usually pixels).

These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width is the value of X\_CH\_SIZE. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines is determined explicitly by the value of Y\_CH\_SIZE.

For device fonts, the character size is fixed. When the device font system is in use, the value of X\_CH\_SIZE is silently ignored, and only the Y\_CH\_SIZE value is used.

## **X\_PX\_CM**

## **Y\_PX\_CM**

The approximate number of pixels per centimeter in the X and Y directions.

## **X\_SIZE**

## **Y\_SIZE**

The total size of the display or window in the X and Y directions, in device units.

## X\_VSIZE

## Y\_VSIZE

The size of the visible area of the display or window. This area can be smaller than the total size fields.

## ZOOM

This field contains the current X and Y zoom factors for the display or window. This field has relevance only with devices equipped with hardware zoom. A zoom factor of [1, 1] is normal.

## !ORDER

Controls the direction of image transfers when using the TV, TVSCL, and TVRD procedures. If !ORDER is 0, images are transferred from bottom to top, i.e. the row with a 0 subscript is written on the bottom. Setting !ORDER to 1, transfers images from top to bottom.

## !P

The main plotting system variable structure. All fields, except !P.MULTI, have a directly corresponding keyword parameter in the plot procedures: PLOT, OPLOT, CONTOUR, and SURFACE. Fields, in alphabetical order, are:

## BACKGROUND

The background color index. When erasing the screen or page, all pixels are set to this color. The default value is 0. Not all devices support this feature.

### Warning

---

If !P.NOERASE (or the NOERASE keyword) is set, the value of !P.BACKGROUND (or the BACKGROUND keyword) is ignored.

---

## CHANNEL

The default source or destination channel. This field has meaning only on graphics devices that contain multiple display channels, and is device dependent. It may contain either a channel mask or index.

## CHARSIZE

The overall character size of all annotations when Hershey fonts are selected. This field has no effect on the character size when hardware (device) fonts are selected, except for devices that support scalable pixel sizes (i.e., Postscript). Note, however, that !P.CHARSIZE always affects the layout and scaling of a plot, regardless of the font system being used. The default size is 1.0.

## CHARTHICK

An integer specifying the thickness of the lines used to draw the characters when using the vector drawn fonts. This field has no effect on the appearance of characters drawn with the hardware fonts. Normal thickness is 1.

## CLIP

The device coordinates of the clipping window, a 6-element vector of the form  $[x_0, y_0, x_1, y_1, z_0, z_1]$ , specifying two opposite corners of the volume to be displayed. In the case of two-dimensional displays, the Z coordinates can be omitted. Normally, the clipping window coordinates are implicitly set by PLOT, CONTOUR, SHADE\_SURF, and SURFACE to correspond to the plot window. You may also manually set !P.CLIP if you want to specify a different rectangular clipping window or if the clipping coordinates have not yet been set in the current IDL session.

## COLOR

The default color index. To set the color of a plot to color-index 120, use the following statement:

```
x = FINDGEN(30)
y = FINDGEN(30)
PLOT, X, Y, COLOR = 120
```

Future plots are not affected and are drawn with color index !P.COLOR, which is normally set to the number of available colors minus one. Test this by entering,

```
PLOT, X, Y
```

The interpretation of the color index varies among the devices supported by IDL. With color video displays, this index selects a color (normally a red, green, blue (RGB) triple stored in a device table). You can control the color selected by each color index with the TVLCT procedure which loads the device color tables.

Other devices have a fixed color associated with each color index. With plotters, for example, the correspondence between colors and color index is established by the order of the pens in the carousel.

To change the default color of future plots, use a statement such as:

```
!P.COLOR = 120
```

which sets the default color to color-index 12. You can override this default at any time by including the `COLOR` keyword in the graphic routine call. See “[N\\_COLORS](#)” on page 4826 for more information on defining a color.

## FONT

An integer that specifies the graphics text font system to use. Set `FONT` equal to -1 to select the Hershey character fonts, which are drawn using vectors. Set `FONT` equal to 0 (zero) to select the device font of the output device. Set `FONT` equal to 1 (one) to select the TrueType font system. See [Appendix H, “Fonts”](#), for a complete description of IDL’s font systems.

## LINestyle

The default style of the lines used to connect points. A line style index of 0 yields a solid line. See “[LINestyle](#)” on page 4782 for a description of the linestyles.

## MULTI

`!P.MULTI` allows making multiple plots on a page or screen. It is a 5-element integer array defined as follows:

`!P.MULTI[0]` contains the number of plots remaining on the page. If `!P.MULTI[0]` is less than or equal to 0, the page is cleared, the next plot is placed in the upper left hand corner, and `!P.MULTI[0]` is reset to the number of plots per page.

Setting `!P.MULTI[0]` to a value greater than zero can be used to manually set the plotting area to a specific row and column. For example, to plot in the lower left corner of a window of two rows and two columns, set `!P.MULTI` as follows:

```
!P.MULTI = [2, 2, 2]
PLOT, X, Y
```

`!P.MULTI[1]` is the number of plot columns per page. If this value is less than or equal to 0, one is assumed. If more than two plots are ganged in either the `X` or `Y` direction, the character size is halved.

`!P.MULTI[2]` is the number of rows of plots per page. If this value is less than or equal to 0, one is assumed.

`!P.MULTI[3]` contains the number of plots stacked in the `Z` dimension.

`!P.MULTI[4]` is 0 to make plots from left to right (column major), and top to bottom, and is 1 to make plots from top to bottom, left to right (row major).

**Note**

---

If !P.MULTI[0] is zero, an erase will occur before the current plot is displayed (unless the /NOERASE keyword is set). This is true no matter whether !P.POSITION and/or !P.REGION are set.

---

For example, to gang two plots across the page:

```
!P.MULTI = [0, 2, 0, 0, 0]
PLOT, X0, Y0                ;Make left plot.
PLOT, X1, Y1                ;Right plot.
```

To gang two plots vertically:

```
!P.MULTI = [0, 0, 2, 0, 0]
PLOT, X0, Y0                ;Make top plot.
PLOT, X1, Y1                ;Bottom plot.
```

To make four plots per page, two across and two up and down:

```
!P.MULTI = [0, 2, 2, 0, 0]
```

and then call plot four times.

To reset !P.MULTI back to the normal one plot per page:

```
!P.MULTI = 0
```

See [“Multiple Plots on a Page”](#) on page 1675 for additional examples. See [“Specifying the Location of the Plot”](#) on page 1677 for information on how !P.MULTI relates to plot location.

**NOCLIP**

A field which, if set, inhibits the clipping of the graphic vectors and vector-drawn text. By default, most routines clip to the plotting window, with the exception of PLOTS and XYOUTS. !P.CLIP contains the clipping rectangle.

**NOERASE**

Set this field to a non-zero value to inhibit erasing the screen before plotting.

**Warning**

---

If !P.NOERASE (or the NOERASE keyword) is set, the value of !P.BACKGROUND (or the BACKGROUND keyword) is ignored.

---

**NSUM**

The number of adjacent points to average to obtain a plotted point.

## POSITION

Specifies the normalized coordinates of the rectangular plot window. This is a four element floating point vector  $(x_0, y_0, x_1, y_1)$  containing the normalized coordinates of the plot-data window, where  $(x_0, y_0)$  is the origin, and  $(x_1, y_1)$  is the upper right corner.

!P.POSITION determines the plotting window. This variable is ignored if  $x_0$  equals  $x_1$  (that is, if !P.POSITION[0] EQ !P.POSITION[2], which is the default), or if the **POSITION** keyword is present. If set, it overrides the effect of the MARGIN and !P.MULTI variables and keywords.

---

### Note

If !P.POSITION (or the POSITION keyword) or !P.REGION is set, all but the first element of !P.MULTI are ignored.

---

See “[Specifying the Location of the Plot](#)” on page 1677 for more information.

## PSYM

The default plotting symbol index. Each point drawn by PLOT, PLOTS, and OPLOT is marked with a symbol if this field is non-zero. The possible symbols are given in “[PSYM](#)” on page 4784.

## REGION

A four element vector that specifies the normalized coordinates of the rectangle enclosing the plot region, which includes the plot data window and its surrounding annotation area. It is in the same form as !P.POSITION,  $(x_0, y_0, x_1, y_1)$ , where  $(x_0, y_0)$  is the origin, and  $(x_1, y_1)$  is the upper right corner. It is ignored if !P.REGION[0] is equal to !P.REGION[2].

---

### Note

!P.POSITION (or the POSITION keyword) takes precedence over !P.REGION.

---

See “[Specifying the Location of the Plot](#)” on page 1677 for more information.

## SUBTITLE

The plot subtitle, placed under the X axis label.

## T

Contains the homogeneous 4 x 4 transformation matrix. This field is a two-dimensional array of double-precision floating-point values. For more information about transformations, refer to “[Coordinates of 3-D Graphics](#)” in Chapter 8 of the *Using IDL* manual.

## T3D

Enables the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix.

## THICK

The thickness of the lines connecting points. 1.0 is normal.

## TITLE

The main plot title.

## TICKLEN

The length of the tick marks, expressed as a fraction of the plot size (from 0.0 to 1.0). The default is 0.02. A value of 0.5 makes a grid. Negative values make the tick marks point outward.

## !X, !Y, !Z

The system variables !X, !Y, and !Z, are structures of type `AXIS`, that affect the appearance and scaling of the three axes. The fields for !X, !Y, and !Z have identical fields with identical meanings and usage. In addition, almost all fields have corresponding keyword parameters, with identical function, but with temporary effect. For example, to suppress the minor tick marks on the X axis using the !X system variable, you could use the command:

```
!X.MINOR = -1
```

To suppress the tick marks for just one call to plot, you could use the command:

```
PLOT, X, Y, XMINOR = -1
```

The name of the keyword parameter is simply the name of the system variable field, prefixed with the letter X, Y, or Z.

The fields for these system variables, in alphabetical order are:

## CHARSIZE

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This field has no meaning when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor. For example, setting !P.CHARSIZE to 2.0, and !X.CHARSIZE to 0.5 results in a character size of 1.0 for the X axis.

## CRANGE

The output axis range. Setting this variable has no effect; set ![XYZ].RANGE to change the range. ![XYZ].CRANGE[0] always contains the minimum axis value, and ![XYZ].CRANGE[1] contains the maximum axis value of the last plot before extending the axes.

### Note

---

If the axis is logarithmic, the CRANGE field reports the log (base 10) of the minimum and maximum axis values.

---

### Example 1:

```
;Create a 10-element array.
a = INDGEN(10)

;Plot the straight line.
PLOT, a

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

### IDL prints:

```
0.00000      10.0000
```

### Example 2:

```
;Plot a with logarithmic scaling on the X axis.
PLOT, a, /XLOG

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

The axis is scaled from  $10^{-12}$  to  $10^2$ . IDL prints:

```
-12.0000      2.00000
```

## GRIDSTYLE

The index of the linestyle to be used for tick marks and grids. See [“LINESTYLE”](#) on page 4782 for a description of the linestyles

## MARGIN

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. The plot window is the rectangular area that contains the plot data, i.e. the area enclosed by the axes.

The default values for !X.MARGIN are [10, 3] yielding a 10-character wide left margin and a 3-character wide right margin. The values for !Y.MARGIN are [4, 2], for a 4-character high bottom margin and a 2-character high top margin. While specifying !Z.MARGIN will not cause an error, Z margins are currently ignored.

When calculating the size and position of the plot window, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field. See [“Specifying the Location of the Plot”](#) on page 1677 for more information.

## MINOR

The number of minor tick mark intervals. If !X.MINOR is 0, the default, the number of minor tick intervals is automatically determined from the tick mark increment. You can force a given number of minor tick intervals by setting this field to the desired number. To suppress minor tick marks, set !X.MINOR to -1.

## OMARGIN

A 2-element array specifying the “outer” margin on the left (bottom) and right (top) sides of a multi-plot window, in units of character size. A multi-plot window is created by setting the !P.MULTI system variable field. OMARGIN controls the amount of space around the entire plot area, including individual plot margins set with !X.MARGIN and !Y.MARGIN. The default values for !X.OMARGIN and !Y.OMARGIN are [0, 0].

When calculating the size and position of the individual plots, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

## RANGE

The input axis range, a 2-element vector. The first element is the axis minimum, and the second is the maximum. Set this field, or use the corresponding keyword parameter, to specify the data range to plot. If axis end point rounding is selected (see STYLE above), the final axis range may not be equal to this input range. The field !X.CRANGE contains the axis range used for the plot before extending the axes. Set both elements equal to 0 for automatic axis ranges:

```
!X.RANGE = 0
```

For example, to force the X axis to run from 5.5 to 8.3:

```
!X.RANGE = [5.5, 8.3]
PLOT, X, Y
```

Alternatively, by using keywords:

```
PLOT, X, Y, X RANGE=[5.5, 8.3]
```

Note that even though the range was set to (5.5, 8.3), the resulting plot has a range of (5.5, 8.5), because axis rounding is the default.

## REGION

Contains the normalized coordinates of the region. This field is similar to WINDOW, in that it is set by the graphics procedures and is a 2-element floating point array. To change the default plotting region, set !P.REGION.

## S

The scaling factors for converting between data coordinates and normalized coordinates (a 2-element array). The formula for conversion from data ( $X_d$ ) to normalized ( $X_n$ ) coordinates is  $X_n = S_1 X_d + S_0$

If logarithmic scaling is in effect, substitute  $\log_{10}(X_d)$  for  $X_d$ .

The CONVERT\_COORD function can be used to convert between coordinate systems. The user should save and restore these fields when switching between windows or devices with different sizes and/or scaling.

## STYLE

The style of the axis encoded as bits in a longword. The axis style can be set to exact, extended, none, or no box using this field. The following table lists the axis style bit values:

Bit	Value	Function
0	1	Exact. By default, the end points of the axis are rounded in order to obtain even tick increments. Setting this bit inhibits rounding, making the axis fit the data range exactly.
1	2	Extend. If this bit is set, the axes are extended by 5% in each direction, leaving a border around the data.
2	4	None. If this bit is set, the axis and its annotation are not drawn.
3	8	No box. Normally, PLOT and CONTOUR draw a box-style axis with the data window surrounded by axes.
4	16	Inhibits setting the Y axis minimum value to zero when the data are all greater than 0. The keyword YNOZERO sets this bit temporarily.

*Table D-26: Axis Style Bit Values*

Note that this system variable field is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the !X.STYLE system variable to 1+8, or 9.

For example, to set the Y axis style to exact using the !Y system variable:

```
!Y.STYLE = 1
```

or by using a keyword parameter:

```
PLOT, X, Y, YSTYLE = 1
```

## THICK

The thickness of the axis line. 1.0 is normal.

## TICKFORMAT

Set this field to a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels.

See “[XYZ]TICKFORMAT” on page 4790 for more information.

## TICKINTERVAL

A scalar indicating the interval between major tick marks for the first axis level. This setting takes precedence over ![XYZ].TICKS.

For example, if !X.TICKUNITS=[“Seconds”, “Hours”, “Days”], and !X.TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

See “[XYZ]TICKINTERVAL” on page 4793 for more information.

## TICKLAYOUT

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

See “[XYZ]TICKLAYOUT” on page 4793 for more information.

## TICKLEN

The lengths of tick marks (expressed in normal coordinates) for the individual axes.

## TICKNAME

The annotation for each tick. A string array of up to 60 elements. Setting elements of this array allows direct specification of the tick label. If this element contains a null string, the default value, IDL annotates the tick with its numeric value. Setting the element to a 1-blank string suppresses the tick annotation.

For example, to produce a plot with an abscissa labeled with the days of the week:

```
;Set up X axis tick labels.
!X.TICKNAME = ['SUN', 'MON', 'TUE', 'WED', $
              'THU', 'FRI', 'SAT']

;Use six tick intervals, requiring seven tick labels.
!X.TICKS = 6

;Plot the data, this assumes that Y contains 7 elements.
PLOT, Y
```

The same plot can be produced, using keyword parameters, with:

```
;Set fields, as above, only temporarily.
PLOT, Y, XTICKN = ['SUN', 'MON', 'TUE', 'WED', $
                 'THU', 'FRI', 'SAT'], XTICKS = 6
```

## TICKS

The number of major tick intervals to draw for the axis. If !X.TICKS is set to 0, the default, IDL will select from three to six tick intervals. Setting this field to  $n$ , where  $n > 1$ , produces exactly  $n$  tick intervals, and  $n+1$  tick marks. Setting this field equal to 1 suppresses tick marks.

## TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling.

### Note

---

The singular form of each of the time value strings is also acceptable (e.g, !X.TICKUNITS='Day' is equivalent to !X.TICKUNITS='Days').

---

### Note

---

To set the ![XYZ].TICKUNITS field to a single string, the following approach is recommended:

```
!X.TICKUNITS = '' ; Clear all previous tick unit
strings.
!X.TICKUNITS = ['Days'] ;Single unit string in array.
```

The following:

```
!X.TICKUNITS = 'Days'
```

will copy the 'Days' string to all levels, resulting in a multi-level axis.

---

See “[XYZ]TICKUNITS” on page 4795 for more information.

## TICKV

An array of up to 60 elements containing the data values for each tick mark. You can directly specify the location of each tick by setting !X.TICKS to the number of tick marks (the number of intervals plus 1) and storing the data values of the tick marks in

`!X.TICKV`. If, as is true by default, `!X.TICKV[0]` is equal to `!X.TICKV[1]`, IDL automatically determines the value of the tick marks.

## **TITLE**

A string containing the axis title.

## **TYPE**

The type of axis, 0 for linear, 1 for logarithmic.

## **WINDOW**

Contains the normalized coordinates of the axis end points, the plot data window. This field is set by `PLOT`, `CONTOUR`, `SHADE_SURF`, and `SURFACE`. Changing its value has no effect. A 2-element floating point array. To change the default plotting window, set `!P.POSITION`. The keyword parameter `POSITION` sets the plot data window on a per call basis.

# Appendix E

# IDL Preferences

The following topics are included in this appendix:

---

<a href="#">About IDL Preferences</a> . . . . .	4842	<a href="#">X Window System Graphics Preferences</a>	4866
<a href="#">General User Environment Preferences</a> . .	4851	<a href="#">Windows IDE Preferences</a> . . . . .	4870
<a href="#">Directory and Search Path Preferences</a> . .	4855	<a href="#">Motif IDE Preferences</a> . . . . .	4880
<a href="#">!CPU Settings Preferences</a> . . . . .	4859	<a href="#">Windows Runtime Preferences</a> . . . . .	4885

<a href="#">Windows Graphics Preferences</a> . . . . .	4862		

# About IDL Preferences

*Preferences* are internal values that control various aspects of the environment that IDL presents to its users. Preferences supply initial values for many system variables and control the layout of the IDL development environment (IDLDE) and a variety of other aspects of IDL's behavior. Preferences can be specified from a variety of sources. They persist between IDL sessions, meaning that once you get them set in a way that satisfies your needs, you can forget them, and IDL will behave in the way you have specified every time you run it.

Preferences are built into the IDL system and are fixed in number and purpose. Each preference has a name that starts with `IDL_`, and these names are case insensitive. There are two data types, string and integer (numeric). The numeric preferences are further specialized:

- A numeric preference can have a minimum and/or maximum value beyond which it is not allowed to be set.
- A numeric preferences can be discrete, meaning that the possible values are constrained to be one of a fixed set of values. In most cases, IDL lets you reference these values using case-insensitive mnemonic names called *aliases* that make them easier to use and remember. For example, many of IDL's preferences are of an integer type called `BOOLEAN`. Boolean preferences are discrete, with possible values of 1 and 0. The aliases "True", "Yes", and "On" are accepted for the value 1, and "False", "No", and "Off" for 0.

The complete set of IDL preferences are documented later in this appendix, starting with "[General User Environment Preferences](#)" on page 4851. You can view your current preferences from within IDL by using the following command:

```
HELP, /PREFERENCES
```

The default display shows the preference names, their values, and the source of those values. For a detailed complete view of their state, add the `FULL` keyword to the `HELP` command. See the `PREFERENCES` keyword for more information on its output.

This section of the appendix contains the following information:

- "[Understanding Preference Sources](#)" on page 4843
- "[Changing Preference Values](#)" on page 4846
- "[Understanding Preference Files](#)" on page 4849
- "[Using Preference Etiquette](#)" on page 4849

## Understanding Preference Sources

The value of each preference can come from a variety of sources. There is a hierarchy to these sources, and IDL will use the value from the source with the highest priority. This value is called the effective value, to reflect the fact that there might be several sources for a given preference, but only one of them is actually used.

A given IDL preference can come from one of the following sources. These sources are listed in order of priority; the ones at the top will be used in preference to the ones below. The rest of this section describes the sources, listed here in descending order of priority:

- [“Command Line”](#) on page 4843
- [“Environment Variable”](#) on page 4844
- [“IDL Distribution Preference File”](#) on page 4845
- [“User Preference File”](#) on page 4845
- [“IDL Default Value”](#) on page 4846

### Command Line

You can specify preference values from the IDL command line. There are two possible forms of this feature. The first form is specifying the preference name and value directly on the command line. For example, the following starts IDL while setting the default graphics device to PostScript:

```
% idl -IDL_DEVICE ps
```

The second form is using the `-pref` command-line option to specify an IDL preference file that IDL reads when it starts. For information on the syntax of this file, see [“Understanding Preference Files”](#) on page 4849. For example, suppose you had a file named `thr.pref` containing the following lines, which set parameters used by the IDL thread pool:

```
IDL_CPU_TPOOL_MAX_ELTS : 1000000
IDL_CPU_TPOOL_MIN_ELTS : 500000
IDL_CPU_TPOOL_NTHREADS : 4
```

Starting IDL with the following command causes these three preferences from `thr.pref` to take effect:

```
% idl -pref=thr.pref
```

Preferences specified directly on the command line take precedence over those specified within a command-line preference file. The direct form is mainly useful for ad-hoc interactive use of IDL, while the preference file form is of particular interest

to those writing stand-alone applications in IDL, especially when using the runtime or virtual machine modes of operation. The use of a command line preference file lets authors of such applications control the values of preferences important to the application in a way that is user-adjustable and not hardwired into the application's code.

If a preference is set at the command-line, IDL considers it to be read-only. IDL uses the value provided for the duration of the current IDL session, but refuses to let you attempt to change it with the `PREF_SET` procedure. Preferences set at the command line are not written to the current user's preferences file. To alter the preference, you should modify it at the source by restarting IDL with the new value on the command line.

## Environment Variable

Environment variables are an operating-system mechanism by which a table of names and associated values are passed between related processes. A parent process passes a copy of its environment to each child process that it creates. Under UNIX, environment variables are usually set in the user's shell-initialization files (`.cshrc`, `.login`, `.profile`, `.bashrc`, etc.). Under Microsoft Windows, the system environment variable dialog is commonly used for this purpose.

Any IDL preference can have its value defined by an environment variable of the same name. For example, to set the value of the `IDL_PATH` preference, which supplies the initial value for the `!PATH` system variable, you would define an environment variable named `IDL_PATH`.

### Note

---

Although IDL's preference names are internally case-insensitive, the UNIX environment is case-sensitive. Therefore, you must specify the environment-variable name in uppercase for IDL under UNIX to recognize it. In contrast, the Microsoft Windows environment is case-insensitive, and IDL recognizes any case. A simple rule that will always work is to always use uppercase environment-variable names.

---

To define an environment variable under Microsoft Windows, use the Environment Variables dialog available through the Windows control panel. Open the dialog by selecting **Start** → **Settings** → **Control Panel** → **System** → **Advanced** → **Environment Variables**.

To define an environment variable under UNIX, enter the following command (given here in `ksh/bash` format; adjust the command as necessary for your shell):

```
export IDL_GR_X_RENDERER=1
```

A preference specified by an environment variable is recognized by any version of IDL running on your system. For this reason, it is often desirable to avoid their use in favor of using a preference file.

If a preference is set by an environment variable, IDL considers it to be read-only. IDL uses the value provided for the duration of the current IDL session, but refuses to let you attempt to change it with the [PREF\\_SET](#) procedure. Preferences set via environment variables are not written to the current user's preferences file. To alter the environment variable, you should modify it at the source (UNIX shell-configuration file or Windows system dialog). Before the change is visible to IDL, you need to exit IDL and restart it.

## IDL Distribution Preference File

Every IDL distribution contains an `idl.pref` file within the `pref` subdirectory of the resource directory (`<IDL_DIR>/resource/pref/idl.pref`). The file's syntax is the same as that of the user preference file; for more information, see [“Understanding Preference Files”](#) on page 4849. The file serves as a single place where system administrators can establish global defaults for all of their IDL users, without having to edit the preference file for each of those users separately.

For example, IDL uses a thread pool on systems with multiple CPUs in order to carry out numerical operations more quickly. The default is to use the same number of threads as the system has CPUs, in order to use the hardware to best advantage. This default is usually correct for single-user systems, but can be inconvenient at locations where large multi-CPU systems are being shared simultaneously by scientists using IDL for unrelated work. In such a case, the unrelated IDLs battle each other for CPU access and slow down overall system throughput. The system administrator can establish a more productive default by putting a line such as the following in the distribution preference file:

```
IDL_CPU_TPOOL_NTHREADS : 1
```

If a preference is set by the distribution preference file, IDL considers it to be read-only. IDL uses the value provided for the duration of the current IDL session, but refuses to let you attempt to change it with the [PREF\\_SET](#) procedure. Preferences set in the IDL distribution preference file are not written to the current user's preferences file. To alter such a preference, you should modify it at the source by changing the contents of the distribution preference file. You need to exit IDL and restart it before the change is visible to IDL.

## User Preference File

IDL user preferences are kept in a file named `idl.pref`. The [APP\\_USER\\_DIR](#) function is used to determine the location of this file. A distinct and separate user

preference file is maintained for each combination of IDL version and operating-system family (UNIX or Microsoft Windows). The path to this file is displayed by the following command:

```
HELP, /PREFERENCES
```

Although you can edit this file directly with any text editor, RSI recommends that you instead use the IDL-supplied mechanisms for making changes. The IDLDE offers a graphical user interface for managing preferences. See [Chapter 3, “Setting IDL Preferences”](#) in the *Using IDL* manual for more information. You can also use the [PREF\\_SET](#) and [PREF\\_COMMIT](#) procedures for lower-level command-line-based access to the same functionality.

For more information, see [“Understanding Preference Files”](#) on page 4849.

## IDL Default Value

Every IDL preference has a built-in default value. This is the value that IDL will use for the preference if a value is not set by any of the other sources described above. You can use the following command to see the default values for all preferences:

```
HELP, /PREFERENCES, /FULL
```

For information on the output, see the documentation for the [PREFERENCES](#) and [FULL](#) keywords to [HELP](#).

## Changing Preference Values

This section provides information on setting and committing changes to IDL preferences, including details of the routines used to work with preferences, the pending state of changed preferences, and when committed preference changes take effect.

### Preference Routines

There are four routines in IDL that provide user-level access to the preference system:

- **PREF\_COMMIT** — used to commit preferences or discard pending values. See [“PREF\\_COMMIT”](#) on page 1735.
- **PREF\_SET** — used to set the value of a user preference by providing a new value or by setting it to its default value. See [“PREF\\_SET”](#) on page 1745.
- **PREF\_GET** — used to obtain detailed information about the status of a preference. See [“PREF\\_GET”](#) on page 1738.

- **PREF\_MIGRATE** — used to import preferences from other versions of IDL into the current version. This routine is written in the IDL language, and uses the other three routines above to do the actual work. See “[PREF\\_MIGRATE](#)” on page 1743.

---

**Note**

Authors of IDL applications should not use these routines in their code to make preference changes. See “[Using Preference Etiquette](#)” on page 4849 for more information.

---

## The Pending State

Unless the current effective value for a preference is read-only, IDL allows you to change the value of any preference with the [PREF\\_SET](#) procedure. When you set a new value for a preference, the preference enters a pending state. IDL remembers the change, but continues to use the previously active effective value. In order to make a pending preference value take effect, it must be committed. To commit a preference, IDL takes the following steps:

1. Writes a new user preference file which merges the new changes with the previously specified preference values.
2. Updates its internal state to make the pending values current.
3. Notifies the various parts of IDL that depend on the altered preference so that they can adapt to the change.

There are two ways to commit a preference:

- **PREF\_COMMIT** — used to commit preferences already in the pending state (see “[PREF\\_COMMIT](#)” on page 1735)
- **PREF\_SET** — used with the **COMMIT** keyword to set and commit a specific preference in a single operation (see “[PREF\\_SET](#)” on page 1745)

The pending state is useful for applications that allow users to manipulate preferences. In such an application, the user is typically allowed to make changes, but those changes can be discarded without taking effect if the user clicks the **Cancel** button. To implement this, an application uses [PREF\\_SET](#) to make the user's changes. If the user confirms the changes by clicking **Done**, [PREF\\_COMMIT](#) makes them permanent. Otherwise, they can be discarded by use of the [RESET](#) keyword. The pending state lifts the burden of tracking a user's changes from such applications, and greatly simplifies their implementation.

**Note**

Pending changes are indicated as such in `HELP, /PREFERENCES` output.

**Note**

Authors of IDL applications should not use these routines in their code to make preference changes. See “[Using Preference Etiquette](#)” on page 4849 for more information.

## When Committed Changes Take Effect

Once a new preference value has been committed, its new value is used by the rest of IDL to determine some particular aspect of its operation. This change can take effect at one of three possible times:

- **Immediately** — in most cases, changes to a preference are reflected in IDL’s operation immediately. For example, preferences are used to supply default values for many system variables. Usually, a change to a preference results in the associated system variable changing to the new value as soon as the new preference value is committed.
- **On reset or restart** — a few preferences do not take effect until the next use of the `.reset_session` or `.full_reset_session` executive commands, or until IDL is exited and restarted. One example of this group is the [IDL\\_DEVICE](#) preference, which specifies the default direct graphics device. Changes to [IDL\\_DEVICE](#) do not cause your current graphics device to be immediately reset. If you later use a reset executive command or restart IDL, however, the new default is used.
- **On restart** — a very small number of preferences only take effect in subsequent IDL sessions. The [IDL\\_DLM\\_PATH](#) preference is one such preference. Changes to [IDL\\_DLM\\_PATH](#) are not seen in the current IDL session, but take effect the next time IDL is run.

The output from the following command describes when changes to each preference take effect:

```
HELP, /PREFERENCES, /FULL
```

For information on the output, see the documentation for the [PREFERENCES](#) and [FULL](#) keywords to [HELP](#).

## Understanding Preference Files

An IDL preference file is a simple text file in which each preference is specified on a single line. The line consists of the preference name, followed by a colon (:) character, followed by the preference value. Empty and comment lines are allowed; IDL ignores them.

---

### Note

If you use the API functionality to commit preference changes, IDL overwrites the user preference file accordingly. Doing so removes any comments that you manually added to the file.

---

Here is a sample preference file:

```
# Sample IDL preference file
# Author: RSI

# No user information in SAVE and JOURNAL files
IDL_DATAFILE_USER_COMMENTS : 0

# Suppress information messages (alias used)
IDL_QUIET : on

# Buffer size = 50 lines
IDL_RBUF_SIZE : 50
```

You can give a preference file any name and extension, but you might want to use the `.pref` extension for clarity.

While you can create and edit preference files using any text editor, in general it is better to modify the user preference file using the API functionality (see [“Preference Routines”](#) on page 4846).

## Using Preference Etiquette

The IDL’s preference system routines [PREF\\_SET](#) and [PREF\\_COMMIT](#) provide programmatic control over the values of preferences saved in an individual user’s preference file. **In general, as an IDL application author, you should not use these routines in IDL code.** Since preference values set in the user preference file persist between sessions, changes made by your application using these routines will affect your end user’s IDL environment even when he or she is running other applications.

Preference files loaded at application startup provide a much more user-friendly mechanism for specifying preference values that apply only to your application. To use this mechanism, create a preference file that contains the preference values you

want to have in effect when your application runs, and include the name of the preference file in the command that launches your application via the `-pref` command-line option. (See “[Command Line Options for IDL Startup](#)” in Chapter 1 of the *Using IDL* manual for details.)

# General User Environment Preferences

This section describes the preferences for the general user environment.

## IDL\_DATAFILE\_USER\_COMMENTS

The `IDL_DATAFILE_USER_COMMENTS` preference specifies whether or not IDL is allowed to put comments that include user and host name into generated data files, such as `SAVE` and `JOURNAL` files. Such comments are usually considered to be helpful in most environments, but can be a problem for those working in secure environments with specific rules governing the information that is allowed to leave a given security level.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

## IDL\_DEVICE

IDL's direct graphics system always operates on the current graphics device, which you can change with the `SET_PLOT` procedure. The `IDL_DEVICE` preference specifies the initial graphics device that starts out as current.

Committed changes take effect at the next `.reset_session` executive command or in future IDL sessions. The default value is the window system supported by IDL for the target platform: "X" for UNIX systems and "WIN" for Microsoft Windows.

## IDL\_EDIT\_INPUT

The `IDL_EDIT_INPUT` preference sets the initial value of the `!EDIT_INPUT` system variable, which determines whether or not the tty-based (non-IDE) command-line version of IDL does command-line editing when reading commands. For related

information on the command recall buffer, see “[IDL\\_RBUF\\_PERSIST](#)” on page 4853 and “[IDL\\_RBUF\\_SIZE](#)” on page 4854.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

## IDL\_EXCEPT

The `IDL_EXCEPT` preference sets the initial value of the `!EXCEPT` system variable, which controls when IDL checks for invalid mathematical computations (exceptions).

Value	Aliases
0	Never, No
1	OnInterpreterHalt, Halt
2	AfterStmt, Stmt

Committed changes take effect immediately. The default value is OnInterpreterHalt (1).

## IDL\_MORE

The `IDL_MORE` preference sets the initial value of the `!MORE` system variable, which controls whether IDL should paginate help output sent to a TTY device or IDLDE log window.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

## IDL\_MSG\_PREFIX

The IDL\_MSG\_PREFIX preference sets the value of the [!ERROR\\_STATE.MSG\\_PREFIX](#) system variable, which determines the prefix string used for error messages.

Committed changes take effect immediately. The default value is ' % '.

## IDL\_PROMPT

The IDL\_PROMPT preference sets the value of the [!PROMPT](#) system variable, which contains the text string that IDL uses to prompt for input.

Committed changes take effect immediately. The default value is ' IDL> '.

## IDL\_QUIET

The IDL\_QUIET preference sets the value of the [!QUIET](#) system variable, which controls whether informational messages are printed (value is 0) or suppressed (1).

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

## IDL\_RBUF\_PERSIST

The IDL\_RBUF\_PERSIST preference determines whether the IDL command recall buffer is saved between IDL sessions. For related information on the recall buffer, see [“IDL\\_EDIT\\_INPUT”](#) on page 4851 and [“IDL\\_RBUF\\_SIZE”](#) on page 4854.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

**Note** 

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Log and Command Window Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_RBUF\_SIZE

The IDL\_RBUF\_SIZE preference sets the size of the IDL command recall buffer. It must be set to a value greater than or equal to 1. For related information on the recall buffer, see [“IDL\\_EDIT\\_INPUT”](#) on page 4851 and [“IDL\\_RBUF\\_PERSIST”](#) on page 4853.

Committed changes take effect immediately. The default value is 20.

**Note** 

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Log and Command Window Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

# Directory and Search Path Preferences

This section describes the preferences for directories and search paths.

## IDL\_DIR

The `IDL_DIR` preference provides the value of the `!DIR` system variable, which contains the location of the IDL distribution that contains the currently running IDL program.

You cannot set `IDL_DIR` by using user or distribution preference files. The only valid sources for its value are the IDL command line, the `IDL_DIR` environment variable, or IDL's built-in default value (preferred when possible). The reason for this restriction is that the IDL distribution is an intrinsic part of the IDL program; it must be known before IDL starts running and is not something that can be changed afterwards.

The default value under UNIX is `'/usr/local/rsi/idl_xx'`, where `xx` represents the IDL version. The default value under Microsoft Windows is the location where the IDL installer wrote the IDL files on your system (typically `C:\RSI\IDLxx`, where `xx` represents the IDL version).

## IDL\_DLM\_PATH

The `IDL_DLM_PATH` provides the value of the `!DLM_PATH` system variable, which contains the directories from which IDL loads dynamically loadable modules (DLMs).

Committed changes take effect in future IDL sessions. The default value is `'<IDL_DEFAULT>'`, a special token which IDL replaces at startup with the correct set of directories from the IDL distribution for the currently running version of IDL. If you add directories to `IDL_DLM_PATH`, you should be careful to retain `<IDL_DEFAULT>` in your new value, or IDL will fail to find the RSI-provided DLM files. For example, you can use one of the following commands to add your own DLM directory. Under Windows:

```
PREF_SET, 'IDL_DLM_PATH', 'C:\your\path\here;<IDL_DEFAULT>', $  
/COMMIT
```

Under UNIX:

```
PREF_SET, 'IDL_DLM_PATH', '/your/path/here:<IDL_DEFAULT>', $  
/COMMIT
```

See “[EXPAND\\_PATH](#)” on page 687 for more information on special syntax and `<IDL_>` tokens you can use in the path definition string. DLM files are IDL- and platform-specific. If you use DLMS with multiple versions of IDL, you might find the `<IDL_BIN_DIRNAME>` token of particular interest when setting up your DLM directories.

## IDL\_HELP\_PATH

The `IDL_HELP_PATH` preference sets the value of the `!HELP_PATH` system variable, which determines the directories where IDL searches for online help files.

Committed changes take effect immediately. The default value is `'<IDL_DEFAULT>'`, a special token which IDL replaces at startup with the correct set of directories from the IDL distribution for the currently running version of IDL. If you add directories to `IDL_HELP_PATH`, you should be careful to retain `<IDL_DEFAULT>` in your new value, or IDL will fail to find the RSI-provided help files. For example, you can use one of the following commands to add your own help directory. Under Windows:

```
PREF_SET, 'IDL_HELP_PATH', 'C:\your\path\here;<IDL_DEFAULT>', $
/COMMIT
```

Under UNIX:

```
PREF_SET, 'IDL_HELP_PATH', '/your/path/here:<IDL_DEFAULT>', $
/COMMIT
```

See “[EXPAND\\_PATH](#)” on page 687 for more information on special syntax and `<IDL_>` tokens you can use in the path definition string.

## IDL\_MAKE\_DLL\_COMPILE\_DIRECTORY

The `IDL_MAKE_DLL_COMPILE_DIRECTORY` preference sets the initial value of the `!MAKE_DLL_COMPILE_DIRECTORY` system variable, which specifies the location where the `MAKE_DLL` and `CALL_EXTERNAL` (with the `AUTO_GLUE` keyword set) routines do their work. A null string (`''`) for this preference specifies that IDL should create an appropriate platform-specific directory underneath the `.idl` subdirectory of the user’s home directory. This default value is highly recommended because it automatically handles multi-platform issues.

Committed changes take effect at the next `.reset_session` executive command or in future IDL sessions. The default value is a null string (`''`).

## IDL\_PATH

The `IDL_PATH` preference provides the initial value of the `!PATH` system variable, which determines the directories that IDL searches for include files and programs written in the IDL language (`.pro` and `.sav`).

Committed changes take effect immediately. The default value is '`<IDL_DEFAULT>`', a special token which IDL replaces at startup with the correct set of directories from the IDL distribution for the currently running version of IDL. If you add directories to `IDL_PATH`, you should be careful to retain `<IDL_DEFAULT>` in your new value, or IDL will fail to find the RSI-provided library files. For example, you can use one of the following commands to add your own library directory. Under Windows:

```
PREF_SET, 'IDL_PATH', 'C:\your\path\here;<IDL_DEFAULT>', $
/COMMIT
```

Under UNIX:

```
PREF_SET, 'IDL_PATH', '/your/path/here:<IDL_DEFAULT>', $
/COMMIT
```

See [“EXPAND\\_PATH”](#) on page 687 for more information on special syntax and `<IDL_>` tokens you can use in the path definition string.

---

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Search Path / IDL Files Search Path”](#) under [“Path Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_PATH\_CACHE\_DISABLE

The `IDL_PATH_CACHE_DISABLE` preference determines whether or not the IDL path cache is enabled when IDL starts. For more information on the path cache, see [“PATH\\_CACHE”](#) on page 1646.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0), meaning that the cache is enabled.

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Enable Path Cache”](#) under [“Path Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_STARTUP

The IDL\_STARTUP preference provides the path of a batch file that is executed automatically each time IDL is started and following a `.reset_session` or `.full_reset_session` executive command. (See [“Startup Files”](#) in Chapter 1 of the *Using IDL* manual for more information on startup files.) A null string (") indicates that there is no startup file.

Committed changes take effect at the next `.reset_session` executive command or in future IDL sessions. The default value is a null string (").

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Startup File”](#) under [“Startup Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_TMPDIR

The IDL\_TMPDIR preference provides the location of a directory to be used for creating temporary scratch files, as returned by the [GETENV](#) function, if its value is non-null. If the value is a null string, GETENV instead returns the path of the standard directory used for this purpose by the current operating system.

Committed changes take effect immediately. The default value is a null string (").

# !CPU Settings Preferences

The preferences with names starting with the `IDL_CPU_` prefix supply default values for the related fields of the `!CPU` system variable.

## IDL\_CPU\_TPOOL\_MAX\_ELTS

The `IDL_CPU_TPOOL_MAX_ELTS` preference sets the default value of the `!CPU.TPOOL_MAX_ELTS` system variable, which sets the maximum number of elements in a computation for which IDL uses the thread pool.

Committed changes take effect immediately. The default value is 0, meaning that no maximum limit is imposed, and any computation with at least `!CPU.TPOOL_MIN_ELTS` is a candidate for the thread pool.

## IDL\_CPU\_TPOOL\_MIN\_ELTS

The `IDL_CPU_TPOOL_MIN_ELTS` preference provides the value of the `!CPU.TPOOL_MIN_ELTS` system variable, which sets the number of elements in a computation that are necessary before IDL uses the thread pool to perform the work.

Committed changes take effect immediately. The default value is 100000.

## IDL\_CPU\_TPOOL\_NTHREADS

The `IDL_CPU_TPOOL_NTHREADS` preference specifies the initial value of the `!CPU.TPOOL_NTHREADS` system variable, which sets the number of threads that IDL uses in thread-pool computations.

Committed changes take effect immediately. The default value is 0, which causes IDL to use a thread for every CPU contained in the system on which IDL is currently running.

## IDL\_CPU\_VECTOR\_ENABLE

The `IDL_CPU_VECTOR_ENABLE` preference provides the initial value of the `!CPU.VECTOR_ENABLE` system variable if the system supports a vector unit

(!CPU.HW\_VECTOR is True). It is ignored if the system lacks a vector unit (!CPU.HW\_VECTOR is False).

<b>Value</b>	<b>Aliases</b>
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

# General Graphics Preferences

Preferences in this category are supported by all versions of IDL.

## IDL\_GR\_TILECACHESIZE

The `IDL_GR_TILECACHESIZE` preference controls how much memory (in megabytes) IDL can use for caching image tiles. IDL allocates memory for caching a tile each time `IDLgrImage::SetTitleData` is called. When the amount of allocated memory reaches the value of `IDL_GR_TILECACHESIZE`, the least recently viewed tile or tiles are freed to make room for the new tile. Therefore, the amount of memory used for caching tiles will not grow above this value.

Committed changes take effect immediately. The default value is 256.

## IDL\_GR\_TTCACHESIZE

IDL saves TrueType fonts as a set of glyphs; each glyph represents the triangulation data for drawing one character. To minimize the number of times common glyphs must be computed, IDL uses a cache to retain recently computed glyphs in the hope that they can be reused. When IDL finds a needed glyph in the cache, it uses the glyph immediately without rebuilding it. The `IDL_GR_TTCACHESIZE` preference sets the size of the TrueType glyph cache. It must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 256, roughly two TrueType font sets.

---

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see "[True Type Fonts Section](#)" under "[Graphics Preferences](#)" in Chapter 3 of the *Using IDL* manual.

---

# Windows Graphics Preferences

Preferences in this section control the default behavior of graphics produced by the Microsoft Windows window system.

## IDL\_GR\_WIN\_HEIGHT

The `IDL_GR_WIN_HEIGHT` preference sets the default height of a graphics window created by the Microsoft Windows direct graphics device ('WIN'). It controls the height of a window created by the `WINDOW` procedure unless you specify an explicit height to `WINDOW` or the `IDL_GR_WIN_QSCREEN` preference is True (1). `IDL_GR_WIN_HEIGHT` must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 512.

### Note

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Window Layout / Windows Size Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_GR\_WIN\_LAYOUT

The `IDL_GR_WIN_LAYOUT` preference specifies the default placement of graphics windows created by the Microsoft Windows direct graphics device ('WIN'). A value of Tile (0) causes windows to be created side-by-side with no overlap. A value of Cascade (1) causes them to be created overlapping.

Value	Alias
0	Tile
1	Cascade

Committed changes take effect immediately. The default value is Tile (0).

### Note

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Window Layout / Windows Size Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_GR\_WIN\_ONTOP

If the `IDL_GR_WIN_ONTOP` preference is set, graphics windows created by the Microsoft Windows direct graphics device ( 'WIN' ) always float above all other IDL windows.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Window Layout / Windows Size Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_GR\_WIN\_QSCREEN

If the `IDL_GR_WIN_QSCREEN` preference is set to True (1), the [IDL\\_GR\\_WIN\\_HEIGHT](#) and [IDL\\_GR\\_WIN\\_WIDTH](#) preferences are ignored. Instead, the default size of a graphics window created by the Microsoft Windows direct graphics device ( 'WIN' ) is one-fourth the size of the screen.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Window Layout / Windows Size Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_GR\_WIN\_RENDERER

IDL supports two methods of rendering object graphics: with a hardware graphics accelerator or with a software rendering package. The IDL\_GR\_WIN\_RENDERER preference determines the default method used for volume rendering.

Value	Alias
0	Hardware
1	Software

Committed changes take effect immediately. The default value is Hardware (0).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Default Object Graphics Renderer / Graphics Attributes Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_GR\_WIN\_RETAIN

The IDL\_GR\_WIN\_RETAIN preference sets the default method used to provide backing store for windows. When backing store is enabled, a copy of each graphics window is kept in memory; the copy is used to refresh the window when it has been covered and uncovered. IDL's performance might increase when no backing store is used because the amount of memory required to provide backing store can affect the speed at which IDL will run. Settings of this preference correspond to settings of the RETAIN keyword to the DEVICE procedure. See [“Keywords Accepted by the IDL Devices”](#) on page 4687 for more information

Value	Aliases
0	None
1	Server, System
2	IDLPixmap

Committed changes take effect immediately. The default value is Server (1).

**Note** 

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Backing Store Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_GR\_WIN\_WIDTH

The IDL\_GR\_WIN\_WIDTH preference sets the default width of a graphics window created by the Microsoft Windows direct graphics device ('WIN'). It controls the width of a window created by the [WINDOW](#) procedure unless you specify an explicit width to WINDOW or the [IDL\\_GR\\_WIN\\_QSCREEN](#) preference is True (1). IDL\_GR\_WIN\_WIDTH must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 640.

**Note** 

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Window Layout / Windows Size Section”](#) under [“Graphics Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

# X Window System Graphics Preferences

The preferences in this section are specific to versions of IDL that support the X Window System. They do not exist in the Microsoft Windows version of IDL.

## IDL\_GR\_X\_COLORS

The `IDL_GR_X_COLORS` preference specifies the number of color-table indices to allocate from the shared colormap used by direct graphics. If the value is positive, the specified number of indices are allocated. If the value is negative, all but the specified number are allocated. If the value is 0, all or most of the available color indices are allocated. See the documentation for the [COLORS](#) keyword to the `WINDOW` procedure for more information on this topic.

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The default value is 0.

## IDL\_GR\_X\_DEPTH

The `IDL_GR_X_DEPTH` preference specifies the depth, in bits, of the visual used by IDL.

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The default value is 0, meaning that IDL selects a visual from those available in the server, using the rules described in the documentation for the X Window device.

## IDL\_GR\_X\_HEIGHT

The `IDL_GR_X_HEIGHT` preference sets the default height of a graphics window created by the X Window System direct graphics device ( 'x' ). It controls the height of a window created by the [WINDOW](#) procedure unless you specify an explicit height to `WINDOW` or the [IDL\\_GR\\_X\\_QSCREEN](#) preference is True (1). `IDL_GR_X_HEIGHT` must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 512.

### Note

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see “[Window Layout / Windows Size Section](#)” under “[Graphics Preferences](#)” in Chapter 3 of the *Using IDL* manual.

---

## IDL\_GR\_X\_QSCREEN

If the IDL\_GR\_X\_QSCREEN preference is set to True (1), the IDL\_GR\_X\_HEIGHT and IDL\_GR\_X\_WIDTH preferences are ignored. Instead, the default size of a graphics window created by the X Window System direct graphics device ('X') is one-fourth the size of the screen.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see "[Window Layout / Windows Size Section](#)" under "[Graphics Preferences](#)" in Chapter 3 of the *Using IDL* manual.

## IDL\_GR\_X\_RENDERER

IDL supports two methods of rendering object graphics: with a hardware graphics accelerator or with a software rendering package. The IDL\_GR\_X\_RENDERER preference determines the default method used for volume rendering.

Value	Alias
0	Hardware
1	Software

Committed changes take effect immediately. The default value is Hardware (0).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see "[Default Object Graphics Renderer / Graphics Attributes Section](#)" under "[Graphics Preferences](#)" in Chapter 3 of the *Using IDL* manual.

## IDL\_GR\_X\_RETAIN

The `IDL_GR_X_RETAIN` preference specifies the default type of backing store to use for direct graphics windows. Note that you can override this default using the `RETAIN` keyword to the `WINDOW` or `DEVICE` procedures.

Value	Aliases
0	None
1	Server, System
2	IDLPixmap

Committed changes take effect immediately. The default value is Server (1).

---

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see "[Backing Store Section](#)" under "[Graphics Preferences](#)" in Chapter 3 of the *Using IDL* manual.

---

## IDL\_GR\_X\_VISUAL

The `IDL_GR_X_VISUAL` preference specifies the preferred X11 visual class for direct graphics windows.

Value	Alias
0	None
1	StaticGray
2	GrayScale
3	StaticColor
4	PseudoColor
5	TrueColor
6	DirectColor

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The

default value is None (0), meaning that IDL selects a visual from those available in the server, using the rules described in the documentation for the X Windows device (see “[The X Windows Device](#)” on page 4762).

## IDL\_GR\_X\_WIDTH

The IDL\_GR\_X\_WIDTH preference sets the default width of a graphics window created by the X Window System direct graphics device ( 'x' ). It controls the width of a window created by the [WINDOW](#) procedure unless you specify an explicit width to WINDOW or the [IDL\\_GR\\_X\\_QSCREEN](#) preference is True (1). IDL\_GR\_X\_WIDTH must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 640.

---

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see “[Window Layout / Windows Size Section](#)” under “[Graphics Preferences](#)” in Chapter 3 of the *Using IDL* manual.

---

# Windows IDE Preferences

The preferences in this section are specific to the Microsoft Windows version of IDL, and control default settings for the IDL development environment (IDLDE). They do not exist in non-Microsoft Windows versions.

## IDL\_WDE\_EDIT\_BACKUP

If the IDL\_WDE\_EDIT\_BACKUP preference is set to True (1), the IDLDE editor creates a backup of the original file before saving a file in an IDL editor window.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Backup on Save”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_[B|F]COLOR\_\*

The IDLDE editor uses colors to display various categories of text. Each category has a background color, specified with an IDL\_WDE\_EDIT\_BCOLOR preference, and foreground color, specified with an IDL\_WDE\_EDIT\_FCOLOR preference. For example, the background color used to display comments is IDL\_WDE\_EDIT\_BCOLOR\_COMMENT while the foreground color is IDL\_WDE\_EDIT\_FCOLOR\_COMMENT.

The available editor text color preferences are summarized in the following table, along with the default background and foreground color for each category:

Preference	Category	Back-ground	Fore-ground
IDL_WDE_EDIT_[B F]COLOR_COMMENT	Comment	White	DarkGreen

Preference	Category	Back-ground	Fore-ground
IDL_WDE_EDIT_[B F]COLOR_KEYWORD	IDL identifier	White	DarkRed
IDL_WDE_EDIT_[B F]COLOR_NUMBER	Number	White	LightBrown
IDL_WDE_EDIT_[B F]COLOR_SFUN	System function	White	Blue
IDL_WDE_EDIT_[B F]COLOR_SPRO	System procedure	White	DarkBlue
IDL_WDE_EDIT_[B F]COLOR_STRING	String	White	Red
IDL_WDE_EDIT_[B F]COLOR_UFUN	User function	White	Cyan
IDL_WDE_EDIT_[B F]COLOR_UPRO	User procedure	White	DarkCyan

The following colors are available:

Value	Alias
0	White
1	LightGray
2	Black
3	Red
4	DarkRed
5	Blue
6	DarkBlue
7	Cyan
8	DarkCyan
9	DarkGreen
10	Yellow
11	LightBrown

Committed changes take effect immediately.

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Colors Section \(Windows Only\)”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_CHROMACODE

The IDL\_WDE\_EDIT\_CHROMACODE preference determines whether color is used for syntax highlighting to highlight different aspects of IDL syntax.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Syntax Highlighting \(Windows Only\)”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_COMPILE\_OPTION

The IDL\_WDE\_EDIT\_COMPILE\_OPTION preference determines how the IDLDE editor handles requests to compile modified code contained within an editor window. It can handle such requests by asking whether you want to save your changes first, automatically save any changes before compiling, or compile from memory without saving the changes.

Value	Alias
0	AskToSave
1	AutoSave
2	CompileFromMemory

Committed changes take effect immediately. The default value is AskToSave (0).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Compiling Section”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_CWD

When you open a file in the IDLDE editor, the setting of the IDL\_WDE\_EDIT\_CWD preference determines whether the current working directory for the IDL process is changed to the directory containing the opened file.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Files Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_FONT

The IDL\_WDE\_EDIT\_FONT preference sets the font used by the IDLDE editor. The font is specified as a string containing four comma-separated parts in the following form:

Name, PointSize, IsBold, IsItalic

Where:

- **Name** — name of the font
- **PointSize** — size of the font
- **IsBold** — 0 for normal weight characters and 1 for bold
- **IsItalic** — 0 for normal characters and 1 for italic

Committed changes take effect immediately. The default value is 'Courier, 10, 0, 0'.

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Microsoft Windows”](#) under [“Font Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_OPEN\_ON\_DEBUG

If IDL execution halts because of an error and the IDL\_WDE\_EDIT\_OPEN\_ON\_DEBUG preference is set to True (1), the IDLDE opens the file containing the error and positions it to display the line with the problem.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Open on Debug \(Windows Only\)”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_READONLY

If the IDL\_WDE\_EDIT\_READONLY preference is set to True (1), files opened by the IDLDE editor are opened in read-only mode and cannot be modified.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see "[Files Section](#)" under "[General Preferences](#)" in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_TAB\_ENABLE

The IDL\_WDE\_EDIT\_TAB\_ENABLE preference determines whether or not the IDLDE editor inserts a tab character (ASCII 9) when you press the **Tab** key. If it is set to True (1), the editor inserts tabs; otherwise, the editor inserts the number of space characters specified by the [IDL\\_WDE\\_EDIT\\_TAB\\_WIDTH](#) preference.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see "[Tabs Section \(Windows Only\)](#)" under "[Editor Preferences](#)" in Chapter 3 of the *Using IDL* manual.

## IDL\_WDE\_EDIT\_TAB\_SP\_ON\_SAVE

The IDL\_WDE\_EDIT\_TAB\_SP\_ON\_SAVE preference controls how the IDLDE editor handles tab characters (ASCII 9) in a file when saving that file. If it is set to True (1), the editor replaces tabs with the number of spaces specified by the [IDL\\_WDE\\_EDIT\\_TAB\\_WIDTH](#) preference when the file is written.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Tabs Section \(Windows Only\)”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_EDIT\_TAB\_WIDTH

The IDL\_WDE\_EDIT\_TAB\_WIDTH preference controls how tabs are displayed by the IDLDE editor:

- It displays tab characters (ASCII 9) using a width of IDL\_WDE\_EDIT\_TAB\_WIDTH spaces
- If [IDL\\_WDE\\_EDIT\\_TAB\\_ENABLE](#) is False (0), the editor inserts IDL\_WDE\_EDIT\_TAB\_WIDTH blank characters into the file when you press the **Tab** key
- If [IDL\\_WDE\\_EDIT\\_TAB\\_SP\\_ON\\_SAVE](#) is True (1), the editor inserts IDL\_WDE\_EDIT\_TAB\_WIDTH blank characters into the file in place of any tab characters in the file when the file is saved

This preference must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 4.

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Tabs Section \(Windows Only\)”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_EXIT\_CONFIRM

If the IDL\_WDE\_EXIT\_CONFIRM preference is set to True (1), the IDLDE displays a warning dialog when you exit IDL.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Program Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_INPUT\_FONT

The `IDL_WDE_INPUT_FONT` preference sets the font used by the command line. The font is specified as a string containing four comma-separated parts in the following form:

Name, PointSize, IsBold, IsItalic

Where:

- **Name** — name of the font
- **PointSize** — size of the font
- **IsBold** — 0 for normal weight characters and 1 for bold
- **IsItalic** — 0 for normal characters and 1 for italic

Committed changes take effect immediately. The default value is `'MS Sans Serif, 8, 1, 0'`.

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Microsoft Windows”](#) under [“Font Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_LOG\_FONT

The `IDL_WDE_LOG_FONT` preference sets the font used by the output log window. The font is specified as a string containing four comma-separated parts in the following form:

Name, PointSize, IsBold, IsItalic

Where:

- **Name** — name of the font
- **PointSize** — size of the font
- **IsBold** — 0 for normal weight characters and 1 for bold

- **IsItalic** — 0 for normal characters and 1 for italic

Committed changes take effect immediately. The default value is 'MS Sans Serif, 8, 0, 0'.

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Microsoft Windows”](#) under [“Font Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_LOG\_LINES

The IDL\_WDE\_LOG\_LINES preference controls the maximum number of lines to display in the output log window. It must be set to a value greater than or equal to 1. Committed changes take effect in future IDL sessions. The default value is 1000.

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Log and Command Window Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_LOG\_TRIM

The IDL\_WDE\_LOG\_TRIM preference controls the number of lines that are deleted from the top of the output log when the maximum number of lines, specified by [IDL\\_WDE\\_LOG\\_LINES](#), is reached. It must be set to a value greater than or equal to 1.

Committed changes take effect in future IDL sessions. The default value is 100.

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Log and Command Window Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_SPLASHSCREEN

If the IDL\_WDE\_SPLASHSCREEN preference is set to True (1), the IDLDE displays the IDL splash screen on startup.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect in future IDL sessions. The default value is True (1).

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Program Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_WDE\_START\_DIR

The IDL\_WDE\_START\_DIR preference, if not set to a null string ("), specifies the initial working directory to be established when IDL starts. When you start IDL from the Windows Start menu or by clicking on a desktop icon, the initial working directory provided by the Windows operating system is usually a system location of no interest to IDL users. Setting IDL\_WDE\_START\_DIR lets you to specify a more useful location.

Committed changes take effect immediately. The default value is the user's home directory.

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Working Directory”](#) under [“Startup Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

# Motif IDE Preferences

The preferences in this section are specific to versions of IDL that support the Motif interactive development environment (IDLDE) interface to the IDL system. They do not exist in the Microsoft Windows version of IDL.

## IDL\_MDE\_EDIT\_BACKUP

If the `IDL_MDE_EDIT_BACKUP` preference is set to True (1), the IDLDE editor creates a backup of the original file before saving a file in an editor window.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

### Note

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Backup on Save”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_MDE\_EDIT\_COMPILE\_OPTION

The `IDL_MDE_EDIT_COMPILE_OPTION` preference determines how the IDLDE editor handles requests to compile modified code contained within an editor window. It can handle such requests by asking whether you want to save your changes first, automatically save any changes before compiling, or compile from memory without saving the changes.

Value	Alias
0	AskToSave
1	AutoSave
2	CompileFromMemory

Committed changes take effect immediately. The default value is AsktoSave (0).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Compiling Section”](#) under [“Editor Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_MDE\_EDIT\_CWD

When you open a file in the IDLDE editor, the IDL\_MDE\_EDIT\_CWD preference determines whether the current working directory for the IDL process is changed to the directory containing the opened file.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Files Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

## IDL\_MDE\_EDIT\_READONLY

If the IDL\_MDE\_EDIT\_READONLY preference is set to True (1), files opened by the IDLDE editor are opened in read-only mode and cannot be modified.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Files Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_MDE\_EXIT\_CONFIRM

If the IDL\_MDE\_EXIT\_CONFIRM preference is set, the IDLDE displays a warning dialog when you exit IDL.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Program Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_MDE\_LOG\_LINES

The IDL\_MDE\_LOG\_LINES preference controls the maximum number of lines to display in the output log window. It must be set to a value greater than or equal to 1.

Committed changes take effect in future IDL sessions. The default value is 1000.

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Log and Command Window Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_MDE\_LOG\_TRIM

The IDL\_MDE\_LOG\_TRIM preference controls the number of lines that are deleted from the top of the output log when the maximum number of lines, specified by

`IDL_MDE_LOG_LINES`, is reached. It must be set to a value greater than or equal to 1.

Committed changes take effect in future IDL sessions. The default value is 250.

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Log and Command Window Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_MDE\_SPLASHSCREEN

If the `IDL_MDE_SPLASHSCREEN` preference is set, the IDLDE displays the IDL splash screen on startup.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect in future IDL sessions. The default value is True (1).

---

**Note**

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Program Section”](#) under [“General Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

## IDL\_MDE\_START\_DIR

The `IDL_MDE_START_DIR` preference, if not set to a null string ("), specifies the initial working directory to be established when the IDLDE starts. Typically, UNIX users want their IDL initial working directory to be inherited from the working directory of the shell from which they start it. However, this preference can be useful in environments where the IDLDE is started by clicking on a desktop icon. In such an environment, the initial working directory might not be a location that is of interest to IDL users.

Committed changes take effect immediately. The default value is a null string (").

**Note**

---

You can set this preference in the IDLDE's Preferences dialog. For more information, see [“Working Directory”](#) under [“Startup Preferences”](#) in Chapter 3 of the *Using IDL* manual.

---

# Windows Runtime Preferences

These preferences exist to support the use of IDL runtime and the IDL Virtual Machine under Microsoft Windows. They are not present in non-Windows versions of IDL.

Under Microsoft Windows, the `idlrt.exe` program runs runtime or virtual-machine applications. The preferences described here provide default values for parameters to that program if they are not explicitly provided.

If IDL finds an IDL preference file named `idl.pref` in the directory containing the IDL DLL, IDL treats it as a command-line preference file and automatically reads and processes it. This is the most likely way in which the preferences specified in this section are used.

## IDL\_WINRT\_FILE

If you run `idlrt.exe` without specifying an IDL SAVE file, the `IDL_WINRT_FILE` preference supplies the name of the file to use.

Committed changes take effect at the next `idlrt.exe` invocation. The default value is a null string (").

## IDL\_WINRT\_FILE\_TYPE

If you run `idlrt.exe` without specifying the licensing mode under which it is expected to run, the `IDL_WINRT_FILE_TYPE` preference supplies the mode.

Value	Alias
0	Runtime
1	EmbeddedRuntime
2	VirtualMachine

Committed changes take effect at the next `idlrt.exe` invocation. The default value is Runtime (0).

## IDL\_WINRT\_ICON

The `IDL_WINRT_ICON` preference specifies the file containing the icon to use with a runtime or virtual-machine application.

Committed changes take effect at the next `idlrt.exe` invocation. The default value is a null string (`"`), indicating that the standard IDL icon should be used.

# Support for Obsolete Preference Mechanisms

Versions of IDL previous to version 6.2 did not have the preference system described in this appendix. Those older versions used different mechanisms to communicate user settings at startup:

- **!EDIT\_INPUT and recall buffer size** — the default size of the IDL command recall buffer is 20 lines. To change this, you were allowed to set the value of the **!EDIT\_INPUT** system variable to any value larger than 1 within your IDL startup file (as controlled by the **IDL\_STARTUP** preference). If IDL found such a value for **!EDIT\_INPUT**, it used it to size the recall buffer.
- **X11 Graphics Options** — a number of X11 options can be specified with X11 resources, commonly specified in `.xdefaults` or `.idlide` files.

To provide backwards compatibility with older versions, current versions of IDL are still able to check those sources for user settings and to transfer them, if found, to the corresponding IDL preference setting. The following table shows how IDL maps from one to the other:

Source	IDL Preference
( <code>!EDIT_INPUT</code> <code>gt</code> 1) in IDL startup file	<code>IDL_RBUF_SIZE</code>
<code>idl.retain</code> (X11 resource)	<code>IDL_GR_X_RETAIN</code>
<code>idl.graphicsWindowWidth</code> (X11 resource)	<code>IDL_GR_X_WIDTH</code>
<code>idl.graphicsWindowHeight</code> (X11 resource)	<code>IDL_GR_X_HEIGHT</code>
<code>idl.graphicsWindow14Screen</code> (X11 resource)	<code>IDL_GR_X_QSCREEN</code>
<code>idl.graphicsFontCache</code> (X11 resource)	<code>IDL_GR_TTCACHESIZE</code>
<code>idl.renderer</code> (X11 resource)	<code>IDL_GR_X_RENDERER</code>
<code>idl.gr_visual</code> (X11 resource)	<code>IDL_GR_X_VISUAL</code>
<code>idl.gr_depth</code> (X11 resource)	<code>IDL_GR_X_DEPTH</code>
<code>idl.colors</code> (X11 resource)	<code>IDL_GR_X_COLORS</code>

In all such cases, IDL goes through the following steps:

1. If the **IDL\_PREF\_OBSOLETE\_MIGRATE** preference is set to True (1), the IDL preference system examines the obsolete source. Otherwise, it quietly ignores the source.

2. If all of the following are true, IDL updates the user-preference file so that it contains the value from the obsolete source:
  - An obsolete source provides a value for a preference value
  - The value it provides is different from the IDL default value for that preference
  - The current value of the corresponding IDL preference has the default source (i.e., it has not been set)

In this way, the value migrates from the older mechanism into the IDL preference system. This migration can happen only once because once a preference has migrated, the IDL preference no longer has the default source.

3. If the value was migrated, IDL issues an informational message explaining that it has happened.
4. If a value from an obsolete source exists, but IDL is unable to use it for any of the reasons described in Step 2, and if the `IDL_PREF_OBSOLETE_WARN` preference is set to True (1), IDL issues an informational message explaining that the obsolete value was seen, but not used.

This process is intended as an aid to migration from the older system to the newer one. The default values of both preferences used to control it is True (1), in order to maximize the number of users it can assist. However, if you have successfully moved to newer versions of IDL or find the messages they produce annoying, you can set both preferences to False by using the following commands:

```
PREF_SET, 'IDL_PREF_OBSOLETE_MIGRATE', 'False'
PREF_SET, 'IDL_PREF_OBSOLETE_WARN', 'False'
PREF_COMMIT
```

Alternatively, you can edit IDL startup files, `.xdefault` files, `.idlde` files, and any other X11 resource files to remove the obsolete settings.

## IDL\_PREF\_OBSOLETE\_MIGRATE

The `IDL_PREF_OBSOLETE_MIGRATE` preference determines whether the IDL preference system consults older sources of information when determining preference values. See the description above for more information on this preference.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

## **IDL\_PREF\_OBSOLETE\_WARN**

If [IDL\\_PREF\\_OBSOLETE\\_MIGRATE](#) is set to True (1) and an obsolete source provides a value that cannot be used, the `IDL_PREF_OBSOLETE_WARN` preference determines whether or not IDL issues an informational message explaining that this has happened. See the description above for more information on this preference.

<b>Value</b>	<b>Aliases</b>
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

# Appendix F

# Special Characters

Within the IDL environment, a number of characters have special meanings.

The following table lists characters with special interpretations and states their functions in IDL. These characters are discussed further in the descriptions following the table.

Character	Function
!	First character of system variable names and font-positioning commands
'	Delimit string constants
	Indicate part of octal or hex constant
;	Begin comment field

*Table F-27: Special Characters*

Character	Function
\$	Continue current command on the next line
	Issue operating system command if entered on a line by itself
"	Delimit string constants or precede octal constants
.	Indicate constant is floating point
	Start executive command
&	Separate multiple statements on one line
:	End label identifiers
	Separate start and end subscript ranges
*	Multiplication operator
	Array subscript range
	Pointer dereference (if in front of a valid pointer)
@	Include file
	Execute IDL batch file
?	Invokes online help when entered at the IDL command line
	Part of the ?: ternary operator used in conditional expressions

*Table F-27: Special Characters (Continued)*

## Exclamation Point (!)

The exclamation point is the first character of names of IDL system-defined variables. System variables are predefined scalar variables of a fixed type. Their purpose is to override defaults for system procedures, to return status information, and to control the action of IDL.

## Apostrophe (')

The apostrophe delimits string literals and indicates part of an octal or hex constant.

## Semicolon (;)

The semicolon is the first character of the optional comment field of an IDL statement. All text on a line following a semicolon is ignored by IDL. A line can consist of a comment only or both a valid statement and a comment.

## Dollar Sign (\$)

The dollar sign at the end of a line indicates that the current statement is continued on the following line. The dollar sign character can appear anywhere a space is legal except within a string constant or between a function name and the first open parenthesis. Any number of continuation lines are allowed.

When the \$ character is entered as the first character after the IDL prompt, the rest of the line is sent to the operating system as a command. If \$ is the only character present, an interactive subprocess is started. Under UNIX, IDL execution suspends until the new shell process terminates.

## Quotation Mark ("")

The quotation mark precedes octal numbers, which are always integers, and delimits string constants. Example: "100B is a byte constant equal to 64 base 10 and "Don't drink the water" is a string constant.

## Period (.)

The period or decimal point indicates in a numeric constant that the number is of floating-point or double-precision type. Example: 1.0 is a floating-point number. Also, in response to the IDL prompt, the period begins an executive command. For example,

```
.run myfile
```

causes IDL to compile the file *myfile.pro*. If *myfile.pro* contains a main program, the program also will be executed. In addition, the period precedes the name of a tag when referring to a field within a structure. For example, a reference to a tag called NAME in a structure stored in the variable A is A.NAME.

## Ampersand (&)

The ampersand separates multiple statements on one line. Statements can be combined until the maximum line length is reached. For example, the following line contains two statements:

```
I = 1 & PRINT, 'value:', I
```

## Colon (:)

The colon ends label identifiers. Labels can only be referenced by GOTO and ON\_ERROR statements. The following line contains a statement with the label LOOP1.

```
LOOP1: X = 2.5
```

The colon also separates the starting and ending subscripts in subscript range specifiers. For example, A(3:6) designates elements three to six of the variable A.

## Asterisk (\*)

The asterisk represents one of the following, depending on context:

1. Multiplication ( $3 * 3$ ).
2. An ending subscript range equal to the size of the dimension. For example, A[3:\*] represents all elements of the vector A from A[3] to the last element, while B[\* , 3] represents all elements of row four of matrix B.
3. A pointer dereference operation. For example, if ptr is a valid pointer (created via the PTR\_NEW function), then \*ptr is the value held by the heap variable that ptr points to. For more information on IDL pointers, see [Chapter 17, “Pointers”](#) in the *Building IDL Applications* manual.

## At Sign (@)

The “at” sign is used both as an include character and to signal batch execution.

### @ as an Include Character

The “at” sign at the beginning of a line causes the IDL compiler to substitute the contents of the file whose name appears after the @ for the line. If the full path name is not specified after the @ symbol, IDL searches the current directory and the list of directories specified by the system variable !PATH.

For example, the line

```
@doit
```

when included in a file, causes the file *doit.pro* to be compiled in its place. (The suffix *.pro* is the default for IDL program files.) When the end of the file is reached, compilation resumes at the line after the @.

## @ to Signal Batch Processing

When IDL is running in interactive mode, a line beginning with the character @ is entered in response to the IDL prompt and the file is opened for batch input. See [Chapter 3, “Executing Batch Jobs in IDL”](#) in the *Building IDL Applications* manual for details.

## Question Mark (?)

The question mark is used as follows:

- When entered at the IDL command line, the IDL online help facility is invoked.
- Used in conditional expressions as part of the ?: ternary operator. For example:

```
; A shorter way of saying IF (a GT b) THEN z=a ELSE z=b:  
z = (a GT b) ? a : b
```

For more on conditional expressions, see [“Working with Conditional Expressions”](#) in Chapter 12 of the *Building IDL Applications* manual.

## Appendix G

# Reserved Words

Variables, user-written procedures, and user-written functions should not have the same names as IDL functions or procedures. Re-using names of IDL routines can lead to syntax errors or to “hiding” variables. In addition, certain words representing IDL language constructs are strictly forbidden—using any of these *reserved words* as a variable, procedure, or function name will cause an immediate syntax error. The following table lists all of the reserved words in IDL.

AND	BEGIN	BREAK
CASE	COMMON	COMPILE_OPT
CONTINUE	DO	ELSE
END	ENDCASE	ENDELSE
ENDFOR	ENDIF	ENDREP
ENDSWITCH	ENDWHILE	EQ
FOR	FORWARD_FUNCTION	FUNCTION

GE	GOTO	GT
IF	INHERITS	LE
LT	MOD	NE
NOT	OF	ON_IOERROR
OR	PRO	REPEAT
SWITCH	THEN	UNTIL
WHILE	XOR	

# Appendix H

<a href="#">About Device Fonts</a> . . . . .	4910		

# Overview of Fonts in IDL

IDL uses three font systems for writing characters on the graphics device: Hershey (vector) fonts, TrueType (outline) fonts, and device (hardware) fonts. This chapter describes each of the three types of fonts, discusses when to use each type, and explains how to use fonts when creating graphical output in IDL.

## Hershey Vector Fonts

Hershey vector-drawn fonts, also referred to as *Hershey fonts*, are drawn as lines. They are device-independent (within the limits of device resolution) and can be used in Direct Graphic and Object Graphic displays. All Hershey vector fonts included with IDL are guaranteed to be available in any IDL installation. See [“About Hershey Vector Fonts”](#) on page 4904 for additional details.

## TrueType Fonts

TrueType fonts, also referred to here as *outline fonts*, are drawn as character outlines, which are filled when displayed. They are largely device-independent, but do have some device-dependent characteristics. Four TrueType font families are included with IDL; these fonts should display in a similar way on any IDL platform. TrueType font support for IDL Object Graphics was introduced in IDL version 5.0 and support in IDL Direct Graphics was introduced in IDL version 5.1. See [“About TrueType Fonts”](#) on page 4906 for additional details.

## Device Fonts

Device fonts, also referred to as *hardware fonts*, rely on character-display hardware or software built in to a specific display device, and include PostScript fonts. Device fonts, necessarily, are device-dependent and differ from platform to platform and display device to display device. Device fonts are supported in IDL Direct Graphics. See [“About Device Fonts”](#) on page 4910 for additional details.

# Choosing a Font Type

Some of the issues involved in choosing between Hershey vector, TrueType, and device fonts are explained below.

## Appearance

Hershey vector-drawn characters are of medium quality, suitable for most uses. TrueType characters are of relatively high quality, although at some point sizes the triangulation process (described in [“About TrueType Fonts”](#) on page 4906) may cause characters to appear slightly jagged. The appearance of device characters varies from mediocre (characters found in many graphics terminals) to publication quality (PostScript).

## Three-Dimensional Transformations

Hershey vector or TrueType fonts should always be used with three-dimensional transformations. Both vector and TrueType characters pass through the same transformations as the rest of the plot, yielding a better looking plot. See [“Coordinates of 3-D Graphics”](#) in Chapter 8 of the *Using IDL* manual for more information, and the “Examples” section of [“T3D”](#) on page 2292 for an example of vector-drawn characters with three-dimensional graphics. Device characters are not subject to the three-dimensional transforms.

## Portability

The Hershey vector-drawn fonts work using any graphics device and look the same on every device (within the limitations of device resolution) on any system supported by IDL.

TrueType fonts are available only on the X, WIN, PRINTER, PS, and Z Direct Graphics devices, and in IDL’s Object Graphics system. If you use only the fonts supplied with IDL, TrueType fonts also look the same on every supported device (again within the limits of the device resolution). If you use TrueType fonts other than those supplied with IDL, your font may not be installed on the system which runs your program. In this case, IDL will substitute a known font for the missing font.

The appearance, size, and availability of device fonts varies greatly from device to device. Many, if not most, of the positioning and font changing commands recognized by the Hershey vector-drawing routines are ignored when using device fonts. The exception to this rule is the Direct Graphics PS device; if you use one of the PostScript fonts supported by IDL, the PostScript output from the PS device will be identical between platforms.

## Computational Time

Device fonts are generally rendered the most quickly, since the hardware device or operating system handles all computations and caching.

It takes more computer time to draw characters with line vectors and generally results in more input/output. However, this is not an important issue unless the plot contains a large number of characters or the transmission link to the device is very slow.

The initial triangulation step used when displaying TrueType fonts for the first time can be computationally expensive. However, since the font shapes are cached, subsequent uses of the same font are relatively speedy.

## Flexibility

Hershey vector-drawn fonts provide a great deal of flexibility. There are many different typefaces available, as shown in the tables at the end of this chapter. In addition, such fonts can be arbitrarily scaled, rotated, and transformed.

TrueType fonts support fewer embedded formatting commands than do the vector fonts, and cannot be scaled, rotated, or transformed.

The abilities of hardware-generated characters differ greatly between devices so it is not possible to make a blanket statement on when they should be used—the best font to use depends on the available hardware. In general, however, the Hershey vector or TrueType fonts are easier to use and often provide superior results to what is available from the hardware. See the discussion of the device you are using in [Appendix A, “IDL Direct Graphics Devices”](#) for details on the hardware-generated characters provided by that device.

## Print Quality

For producing publication-quality output, we recommend using either the TrueType font system, or the Direct Graphics PS device and one of the PostScript fonts supported by IDL.

# Fonts in IDL Direct vs. Object Graphics

The majority of this section deals with IDL Direct Graphics. However, the Hershey vector and TrueType font systems described here are also available in the IDL Object Graphics system as described in [Chapter 9, “Annotating an Object Display”](#) in the *Object Programming* manual.

## IDL Direct Graphics

When generating characters for Direct Graphics plots, IDL uses the font system specified by setting the `!P.FONT` system variable to one of the following values:

-1	Use Hershey vector-drawn fonts—the default
0	Use device fonts (fonts supplied by the graphics device)
1	Use TrueType fonts

The IDL system variable `!P.FONT` setting can be overridden for a single IDL Direct Graphics routine (`AXIS`, `CONTOUR`, `PLOT`, `SHADE_SURF`, `SURFACE`, or `XYOUTS`) by setting the `FONT` keyword equal to -1, 0, or 1.

Once a font system has been selected, an individual font can be chosen either via a formatting command embedded in a text string as described in [“Embedded Formatting Commands”](#) on page 4919, or by setting the value of the `SET_FONT` keyword to the `DEVICE` routine (see [“SET\\_FONT”](#) on page 4716). Also see [“Using TrueType Fonts”](#) on page 4907 and [“Using Device Fonts”](#) on page 4911 for additional examples of using `SET_FONT`.

## IDL Object Graphics

IDL Object Graphics can use the Hershey vector and TrueType font systems. Like Direct Graphics, embedded formatting commands can change the characteristics or position of text within a text string as described in [“Embedded Formatting Commands”](#) on page 4919. TrueType fonts you add to your IDL installation as described in [“About TrueType Fonts”](#) on page 4906 will be available to the Object Graphics system. Device fonts (including PostScript fonts) are unavailable in Object Graphics. See [Chapter 9, “Annotating an Object Display”](#) in the *Object Programming* manual for information on using creating and using `IDLgrText` and `IDLgrFont` objects.

# About Hershey Vector Fonts

The image shows the text "A Hershey Font" rendered in a light gray, thin-lined font style characteristic of Hershey vector fonts. The letters are composed of simple geometric shapes and lines, giving them a clean, technical appearance.

*Figure H-10: Hershey Font*

The Hershey vector fonts used by IDL were digitized by Dr. A.V. Hershey of the Naval Weapons Laboratory. Characters in the vector fonts are stored as equations, and can be scaled and rotated in three dimensions. They are drawn as lines on the current graphics device, and are displayed quickly and efficiently by IDL. The Hershey vector fonts are built into IDL itself, and are always available.

All the available fonts are illustrated in [“Hershey Vector Font Samples”](#) on page 4933. The default Hershey vector font is Font 3, Simplex Roman.

## Using Hershey Vector Fonts

To use the Hershey vector font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to -1 (negative one), or set the `FONT` keyword of one of the Direct Graphics routines equal to -1. The vector font system is the default font system for IDL. To use the vector font system with IDL Object Graphics, consult [“Creating Font Objects”](#) in Chapter 9 of the *Object Programming* manual.

Once the vector font system is selected, use an embedded formatting command to select a vector font (or fonts) for each string (see [“Embedded Formatting Commands”](#) on page 4919 for details). The font selected “sticks” from string to string; that is, if you change fonts in one string, future strings will use the new font until you change it again or exit IDL.

For example, to use the Duplex Roman Hershey vector font for the title of a plot, you would use a command that looks like this:

```
PLOT, mydata, TITLE="!5Title of my plot"
```

Also see the following to modify the characteristics of a TrueType font:

- Change font size — see [“Specifying Font Size”](#) on page 4917.
- Change font usage or position — see [“Embedded Formatting Commands”](#) on page 4919. Embedded formatting commands are in-line commands that allow you to position text and change fonts within a single line of text.

## ISO Latin 1 Encoding

The default Hershey vector font (Font 3, Simplex Roman) follows the ISO Latin 1 Encoding scheme and contains many international characters. The illustration of this font under [“Hershey Vector Font Samples”](#) on page 4933 can be used to find the octal codes for the special characters.

For example, suppose you want to display some text with an Angstrom symbol in it. Looking at the chart of font 3, we see that the Angstrom symbol has octal code 305. Non-printable characters can be represented in IDL using octal or hexadecimal notation and the `STRING` function (see [“Non-Printing Characters”](#) in Chapter 14 of the *Building IDL Applications* manual for details). So the Angstrom can be printed by inserting a `STRING ("305B)` character in the text string as follows:

```
XYOUTS, .1, .5, 'Here is an Angstrom symbol: ' + STRING("305B), $  
/NORM, CHARSIZE=3
```

## Customizing the Hershey Vector Fonts

The `EFONT` procedure is a widget application that allows you to edit the Hershey fonts and save the results. Use this routine to add special characters or completely new, custom fonts to the Hershey fonts.

## About TrueType Fonts

# A TrueType Font

*Figure H-11: TrueType Font*

Beginning with version 5.2, IDL includes the following five TrueType font families:

Font Family	Italic	Bold	BoldItalic
Courier	Courier Italic	Courier Bold	Courier Bold Italic
Helvetica	Helvetica Italic	Helvetica Bold	Helvetica Bold Italic
Monospace Symbol			
Times	Times Italic	Times Bold	Times Bold Italic
Symbol			

*Table H-28: TrueType Font Names*

When TrueType fonts are rendered on an IDL graphics device or destination object, the font outlines are first scaled to the proper size. After scaling, IDL converts the character outline information to a set of polygons using a triangulation algorithm. When text in a TrueType font is displayed, IDL is actually drawing a set of polygons calculated from the font information. This process has two side effects:

1. Computation time is used to triangulate and create the polygons. This means that you may notice a slight delay the first time you use text in a particular font and size. Once the polygons have been created, the information is cached by IDL and there is no need to re-triangulate each time text is displayed. Subsequent uses of the same font and size happen quickly.
2. Because the TrueType font outlines are converted into polygons, you may notice some chunkiness in the displayed characters, especially at small point sizes. The smoothness of the characters will vary with the quality of the TrueType font you are using, the point size, and the general smoothness of the font outlines.

## Using TrueType Fonts

To use the TrueType font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to 1 (one), or set the `FONT` keyword to on one of the Direct Graphics routines equal to 1. Consult “[Creating Font Objects](#)” in Chapter 9 of the *Object Programming* manual for information on using the TrueType font system with IDL Object Graphics.

Once the TrueType font system is selected, use the `SET_FONT` keyword to the `DEVICE` routine to select the font to use. The value of the `SET_FONT` keyword is a *font name string*. The font name is the name by which IDL knows the font; the names of the TrueType fonts included with IDL are listed under “[About TrueType Fonts](#)” on page 4906. Finally, specify the `TT_FONT` keyword in the call to the `DEVICE` procedure. For example, to use Helvetica Bold Italic, use the following statement:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

To use Times Roman Regular:

```
DEVICE, SET_FONT='Times', /TT_FONT
```

IDL’s default TrueType font is 12 point Helvetica regular.

Also see the following to modify the characteristics of a TrueType font:

- Change font size — see “[Specifying Font Size](#)” on page 4917.
- Change font usage or position — see “[Embedded Formatting Commands](#)” on page 4919. Embedded formatting commands are in-line commands that allow you to position text and change fonts within a single line of text. A subset of the embedded formatting commands available for use with the Hershey vector fonts are also available when using the TrueType font system.

## IDL TrueType Font Resource Files

The TrueType font system relies on a resource file named `ttfont.map`, located in the `resource/fonts/tt` subdirectory of the IDL directory. The format of the `ttfont.map` file is:

```
FontName      FileName      DirectGraphicsScale      ObjectGraphicsScale
```

where the fields in each column must be separated by white space (spaces and/or tabs). The fields contain the following information

The *Fontname* field contains the name that would be used for the `SET_FONT` keywords to the `DEVICE` routine.

The *Filename* field contains the name of the TrueType font file. On UNIX platforms, IDL will search for the file specified in the *FileName* field in the current directory (that is, in the `resource/fonts/tt` subdirectory of the IDL directory) if a bare filename is provided, or it will look for the file in the location specified by the fully-qualified file name if a complete path is provided. Because different platforms use different path-specification syntax, we recommend that you place any TrueType font files you wish to add to the `ttfont.map` file in the `resource/fonts/tt` subdirectory of the IDL directory. On Windows platforms, this entry may be '\*', in which case the font will be loaded from the operating system font list, but that the following two scale entries will be honored.

The *DirectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Direct Graphics device. If you want the tallest character in the font to fit exactly within the vertical dimension of the device's current character size (as set via the `SET_CHARACTER_SIZE` keyword to the `DEVICE` procedure, described in [“Specifying Font Size”](#) on page 4917), set the scale factor equal to 1.0. Change the scale factor to a smaller number to scale a smaller portion of the tallest character into the character size.

For example, suppose the tallest character in your font is “Ã”. Setting the scale factor to 1.0 will scale this character to fit the current character size, and then apply the same scaling to all characters in the font. As a result, the letter “M” will fill only approximately 85% of the full height of the character size. To scale the font such that the height of the “M” fills the vertical dimension of the character size, you would include the value 0.85 in the scale field of the `ttfont.map` file.

The *ObjectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Object Graphics device. (This field works just like the *DirectGraphicsScale* field.) This scale factor should be set to 1.0 if the maximum ascent among all glyphs within a given font is to fit exactly within the font size (as set via the `SIZE` property to the `IDLgrFont` object).

## Adding Your Own Fonts

To add a your own font to the list of fonts known to IDL, use a text editor to edit the `ttfont.map` file, adding the *FontName*, *FileName*, *DirectGraphicsScale*, and *ObjectGraphicsScale* fields for your font. You will need to restart IDL for the changes to the `ttfont.map` file to take effect. On Windows systems, you can use fonts that are not mentioned in the `ttfont.map` file, as long as they are installed in the Fonts control panel, as described below.

**Warning**

If you choose to modify the `ttfont.map` file, be sure to keep a backup copy of the original file so you can restore the defaults if necessary. Note also that applications that use text may appear different on different platforms if the scale entries in the `ttfont.map` file have been altered.

## Where IDL Searches for Fonts

The TrueType font files included with IDL are located in the `resource/fonts/tt` subdirectory of the IDL directory. When attempting to resolve a font name (specified via the `FONT` keyword to the `DEVICE` procedure), IDL will look in the `ttfont.map` file first. If it fails to find the specified font file in the `ttfont.map` file, it will search for the font file in the following locations:

### UNIX

No further search will be performed. If the specified font is not included in the `ttfont.map` file, IDL will substitute Helvetica.

### Microsoft Windows

If the specified font is not included in the `ttfont.map` file, IDL will search the list of fonts installed in the system (the fonts installed in the Font control panel). If the specified font is not found, IDL will substitute Helvetica.

**Note**

To get the list, you can use the following command, which returns in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

## About Device Fonts

# *A PostScript Font*

Figure H-12: PostScript Font

Device, or hardware, fonts are fonts that are provided directly by your system's hardware or by software other than IDL. In past releases of IDL, we have used the term "*hardware fonts*" extensively to discuss these types of fonts. This is because in the early days of IDL, computer displays were either text-only terminals or dedicated graphics display devices such as plotters or Tektronix graphics terminals. These graphics displays generally came with a set of fonts built-in; when IDL asked the device to display characters in a built-in font, it was making a request to the hardware to display those characters.

As computer displays have become more sophisticated, the concept of fonts provided "by the hardware" has expanded to include fonts provided by the computer's operating system, or by font-management software. For example, many computers now use font management software like Adobe Type Manager to manage the fonts made available by the operating system to all applications. We use the term "device font" to refer to a font that is available to one of IDL's graphics devices from a source *other than IDL itself*. (In this case, a "graphics device" can be a Direct Graphics device as specified by the DEVICE routine.) While device fonts may include fonts only available because a particular piece of hardware knows how to draw characters in that font (a pen plotter is an example of a device that may still have its own special fonts), in most cases device fonts are fonts supplied by the operating system to any application that may want to use them.

### Which Device Fonts Are Available?

To determine which device fonts are available on your system and the exact font strings to specify for each, use the [GET\\_FONTNAMES](#) keyword to the DEVICE

procedure. Use one of the following operating-system specific methods to determine which fonts are available:

- **UNIX** — on most systems, the `xlsfonts` utility displays a list of fonts available to the operating system.
- **Microsoft Windows** — Fonts available to the system are displayed in the Fonts control panel. You may also have other fonts available if you use font-management software such as Adobe Type Manager.

## Using Device Fonts

To use the Device font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to 0 (zero), or set the `FONT` keyword to one of the Direct Graphics routines equal to 0.

Once the Device font system is selected, use the `SET_FONT` keyword to the `DEVICE` routine to select the font to use. Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

### UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`. You can use the `xlsfonts` command to list available X Windows fonts.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

### Microsoft Windows

The `SET_FONT` keyword should be set to a string with the following form:

```
!P.FONT = 0
DEVICE, SET_FONT="font*modifier1*modifier2*...modifiern"
```

where the asterisk (\*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF

- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = "Garamond*ITALIC*24"
PLOT, FINDGEN(10), TITLE = "IDL Plot"
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size. See “[SET\\_FONT](#)” on page 4716 for more information.

---

#### Note

If you set the output device to PostScript (`SET_PLOT, 'PS'`), attempting to use the (\*) delimiter with `SET_PLOT` will cause an error. You must use `SET_PLOT` with specific PostScript font strings as described in the following section.

---

## Fonts and the PostScript Device

A special set of device fonts are available when the current Direct Graphics device is `PS` (PostScript). IDL includes font metric information for 35 standard PostScript fonts, and can create PostScript language files that include text in these fonts. (The 35 fonts known to IDL are listed in the following table ([Table H-29](#)); these are standard fonts included in memory in the vast majority of modern PostScript printers.) The PostScript font metric files (\*.afm files) are located in the `resource/fonts/ps` subdirectory of the IDL directory.

### Using PostScript Fonts

To use a PostScript font in your Direct Graphics output, you must first specify that IDL use the device font system, then switch to the `PS` device, then choose a font using the `SET_FONT` keyword to the `DEVICE` procedure.

The following IDL commands choose the correct font system (0 designates the device font system), set the graphics device, select the font Palatino Roman, open a PostScript file to print to, plot a simple data set, and close the PostScript file:

```
!P.FONT = 0
SET_PLOT, 'PS'
DEVICE, SET_FONT='Palatino-Roman', FILE='testfile.ps'
PLOT, INDGEN(10), TITLE = 'My Palatino Title'
DEVICE, /CLOSE
```

Allowable values for the SET\_FONT keyword are listed in the following table.

---

### Note

Subsequent PostScript output will continue to use the font Palatino Roman until you explicitly change the font again, or exit IDL.

---

---

### Note

When using SET\_FONT with the PostScript device on Windows, you cannot use the (\*) delimiter to specify font characteristics as described in “[Microsoft Windows](#)” on page 4909. You must use the names shown in the following table, without modifiers.

---

You can also specify PostScript fonts using a set of keywords to the DEVICE procedure. The keyword combinations for the fonts included with IDL are listed in the following table. For example to use the PostScript font Palatino Bold Italic, you could use either of the following DEVICE commands:

```
DEVICE, SET_FONT = 'Bookman-LightItalic'
DEVICE, /BKMAN, /LIGHT, /ITALIC
```

PostScript Font SET_FONT Value	DEVICE Keywords
AvantGarde-Book	/AVANTGARDE, /BOOK
AvantGarde-BookOblique	/AVANTGARDE, /BOOK, /OBLIQUE
AvantGarde-Demi	/AVANTGARDE, /DEMI
AvantGarde-DemiOblique	/AVANTGARDE, /DEMI, /OBLIQUE
Bookman-Demi	/BKMAN, /DEMI
Bookman-DemiItalic	/BKMAN, /DEMI, /ITALIC

Table H-29: The Standard 35 PostScript Fonts

<b>PostScript Font SET_FONT Value</b>	<b>DEVICE Keywords</b>

Table H-29: The Standard 35 PostScript Fonts (Continued)

## Changing the PostScript Font Assigned to an Index

You can change the PostScript font assigned to a given font index using the [FONT\\_INDEX](#) keyword to the DEVICE procedure. Font indices and their use are discussed in “[Embedded Formatting Commands](#)” on page 4919. There is a slot available for a user-defined font (index number 20). However, any index from 3 to 20 can contain a user-defined font. See “[Adding Your Own PostScript Fonts](#)” on page 4916 for details.

After choosing the PostScript device using `SET_PLOT, 'PS'`, you can see which fonts are associated with the available index numbers by typing `HELP, /DEVICE` at the command line. You can add default fonts or user-defined fonts to the font mapping list. In the following example, a font that is not mapped to a font index number by default (but is a standard PostScript font) is associated with index number 20 and used in the plot title.

```
SET_PLOT, 'PS'
!P.FONT=0
DEVICE, SET_FONT = 'ZapfChancery-MediumItalic', FONT_INDEX=20
PLOT, INDGEN(10), TITLE='!20Simple Plot Example'
DEVICE, /CLOSE
```

View the default `idl.ps` file to see the results.

Changing the font index assigned to a font can be useful when changing PostScript fonts in the middle of a text string. For example, the following statements map Palatino Bold Italic to font index 4, and then output text using that font and the Symbol font:

```
; Map the font selected by !4 to be PalatinoBoldItalic:
DEVICE, /PALATINO, /BOLD, /ITALIC, FONT_INDEX=4
```

```
; Output "Alpha :" in PalatinoBoldItalic followed by an  
; Alpha character:  
XYOUTS, .3, .5, /NORMAL, "!4Alpha: !9a", FONT=0, SIZE=5.0
```

## Adding Your Own PostScript Fonts

Because the 35 PostScript fonts included with IDL are built in to a PostScript printer's memory, the IDL distribution includes only the font metric files, which provide positioning information. In addition, the `.afm` files used by IDL are specially processed to provide the information in a format IDL expects.

You can add your own PostScript fonts to the list of fonts known to IDL if you have access to the PostScript font file (usually named `font.pfb`) to load into your printer and to the `font.afm` file supplied by Adobe. You can convert the standard `.afm` file into a file IDL understands using the IDL routine [PSAFM](#). Consult the file `README.TXT` in the `resource/fonts/ps` subdirectory of the IDL directory for details on adding PostScript fonts to your system. In general, you will need to do the following:

1. Add the font to the `resource/fonts/ps` subdirectory of the IDL directory using [PSAFM](#).
2. Add an entry for the font to the `fonts.map` file located in the `resource/fonts/ps` directory. You can locate the required fontname by examining the font file in a text editor.
3. Use the font directly by calling it with `SET_FONT` or add it to the list of font mappings using `FONT_INDEX`. See [“Changing the PostScript Font Assigned to an Index”](#) on page 4915 for details.

# Controlling Size, Position and Font Use

The way font size is set depends upon the type of font and whether the font is being rendered in Direct or Object Graphics. See one of the followings:

- Direct Graphics — See [“Controlling Size, Position and Font Use”](#) on page 4917
- Object Graphics — See [“Fonts”](#) in Chapter 9 of the *Object Programming* manual

You can control the position of individual characters, and the font with which individual characters in a text string are rendered by using embedded formatting commands. See [“Embedded Formatting Commands”](#) on page 4919 for details.

## Specifying Font Size

The size of a device font is specified when the font is defined. See [“Using Device Fonts”](#) on page 4911 for details. The size of a Hershey vector or TrueType font is specified by using the `SET_CHARACTER_SIZE` keyword to the `DEVICE` procedure. The `SET_CHARACTER_SIZE` keyword takes a two-element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value  $[x, y]$  to the `SET_CHARACTER_SIZE` keyword may produce characters of different sizes in different fonts.

---

### Note

While the first element of the vector specified to `SET_CHARACTER_SIZE` is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

---

For example, the following IDL commands display the word “Hello There” on the screen in Courier Bold Italic, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines. Use `FONT=1` to specify the TrueType font system:

```
DEVICE, SET_FONT='Courier Bold Italic', /TT_FONT, $
      SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere', FONT=1
```

The same example can be replicated using Hershey vector fonts. To use a vector font, specify the font using an embedded formatting command (explained in detail in [“Embedded Formatting Commands”](#) on page 4919). For example, to display the text in Triplex Italic, Hershey vector font number 18, use `!18` at the beginning of the string. As the vector font system is the default, you do not need to use the `FONT` keyword to `XYOUTS`.

```
DEVICE, SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, '!18Hello!CThere'
```

To return to using the default Helvetica font, change `!18` to `!3`:

```
XYOUTS, 0.1, 0.5, '!3Hello!CThere'
```

You can also use the `CHARSIZE` keyword to the graphics routines or the `CHARSIZE` field of the `!P` System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note that changing the `CHARSIZE` adjusts both the character size and the space between lines.

# Embedded Formatting Commands

When you use Hershey vector, TrueType, and some device fonts, text strings can include embedded formatting commands that facilitate subscripting, superscripting, and equation formatting. The method used is similar to that developed by Grandle and Nystrom (1980). Embedded formatting commands are always introduced by the exclamation mark, (!). (The string “! !” is used to produce a literal exclamation mark.)

---

**Tip**

Set the `ENABLE_FORMATTING` property on the `IDLgrText` object to use formatting commands in Object Graphics.

---

---

**Note**

Embedded formatting commands prefaced by the exclamation mark have no special significance for hardware-generated characters unless the ability is provided by the particular device in use. The IDL PostScript device driver accepts many of the standard embedded formatting commands, and is described here. If you wish to use hardware fonts with IDL Direct Graphics devices other than the PostScript device, consult the description of the device in [Appendix A, “IDL Direct Graphics Devices”](#) before trying to use these commands with hardware characters.

---

You can determine whether embedded formatting commands are available for use with device fonts on your current graphics device by inspecting bit 12 of the *Flags* field of the `!D`. Use the IDL statement:

```
IF (!D.FLAGS AND 4096) NE 0 THEN PRINT, 'Bit is set.'
```

to determine whether bit 12 of the *Flags* field is set for the current graphics device.

## Changing Fonts within a String

You can change fonts one or more times within a text string using the embedded font commands shown in the table below. The character following the exclamation mark can be either upper or lower case.

Examples of commands used to change fonts in mid-string are included in “[Formatting Command Examples](#)” on page 4923.

<b>Command</b>	<b>Hershey Vector Font</b>	<b>TrueType Font</b>	<b>PostScript Font</b>
!3	Simplex Roman (default)	Helvetica	Helvetica
!4	Simplex Greek	Helvetica Bold	Helvetica Bold
!5	Duplex Roman	Helvetica Italic	Helvetica Narrow
!6	Complex Roman	Helvetica Bold Italic	Helvetica Narrow Bold Oblique
!7	Complex Greek	Times	Times Roman
!8	Complex Italic	Times Italic	Times Bold Italic
!9	Math/special characters	Symbol	Symbol
!M	Math/special characters (change effective for one character only)	Symbol	Symbol
!10	Special characters	Symbol *	Zapf Dingbats
!11(!G)	Gothic English	Courier	Courier
!12(!W)	Simplex Script	Courier Italic	Courier Oblique
!13	Complex Script	Courier Bold	Palatino
!14	Gothic Italian	Courier Bold Italic	Palatino Italic
!15	Gothic German	Times Bold	Palatino Bold
!16	Cyrillic	Times Bold Italic	Palatino Bold Italic
!17	Triplex Roman	Helvetica *	Avant Garde Book
!18	Triplex Italic	Helvetica *	New Century Schoolbook
!19		Helvetica *	New Century Schoolbook Bold
!20	Miscellaneous	Helvetica *	Undefined User Font

*Table H-30: Embedded Font Selection Commands*

Command	Hershey Vector Font	TrueType Font	PostScript Font
!X	Revert to the entry font	Revert to the entry font	Revert to the entry font

\* The font assigned to this index may be replaced in a future release of IDL.

*Table H-30: Embedded Font Selection Commands (Continued)*

## Positioning Commands

The positioning and other font-manipulation commands are described in the following table. Examples of commands used to position text are included in [“Formatting Command Examples”](#) on page 4923.

Command	Action
!A	Shift above the division line.
!B	Shift below the division line.
!C	“Carriage return,” begins a new line of text. Shift back to the starting position and down one line. This command also performs an implicit “!N” command, returning to the normal level and character size at the beginning of the new line.
!D	Shift down to the first level subscript and decrease the character size by a factor of 0.62.
!E	Shift up to the exponent level and decrease the character size by a factor of 0.44.
!I	Shift down to the index level and decrease the character size by a factor of 0.44.
!L	Shift down to the second level subscript. Decrease the character size by a factor of 0.62.
!N	Shift back to the normal level and original character size.
!R	Restore position. The current position is set from the top of the saved positions stack.

*Table H-31: Vector-Drawn Positioning and Miscellaneous Commands*

Command	Action
!S	Save position. The current position is saved on the top of the saved positions stack.
!U	Shift to upper subscript level. Decrease the character size by a factor of 0.62.
!X	Return to the entry font.
!Z( $u_0, u_1, \dots, u_n$ )	Display one or more character glyphs according to their unicode value. Each $u_i$ within the parentheses will be interpreted as a 16-bit hexadecimal unicode value. If more than one unicode value is to be included, the values should be separated by commas.
!!	Display the ! symbol.

*Table H-31: Vector-Drawn Positioning and Miscellaneous Commands*

---

**Tip**

See [“Formatting Command Examples”](#) on page 4923 for examples that change the characteristics of fonts within a text string.

---

# Formatting Command Examples

The figure below illustrates the relative positions and effects on character size of the level commands. In this figure, the word “Normal” positioned with the letters “!N” are normal level and size characters.

*Figure H-13: Positioning Commands with Hershey Vector Fonts (Top) and TrueType Fonts (Bottom)*

The positioning shown was created with the following command:

```
XYOUTS, 0.1, 0.3, SIZE=3, $
'!LLower!S!EExponent!R!IIIndex!N Normal' + $
'!S!EExp!R!IIInd!N!S!U Up!R!D Down!N!S!A Above!R!B Below'
```

See “[Object Graphics Embedded Formatting Examples](#)” in Chapter 9 of the *Object Programming* manual for a similar Object Graphics example.

## A Complex Equation

Embedded positioning commands and the Hershey vector font system can be used to create the integral shown below:

$$\int_p^x \rho_i U_i^2 dx$$

Figure H-14: An Integral Created with the Hershey Vector Fonts

The command string used to produce the integral is:

```
XYOUTS, 0, .2, $
  '!MI!S!A!E!8x!R!B!Ip!N !7q!Ii!N!8U!S!E2!R!Ii!Ndx', $
  SIZE = 3, /NORMAL
```

Remember that the case of the letter in an embedded command is not important. The string may be broken down into the following components:

### !MI

Changes to the math set and draws the integral sign, uppercase I.

### !S

Saves the current position on the position stack.

### !A!E!8x

Shifts above the division line and to the exponent level, switches to the Complex Italic font (Font 8), and draws the “x.”

**!R!B!p**

Restores the position to the position immediately after the integral sign, shifts below the division line to the index level, and draws the “*p*.”

**!N !7q**

Returns to the normal level, advances one space, shifts to the Complex Greek font (Font 7), and draws the Greek letter rho, which is designated by “*q*” in this set.

**!i!N**

Shifts to the index level and draws the “*i*” at the index level. Returns to the normal level.

**!8U**

Shifts to the Complex Italic font (Font 8) and outputs the upper case “*U*.”

**!S!E2**

Saves the position and draws the exponent “2.”

**!R!i**

Restores the position and draws the index “*i*.”

**!N dx**

Returns to the normal level and outputs “*dx*.”

**Note**

---

The equation shown in the figure above could not be created so simply using the TrueType font system, because the large integral symbol is broken into two or more characters in the TrueType fonts.

---

## Hershey Vector-Drawn Font Example

IDL uses Hershey vector-drawn fonts when the value of the system variable !P.FONT is -1. This is the default condition. Initially, all characters are drawn using the Simplex Roman font (Font 3). When plotting, font changing commands may be embedded in the title strings keyword arguments (XTITLE, YTITLE, and TITLE) to

select other fonts. For example, the following statement uses the Complex Roman font (Font 6) for the  $x$ -axis title:

```
PLOT, X, XTITLE = '!6X Axis Title'
```

This font remains in effect until explicitly changed. The order in which the annotations are drawn is main title,  $x$ -axis numbers,  $x$ -axis title,  $y$ -axis numbers, and  $y$ -axis title. Strings to be output also may contain embedded information selecting subscripting, superscripting, plus other features that facilitate equation formatting.

The following statements were used to produce the figure below. They serve as an example of a plot using Hershey vector-drawn characters and of equation formatting.

*Figure H-15: Example of a Hershey Vector-drawn Plot*

```
; Define an array:
X = FLTARR(128)
; Make a step function:
X[30:40] = 1.0
; Take FFT and magnitude:
X = ABS(FFT(X, 1))
; Produce a log-linear plot. Use the Triplex Roman font for the
; x title (!17), Duplex Roman for the y title (!5), and Triplex
; Italic for the main title (!18). The position keyword is used to
; shrink the plotting window:
PLOT, X[0:64], /YLOG, XTITLE = '!17Frequency', $
      YTITLE = '!5Power', $
      TITLE = '!18Example of Vector Drawn Plot', $
```

```
        POSITION = [.2, .2, .9, .6]
; String to produce equation:
SS = '!6F(s) = (2!4p)!e-1/2!n !mi!s!a!e!m' + STRING( "44b) $"
    + '!r!b!i-!m' + STRING( "44b) + '!nF(x)e!e-i2!4p!3xs!ndx'
; Output string over plot. The NOCLIP keyword is needed because
; the previous plot caused the clipping region to shrink:
XYOUTS, 0.1, .75, SS, SIZE = 3, $
        /NORMAL, /NOCLIP
```

---

**Note**

See “[Object Graphics Embedded Formatting Examples](#)” in Chapter 9 of the *Object Programming* manual for a similar Object Graphics example.

---

# TrueType Font Samples

The following figures show roman versions of the four TrueType font families included with IDL. The character sets for the bold, italic, and bold italic versions of these fonts are the same as the roman versions.

The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 'Helvetica', 'Helvetica', /TT_FONT
```

For more information, see [“SHOWFONT”](#) on page 2105.

## Note

---

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the copyright symbol is octal 251.

---

TrueType font samples include the following:

- [“Helvetica”](#) on page 4929
- [“Times”](#) on page 4930
- [“Courier”](#) on page 4931
- [“Symbol”](#) on page 4932

# Hershey Vector Font Samples

The following figures show samples of various Hershey vector-drawn fonts. The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 3, 'Simplex Roman'
```

To output this figure to a postscript file, you would use the following commands:

```
SET_PLOT, 'PS'
SHOWFONT, 3, 'Simplex Roman'
DEVICE, /CLOSE
```

For more information, see [“SHOWFONT”](#) on page 2105.

## Note

---

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the “\$” symbol is octal 44.

---

## Appendix I

# IDL GUIBuilder Widget Reference

The following topics are covered in this chapter:

---

<a href="#">Common Widget Properties</a> .....	4952	<a href="#">Droplist Widget Properties</a> .....	4991
<a href="#">Base Widget Properties</a> .....	4958	<a href="#">Listbox Widget Properties</a> .....	4994
<a href="#">Button Widget Properties</a> .....	4972	<a href="#">Draw Widget Properties</a> .....	4998
<a href="#">Text Widget Properties</a> .....	4978	<a href="#">Table Widget Properties</a> .....	5005
<a href="#">Label Widget Properties</a> .....	4985	<a href="#">Tab Widget Properties</a> .....	5015
<a href="#">Slider Widget Properties</a> .....	4987	<a href="#">Tree Widget Properties</a> .....	5018

# Common Widget Properties

There are several attribute and event property values you can set for all widgets. The attribute properties include the name of the widget and the sizing properties. The event properties include creation, realization, destruction, and tracking events.

## Note

---

For information on how to open and use the GUIBuilder and the Properties dialog, see [Chapter 29, “Using the IDL GUIBuilder”](#) in the *Building IDL Applications* manual.

---

The following sections describe the common properties:

- [Common Attributes](#)
- [Common Events](#)

## Common Attributes

The following attributes are common to all widgets:

<a href="#">Name</a>	<a href="#">X Offset</a>
<a href="#">Component Sizing</a>	<a href="#">X Size</a>
<a href="#">Frame</a>	<a href="#">Y Offset</a>
<a href="#">Sensitive</a>	<a href="#">Y Size</a>

## Name

The Name attribute specifies the name of the component. This value can be any string that is unique to the widget hierarchy of the interface, but the string cannot contain spaces. For each widget you create in the IDL GUIBuilder, a default name is supplied, and this name is in the `WID_<TYPE>_<NUMBER>` format.

If you copy and paste a widget in the IDL GUIBuilder, the new widget is given a unique name based on the name of the one you copied. A number is added to the first widget's name, or an existing number is incremented.

You can use the Name value for the widget in your event callback routines. For example, you can use the specified name to find the widget, using the `FIND_BY_UNAME` keyword to the `WIDGET_INFO` function. Set the name for

each widget to a name that makes sense to you; set the name value to something that is easy to remember and easy to use in your code.

In the generated `*.pro` file, this value is specified with the `UNAME` keyword to the widget creation routines.

## Component Sizing

The Component Sizing keyword determines how the component is sized, which is by one of the following methods:

- **Default:** The widget is sized to a natural or implicit size. This is the default setting for the attribute. For example, a label widget's natural size is determined by the size of the text it is displaying with extra space for margins. The default size for each widgets is controlled by several things, including displayed font size and the characteristics of the operating system displaying the interface.
- **Explicit:** The widget size is determined by several attributes, which include [Layout](#) for the base and its own [X Size](#) and [Y Size](#) keywords.

In the generated `*.pro` widget file, this value is specified with the `XSIZE` and `YSIZE` keywords to the widget creation routines.

### Note

---

The default size of text widgets on Motif is based on the width of text, but the default size for text widgets on Windows is approximately 20 characters.

---

## Frame

The Frame attribute determines if the widget will have a frame or border around it. These are the possible values:

- **False:** The widget will have no frame drawn around it. This is the default value.
- **True:** The widget will have a frame or border around it.

In the generated `*.pro` widget file, this value is specified by the `FRAME` keyword to the widget creation routines.

### Note

---

The Frame attribute is not available for top-level base widgets.

---

## Sensitive

The Sensitive attribute determines if the selected widget is active or not active on startup. You can set this value to determine if the user can access and manipulate the widget immediately after creation. These are the possible values:

- True: The widget is initially displayed as enabled and accepts keyboard or mouse input and generates events. This is the default value.
- False: The widget is initially displayed as disabled and does not accept keyboard or mouse input. The appearance of most widgets change when the False value is set, but the appearance does not always change to indicate this state.

In the generated `*.pro` file, this value is specified with the SENSITIVE keyword to the widget creation routines.

---

### Note

To change the sensitivity of a widget after the widget is created, use the WIDGET\_CONTROL function with the SENSITIVE keyword.

---

## X Offset

The X Offset attribute specifies the X offset of the component from its parent. The possible values for X Offset are  $0$  to  $n$ , in pixels; any number is valid. The [Y Offset](#) attribute specifies the Y offset.

In the generated `*.pro` file, this value is specified with the XOFFSET keyword to the widget creation routines.

---

### Note

The X Offset attribute value is *not* used with base widgets that have the [Layout](#) attribute set to Row or Column.

---

## X Size

The X Size attribute specifies the width of the visible component in pixels. This attribute is disabled when [Component Sizing](#) is set to Default (and the default size is used). To enable this value, set Component Sizing to Explicit. The possible values for X Size are  $0$  to  $n$ , in pixels.

In the generated `*.pro` file, this value is specified with the SCR\_XSIZE keyword to the widget creation routines.

---

**Note**

If you add scroll bars to a widget, use the widget-specific X Scroll attribute to set the width of the virtual area.

---

## Y Offset

The Y Offset attribute specifies the Y offset of the component from its parent in pixels. The possible values for Y Offset are 0 to  $n$ , in pixels; any number is valid. The [X Offset](#) attribute specifies the X offset.

In the generated `*.pro` file, this value is specified by the YOFFSET keyword to the widget creation routines.

---

**Note**

The Y Offset attribute value is *not* used with base widgets that have the [Layout](#) attribute set to Row or Column.

---

## Y Size

The Y Size attribute specifies the height of the visible component in pixels. This attribute is disabled when [Component Sizing](#) is set to Default (and the default size is used). To enable this value, set Component Sizing to Explicit. The possible values for Y Size are 0 to  $n$ , in pixels.

In the generated `*.pro` file, this value is specified with the SCR\_YSIZE keyword to the widget creation routines.

---

**Note**

If you add scroll bars to a widget, use the widget-specific Y Scroll attribute to set the height of the virtual area.

---

## Common Events

The following events are common to all widgets (by default, no event values are set):

[Handle Event](#)

[OnTimer](#)

[OnDestroy](#)

[OnTracking](#)

[OnRealize](#)

[PostCreation](#)

## Handle Event

The Handle Event value is the function name that is called when an event arrives from a widget that is rooted in an IDL GUIBuilder-created widget in the hierarchy. All events are sent to this event function, except for creation and destruction events.

For example, if you add a compound widget to an interface, using the [PostCreation](#) event procedure for a base widget, you should set the Handle Event value for that parent base widget (for the compound widget's parent widget). Then, you can handle all the events returned by the compound widget using this event function value.

In the generated `*_eventcb.pro` file, the event function place holder looks like this:

```
Function <Name>, Event

    return, Event
End
```

where *Name* is the name of the event function you specify. *Event* is the returned event structure, which is specific to the widget event.

For an example of how to handle the generated Handle Event function, see [“Adding Compound Widgets”](#) in Chapter 29 of the *Building IDL Applications* manual.

## OnDestroy

The OnDestroy value is the routine name that is called when the widget is destroyed. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, wWidget
```

where *RoutineName* is the name of the event procedure you specify. *wWidget* is the IDL widget identifier.

## OnRealize

The OnRealize value is the routine name that is called automatically when the widget is realized. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, wWidget
```

where *RoutineName* is the name of the event procedure you specify. *wWidget* is the IDL widget identifier.

## OnTimer

The `OnTimer` value is the routine name that is called when a timer event is detected for a widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the returned event structure, which has the 3 standard event tags and looks like this:

```
{ WIDGET_TIMER, ID:0L, TOP:0L, HANDLER:0L }
```

You must set timer events for a widget, using the `WIDGET_CONTROL` function. The code generated by the IDL GUIBuilder only routes the events.

## OnTracking

The `OnTracking` value is the routine name that is called when the widget receives a tracking event, which occurs when the mouse pointer *enters* or *leaves* the region of the widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the returned structure, which is of the following type:

```
{ WIDGET_TRACKING, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

`ENTER` is 1 if the tracking event is an entry event, and 0 if it is an exit event.

## PostCreation

The `PostCreation` value is the routine name that is called after the widget is created, but before it is realized. In the generated `*_eventcb.pro` file, the calling sequence looks like this:

```
pro <RoutineName>, wWidget
```

where *RoutineName* is the name of the event procedure you specify. `wWidget` is the IDL widget identifier.

# Base Widget Properties

A base widget holds other widgets, including other base widgets. You can create groupings of widgets by using a base widget, thus forming a widget hierarchy.

When you open the IDL GUIBuilder, a top-level base is created, and you build your interface in this base. Top-level bases are a special class of the base widgets that are created without parent widgets; they act as the top-level parent in the widget hierarchy.

In addition, you can make top-level bases *float* above their group leaders, with the [Floating](#) attribute, or you can make them *modal* dialogs, with the [Modal](#) attribute. Modal dialogs interrupt program execution until the user closes them. When you make a top-level base floating or modal, you must provide a group leader when calling the generated code, by using the `GROUP_LEADER` keyword.

When programming in IDL, you create base widgets using the `WIDGET_BASE` function. For more information, see “[WIDGET\\_BASE](#)” in the *IDL Reference Guide* manual.

In the IDL GUIBuilder, you can add a menubar to the top-level base by using the Menu Editor. For more information on the Menu Editor, see “[Using the Menu Editor](#)” in Chapter 29 of the *Building IDL Applications* manual.

## Note

---

A base widget’s layout is controlled by where you place it and the properties of its parent base.

---

## Base Widget Attributes

For base widgets, you can set common attributes and base-specific attributes. For a list attributes common to all widgets, see “[Common Attributes](#)” on page 4952.

Some of the base widget attributes apply to top-level bases only, and this limitation is noted in the following list of base widget attributes:

<a href="#"># of Rows/Columns</a>	<a href="#">Space</a>
<a href="#">Alignment</a>	<a href="#">System Menu</a>
<a href="#">Allow Closing</a>	<a href="#">Tab Mode</a>
<a href="#">Allow Moving</a>	<a href="#">Title</a>

Floating	Title Bar
Grid Layout	Visible
Layout	X Pad
Minimize/Maximize	X Scroll
Modal	Y Pad
Scroll	Y Scroll

## # of Rows/Columns

The # of Rows/Columns attribute specifies the number of Columns or Rows to use when laying out the base. This attribute is valid only when the [Layout](#) attribute is set to Column or Row. The possible values for this setting are 1 to  $n$ , and the default value is 1.

In the generated `*.pro` file, this value is specified with the `COLUMN` or the `ROW` keyword to the widget creation routine.

For information on other properties that control the layout of contained widgets, see [Alignment](#), [Layout](#), [Space](#), [X Pad](#), and [Y Pad](#).

## Alignment

The Alignment attribute defines how components are aligned in the base. The way in which the value of this attribute affects the display of widgets depends on the value of the Layout attribute. The following is a list possible values for the Alignment attribute, and each value description includes information on how it works with the [Layout](#) settings:

- **Center:** Aligns the contained widgets with the center this parent base. This is the default value. For this setting to take effect, the Layout setting must be Row or Column. With Row set, the contained widgets are vertically centered. With Column set, the contained widgets are horizontally centered.
- **Top:** Aligns contained widgets with the top of this parent base. For this setting to take effect, the Layout setting must be Row.
- **Bottom:** Aligns the contained widgets with the bottom of this parent base. For this setting to take effect, the Layout setting must be Row.
- **Left:** Aligns the contained widgets with the left side of this parent base. For this setting to take effect, the Layout setting must be Column.

- **Right:** Aligns the contained widgets with the right side of this parent base. For this setting to take effect, the `Layout` setting must be `Column`.
- **Default:** Uses the default layout.

In the generated `*.pro` file, these settings are specified with the `BASE_ALIGN_CENTER`, `BASE_ALIGN_TOP`, `BASE_ALIGN_BOTTOM`, `BASE_ALIGN_LEFT`, and `BASE_ALIGN_RIGHT` keywords to the widget creation routine.

For information on other properties that control the layout of contained widgets, see [# of Rows/Columns](#), [Layout](#), [Space](#), [X Pad](#), and [Y Pad](#).

## Allow Closing

The `Allow Closing` attribute determines if the top-level base can be closed by the user. By default, this value is set to `True` and the base can be closed. To make it so the top-level base cannot be close, set this value to `False`.

In the generated `*.pro` file, this value is specified with the `TLB_FRAME_ATTR` keyword to the widget creation routine.

For information on other properties that control aspects of top-level bases, see the [Allow Moving](#), [Minimize/Maximize](#), [System Menu](#), and [Title Bar](#) properties.

### Note

---

This attribute setting is used with top-level bases only. Note that this setting is only a hint to the window system and might be ignored by some window managers.

---

## Allow Moving

The `Allow Moving` attribute determines if the base can be moved. By default, this value is set to `True`, and the base can be moved. To suppress this behavior, set this value to `False`.

In the generated `*.pro` file, this value is specified with the `TLB_FRAME_ATTR` keyword to the widget creation routine.

For information on other attribute settings that control aspects of top-level bases, see the [Allow Closing](#), [Minimize/Maximize](#), [System Menu](#), and [Title Bar](#) attributes.

### Note

---

This attribute setting is used with top-level bases only. Note that this setting is only a hint to the window system and might be ignored by some window managers.

---

## Floating

The Floating attribute determines if the top-level base is a floating base (always on top). By default, this setting is False, indicating that the base is *not* a floating base. To create a floating base, set this attribute to True.

If you make a top-level base floating, you must set the GROUP\_LEADER keyword to a valid widget ID when calling the generated procedure.

In the generated \*.pro file, this value is specified with the FLOATING keyword to the widget creation routine.

---

**Note**

This attribute setting is used with top-level bases only.

---

## Grid Layout

The Grid Layout attribute determines if the base will have a grid layout, in which all columns have the same width, or in which all rows have the same height. These are the possible values:

- False: Columns or rows will not be the same size. This is the default value.
- True: Column widths or row heights are taken from the largest child widget. If you set this attribute to True, you must also set the [Layout](#) attribute to Column or Row and the [# of Rows/Columns](#) attribute to more than 1.

In the generated \*.pro file, this value is specified with the GRID\_LAYOUT keyword to the widget creation routine.

## Layout

The Layout attribute specifies how components are laid out in the base. These are the possible values:

- Bulletin: Indicates that you can position the widgets anywhere on the base. This is the default setting.
- Column: Indicated that widgets should be in columns. If you set this value, you should also set the [# of Rows/Columns](#) attribute and the [Alignment](#) attribute.
- Row: Indicated that widgets should be in rows. If you set this value, you should also set the [# of Rows/Columns](#) attribute and the [Alignment](#) attribute.

**Note**

---

When using code generated by the IDL GUIBuilder on other non-Windows platforms, more consistent results are obtained by using a row or column layout for your bases instead of a bulletin board layout. By using a row or column layout, differences in the default spacing and decorations (e.g., beveling) of widgets on each platform can be avoided

---

The number of child widgets placed in each column or row is calculated by dividing the number of created child widgets by the number of columns or rows specified ([# of Rows/Columns](#)). When one column or row is filled, a new one is started.

The width of each column or the height of the row is determined by the largest widget in that column or row. If you set the [Grid Layout](#) attribute to True, all columns or rows are the same size; they are the size of the largest widget.

If you set the [Alignment](#) attribute for the base, the contained widgets are their “natural” size. If you do not set the Alignment attribute for the base or the child widgets, all contained widgets will be sized to the width of the column or the height of the row.

For information on other properties that control the layout of contained widgets, see [# of Rows/Columns](#), [Alignment](#), [Space](#), [X Pad](#), and [Y Pad](#).

In the generated `*.pro` file, this value is specified with the COLUMN or the ROW keyword to the widget creation routine.

**Note**

---

When you create a radio button or checkbox, it is created in a base, and you can add more radio buttons or checkboxes to that base (the added widgets must all be of the same type). The base in which radio buttons and checkboxes are created has a column layout setting, and buttons you add will be lined up in a column format.

---

## Minimize/Maximize

The Minimize/Maximize attribute determines if the top-level base can be resized, minimized, and maximized. By default, this value is set to True. To disable this behavior, set this attribute to False.

In the generated `*.pro` file, this value is specified with the TLB\_FRAME\_ATTR keyword to the widget creation routine.

For information on other attribute settings that control aspects of top-level bases, see the [Allow Closing](#), [Allow Moving](#), [System Menu](#), and [Title Bar](#) attributes.

---

**Note**

This attribute setting is used with top-level bases only. Note that this setting is only a hint to the window system and might be ignored by some window managers.

---

## Modal

The Modal attribute determines if this top-level base is a modal dialog. By default, this value is set to False. To make the base a modal dialog, set this attribute to True.

If you set the Modal attribute to True, you cannot set the [Scroll](#) attribute, and you cannot define a menu for the top-level base. In addition, the [Sensitive](#) common attribute and the [Visible](#) base widget attribute are also disabled.

If you make a top-level base a modal dialog, you must set the GROUP\_LEADER keyword to a valid widget ID in the generated procedure.

In the generated \*.pro file, this value is specified with the MODAL keyword to the widget creation routine.

---

**Note**

This attribute setting is used with top-level bases only.

---

## Scroll

The Scroll attribute determines if the base widget will support scrolling. By default, this attribute is set to False, and the base will not support scrolling. To give the widget scroll bars and allow for viewing portions of the widget contents that are not currently in the viewport area, set the Scroll attribute to True. In the IDL GUIBuilder, scroll bars on bases are live so that you can work on the entire virtual area of your application.

If you set the [Modal](#) attribute to True, you cannot set the Scroll attribute.

In the generated \*.pro file, this value is specified with the SCROLL keyword to the widget creation routine.

To set the size of the scrollable region, use the [X Scroll](#) and [Y Scroll](#) attributes.

## Space

The Space attribute specifies the number of pixels between the contained widgets (the children) in a column or row [Layout](#). By default, this value is set to 3 pixels and that is the space between the contained widgets. Valid values for this attribute are 0 to *n* pixels.

In the generated `*.pro` file, this value is specified with the `SPACE` keyword to the widget creation routine.

To set the space from the edge of the base, use the [X Pad](#) and [Y Pad](#) properties. For information on other properties that control the layout of contained widgets, see [# of Rows/Columns](#), [Alignment](#), and [Layout](#).

---

**Note**

You cannot set this attribute on a base containing radio buttons or checkboxes.

---

## System Menu

The System Menu attribute determines if the system menu is displayed or suppressed on a top-level base. By default, this value is set to `True`, indicating that the system menu will be used. To suppress the menu, set this attribute to `False`.

In the generated `*.pro` file, this value is specified with the `TLB_FRAME_ATTR` keyword to the widget creation routine.

For information on other attribute settings that control aspects of top-level bases, see the [Allow Closing](#), [Allow Moving](#), [Minimize/Maximize](#), and [Title Bar](#) attributes.

---

**Note**

This attribute setting is used with top-level bases only.

---

## Tab Mode

The Tab Mode attribute specifies what support the base has for receiving or losing focus through tabbing. By default, this value is set to `None` for a top level base, and to `Inherit` for subsequent bases.

---

**Note**

It is not possible to tab to disabled (`Sensitive = False`) or hidden (`Visible = False`) widgets.

---

Allowable values are:

Value	Description
Inherit	Upon creation, the subsequent base inherits the tabbing support of the parent base. This is the default for child widgets.
None	Disallow tabbing into or out of the base. This is the default for top level bases. This value is inherited by subsequent bases and widgets unless explicitly set for the individual base or widget.
In and Out	Allow tabbing into and out of the base.
In Only	Allow tabbing into the base only.
Out Only	Allow tabbing off of the base only.

*Table I-32: Allowable Tab Mode Values*

---

#### Note

The default tab mode of lower level bases and widgets is Inherit. The tabbing support defined for a top level or parent base is inherited by widget children unless otherwise specified.

---

---

#### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see [“Tabbing in Widget Applications”](#) on page 869.

## Title

The Title attribute specifies the title of a top-level base. By default, this value is set to IDL, but you can change it to any string.

In the generated \*.pro file, this value is specified with the TITLE keyword to the widget creation routine.

---

**Note**

This attribute setting is used with top-level bases only.

---

## Title Bar

The Title Bar attribute determines if the title bar will be displayed. By default, this value is set to True, and the title bar is displayed. To suppress the display of the title bar, set this value to False.

In the generated \*.pro file, this value is specified with the TLB\_FRAME\_ATTR keyword to the widget creation routine.

For information on other attribute settings that control aspects of top-level bases, see the [Allow Closing](#), [Allow Moving](#), [Minimize/Maximize](#), and [System Menu](#) attributes.

---

**Note**

This attribute setting is used with top-level bases only. Note that this setting is only a hint to the window system and might be ignored by some window managers.

---

## Visible

The Visible attribute specifies whether to show or hide the base component and its descendants. Show, the default value, specifies to display the hierarchy when realized. The Hide value specifies that the hierarchy should *not* be displayed initially. This mapping operation applies only to base widgets.

In the generated \*.pro file, this value is specified with the MAP keyword to the widget creation routine.

---

**Note**

If you set the [Modal](#) attribute to True, you cannot set the Visible attribute value.

---

## X Pad

The X Pad attribute specifies the horizontal space (in pixels) between child widgets and the edges of rows or columns. By default, this value is set to 3 pixels, indicating that there are 3 pixels between the edge of the base and the contained widgets. Valid values for this attribute are 0 to *n* pixels.

In the generated `*.pro` file, this value is specified with the `XPAD` keyword to the widget creation routine.

To set the space between widgets, use the [Space](#) attribute. For information on other attributes that control the layout of contained widgets, see [# of Rows/Columns](#), [Alignment](#), [Layout](#), and [Y Pad](#).

---

**Note**

You cannot set this attribute for a base that contains radio buttons or checkboxes. In the IDL GUIBuilder, a base is created when you add a radio button or checkbox to an interface, and you can add more radio buttons or checkboxes to that base. When you add the buttons, they are lined up in a column format.

---

## X Scroll

The X Scroll attribute specifies the width in pixels of the base area, which includes the exposed as well as the virtual area. There is no default value set, but you can set this value to any number of pixels from 0 to  $n$ . To add scroll bars to the base, use the [Scroll](#) attribute, and to set the height of the scrollable base area, use the [Y Scroll](#) attribute.

In the generated `*.pro` file, this value is specified with the `XSIZE` keyword to the widget creation routine.

---

**Note**

To set the width of the displayed widget, use the [X Size](#) common attribute.

---

## Y Pad

The Y Pad attribute specifies the vertical space (in pixels) between child components and the edge of the base in a row or column [Layout](#). By default, this value is set to 3 pixels, indicating that there are 3 pixels between the edge of the base and the contained widgets. Valid values for this attribute are 0 to  $n$  pixels.

In the generated `*.pro` file, this value is specified with the `YPAD` keyword to the widget creation routine.

To set the space between widgets, use the [Space](#) attribute. For information on other attributes that control the layout of contained widgets, see [# of Rows/Columns](#), [Alignment](#), [Layout](#), and [X Pad](#).

**Note**

---

You cannot set this attribute on a base containing radio buttons or checkboxes. In the IDL GUIBuilder, a base is created when you add a radio button or checkbox to an interface, and you can add more radio buttons or checkboxes to that base.

---

**Y Scroll**

The Y Scroll attribute specifies the height in pixels of the base area, which includes the exposed as well as the virtual area. There is no default value set, but you can set this value to any number of pixels from 0 to *n*.

To add scroll bars to the base, use the [Scroll](#) attribute, and to set the width of the base area, use the [X Scroll](#) attribute.

In the generated \*.pro file, this value is specified with the YSIZE keyword to the widget creation routine.

**Note**

---

To set the height of the displayed widget, use the [Y Size](#) common attribute.

---

**Base Widget Events**

For base widgets, you can set common event properties and base-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

The following is a list of event properties specific to base widgets:

<a href="#">OnContextEvent</a>	<a href="#">OnKillRequest</a>
<a href="#">OnFocus</a>	<a href="#">OnMove</a>
<a href="#">OnIconify</a>	<a href="#">OnSizeChange</a>

**OnContextEvent**

The OnContextEvent value is the routine name that is called when the user clicks the right-hand mouse button over the base widget. In the generated \*\_eventcb.pro file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. *Event* is the returned event structure returned when the user clicks the right-hand mouse button and is of the following type:

```
{ WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget.

## OnFocus

The OnFocus value is the routine name that is called when the keyboard focus of the base changes. In the generated *\*\_eventcb.pro* file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. *Event* is the event structure returned when the keyboard focus changes and is of the following type:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ENTER returns 1 if the base is gaining the keyboard focus, and returns 0 if the base is losing the keyboard focus.

## OnIconify

The OnIconify value is the routine that is called when the user iconifies or restores the top-level base widget. In the generated *\*\_eventcb.pro* file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. *Event* is the event structure returned when a user iconifies or restores the widget using the window manager and is of the following type:

```
{ WIDGET_TLB_ICONIFY, ID:0L, TOP:0L, HANDLER:0L, ICONIFIED:0 }
```

ICONIFIED is 1 (one) if the user iconified the base and 0 (zero) if the user restored the base.

### Note

---

This event procedure is valid for top-level bases only.

---

## OnKillRequest

The `OnKillRequest` value is the routine that is called when the user attempts to kill the top-level base widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when a user tries to destroy the widget using the window manager and is of the following type:

```
{ WIDGET_KILL_REQUEST, ID:0L, TOP:0L, HANDLER:0L }
```

Note that this event structure contains the standard three fields that all widgets contain.

---

### Note

This event procedure is valid for top-level bases only.

---

## OnMove

The `OnMove` value is the routine that is called when the user moves the top-level base widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when a user moves the widget and is of the following type:

```
{ WIDGET_TLB_MOVE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

X and Y are the new location of the top left corner of the base.

---

### Note

This event procedure is valid for top-level bases only.

---

## OnSizeChange

The `OnSizeChange` value is the name of the routine that is called when the top-level base has been resize. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when the top-level base is resized by the user and is of the following type:

```
{ WIDGET_BASE, ID:0L, TOP:0L, HANDLER:0L, X:0, Y:0 }
```

The X and Y fields return the new width of the base, not including any frame provided by the window manager.

**Note**

---

This event procedure is valid for top-level bases only.

---

# Button Widget Properties

In IDL, a button widget can be a button (push button), radio button, or checkbox.

A push button is activated by a single-click. Push buttons can be of any size. You can set the `Menu` attribute to `yes` for a button widget, and then it can contain a pull-down menu. When you do so, the `Label` is enclosed in a box to indicate that the button is a menu button.

Radio buttons have two states, set and unset, and they belong to a group that allows only one radio button selection for that group. The group is defined as all buttons contained in the same exclusive base widget. When a radio button in a base (in a group) is selected, any other button selection in that base is cleared. When you create a radio button in the IDL GUIBuilder, it is created in an exclusive base widget, and you can add only radio buttons to that base.

Checkboxes have two states, set and unset, and they are grouped in a non-exclusive base widget. The base widget allows for any number of checkboxes to be set at one time, and you can also use single checkboxes in your interface. When you create a checkbox in the IDL GUIBuilder, it is created in a non-exclusive widget base, and you can add only checkboxes to this base.

When programming in IDL, you create push buttons, radio buttons, and checkboxes using the `WIDGET_BUTTON` function. For more information, see “`WIDGET_BUTTON`” in the *IDL Reference Guide* manual.

---

**Note**

The bases in which radio buttons and checkboxes are created have the `Layout` attribute set to `column` so when you add more widgets they are lined up appropriately.

---

## Creating Multiple Radio Buttons or Checkboxes

To create several radio buttons or checkboxes in a base widget:

1. Click on the radio button or checkbox tool, and click on the location to add the button. This creates a base with one radio button or checkbox in it.
2. Click on the radio button or checkbox tool, and click in the radio button or checkbox base area you just created. This adds a radio button or checkbox to the base.

When you drop a button in an exclusive or non-exclusive base, the added buttons line up in columns; by default, these exclusive and non-exclusive bases have their [Layout](#) attribute set to Column.

3. Repeat step 2 until you have the desired number of buttons.
4. If you want to change the layout of the checkboxes or radio buttons, you can open the Properties dialog and set the [Layout](#) common attribute for the base widget to Row or Bulletin.
5. To set the properties for each button in the base, open the Properties dialog, click the push pin button to keep it on top, then click on each radio button or checkbox to set their individual properties.

## Button, Radio Button, and Checkbox Widget Attributes

For button widgets, you can set common attributes and button-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. The following is a list of button widget attributes, which apply to push buttons, radio buttons, and/or checkboxes:

<a href="#">Alignment</a>	<a href="#">Tab Mode</a>
<a href="#">Bitmap</a>	<a href="#">Tooltip</a>
<a href="#">Label</a>	<a href="#">Type</a>
<a href="#">No Release</a>	

### Alignment

The [Alignment](#) attribute specifies how the text label is aligned in the button widget. These are the possible alignment values:

- [Center](#): The label text is centered.
- [Left](#): The label text is left-justified.
- [Right](#): The label text is right-justified.

In the generated \* .pro file, this value is specified by the `ALIGN_CENTER`, the `ALIGN_LEFT`, or the `ALIGN_RIGHT` keyword to the widget creation routine.

## Bitmap

The Bitmap attribute allows you to select a bitmap to be displayed in the push button, and it allows you to access the Bitmap Editor to create or modify a bitmap file (\*.bmp file). This value applies only to buttons (not to radio buttons or checkboxes).

To set this value, set the [Type](#) value to Bitmap, then the Bitmap attribute displays in the Properties dialog. When the button type is “Bitmap”, you can set the Bitmap attribute to the path and name of the bmp file.

When you click on the arrow in the Bitmap attribute Value field, you can choose from the following options:

- **Select Bitmap:** Launches an Open dialog that you can use to locate and select the existing \*.bmp file to be placed in the button.
- **Edit Bitmap:** Launches an Open dialog that you can use to locate and select the existing \*.bmp file to be opened in the Bitmap Editor. You can modify the bitmap and save it. The bitmap is then displayed in the button.
- **New Bitmap:** Opens the Bitmap Editor which you can use to create and save a bitmap. When you save the new bitmap, it is displayed in the button.

In the generated \*.pro file, this value is specified with the VALUE and Bitmap keyword to the widget creation routine.

For information on using the Bitmap Editor, see [“Using the Bitmap Editor”](#) in Chapter 29 of the *Building IDL Applications* manual.

## Label

The Label attribute specifies the text label for a button. If you set the [Type](#) attribute to [Bitmap](#) (for push buttons only), this value is not displayed. For radio buttons and checkboxes, the label value is the text string displayed next to the button. By default, this value is set to Button, and you can change it to any string.

In the generated \*.pro file, this value is specified with the VALUE keyword to the widget creation routine.

## No Release

The No Release attribute enables and disables the dispatching of button release events for radio buttons and checkboxes. Normal buttons do not generate events when released, but radio buttons and checkboxes can return separate events for the select and release actions.

These are the possible values:

- True: The release event is not returned; only the select event is returned. This is the default setting.
- False: Both the release and select events are returned.

In the generated `*.pro` file, this values is specified with the `NO_RELEASE` keyword to the widget creation routine.

---

**Note**

The No Release attribute is for radio buttons and checkboxes only.

---

## Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to Inherit.

---

**Note**

For radio buttons, the tab mode is automatically inherited from the parent base and cannot be individually specified.

---

---

**Note**

It is not possible to tab to disabled (`Sensitive = False`) or hidden (`Visible = False`) widgets.

---

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-33: Allowable Tab Mode Values*

---

**Note**

The default tab mode of a widget is Inherit. The tabbing support defined for the parent base, described in [“Base Widget Attributes”](#) on page 4958, is inherited by widget children unless otherwise specified.

---

---

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see [“Tabbing in Widget Applications”](#) on page 869.

## Tooltip

The Tooltip attribute specifies a short text string that will be displayed when the mouse cursor is positioned over the button. The length of the tooltip is not explicitly limited, but since tooltips are displayed in a single line, it is best to keep the text short.

## Type

The Type attribute specifies the type of push button.

---

**Note**

This attribute applies only to push buttons, not to radio buttons or checkboxes.

---

The possible values are:

- Push: The button widget is a plain push button. This is the default value.
- Menu: The button contains a menu. After you select this value, you can right-click on the button widget, choose Edit Menu, and define a menu to display, using the Menu Editor. See [“Using the Menu Editor”](#) in Chapter 29 of the *Building IDL Applications* manual for details on using the Menu Editor.
- Bitmap: The button displays a bitmap, which you would use to create a toolbar for example. If you change the Type value to Bitmap, the [Bitmap](#) attribute is displayed and you can select, modify, or create a bitmap to display on the button.

In the generated `*.pro` file, this value is specified with the `MENU` or `VALUE` keywords to the widget creation routine.

## Button, Radio Button, and Checkbox Widget Events

For button widgets, you can set common event properties and button-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

The following is the event property specific to button widgets; it applies to push buttons, radio buttons, and checkboxes:

### OnButtonPress

The `OnButtonPress` value is the routine that is called when the button is pressed, or when a button is released for a radio button or checkbox button. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the returned event structure, which is of the following type:

```
{ WIDGET_BUTTON, ID:0L, TOP:0L, HANDLER:0L, SELECT:0 }
```

`SELECT` is set to 1 if the button was set, and 0 if released. Push buttons do not generate events when released, so `SELECT` will always be 1 for a push button. However, radio buttons and checkboxes are toggle buttons, and thus return separate events for the set and the release actions. To control whether or not release events are returned, set the [No Release](#) attribute.

# Text Widget Properties

Use text widgets to display text, and optionally, use them to accept textual input from users. The text widgets can have one or more lines, and if necessary, the widget can contain scroll bars to allow for viewing longer text.

When programming in IDL, you create text widgets using the `WIDGET_TEXT` function. For more information, see “[WIDGET\\_TEXT](#)” in the *IDL Reference Guide* manual.

---

**Note**

Use text widgets for displaying large amounts of text, or when you want the user to be able to edit the text. Use label widgets to display single-line labels that the user cannot edit.

---

## Text Widget Attributes

For text widgets, you can set common attributes and text-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. The following are the attributes specific to text widgets:

[Editable](#)

[Tab Mode](#)

[Height](#)

[Width](#)

[Initial Value](#)

[Word Wrapping](#)

[Scroll](#)

### Editable

The `Editable` attribute determines if the text widget is editable or not. By default, this value is set to `False`, which means the text widget is not editable. To make the text widget editable, set this value to `True`.

In the generated `*.pro` file, this value is specified with the `EDITABLE` keyword to the widget creation routine.

### Height

The `Height` attribute specifies the height of the text widget in text lines. Valid values for this attribute are 1 to  $n$ . The default value, is 1, or one text line.

Note that the physical height of the text widget depends on the value of the Height attribute and on the size of the font used. The default font size is used, unless you modify your generated code to use a different font, and the default font size is platform specific.

In the generated `*.pro` file, this value is specified by the YSIZE keyword to the widget creation routine.

## Initial Value

The Initial Value attribute specifies the initial array of values that are placed in the text widget. You can enter either a string or an array of strings.

To enter more than one string in the Value field, type in a string, then press Control+Enter (at the end of each line). This moves you to the next line. When you have entered the strings you want, press Enter to set the values.

In the generated `*.pro` file, this value is specified by the VALUE keyword to the widget creation routine.

### Note

---

Variables returned by the GET\_VALUE keyword to WIDGET\_CONTROL are always string arrays, even if a scalar string is specified in the call to WIDGET\_TEXT.

---

## Scroll

The Scroll attribute determines if the text widget displays scroll bars. By default, this value is set to False, which indicates that no scroll bars will be displayed. To have the text widget display scroll bars, set this value to True.

In the generated `*.pro` file, this value is specified by the SCROLL keyword to the widget creation routine.

## Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to Inherit.

### Note

---

It is not possible to tab to disabled (Sensitive = False) or hidden (Visible = False) widgets.

---

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-34: Allowable Tab Mode Values*

---

#### Note

The default tab mode of a widget is Inherit. The tabbing support defined for the parent base, described in [“Base Widget Attributes”](#) on page 4958, is inherited by widget children unless otherwise specified.

---

---

#### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the TAB\_MODE keyword to the widget creation routine. For more information on tabbing among widgets, see [“Tabbing in Widget Applications”](#) on page 869.

## Width

The Width attribute specifies the width of the text widget in characters. Valid values for this attribute are 0 to  $n$ . By default, Width is set to 0, which indicates that default IDL sizing should be used when, as long as default [Component Sizing](#) is also set.

Note that the physical width of the text widget depends on the value of the Width attribute and on the size of the font used. The default font size varies according to your windowing system. On Windows, the default size is roughly 20 characters. On Motif, the default size depends on the system default.

In the generated `*.pro` code, this value is specified with the `XSIZE` keyword.

## Word Wrapping

The Word Wrapping attribute determines whether scrolling or multi-line text widgets should automatically break lines between words to keep the text from extending past the right edge of the text display area. By default this value is set to `False`, and carriage returns are not automatically entered; the value of the text widget will remain a single-element array. To have the text widget enter carriage returns at the end of lines, change this value to `True`.

In the generated `*.pro` code, this value is specified with the `WRAP` keyword.

## Text Widget Events

For text widgets, you can set common event properties and text-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

You can set the following event values for text widgets:

[OnContextEvent](#)

[OnInsertCh](#)

[OnDelete](#)

[OnInsertString](#)

[OnFocus](#)

[OnTextSelect](#)

## OnContextEvent

The `OnContextEvent` value is the routine name that is called when the user clicks the right-hand mouse button over the text widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when the user clicks the right-hand mouse button and is of the following type:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The `X` and `Y` fields give the device coordinates at which the event occurred, measured from the upper left corner of the text widget.

## OnDelete

The OnDelete value is the routine that is called when text is deleted from the text widget. To set this event value, you must set the [Editable](#) attribute to True.

In the generated `*_eventcb.pro` file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when any amount of text is deleted from a text widget.

The event structure is of the following type:

```
{ WIDGET_TEXT_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L }
```

OFFSET is the (zero-based) character position of the first character to be deleted, and it is also the insertion position that will result when the characters have been deleted. LENGTH gives the number of characters deleted, where 0 (zero) indicates that no characters were deleted.

## OnFocus

The OnFocus value is the routine that is called when the keyboard focus changes. In the generated `*_eventcb.pro` event code, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the returned structure, which is of the following type:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ENTER returns 1 if the text widget is gaining the keyboard focus, or 0 if the text widget is losing the keyboard focus.

## OnInsertCh

The OnInsertCh value is the routine that is called when a single character is inserted in the widget. To set this event value, you must set the [Editable](#) attribute to True.

In the generated `*_eventcb.pro` file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when a single character is typed or pasted into a text widget by a user.

The event structure is of the following type:

```
{ WIDGET_TEXT_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
  CH:0B }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character.

## OnInsertString

The OnInsertString value is the routine that is called when a text string is inserted in the text widget. To set this event value, you must set the [Editable](#) attribute to True.

In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when multiple characters are inserted in to text widget. The event structure is of the following type:

```
{ WIDGET_TEXT_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:'' }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted.

## OnTextSelect

The OnTextSelect value is the routine that is called when text is selected in the text widget. To set this event value, you must also set the [Editable](#) attribute to True.

In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when an area of text is selected. The event structure is of the following type:

```
{ WIDGET_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3, OFFSET:0L,
  LENGTH:0L }
```

This event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character selected, which can also be the insertion position. LENGTH gives the number of characters involved, where zero indicates that no characters are selected.

**Note**

---

Text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert, delete, or movement event, and a separate zero length selection event is *not* sent.

---

# Label Widget Properties

Label widgets display static text. They are similar to single-line text widgets, but they are optimized for small labeling purposes.

There are no label widget-specific event properties.

When programming in IDL, you create label using the `WIDGET_LABEL` function. For more information, see “[WIDGET\\_LABEL](#)” in the *IDL Reference Guide* manual.

---

**Note**

Use label widgets to display single-line labels that you do not want the user to be able to edit. Use text widgets for displaying larger amounts of text, or text that you want the user to be able to edit.

---

## Label Widget Attributes

For label widgets, you can set common attributes and label-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. These are the label widget attributes:

[Alignment](#)

[Text](#)

[Sunken](#)

### Alignment

The Alignment attribute specifies how label [Text](#) is aligned. These are the possible values:

- Left: The text is left-justified. This is the default value.
- Center: The text is centered.
- Right: The text is right-justified.

In the generated `*.pro` file, this value is specified with the `ALIGN_CENTER`, the `ALIGN_RIGHT`, or the `ALIGN_LEFT` keyword to the widget creation routine.

### Sunken

The Sunken attribute specifies whether the label should be displayed with a “sunken” border. Sunken borders are often used for status lines and other interface elements in

which the text of the label changes based on user actions or the state of the application.

## Text

The Text attribute specifies the text string that is displayed in the label widget. By default, this value is set to Label, and you can set it to any string.

In the generated \*.pro file, this value is specified with the VALUE keyword to the widget creation routine.

## Label Widget Events

There are *no* events specific to Label widgets. For a list of the common widget events, see [“Common Events”](#) on page 4955.

# Slider Widget Properties

Horizontal or vertical slider widgets allow for the selection of a value within a range of possible integer values. A slider widget is a rectangular region representing a range of values, with a sliding pointer inside that indicates or selects the current value. This sliding pointer can be manipulated by the user dragging it with the mouse, or within IDL code.

When programming in IDL, you create horizontal or vertical slider widgets using the `WIDGET_SLIDER` function. See “[WIDGET\\_SLIDER](#)” in the *IDL Reference Guide* manual.

## Horizontal and Vertical Slider Widget Attributes

For slider widgets, you can set common attributes and slider-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. The following is a list of slider attributes:

[Maximum Value](#)

[Suppress Value](#)

[Minimum Value](#)

[Tab Mode](#)

[Position](#)

[Title](#)

### Maximum Value

The Maximum Value attribute specifies the maximum range value for the slider. The default value is 100, but you can set this attribute to any integer. This value works with the [Minimum Value](#) attribute.

In the generated `*.pro` file, this value is specified with the `MAXIMUM` keyword to the widget creation routine.

### Minimum Value

The Minimum Value attribute specifies the minimum range value of the slider. The default value is 0, but you can set this attribute to any integer. This attribute works with the [Maximum Value](#) attribute.

In the generated `*.pro` file, this value is specified with the `MINIMUM` keyword to the widget creation routine.

## Position

The Position attribute specifies the initial value position of the slider. By default this is set to 0, so the initial position will be at 0. You can set this value to any integer within the range of the [Maximum Value](#) and [Minimum Value](#) attribute settings.

In the generated `*.pro` file, this value is specified with the VALUE keyword to the widget creation routine.

## Suppress Value

The Suppress Value attribute controls the display of the current slider value. Sliders work only with integer units. You can use this attribute to suppress the actual value of a slider so that a program can present the user with a slider that seems to work in other units (such as floating-point) or with a non-linear scale. By default, this value is set to False, indicating that the current value, in integer units, should be displayed. To suppress the display of the current values, set this attribute value to True.

In the generated `*.pro` file, this value is specified with the SUPPRESS\_VALUE keyword to the widget creation routine.

## Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to Inherit.

### Note

---

It is not possible to tab to disabled (Sensitive = False) or hidden (Visible = False) widgets.

---

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-35: Allowable Tab Mode Values*

---

**Note**

The default tab mode of a widget is `Inherit`. The tabbing support defined for the parent base, described in “[Base Widget Attributes](#)” on page 4958, is inherited by widget children unless otherwise specified.

---

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see “[Tabbing in Widget Applications](#)” on page 869.

**Title**

The `Title` attribute specifies the label or title that is associate with the slider widget. By default, this is not set; it is an empty string. You can set the title to any string.

In the generated `*.pro` file, this value is specified with the `TITLE` keyword to the widget creation routine.

## Horizontal and Vertical Slider Widget Events

For slider widgets, you can set common event properties and slider-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

This is the event property specific to slider widgets:

**OnChangeValue**

The `OnChangeValue` specifies the routine that is called when the value of the slider is changed. When you set this event value, the calling sequence looks like this in the generated `*_eventcb.pro` file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when a slider is moved.

The event structure is of the following type:

```
{ WIDGET_SLIDER, ID:0L, TOP:0L, HANDLER:0L, VALUE:0L, DRAG:0 }
```

VALUE returns the new value of the slider. DRAG returns integer 1 if the slider event was generated as part of a drag operation, or zero if the event was generated when the user had finished positioning the slider. Note that the slider widget only generates events during the drag operation if the DRAG keyword is set. That is, in most cases, DRAG will return zero.

# Droplist Widget Properties

Droplist widgets display a single entry from a list of possible choices. To choose from the list, click the droplist, then click on the item in the list. On Motif operating systems, the droplist widget looks like a button, which when clicked displays the drop-down list.

When programming in IDL, you create droplist widgets using the `WIDGET_DROPLIST` function. For more information, see “[WIDGET\\_DROPLIST](#)” in the *IDL Reference Guide* manual.

## Droplist Widget Attributes

For droplist widgets, you can set common attributes and droplist-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. These are the droplist attributes:

[Initial Value](#)

[Title](#)

[Tab Mode](#)

### Initial Value

The Initial Value attribute specifies the initial list of values that are placed in the droplist widget. The initial value of a droplist can be a scalar string, or it can be a list of strings. By default, this value is not set, and the droplist is empty.

To enter more than one string in the Value field, type in a string, then press Control+Enter (at the end of each line). This moves you to the next line. When you have entered as many strings as you want, press Enter to set the values.

In the generated `*.pro` file, this value is specified with the `VALUE` keyword to the widget creation routine.

### Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to `Inherit`.

#### Note

---

It is not possible to tab to disabled (`Sensitive = False`) or hidden (`Visible = False`) widgets.

---

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-36: Allowable Tab Mode Values*

---

### Note

The default tab mode of a widget is Inherit. The tabbing support defined for the parent base, described in [“Base Widget Attributes”](#) on page 4958, is inherited by widget children unless otherwise specified.

---

---

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the TAB\_MODE keyword to the widget creation routine. For more information on tabbing among widgets, see [“Tabbing in Widget Applications”](#) on page 869.

## Title

The Title attribute specifies the title string, or label, for the droplist. This value can be any string. By default, this value is set to NULL.

In the generated `*.pro` file, this value is specified by the TITLE keyword to the widget creation routine.

## Droplist Widget Events

For droplist widgets, you can set common event properties and droplist-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

This is the event property specific to droplist widgets:

### OnSelectValue

The OnSelectValue specifies the routine that is called when a droplist item is selected. When a user selects an item from a droplist, the widget deselects the previously selected item, changes the visible item on the droplist, and generates an event.

When you set this event value, the calling sequence looks like this in the generated \*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. *Event* is the event structure returned when a user selects an item from a droplist. The event structure is of the following type:

```
{ WIDGET_DROPLIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L }
```

INDEX returns the index of the selected item. This value can be used to index the array of names originally used to set the widget’s value.

#### Note

---

On some platforms, when a droplist widget contains only one item and the user selects it again, the action does not generate an event. Events are always generated on selection actions if the list contains multiple items.

---

# Listbox Widget Properties

The listbox displays a list of text items from which a user can select, by clicking on them. The listboxes have vertical scroll bars to allow viewing of a long list of items.

When programming in IDL, you create listbox widgets using the `WIDGET_LIST` function. For more information, see “[WIDGET\\_LIST](#)” in the *IDL Reference Guide* manual.

## Listbox Widget Attributes

For listbox widgets, you can set common attributes and listbox-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. These are the listbox widget attributes:

<a href="#">Height</a>	<a href="#">Tab Mode</a>
<a href="#">Initial Value</a>	<a href="#">Width</a>
<a href="#">Multiple</a>	

### Height

The `Height` attribute specifies the height of the listbox based on the number of lines that are visible. The possible values for the attribute are 1 to  $n$ . By default, `Height` is set to 1, which indicates the default size of one line will be used.

Note that the final size of the widget may be adjusted to include space for scroll bars, which are not always visible, so the listbox might be slightly larger than specified.

In the generated `*.pro` file, this value specified with the `YSIZE` keyword to the widget creation routine.

### Initial Value

The `Initial Value` attribute specifies the initial list of values that are placed in the list widget. By default, the list is empty, but you can set this value to a scalar string or a list of strings. List widgets are sized based on the length (in characters) of the longest item specified in the array of values.

To enter more than one string in the `Value` field, type in a string, then press `Control+Enter` (at the end of each line). This moves you to the next line. When you have entered as many strings as you want, press `Enter` to set the values.

In the generated `*.pro` file, this value is specified by the `VALUE` keyword to the widget creation routine.

## Multiple

The `Multiple` attribute determines if the user can select multiple list items. By default, the setting is `False`, which allows for only one selection. To enable multiple list item selection, set this value to `True`. Multiple selections are handled using the method appropriate to the platform the application is running on.

In the generated `*.pro` file, this value is specified with the `MULTIPLE` keyword to the widget creation routine.

## Tab Mode

The `Tab Mode` attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to `Inherit`.

### Note

It is not possible to tab to disabled (`Sensitive = False`) or hidden (`Visible = False`) widgets.

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-37: Allowable Tab Mode Values*

### Note

The default tab mode of a widget is `Inherit`. The tabbing support defined for the parent base, described in “[Base Widget Attributes](#)” on page 4958, is inherited by widget children unless otherwise specified.

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see “[Tabbing in Widget Applications](#)” on page 869.

**Width**

The `Width` attribute specifies the width of the listbox in characters. The possible values for the attribute are 0 to  $n$ . By default, `Width` is set to 0, which indicates that default sizing will be used, as long as the [Component Sizing](#) attribute is set to default.

By default, IDL sizes widgets to fit the situation. However, if the desired effect is not produced, use explicit `Component Sizing` with the `Width` attribute to set your own sizing. The final size of the widget may be adjusted to include space for the scroll bar, which is not always visible, so your widget may be slightly larger than specified.

In the generated `*.pro` file, this value is specified with the `XSIZE` keyword to the widget creation routine.

**Listbox Widget Events**

For listbox widgets, you can set common event properties and listbox-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

The following is the event property specific to listbox widgets:

[OnContextEvent](#)

[OnSelectValue](#)

**OnContextEvent**

The `OnContextEvent` value is the routine name that is called when the user clicks the right-hand mouse button over the list widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when the user clicks the right-hand mouse button and is of the following type:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget.

## OnSelectValue

The OnSelectValue specifies a valid IDL routine name that is called when a list item is selected. When a user clicks on an item in the listbox to select the item, an event is generated.

When you set this event value, the calling sequence looks like this in the generated \*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the returned event structure, which is of the following type:

```
{ WIDGET_LIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, CLICKS:0L }
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This index can be used to subscript the array of names originally used to set the widget's value. CLICKS returns either 1 or 2, depending on how the list item was selected. If the list item is double-clicked, CLICKS is set to 2.

### Note

---

If you are writing a widget application that requires the user to double-click on a list widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.

---

# Draw Widget Properties

Draw widgets are rectangular regions that IDL treats as standard graphics windows. Use draw widgets to display either IDL Direct graphics or IDL Object graphics, depending on the value of the [Graphics Type](#) attribute. You can direct any graphical output that can be produced by IDL to one of these widgets, either by using the [WSET](#) function or by using the object reference of a draw widget's IDLgrWindow object.

Draw widgets can contain scroll bars that allow for viewing of a graphical region larger than the area containing the widget.

When programming in IDL, you create draw area widgets using the WIDGET\_DRAW function. For more information, see “[WIDGET\\_CONTROL](#)” in the *IDL Reference Guide* manual.

## Draw Area Widget Attributes

For a draw area widget, you can set common attributes and draw area-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. These are the draw area-specific attributes:

<a href="#">Color Model</a>	<a href="#">Scroll</a>
<a href="#">Colors</a>	<a href="#">Tooltip</a>
<a href="#">Graphics Type</a>	<a href="#">X Scroll</a>
<a href="#">Renderer</a>	<a href="#">Y Scroll</a>
<a href="#">Retain</a>	

### Color Model

The Color Model attribute specifies the color model that should be used for displaying information on the draw widget. This attribute value is used only when the [Graphics Type](#) attribute is set to Object, for IDL Object Graphics. These are the possible values for the Color Model attribute:

- **Index:** The draw widget's associated IDLgrWindow object uses indexed color.
- **RGB:** The RGB color model is used. This is the default value.

In the generated \*.pro file, this value is specified by the COLOR\_MODEL keyword to the widget creation routine.

## Colors

The Colors attribute specifies the number of colors that the drawable should attempt to use from the system color table. This attribute is only valid with the [Graphics Type](#) attribute is set to Direct, for IDL Direct Graphics. By default, the Color attribute is set to 0, which indicates that IDL will attempt to get all available colors. That is, all or most of the available color indices are allocated, based on the window system in use. You can set the Colors attribute to any integer, but most values will be in the range of  $-256 < n < 256$ .

This attribute has effect only if it is supplied when the first IDL graphics window is created. To use monochrome windows on a color display, set the Colors attribute to 2 for the first window. One color table is maintained for all running IDL windows.

In the generated `*.pro` file, this value is specified by the `COLORS` keyword to the widget creation routine.

## Graphics Type

The Graphics Type attribute specifies the type of graphics that the draw widget will support. These are the possible values:

- **Direct:** The draw widget will display Direct Graphics. This is the default value. The Colors attribute is used only when [Graphics Type](#) is set to Direct.
- **Object:** The draw widget will display IDL Object Graphics. The [Color Model](#) and [Renderer](#) properties are used only when the Graphics Type is set to Object.

In the generated `*.pro` file, this value is specified with the `GRAPHICS_LEVEL` keyword to the widget creation routine.

## Renderer

The Renderer attribute specifies which graphics renderer to use with IDL Object Graphics. That is, for this attribute to be used, the [Graphics Type](#) attribute should be set to Object. These are the possible values for the Renderer attribute:

- **OpenGL:** The platform's native OpenGL renderer is used when drawing objects within the window. If your platform does not have a native OpenGL implementation, IDL's software implementation is used as the renderer. This value is set by default.
- **Software:** IDL's software implementation is used when drawing objects within the window.

In the generated `*.pro` file, this value is specified by the `RENDERER` keyword to the widget creation routine.

For more information, see [“Hardware vs. Software Rendering”](#) in Chapter 12 of the *Object Programming* manual.

---

**Note**

The renderer selection can also affect the maximum size of a draw widget.

---

## Retain

The Retain attribute specifies how backing store is performed in the draw area. These are the possible values:

- None: There is no backing store. When the Retain attribute is set to None, you should track [OnExpose](#) events so that you can handle the redrawing of the screen. This is the default value.
- System: The server or window system should provide backing store.
- IDL Pixmap: IDL should provide backing store.

In the generated `*.pro` file, this value is specified with the `RETAIN` keyword to the widget creation routine.

For information on the use of the Retain attribute with Direct Graphics, see [“Backing Store”](#) in [Appendix A, “IDL Direct Graphics Devices”](#) in the *IDL Reference Guide* manual. For more information on this attribute with IDL Object Graphics, see [“IDLgrWindow::Init”](#) in the *IDL Reference Guide* manual.

## Scroll

The Scroll attribute specifies if the draw area widget will support scrolling, and will have scroll bars. By default, this value is set to `False`, which indicates there are no scroll bars. To display scroll bars, and enable scrolling, set this value to `True`. If you do so, set the size of the scrollable area with the [X Scroll](#) and [Y Scroll](#) properties.

In the generated `*.pro` file, this value is specified with the `SCROLL` keyword to the widget creation routine.

## Tooltip

The Tooltip attribute specifies a short text string that will be displayed when the mouse cursor is positioned over the draw area. The length of the tooltip is not explicitly limited, but since tooltips are displayed in a single line, it is best to keep the text short.

## X Scroll

The X Scroll attribute specifies the width in pixels of the drawing area. This width includes the exposed and virtual area. By default, this value is not set. You can set X Scroll to any width from 0 to  $n$ . If you set this value, also set the [Scroll](#) and [Y Scroll](#) attribute values.

In the generated `*.pro` file, this value is specified with the XSIZE keyword to the widget creation routine.

---

**Note**

To set the width of the displayed widget, use the [X Size](#) common attribute.

---

## Y Scroll

The Y Scroll attribute specifies the height in pixels of the drawing area. This height includes the exposed and virtual area. By default, this value is not set. You can set Y Scroll to any height in pixels from 0 to  $n$ . If you set this value, also set the [Scroll](#) and [X Scroll](#) properties.

In the generated `*.pro` file, this value is specified with the YSIZE keyword to the widget creation routine.

---

**Note**

To set the height of the displayed widget, use the [Y Size](#) common attribute.

---

## Draw Area Widget Events

For draw area widgets, you can set common event properties and draw area-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

These are the draw area event properties:

[OnButton](#)

[OnMotion](#)

[OnExpose](#)

[OnViewportMoved](#)

[OnKeyboard](#)

## OnButton

The OnButton value is the routine that is called when a mouse button event is detected. In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the returned event structure, which is of the following type:

```
{ WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
  PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note that this is the same event structure returned for all draw area events; OnButton, OnExpose, OnMotion, and OnViewportMoved events all return the same structure. Therefore the following paragraphs describe all these events.

TYPE returns a value that describes the type of draw widget interaction that generated an event. If there is a button press, it returns 0, and if there is a button release, it returns 1. If there is motion, it returns 2 (for an OnMotion event). If the viewport moved with the scroll bars, it returns 3 (for an OnViewportMoved event). If the visibility changes, it returns 4 (for an OnExpose event).

The X and Y fields give the device coordinates at which the event occurred, measured from the lower left corner of the drawing area.

PRESS and RELEASE are bitmasks in which the least significant bit represents the left-most mouse button. The corresponding bit of PRESS is set when a mouse button is pressed, and in RELEASE when the button is released. If the event is a motion event, both PRESS and RELEASE returns zero.

CLICKS returns either 1 or 2. If the time interval between button-press events is greater than the time interval for a double-click event for the system, the CLICKS field returns 1. If the time interval between two button-press events is less than the time interval for a double-click event for the platform, the CLICKS field returns 2.

The MODIFIERS field is valid for button press, button release, motion, and keyboard events. It is a bitmask which returns the current state of several keyboard modifier keys at the time the event was generated. If a bit is zero, the key is up. If the bit is set, the key is depressed. See “Widget Events Returned by Draw Widgets” in the *IDL Reference Guide* manual for complete details.

Keyboard events are generated with the value of the TYPE field equal to 5 or 6. If the event was generated by an ASCII keyboard character, the TYPE field will be set to 5 and the ASCII value of the key will be returned in the CH field. (Note that ASCII values can be converted to the string representing the character using the IDL STRING routine.) If the event was generated due to a non-ASCII keyboard character,

the type of the event will be set to 6 and a numeric value representing the key will be returned in the KEY field. See “[Widget Events Returned by Draw Widgets](#)” in the *IDL Reference Guide* manual for complete details.

## OnExpose

The OnExpose value is the routine that is called when the visibility of any portion of the draw window (or viewport) changes or is exposed. In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the returned event structure, which is of the following type:

```
{ WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,  
  PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note that this is the same event structure returned for all draw area events; [OnButton](#), [OnExpose](#), [OnKeyboard](#), [OnMotion](#), and [OnViewportMoved](#) events all return the same structure. For information on this structure, see [OnButton](#).

## OnKeyboard

The OnKeyboard value is the routine that is called when the user presses a key on the keyboard while the draw window has focus. In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the returned event structure, which is of the following type:

```
{ WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,  
  PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note that this is the same event structure returned for all draw area events; [OnButton](#), [OnExpose](#), [OnKeyboard](#), [OnMotion](#), and [OnViewportMoved](#) events all return the same structure. For information on this structure, see [OnButton](#).

## OnMotion

The OnMotion value is the routine that is called when a mouse motion event is detected. In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify.

Event is the returned event structure, which is of the following type:

```
{ WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
  PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note that this is the same event structure returned for all draw area events; [OnButton](#), [OnExpose](#), [OnKeyboard](#), [OnMotion](#), and [OnViewportMoved](#) events all return the same structure. For information on this structure, see [OnButton](#).

## OnViewportMoved

The OnViewportMoved value is the routine that is called when the viewport of a scrolling draw widget is moved, using the scroll bars. In the generated \*\_eventcb.pro file, the calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the returned event structure, which is of the following type:

```
{ WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
  PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note that this is the same event structure returned for all draw area events; [OnButton](#), [OnExpose](#), [OnKeyboard](#), [OnMotion](#), and [OnViewportMoved](#) events all return the same structure. For information on this structure, see [OnButton](#).

# Table Widget Properties

Table widgets display data and allow for data editing by the user. Tables can have one or more rows and one or more columns.

When programming in IDL, you create table widgets using the `WIDGET_TABLE` function. For more information, see “[WIDGET\\_TABLE](#)” in the *IDL Reference Guide* manual.

## Table Widget Attributes

For table widgets, you can set common attributes and table-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. These are the table widget-specific attributes:

<a href="#">Alignment</a>	<a href="#">Resize Columns</a>
<a href="#">Column Labels</a>	<a href="#">Row/Column Major</a>
<a href="#">Disjoint Selection</a>	<a href="#">Row Labels</a>
<a href="#">Display Headers</a>	<a href="#">Scroll</a>
<a href="#">Editable</a>	<a href="#">Tab Mode</a>
<a href="#">Number of Columns</a>	<a href="#">Viewport Columns</a>
<a href="#">Number of Rows</a>	<a href="#">Viewport Rows</a>

### Alignment

The `Alignment` attribute specifies how the text is aligned in the cells. These are the possible values:

- `Left`: The text is left-justified. This is the default value.
- `Right`: The text is right-justified.
- `Center`: The text is centered.

In the generated `*.pro` file, this value is specified with the `ALIGNMENT` keyword to the widget creation routine.

## Column Labels

The Column Labels attribute specifies the labels for the table columns. By default, this value is set to empty strings, but you can set it to any set of strings. To set the labels for table rows, use the [Row Labels](#) attribute.

To enter more than one string in the Value field, type in a string, then press Control+Enter (at the end of each line). This moves you to the next line, or the next label for a column. When you have entered as many labels as you want, press Enter to set the values.

In the generated `*.pro` file, this value is specified with the `COLUMN_LABELS` keyword to the widget creation routine.

## Disjoint Selection

The Disjoint Selection attribute determines whether the user is allowed to select multiple, unconnected cell regions within the table. By default, this value is set to False, indicating that only a single selection is allowed. To allow disconnected regions, set this value to True.

In the generated `*.pro` file, the False value is specified with the `DISJOINT_SELECTION` keyword to the widget creation routine.

## Display Headers

The Display Headers attribute determines if the table headings, the row and column labels, are displayed. By default, this value is set to True, indicating that table heading should be displayed. To disable the display of table headings, set this value to False.

In the generated `*.pro` file, the False value is specified with the `NO_HEADERS` keyword to the widget creation routine.

## Editable

The Editable attribute determines if the table widget is editable or not. By default, this value is set to False, which means the text widget is not editable, and the text is read-only. To make the text widget editable, set this value to True.

In the generated `*.pro` file, this value is specified with the `EDITABLE` keyword to the widget creation routine.

## Number of Columns

The Number of Columns attribute specifies the number of columns in the table widget. This value sets the full, virtual width of the table. By default, it is set to 6.

In the generated `*.pro` file, this value is specified with the `XSIZE` keyword to the widget creation routine.

---

**Note**

To have a scrollable table, set the [Scroll](#) attribute to `True`. Then, to specify the visible size of the table, set the [Viewport Columns](#) attribute.

---

## Number of Rows

The `Number of Rows` attribute specifies the number of rows in the table widget. This value sets the full, virtual height of the table. By default, it is set to 6.

In the generated `*.pro` file, this value is specified with the `YSIZE` keyword to the widget creation routine.

---

**Note**

To have a scrollable table, set the [Scroll](#) attribute to `True`. Then, to specify the visible size of the table, set the [Viewport Columns](#) attribute.

---

## Resize Columns

The `Resize Columns` attribute determines if this user can resize table columns. By default, this value is set to `True`, indicating that the user can resize the columns. To specify that the columns of the table are not resizable by the user, set this value to `False`.

In the generated `*.pro` file, this value is specified with the `RESIZEABLE_COLUMNS` keyword to the widget creation routine.

---

**Note**

If you set the [Display Headers](#) attribute to `False`, the ability to resize the columns is automatically disabled.

---

## Row/Column Major

The `Row/Column Major` attribute specifies how data is transferred to the table widget, either by `Row` or by `Column`. By default, this value is set to `Row`, indicating that the data should be read into the table as if each element of the vector is a structure containing one row's data. To specify that the data should be read into the table as if each element of the vector is a structure containing one column's data, set this value to `Column`. Note that for either setting to work properly the structures must all be of the same type, and must have one field for each column or row in the table.

In the generated \*.pro file, this value is specified with the ROW\_MAJOR or the COLUMN\_MAJOR keyword to the widget creation routine.

## Row Labels

The Row Labels attribute specifies the labels for the table rows. By default, this value is set to empty strings, but you can set it to any set of strings. To set the labels for table columns, use the [Column Labels](#) attribute.

To enter more than one string in the Value field, type in a string, then press Control+Enter (at the end of each line). This moves you to the next line, or the next label for a row. When you have entered as many labels as you want, press Enter to set the values.

In the generated \*.pro file, this value is specified with the ROW\_LABELS keyword to the widget creation routine.

## Scroll

The Scroll attribute determines if the table widget has scroll bars. By default, this value is set to False, indicating that the table will have no scroll bars. To enable scroll bars, set this value to True. If you set this value to True, you can set the size of the scrollable region with the [Viewport Rows](#) and [Viewport Columns](#) properties.

In the generated \*.pro file, this value is specified with the SCROLL keyword to the widget creation routine.

## Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to Inherit.

### Note

It is not possible to tab to disabled (Sensitive = False) or hidden (Visible = False) widgets.

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.

*Table I-38: Allowable Tab Mode Values*

Value	Description
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-38: Allowable Tab Mode Values (Continued)*

---

### Note

The default tab mode of a widget is Inherit. The tabbing support defined for the parent base, described in “[Base Widget Attributes](#)” on page 4958, is inherited by widget children unless otherwise specified.

---

---

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see “[Tabbing in Widget Applications](#)” on page 869.

## Viewport Columns

The Viewport Columns attribute specifies the number of columns that should be visible in the scroll area of the table widget. By default, this value is set to 6.

If you first set the [Scroll](#) attribute to True, you can then set this value to any size from 0 to  $n$  columns within the limits of your full table size. The full table size, or virtual width in columns, is set with the [Number of Columns](#) attribute.

This attribute is used only when the [Component Sizing](#) attribute is set to Default. If you set the Component Sizing attribute to Explicit, either through the Properties dialog or by dragging the component to specific size, the Viewport Columns attribute is ignored, and the [X Size](#) and the [Y Size](#) properties are used.

In the generated `*.pro` file, this value is specified with the `X_SCROLL_SIZE` keyword to the widget creation routine.

## Viewport Rows

The Viewport Rows attribute specifies the number of rows that should be visible in the scroll area of the table widget. By default, this value is set to 6.

If you first set the [Scroll](#) attribute to True, you can then set this value to any size from 0 to  $n$  rows, within the limits of your full table size. The full table size, or virtual height in rows, is set with the [Number of Rows](#) attribute.

This attribute is used only when the [Component Sizing](#) attribute is set to Default. If you set the Component Sizing attribute to Explicit, either through the Properties dialog or by dragging the component to specific size, the Viewport Rows attribute is ignored, and the [X Size](#) and the [Y Size](#) properties are used.

In the generated `*.pro` file, this value is specified with the `Y_SCROLL_SIZE` keyword to the widget creation routine.

## Table Widget Events

For table widgets, you can set common event properties and table-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see [“Common Events”](#) on page 4955.

These are the table widget-specific event properties:

<a href="#">OnCellSelect</a>	<a href="#">OnInsertChar</a>
<a href="#">OnColWidth</a>	<a href="#">OnInsertString</a>
<a href="#">OnDelete</a>	<a href="#">OnInvalidData</a>
<a href="#">OnFocus</a>	<a href="#">OnTextSelect</a>

### OnCellSelect

The `OnCellSelect` value is the routine that is called when cells are selected in the table. When you set this value, the calling sequence looks like this in the generated `*_eventcb.pro` file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify.

Event is the event structure returned when range of cells is selected or deselected and is of the following type:

```
{ WIDGET_TABLE_CELL_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:4,
  SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L }
```

The range of cells selected is given by the zero-based indices into the table specified by the SEL\_LEFT, SEL\_TOP, SEL\_RIGHT, and SEL\_BOTTOM fields. When cells are deselected, either by changing the selection or by clicking in the upper left corner of the table, an event is generated in which the SEL\_LEFT, SEL\_TOP, SEL\_RIGHT, and SEL\_BOTTOM fields contain the value -1.

---

### Note

Two WIDGET\_TABLE\_CELL\_SEL events are generated when an existing selection is changed to a new selection. If your code uses this event, be sure to differentiate between select and deselect events.

---

## OnColWidth

The OnColWidth value is the routine that is called when the column width is changed. When you set this value, the calling sequence looks like this in the generated \*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when a column width is changed by the user and is of the following type:

```
{ WIDGET_TABLE_COLUMN_WIDTH, ID:0L, TOP:0L, HANDLER:0L, TYPE:7,
  COLUMN:0L, WIDTH:0L }
```

COLUMN contains the zero-based column number, and WIDTH contains the new width.

## onDelete

The onDelete value is the routine that is called when text is deleted from the table. When you set this value, the calling sequence looks like this in the generated \*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify.

Event is the event structure returned when any amount of text is deleted from a cell of a table widget and is of the following type:

```
{ WIDGET_TABLE_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L, X:0L, Y:0L }
```

OFFSET is the (zero-based) character position of the first character deleted, and it is the insertion position that will result when the next character is inserted. LENGTH gives the number of characters involved. The X and Y fields give the zero-based address of the cell within the table.

## OnFocus

The OnFocus value is the routine that is called when the keyboard focus of the base changes. When you set it, the calling sequence looks like this in the generated \*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify.

Event is the returned event structure, which is of the following type:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ENTER returns 1 (one) if the table widget is gaining the keyboard focus, or 0 (zero) if the table widget is losing the keyboard focus.

## OnInsertChar

The OnInsertChar value is the routine that is called when text is inserted in the table. When you set this value, the calling sequence looks like this in the generated \*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when a single character is typed into a cell of a table widget and is of the following type:

```
{ WIDGET_TABLE_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
  CH:0B, X:0L, Y:0L }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character. The X and Y fields indicate the zero-based address of the cell within the table.

## OnInsertString

The OnInsertString value is the routine that is called when text is inserted in the table. When you set this value, the calling sequence looks like this in the generated

\*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when multiple characters are pasted into a cell and is of the following type:

```
{ WIDGET_TABLE_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:'', X:0L, Y:0L }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted. The X and Y fields indicate the zero-based address of the cell within the table.

## OnInvalidData

The OnInvalidData value is the routine that is called when invalid data is set in a cell. When you set this value, the calling sequence looks like this in the generated

\*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when the text entered by the user does not pass validation, and the user has finished editing the field (by pressing Tab or Enter). The event structure is of the following type:

```
{ WIDGET_TABLE_INVALID_ENTRY, ID:0L, TOP:0L, HANDLER:0L, TYPE:8,
  STR:'', X:0L, Y:0L }
```

STR contains invalid contents entered by the user as a text string. The X and Y fields contain the cell location.

## OnTextSelect

The OnTextSelect value is the routine that is called when text is selected in the table. When you set this value, the calling sequence looks like this in the generated

\*\_eventcb.pro file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. Event is the event structure returned when an area of text is selected.

The event structure is of the following type:

```
{WIDGET_TABLE_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3,  
  OFFSET:0L, LENGTH:0L, X:0L, Y:0L}
```

This event announces a change in the insertion point. **OFFSET** is the (zero-based) character position of the first character to be selected. **LENGTH** gives the number of characters involved. A **LENGTH** of zero indicates that the widget has no selection, and that the insertion position is given by **OFFSET**. The **X** and **Y** fields indicate the zero-based address of the cell within the table.

# Tab Widget Properties

Tab widgets present a display area on which different “pages” (base widgets and their children) can be displayed by selecting the appropriate tab.

Each tabbed area in a tab widget contains a base widget, to which other controls can be added. When initially created, a tab widget will contain a single tab. To add a tab, right-click on the tabbed portion of the tab widget and select “Add Tab”. The new tab is added at the next logical location in the tab widget. To delete a tab, right-click on the tabbed portion of the tab widget and select “Delete Tab”.

When programming in IDL, you create tab widgets using the `WIDGET_TAB` function. For more information, see “[WIDGET\\_TAB](#)” in the *IDL Reference Guide* manual.

## Tab Widget Attributes

For tab widgets, you can set common attributes and tab-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. In addition, you can modify the attributes of the base widget that makes up the displayed area of each tab.

These are the tab widget-specific attributes:

[Multiple Rows](#)

[Tab Mode](#)

[Location](#)

[Tab Text](#)

### Multiple Rows

The Multiple Rows attribute determines whether tabs will be displayed in multiple rows if the total length of all the tab titles exceeds the width of the largest tab base widget. By default, this value is set to `False`, which means that if the total length of all the tab titles exceeds the space available, scroll bars will be added to the tab interface to allow the user to cycle through the tabs. Set this value to `True` to create tabs in multiple rows if the total length exceeds the available space.

---

#### Note

If the `Location` attribute is set to either `Left` or `Right`, the `Multiple Rows` attribute is automatically set to `True`.

---

In the generated `*.pro` file, this value is specified with the `MULTILINE` keyword to the widget creation routine.

## Location

The Location attribute determines the display location of the tabs on the tab widget. Possible values are Top, Bottom, Left and Right. The default value is Top.

In the generated \*.PRO file, this value is specified with the LOCATION keyword to the widget creation routine.

## Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to Inherit.

### Note

It is not possible to tab to disabled (Sensitive = False) or hidden (Visible = False) widgets.

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-39: Allowable Tab Mode Values*

### Note

The default tab mode of a widget is Inherit. The tabbing support defined for the parent base, described in “[Base Widget Attributes](#)” on page 4958, is inherited by widget children unless otherwise specified.

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see [“Tabbing in Widget Applications”](#) on page 869.

**Tab Text**

The Tab Text attribute specifies the text label used on the currently-selected tab. By default, this attribute contains the name of the base widget that holds the tab’s contents.

In the generated `*.pro` file, this value is specified with the `TITLE` keyword to the widget base creation routine.

**Tab Widget Events**

For tab widgets, you can set common event properties and tab-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see [“Common Events”](#) on page 4955.

These are the tab widget-specific event properties:

**OnTabChange**

The `OnTabChange` value is the routine that is called when the currently-selected tab of the tab widget changes. When you set this value, the calling sequence looks like this in the generated `*_eventcb.pro` file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when a user changes the selected tab and is of the following type:

```
{WIDGET_TAB, ID:0L, TOP:0L, HANDLER:0L, TAB:0L}
```

`TAB` contains the zero-based index of the tab selected.

# Tree Widget Properties

Tree widgets present a hierarchical view that can be used to organize a wide variety of data structures and information.

When you first create a tree widget, it appears in the interface as a blank control, containing no nodes. To add nodes to the tree widget, right-click on the tree widget and select **Edit Tree** from the context menu. See “[Using the Tree Editor](#)” in Chapter 29 of the *Building IDL Applications* manual for details on constructing a tree hierarchy.

When programming in IDL, you create tree widgets using the `WIDGET_TREE` function. For more information, see “[WIDGET\\_TREE](#)” in the *IDL Reference Guide* manual.

## Tree Widget Attributes

For tree widgets, you can set common attributes and tree-specific attributes. For a list of common attributes, see “[Common Attributes](#)” on page 4952. These are the tree widget-specific attributes:

[Multiple Selection](#)

[Tab Mode](#)

### Multiple Selection

The Multiple Selection attribute determines whether the tree widget can perform multiple selection operations. Set this property to True to enable multiple selection, which allows the user to select multiple tree nodes by holding down the Control key while selecting with the mouse. By default this property is set to False.

In the generated `*.pro` file, this value is specified with the `MULTIPLE` keyword to the widget creation routine.

### Tab Mode

The Tab Mode attribute specifies what support the widget has for receiving or losing focus through tabbing. By default, this value is set to Inherit.

---

**Note**

It is not possible to tab to disabled (`Sensitive = False`) or hidden (`Visible = False`) widgets.

---

Allowable values are:

Value	Description
Inherit	Upon creation, the widget inherits the tabbing support of the parent base.
None	Disallow tabbing into or out of the widget.
In and Out	Allow tabbing into and out of the widget.
In Only	Allow tabbing into the widget only.
Out Only	Allow tabbing off of the widget only.

*Table I-40: Allowable Tab Mode Values*

---

#### Note

The default tab mode of a widget is Inherit. The tabbing support defined for the parent base, described in “[Base Widget Attributes](#)” on page 4958, is inherited by widget children unless otherwise specified.

---

---

#### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

In the generated `*.pro` file, this value is specified with the `TAB_MODE` keyword to the widget creation routine. For more information on tabbing among widgets, see “[Tabbing in Widget Applications](#)” on page 869.

## Tree Widget Events

For tree widgets, you can set common event properties and tree-specific event properties. By default, event values are *not* set. For a list of events common to all widgets, see “[Common Events](#)” on page 4955.

These are the tree widget-specific event properties:

[OnContextEvent](#)

[OnTreeSelect](#)

[OnTreeExpand](#)

## OnContextEvent

The `OnContextEvent` value is the routine name that is called when the user clicks the right-hand mouse button over the tree widget. In the generated `*_eventcb.pro` file, the event calling sequence looks like this:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when the user clicks the right-hand mouse button and is of the following type:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The `X` and `Y` fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget.

## OnTreeExpand

The `OnTreeExpand` value is the routine that is called when a folder expand/collapse event is detected. When you set this value, the calling sequence looks like this in the generated `*_eventcb.pro` file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify. `Event` is the event structure returned when a user changes the selected tab, and is of the following type:

```
{WIDGET_TREE_EXPAND, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, EXPAND:0L}
```

The `EXPAND` field contains 1 (one) if the folder expanded or 0 (zero) if the folder collapsed.

## OnTreeSelect

The `OnTreeSelect` value is the routine that is called when the selection state of an item in the tree changes. When you set this value, the calling sequence looks like this in the generated `*_eventcb.pro` file:

```
pro <RoutineName>, Event
```

where *RoutineName* is the name of the event procedure you specify.

Event is the event structure returned when a user changes the selected tab, and is of the following type:

```
{WIDGET_TREE_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, CLICKS:0L}
```

The **CLICKS** field indicates the number of mouse-button clicks that occurred when the event took place. This field contains 1 (one) when the item is selected, or 2 when the user double-clicks on the item.

# Appendix J

# Obsolete Features

The following topics are covered in this appendix:

---

What Are Obsolete Features? . . . . .	5024	SDF Routines Obsolete in IDL 5.3 . . . . .	5041
Features Obsolete in IDL 6.2 . . . . .	5025	Features Obsolete in IDL 5.2 . . . . .	5042
Features Obsolete in IDL 6.1 . . . . .	5027	Features Obsolete in IDL 5.1 . . . . .	5043
Features Obsolete in IDL 6.0 . . . . .	5029	Features Obsolete in IDL 5.0 . . . . .	5044
Features Obsolete in IDL 5.6 . . . . .	5031	Features Obsolete in IDL 4.0 or Earlier	5046
Features Obsolete in IDL 5.5 . . . . .	5032	Obsolete System Variables . . . . .	5053

Features Obsolete in IDL 5.3 . . . . .	5037		

# What Are Obsolete Features?

To improve the overall quality and functionality of IDL, Research Systems, Inc. occasionally replaces existing features with new, improved features. In many cases, existing routines are improved without changing their existing behavior—through improvements of the underlying algorithms, for example, or by adding keyword functionality. In some cases, however, the improved methods are incompatible with the old. In these situations, we consider the routines that we have replaced to be *obsolete*.

For similar reasons, arguments and keywords to existing routines may occasionally become obsolete. In many cases, the functionality activated by the obsolete argument or keyword can be achieved more efficiently using a new argument or keyword. If this is the case, existing code using the obsolete argument or keyword will generally continue to function as it always has, although performance may be better using the new, replacement argument or keyword. In cases where the obsolete argument or keyword activated functionality that is no longer available (perhaps as a result of an operating system upgrade or change), IDL will either quietly ignore the presence of the argument or keyword (if doing so does not affect the resulting output) or warn that an invalid parameter has been specified.

This chapter lists the features that have become obsolete in each version of IDL. These features are not documented in the online help. To view reference information for features obsoleted in IDL version 5.0 and later, see the *Obsolete IDL Features* guide. Features obsoleted in IDL 4.0 and earlier are not documented in the *Obsolete IDL Features* guide. If a `.pro` file for the routine exists, it is located in the `lib/obsolete` subdirectory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the `DOC_LIBRARY` routine.

## Features Obsoleted in IDL 6.2

The following features were present in IDL Version 6.1 but became obsolete in IDL Version 6.2.

Routine	Replaced by	.pro File?
<a href="#">ONLINE_HELP_PDF_INDEX</a>	Nothing: the IDL-Acrobat plugin is no longer supported	
<a href="#">SETUP_KEYS</a>	Nothing; no longer needed	

*Table J-41: Routines Obsoleted in IDL 6.2*

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">HELP</a>	ALL_KEYS keyword	This keyword was replaced by the combination of the KEYS and FULL keywords.
	CALLS keyword	This keyword was replaced by (is now equivalent to) the use of the REVERSE and SCOPE_TRACEBACK routines together.
<a href="#">IDLitTool::RegisterOperation</a>	DISABLE keyword	This keyword has been replaced by the <a href="#">IDLitOperation::QueryAvailability</a> method.

*Table J-42: Arguments and Keywords Obsoleted in IDL 6.2*

Routine	Argument or Keyword	Description
ONLINE_HELP	HTML_HELP keyword	This keyword is no longer necessary; ONLINE_HELP parses the value of the BOOK keyword to determine file type.
	FOLD_CASE keyword	This keyword is no longer necessary; ONLINE_HELP tries to use both the specified case and upper-case versions of the <i>Value</i> string.
	PAGE keyword	This keyword is used by the obsolete IDL-Acrobat plugin.
	SUPPRESS_PLUGIN_ERRORS keyword	This keyword is used by the obsolete IDL-Acrobat plugin.
	TOPICS keyword	This keyword does not work with Microsoft HTML Help (*.chm) files.
WIDGET_CONTROL	CANCEL_BUTTON keyword	Cross-platform UI-toolkit support for this keyword is not available.
	DEFAULT_BUTTON keyword	Cross-platform UI-toolkit support for this keyword is not available.

Table J-42: Arguments and Keywords Obsoleted in IDL 6.2 (Continued)

## Features Obsoleted in IDL 6.1

The following features were present in IDL Version 6.0 but became obsolete in IDL Version 6.1.

Routine	Replaced by	.pro File?
<a href="#">FINDFILE</a>	<a href="#">FILE_SEARCH</a>	
<a href="#">MSG_CAT_CLOSE</a>	<a href="#">IDLffLangCat</a>	
<a href="#">MSG_CAT_COMPILE</a>	<a href="#">IDLffLangCat</a>	
<a href="#">MSG_CAT_OPEN</a>	<a href="#">IDLffLangCat</a>	
<a href="#">IDLffLanguageCat</a>	<a href="#">IDLffLangCat</a>	

*Table J-43: Routines Obsoleted in IDL 6.1*

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">IDLITSYS_CREATETOOL</a>	<a href="#">PANEL_LOCATION</a> keyword	This keyword is no longer honored. Panel location is handled via standard widget layout mechanisms.
<a href="#">IDLitVisualization::Add</a>	<a href="#">GROUP</a> keyword	This keyword was unintentionally and needlessly exposed.
<a href="#">IDLitVisualization::GetCenterRotation</a>	<a href="#">DATA</a> keyword	This keyword is not implemented.
<a href="#">IDLitVisualization::GetProperty</a>	<a href="#">GROUP_PARENT</a> keyword	This keyword was unintentionally and needlessly exposed.

*Table J-44: Arguments and Keywords Obsoleted in IDL 6.1*

Routine	Argument or Keyword	Description
IVolume	CUTTING_PLANES keyword	This keyword has been replaced by CLIP_PLANES.

*Table J-44: Arguments and Keywords Obsoleted in IDL 6.1 (Continued)*

## Features Obsoleted in IDL 6.0

The following features were present in IDL Version 5.6 but became obsolete in IDL Version 6.0.

**Note**

For information about routines replaced by the iTools system, see the *iTools User's Guide*.

Routine	Replaced by	.pro File?
LIVE_CONTOUR	ICONTOUR	
LIVE_CONTROL	iTools system	
LIVE_DESTROY	iTools system	
LIVE_EXPORT	iTools system	
LIVE_IMAGE	IMAGE	
LIVE_INFO	iTools system	
LIVE_LINE	iTools system	
LIVE_LOAD	iTools system	
LIVE_OPLOT	IPLOT	
LIVE_PLOT	IPLOT	
LIVE_PRINT	iTools system	
LIVE_RECT	iTools system	
LIVE_STYLE	iTools system	
LIVE_SURFACE	ISURFACE	
LIVE_TEXT	iTools system	

Table J-45: Routines Obsoleted in IDL 6.0

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">DIALOG_PICKFILE</a>	GROUP keyword	This keyword was replaced by the DIALOG_PARENT keyword.
<a href="#">EXTRACT_SLICE</a>	CUBIC keyword	EXTRACT_SLICE does not support cubic interpolation.
<a href="#">IDLgrVolume::Init</a>	CUTTING_PLANES keyword	This keyword has been replaced by CLIP_PLANES.

*Table J-46: Arguments and Keywords Obsoleted in IDL 6.0*

## Features Obsoleted in IDL 5.6

The following features were present in IDL Version 5.5 but became obsolete in IDL Version 5.6.

Routine	Replaced by	.pro File?
<a href="#">HDF_VD_GETNEXT</a>	<a href="#">HDF_VG_GETNEXT</a>	
<a href="#">VAX_FLOAT</a>	VAX_FLOAT keyword to <a href="#">OPENR/OPENU/OPENW</a>	

*Table J-47: Routines Obsoleted in IDL 5.6*

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">SPAWN</a>	FORCE keyword	This keyword was incorrectly included in the SPAWN documentation.

*Table J-48: Arguments and Keywords Obsoleted in IDL 5.6*

## Features Obsoleted in IDL 5.5

The following features were present in IDL Version 5.4 but became obsolete in IDL Version 5.5.

Routine	Replaced by	.pro File?
DELETE_SYMBOL	n/a	
DELLOG	n/a	
DO_APPLE_SCRIPT	n/a	
ERRORF	ERF	
GET_SYMBOL	n/a	
LJLCT	n/a	
REWIND	n/a	
SET_SYMBOL	n/a	
SETLOG	n/a	
SKIPF	n/a	
TAPRD	n/a	
TAPWRT	n/a	
TRNLOG	n/a	
WEOF	n/a	

*Table J-49: Routines Obsoleted in IDL 5.5*

The following arguments and keywords are obsolete and should not be used in new IDL code.

<b>Routine</b>	<b>Argument or Keyword</b>	<b>Description</b>
<a href="#">IDLgrMPEG::Save</a>	CREATOR_TYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
<a href="#">LIVE_PRINT</a>	SETUP keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
<a href="#">OPEN</a>	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	MACTYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
<a href="#">READ_TIFF</a>	ORDER keyword	This keyword was replaced by the ORIENTATION keyword
<a href="#">SPAWN</a>	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
<a href="#">WIDGET_BASE</a>	APP_MBAR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
<a href="#">WRITE_TIFF</a>	<i>Order</i> argument	The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead.

Table J-50: Arguments and Keywords Obsolete in IDL 5.5

## Features Obsoleted in IDL 5.4

The following features were present in IDL Version 5.3 but became obsolete in IDL Version 5.4.

Routine	Replaced by	.pro File?
POLYFITW	POLY_FIT, MEASURE_ERRORS keyword	polyfitw.pro
RIEMANN	RADON	

*Table J-51: Routines Obsoleted in IDL 5.4*

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
LINFIT	SDEV keyword	This keyword has been replaced by the MEASURE_ERRORS keyword.
LM_FIT	WEIGHTS keyword	This keyword has been replaced by the MEASURE_ERRORS keyword.
OPEN	BINARY keyword	Windows file I/O changed to function like UNIX file I/O.
	NOAUTOMODE keyword	Windows file I/O changed to function like UNIX file I/O.
	NOSDTIO keyword	Keyword was renamed RAWIO.

*Table J-52: Arguments and Keywords Obsoleted in IDL 5.4*

<b>Routine</b>	<b>Argument or Keyword</b>	<b>Description</b>
POLY_FIT	<i>Yfit</i> argument	Argument replaced by the YFIT keyword.
	<i>Yband</i> argument	Argument replaced by the YBAND keyword.
	<i>Sigma</i> argument	Argument replaced by the YERROR keyword.
	<i>Corrm</i> argument	Argument replaced by the COVAR keyword.
REGRESS	<i>Weights</i> argument	Argument replaced by the MEASURE_ERRORS keyword.
	<i>Yfit</i> argument	Argument replaced by the YFIT keyword.
	<i>Const</i> argument	Argument replaced by the CONST keyword.
	<i>Sigma</i> argument	Argument replaced by the SIGMA keyword.
	<i>Ftest</i> argument	Argument replaced by the FTEST keyword.
	<i>R</i> argument	Argument replaced by the CORRELATION keyword.
	<i>Rmul</i> argument	Argument replaced by the MCORRELATION keyword.
	<i>Chisq</i> argument	Argument replaced by the CHISQR keyword.
	<i>Status</i> argument	Argument replaced by the STATUS keyword.
	RELATIVE_WEIGHT keyword	Keyword no longer necessary.

Table J-52: Arguments and Keywords Obsolete in IDL 5.4 (Continued)

Routine	Argument or Keyword	Description
SVDFIT	WEIGHTS keyword	Keyword replaced by the MEASURE_ERRORS keyword.

*Table J-52: Arguments and Keywords Obsoleted in IDL 5.4 (Continued)*

## Features Obsoleted in IDL 5.3

The following features were present in IDL Version 5.2 but became obsolete in IDL Version 5.3.

Routine	Replaced by	.pro File?
HDF_DFSD_* Routines	HDF_SD_* Routines	
<a href="#">RSTRPOS</a>	<a href="#">STRPOS</a> , /REVERSE_SEARCH	rstrpos.pro
<a href="#">STR_SEP</a>	<a href="#">STRSPLIT</a> for single character delimiters <a href="#">STRSPLIT</a> , /REGEX for longer delimiters	str_sep.pro

*Table J-53: Routines Obsoleted in IDL 5.3*

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">BYTEORDER</a>	DTOGFLOAT keyword	This keyword was available only on the VMS platform
	GFLOATTOD keyword	This keyword was available only on the VMS platform.
<a href="#">CALL_EXTERNAL</a>	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	PORTABLE keyword	This keyword was ignored on non-VMS platforms.
	VAX_FLOAT keyword	This keyword was available only on the VMS platform.

*Table J-54: Arguments and Keywords Obsoleted in IDL 5.3*

Routine	Argument or Keyword	Description
DEVICE	DEPTH keyword	This keyword was available only on the VMS platform.
	FONT keyword	This keyword was replaced by the SET_FONT keyword.
DOC_LIBRARY	FILE keyword	This keyword was ignored on non-VMS platforms.
	PATH keyword	This keyword was ignored on non-VMS platforms.
	OUTPUTS keyword	This keyword was available only on the VMS platform.
LINKIMAGE	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
MAKE_DLL	VAX_FLOAT keyword	This keyword was ignored on non-VMS platforms.
OPEN	<i>Record_Length</i> argument	This argument was ignored on non-VMS platforms.
	BLOCK keyword	This keyword was ignored on non-VMS platforms.
	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	EXTENDSIZE keyword	This keyword was ignored on non-VMS platforms.
	FIXED keyword	This keyword was ignored on non-VMS platforms.
	FORTRAN keyword	This keyword was ignored on non-VMS platforms.
INITIALSIZE keyword	This keyword was ignored on non-VMS platforms.	

Table J-54: Arguments and Keywords Obsolete in IDL 5.3 (Continued)

Routine	Argument or Keyword	Description
<a href="#">OPEN</a> , <i>continued</i>	KEYED keyword	This keyword was ignored on non-VMS platforms.
	LIST keyword	This keyword was ignored on non-VMS platforms.
	NONE keyword	This keyword was ignored on non-VMS platforms.
	PRINT keyword	This keyword was ignored on non-VMS platforms.
	SEGMENTED keyword	This keyword was ignored on non-VMS platforms.
	SHARED keyword	This keyword was ignored on non-VMS platforms.
	STREAM keyword	This keyword was ignored on non-VMS platforms.
	SUBMIT keyword	This keyword was ignored on non-VMS platforms.
	SUPERSEDE keyword	This keyword was ignored on non-VMS platforms.
	TRUNCATE_ON_CLOSE keyword	This keyword was ignored on non-VMS platforms.
	UDF_BLOCK keyword	This keyword was ignored on non-VMS platforms.
	VARIABLE keyword	This keyword was ignored on non-VMS platforms.
<a href="#">PRINT/PRINTF</a>	REWRITE keyword	This keyword was ignored on non-VMS platforms.

Table J-54: Arguments and Keywords Obsolete in IDL 5.3 (Continued)

<b>Routine</b>	<b>Argument or Keyword</b>	<b>Description</b>
READ/READF	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
READ_TIFF	UNSIGNED keyword	This keyword became obsolete when IDL began supporting an unsigned 16-bit integer data type.
READU	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
SAVE	XDR keyword	IDL always writes XDR files.
SPAWN	NOCLISYM keyword	This keyword was ignored on non-VMS platforms.
	NOLOGNAM keyword	This keyword was ignored on non-VMS platforms.
	NOTIFY keyword	This keyword was ignored on non-VMS platforms.
WRITEU	REWRITE keyword	This keyword was ignored on non-VMS platforms.

# SDF Routines Obsoleted in IDL 5.3

HDF\_DFSD\_\* routines have been obsoleted in IDL 5.3.

## What is DFSD and Why Are We Obsoleting It?

DFSD is an SD (Scientific Data Model). DFSD is the older, single-file SD form. The newer SD format, MFSD, is referred to in the IDL API as HDF\_SD\_\*. New IDL code should use HDF\_SD\_\* routines rather than HDF\_DFSD\_\* routines.

Version HDF4.1r2 of HDF has obsoleted the DFSD interface, somewhat forcing us to do so as well. IDL 5.3 uses HDF4.1r3 (Version 4.1, revision 3). It is recommended that users convert their old HDF files to the 4.1r3 format.

The following HDF routines have been obsoleted in IDL 5.3.

- [HDF\\_DFSD\\_ADDDATA](#)
- [HDF\\_DFSD\\_DIMGET](#)
- [HDF\\_DFSD\\_DIMSET](#)
- [HDF\\_DFSD\\_ENDSLICE](#)
- [HDF\\_DFSD\\_GETDATA](#)
- [HDF\\_DFSD\\_GETINFO](#)
- [HDF\\_DFSD\\_GETSLICE](#)
- [HDF\\_DFSD\\_PUTSLICE](#)
- [HDF\\_DFSD\\_READREF](#)
- [HDF\\_DFSD\\_SETINFO](#)
- [HDF\\_DFSD\\_STARTSLICE](#)

## Features Obsoleted in IDL 5.2

The following features were present in IDL Version 5.1 but became obsolete in IDL Version 5.2.

Routine	Replaced by	.pro File?
<a href="#">DEMO_MODE</a>	<a href="#">LMGR</a>	demo_mode.pro

*Table J-55: Routines Obsoleted in IDL 5.2*

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">XMANAGER</a>	MODAL keyword	This keyword was replaced by the MODAL keyword to WIDGET_BASE.

*Table J-56: Arguments and Keywords Obsoleted in IDL 5.2*

## Features Obsoleted in IDL 5.1

The following features were present in IDL Version 5.0 but became obsolete in IDL Version 5.1.

Routine	Replaced by	.pro File?
<a href="#">SLICER</a>	<a href="#">SLICER3</a>	slicer3.pro

*Table J-57: Routines Obsoleted in IDL 5.1*

## Features Obsoleted in IDL 5.0

The following features were present in IDL Version 4.0 but became obsolete in IDL Version 5.0.

Routine	Replaced by	.pro File?
DDE Routines	n/a	
GETHELP	OUTPUT keyword to <a href="#">HELP</a>	
HANDLE_CREATE	<a href="#">PTR_NEW</a>	
HANDLE_FREE	<a href="#">PTR_FREE</a>	
HANDLE_INFO	<a href="#">PTR_VALID</a>	
HANDLE_MOVE	n/a	
HANDLE_VALUE	dereference operator	
INP, INPW, OUTP, OUTPW	n/a	
PICKFILE	<a href="#">DIALOG_PICKFILE</a>	
Old RPC API	New RPC API	
.SIZE Executive Command	No longer needed	
TIFF_DUMP	n/a	
TIFF_READ	<a href="#">READ_TIFF</a>	
TIFF_WRITE	<a href="#">WRITE_TIFF</a>	
WIDED	n/a	
WIDGET_MESSAGE	<a href="#">DIALOG_MESSAGE</a>	

Table J-58: Routines Obsoleted in IDL 5.0

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
<a href="#">MESSAGE</a>	TRACEBACK keyword	This keyword is obsolete and is included for compatibility with existing code only. Traceback information is provided by default.

*Table J-59: Arguments and Keywords Obsoleted in IDL 5.0*

## Features Obsoleted in IDL 4.0 or Earlier

The following features became obsolete in IDL version 4.0 or earlier. These features are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `obsolete` subdirectory of the `lib` directory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the `DOC_LIBRARY` routine.

Routine	Argument or Keyword	Description
<a href="#">XMANAGER</a>	BACKGROUND keyword	This keyword was replaced by the TIMER keyword to WIDGET_CONTROL.

*Table J-61: Arguments and Keywords Obsoleted in IDL 4.0 or Earlier*

# Obsolete System Variables

The following IDL system variables became obsolete in the change from VAX IDL (IDL version 1) to IDL version 2. While it is highly unlikely that you will find references to these system variables in existing code, we include them here because they are flagged when the OBS\_SYSVARS field of the !WARN structure is set equal to one. See [Appendix D, “System Variables”](#) for information on IDL system variables.

System Variable	Replaced by
!BCOLOR	BOTTOM keyword to SURFACE
!COLOR	!P.COLOR
!CXMAX	!X.CRANGE[1]
!CXMIN	!X.CRANGE[0]
!CYMAX	!Y.CRANGE[1]
!CYMIN	!Y.CRANGE[0]
!FANCY	No direct equivalent. Use !P.FONT and !P.CHARSIZE
!FLIP	No equivalent.
!GRID	!P.TICKLEN
!HI	No equivalent.
!IGNORE	!P.NOCLIP
!LINETYPE	!P.LINESTYLE
!LO	No equivalent.
!MTITLE	!P.TITLE
!NOERAS	!P.NOERASE
!NORMALCONT	FOLLOW keyword to CONTOUR
!NSUM	!P.NSUM

Table J-62: Obsolete System Variables

<b>System Variable</b>	<b>Replaced by</b>
!PSYM	!P.PSYM
!SC1	!P.POSITION[0] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[0] * !D.X_VSIZE otherwise.
!SC2	!P.POSITION[2] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[1] * !D.X_VSIZE otherwise.
!SC3	!P.POSITION[1] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[0] * !D.X_VSIZE otherwise.
!SC4	!P.POSITION[3] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[1] * !D.X_VSIZE otherwise.
!TERM	DEVICE procedure.
!TYPE	!X.TYPE, !X.STYLE, !Y.TYPE, !Y.STYLE, !P.TICKLEN
!XMAX	!X.RANGE[1]
!XMIN	!X.RANGE[0]
!XTICKS	!X.TICKS
!XTITLE	!X.TITLE
!YMAX	!Y.RANGE[1]
!YMIN	!Y.RANGE[0]
!YTICKS	!Y.TICKS
!YTITLE	!Y.TITLE

# Obsolete Graphics Devices

The following arguments and keywords are obsolete and should not be used in new IDL code.

Graphics Device	Description
<a href="#">The LJ Device</a> (LJ)	The LJ device was only available in IDL for VMS.
<a href="#">The Macintosh Device</a> (MAC)	The MAC device was only available in IDL for Macintosh versions running under OS 9 and earlier. Versions of IDL for Macintosh running under OS X and later use the X device.
