## Chapter 1

# Overview of IDL Syntax

This reference is a complete listing of all built-in IDL functions, procedures, statements, executive commands, and objects, collectively referred to as “commands.” Every IDL language element that can be used either at the command line or in a program is listed alphabetically. A description of each routine follows its name.

---

**Note**

Descriptions of Scientific Data Formats routines (CDF\_\*, EOS\_\*, HDF\_\*, and NCDF\_\* routines) can be found in the *Scientific Data Formats* book.

---

Routines written in the IDL language are noted as such, and the location of the `.pro` file within the IDL distribution is specified. You may wish to inspect the IDL source code for some of these routines to gain further insight into their inner workings.

Conventions used in this reference guide are described below.

# IDL Syntax

The following table lists the elements used in IDL syntax listings:

Element	Description
[ ] (Square brackets)	Indicates that the contents are optional. Do not include the brackets in your call.
[ ] (Italicized square brackets)	Indicates that the square brackets are part of the statement (used to define an array).
Argument	Arguments are shown in italics, and must be specified in the order listed.
KEYWORD	Keywords are all caps, and can be specified in any order. For functions, all arguments and keywords must be contained within parentheses.
/KEYWORD	Indicates a boolean keyword.
<i>Italics</i>	Indicates arguments, expressions, or statements for which you must provide values.
{ } (Braces)	<ul style="list-style-type: none"> <li>Indicates that you must choose one of the values they contain</li> <li>Encloses a list of possible values, separated by vertical lines (   )</li> <li>Encloses useful information about a keyword</li> <li>Defines an IDL structure (this is the only case in which the braces are included in the call).</li> </ul>
(Vertical lines)	Separates multiple values or keywords.
[, <i>Value</i> <sub>1</sub> , ... , <i>Value</i> <sub><i>n</i></sub> ]	Indicates that any number of values can be specified.
[, <i>Value</i> <sub>1</sub> , ... , <i>Value</i> <sub>8</sub> ]	Indicates the maximum number of values that can be specified.

Table 1-1: Elements of IDL Syntax

## Elements of Syntax

### Square Brackets ( [ ] )

- Content between square brackets is optional. Pay close attention to the grouping of square brackets. Consider the following examples:

*ROUTINE\_NAME*, *Value1* [ *Value2*] [ *Value3*]: You must include *Value1*. You do not have to include *Value2* or *Value3*. *Value2* and *Value3* can be specified independently.

*ROUTINE\_NAME*, *Value1* [ *Value2*, *Value3*]: You must include *Value1*. You do not have to include *Value2* or *Value3*, but you must include both *Value2* and *Value3*, or neither.

*ROUTINE\_NAME* [ *Value1* [ *Value2*]]: You can specify *Value1* without specifying *Value2*, but if you specify *Value2*, you must also specify *Value1*.

- Do not include square brackets in your statement unless the brackets are italicized. Consider the following syntax:

*Result* = KRIG2D( *Z* [ *X*, *Y*] [ *BOUNDS*=[*xmin*, *ymin*, *xmax*, *ymax*] )

An example of a valid statement is:

R = KRIG2D( *Z*, *X*, *Y*, *BOUNDS*=[0,0,1,1] )

- Note that when [ *Value1*, ... , *Value<sub>n</sub>*] is listed, you can specify any number of arguments. When an explicit number is listed, as in [ *Value1*, ... , *Value<sub>8</sub>*], you can specify only as many arguments as are listed.

### Braces ( { } )

- For certain keywords, a list of the possible values is provided. This list is enclosed in braces, and the choices are separated by a vertical line ( | ). Do not include the braces in your statement. For example, consider the following syntax:

READ\_JPEG [ *TRUE*={ 1 | 2 | 3 } ]

In this example, you must choose either 1, 2, or 3. An example of a valid statement is:

READ\_JPEG, *TRUE*=1

- Braces are used to enclose the allowable range for a keyword value. Unless otherwise noted, ranges provided are inclusive. Consider the following syntax:

*Result* = CVTTBOM( *Array* [ *THRESHOLD*=*value*{0 to 255} ] )

An example of a valid statement is:

*Result* = CVTTOBM( A, THRESHOLD=150 )

- Braces are also used to provide useful information about a keyword. For example:

[, LABEL=*n*{label every *n*th gridline}]

Do not include the braces or their content in your statement.

- Certain keywords are prefaced by X, Y, or Z. Braces are used for these keywords to indicate that you must choose one of the values it contains. For example, [{X | Y}RANGE=*array*] indicates that you can specify either XRANGE=*array* or YRANGE=*array*.
- Note that in IDL, braces are used to define structures. When defining a structure, you *do* want to include the braces in your statement.

## Italics

- Italicized words are arguments, expressions, or statements for which you must provide values. The value you provide can be a numerical value, such as 10, an expression, such as DIST(100), or a named variable. For keywords that expect a string value, the syntax is listed as KEYWORD=*string*. The value you provide can be a string, such as 'Hello' (enclosed in single quotation marks), or a variable that holds a string value.
- The italicized values that must be provided for keywords are listed in the most helpful terms possible. For example, [, XSIZE=*pixels*] indicates that the XSIZE keyword expects a value in pixels, while [, ORIENTATION=*ccw\_degrees\_from\_horiz*] indicates that you must provide a value in degrees, measured counter-clockwise from horizontal.

## Procedures

IDL procedures use the following general syntax:

PROCEDURE\_NAME, *Argument* [, *Optional\_Argument*]

where PROCEDURE\_NAME is the name of the procedure, *Argument* is a required parameter, and *Optional\_Argument* is an optional parameter to the procedure.

## Functions

IDL functions use the following general syntax:

```
Result = FUNCTION_NAME( Argument [, Optional_Argument] )
```

where *Result* is the returned value of the function, *FUNCTION\_NAME* is the name of the function, *Argument* is a required parameter, and *Optional\_Argument* is an optional parameter. Note that all arguments and keyword arguments to functions should be supplied *within* the parentheses that follow the function's name.

Functions do not always have to be used in assignment statements (i.e., `A=SIN(10.2)`), they can be used just like any other IDL expression. For example, you could print the result of `SIN(10.2)` by entering the command:

```
PRINT, SIN(10.2)
```

## Arguments

The “Arguments” section describes each valid argument to the routine. Note that these arguments are positional parameters that must be supplied in the order indicated by the routine's syntax.

### Named Variables

Often, arguments that contain values upon return from the function or procedure (“output arguments”) are described as accepting “named variables”. A named variable is simply a valid IDL variable name. This variable *does not* need to be defined before being used as an output argument. Note, however that when an argument calls for a named variable, only a named variable can be used—sending an expression causes an error.

## Keywords

The “Keywords” section describes each valid keyword argument to the routine. Note that keyword arguments are formal parameters that can be supplied in any order.

Keyword arguments are supplied to IDL routines by including the keyword name followed by an equal sign (“=”) and the value to which the keyword should be set. The value can be a value, an expression, or a *named variable* (a named variable is simply a valid IDL variable name).

**Note**

---

If you set a keyword equal to an *undefined* named variable, IDL will quietly ignore the value.

---

For example, to produce a plot with diamond-shaped plotting symbols, the `PSYM` keyword should be set to 4 as follows:

```
PLOT, FINDGEN(10), PSYM=4
```

Note the following when specifying keywords:

- Certain keywords are boolean, meaning they can be set to either 0 or 1. These keywords are switches used to turn an option on and off. Usually, setting such keywords equal to 1 causes the option to be turned on. Explicitly setting the keyword to 0 (or not including the keyword) turns the option off. In the syntax listings in this reference, all keywords that are preceded by a slash can be set by prefacing them by the slash. For example, `SURFACE, DIST(10), /SKIRT` is a shortcut for `SURFACE, DIST(10), SKIRT=1`. To turn the option back off, you must set the keyword equal to 0, as in `SURFACE, DIST(10), SKIRT=0`.

In rare cases, a keyword's default value is 1. In these cases, the syntax is listed as `KEYWORD=0`, as in `SLIDE_IMAGE [, Image] [, CONGRID=0]`. In this example, `CONGRID` is set to 1 by default. If you specify `CONGRID=0`, you can turn it back on by specifying either `/CONGRID` or `CONGRID=1`.

- Some keywords are used to obtain values that can be used upon return from the function or procedure. These keywords are listed as `KEYWORD=variable`. Any valid variable name can be used for these keywords, and the variable does not need to be defined first. Note, however, that when a keyword calls for a named variable, only a named variable can be used—sending an expression causes an error.

For example, the `WIDGET_CONTROL` procedure can return the user values of widgets in a named variable using the `GET_UVALUE` keyword. To return the user value for a widget ID (contained in the variable `mywidget`) in the variable `userval`, you would use the command:

```
WIDGET_CONTROL, mywidget, GET_UVALUE = userval
```

Upon return from the procedure, `userval` contains the user value. Note that `userval` did not have to be defined before the call to `WIDGET_CONTROL`.

- Some routines have keywords that are mutually exclusive, meaning only one of the keywords can be present in a given statement. These keywords are grouped together, and separated by a vertical line. For example, consider the following syntax:

```
PLOT, [X,] Y [, /DATA | , /DEVICE | , /NORMAL]
```

In this example, you can choose either DATA, DEVICE, or NORMAL, but not more than one. An example of a valid statement is:

```
PLOT, SIN(A), /DEVICE
```

- Keywords can be abbreviated to their shortest unique length. For example, the XSTYLE keyword can be abbreviated to XST because there are no other keywords in IDL that begin with XST. You cannot shorten XSTYLE to XS, however, because there are other keywords that begin with XS, such as XSIZE.

## Running the Example Code

Some of the code examples used in this manual are part of the IDL distribution. Referenced files are located in the `examples/doc` subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described. See “[!PATH](#)” in Appendix D of the *IDL Reference Guide* manual for information on IDL's path.

# ***Part I: IDL Command Reference***

Chapter 2

# Dot Commands

# .COMPILE

The `.COMPILE` command compiles and saves procedures and programs in the same manner as `.RUN`. If one or more filenames are specified, the procedures and functions contained therein are compiled *but not executed*. If you enter this command at the Command Line of the IDLDE and the files are not yet open, IDL opens the files within Editor windows and compiles the procedures and functions contained therein.

See [RESOLVE\\_ROUTINE](#) for a way to invoke the same operation from within an IDL routine, and [RESOLVE\\_ALL](#) for a way to automatically compile all user-written or library functions called by all currently-compiled routines.

If the `-f` flag is specified, `File` is compiled from the source stored temporarily in `TempFile` rather than on disk in `File` itself. This allows you to make changes to `File` (in an IDLDE editor window, for example), store the modified source into the temporary file (IDLDE does it automatically), compile, and test the changes without overwriting the original code stored in `File`.

---

**Note**

`.COMPILE` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

```
.COMPILE [File1, ..., Filen]
```

```
.COMPILE -f File TempFile
```

## See Also

[.RNEW](#), [.RUN](#)

# .CONTINUE

The `.CONTINUE` command continues execution of a program that has stopped because of an error, a stop statement, or a keyboard interrupt. IDL saves the location of the beginning of the last statement executed before an error. If it is possible to correct the error condition in the interactive mode, the offending statement can be re-executed by entering `.CONTINUE`. After `STOP` statements, `.CONTINUE` continues execution at the next statement. The `.CONTINUE` command can be abbreviated; for example, `.C`. Execution of a program interrupted by typing `Ctrl+C` also can be resumed at the point of interruption with the `.CONTINUE` command.

**Note**

---

`.CONTINUE` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

`.CONTINUE`

# .EDIT

The .EDIT command opens files in IDL Editor windows when called from the Command Line of the IDLDE. This functionality is only available on the Windows and Motif platforms. Note that filenames are separated by spaces, not commas.

---

**Note**

.EDIT is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

`.EDIT File1 [File2 ... Filen]`

# .FULL\_RESET\_SESSION

The `.FULL_RESET_SESSION` command does everything `.RESET_SESSION` does, plus the following:

- Removes all system routines installed via `LINKIMAGE` or a DLM.
- Removes all structure definitions installed via a DLM.
- Removes all message blocks added by DLMs or by the `DEFINE_MSGBLK` or `DEFINE_MSGBLK_FROM_FILE` routines.
- Unloads all sharable libraries loaded into IDL via `CALL_EXTERNAL`, `LINKIMAGE`, or a DLM.
- Re-initializes all DLMs to their unloaded initial state.

---

**Note**

`.FULL_RESET_SESSION` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

```
.FULL_RESET_SESSION
```

# **.GO**

The `.GO` command starts execution at the beginning of a previously-compiled main program.

---

**Note**

`.GO` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## **Syntax**

`.GO`

# .OUT

The .OUT command continues executing statements in the current program until it returns.

**Note**

---

.OUT is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

.OUT

# .RESET\_SESSION

The `.RESET_SESSION` command resets much of the state of an IDL session without requiring the user to exit and restart the IDL session. After the reset is complete, the startup file, if one is specified, is run.

The command performs the following actions in the reset:

- Returns current execution point to `$MAIN$` ([RECALL](#))
- Clears the path cache (see [PATH\\_CACHE](#) for details)
- Closes all files except the standard 3 units, the [JOURNAL](#) file (if any), and any files in use by graphics drivers
- Destroys or removes the following:
  - All local variables in `$MAIN$`
  - All widgets (exit handlers are not called)
  - All windows and pixmaps for the current window system graphics device are closed (including all common blocks)
  - All cursors created with [REGISTER\\_CURSOR](#)
  - All handles
  - All breakpoints
  - All user-defined system variables
  - All pointer and object reference heap variables (object destructors are not called)
  - All user-defined structure definitions
  - All user-defined object definitions
  - All compiled user functions and procedures, including the main program (`$MAIN$`), if any
  - Any memory segments created by [SHMMAP](#)
- Disables [SHMDEBUG](#) mode

- Resets all system variables, including the graphics variables (!ORDER, !MAP, !MOUSE, !P, !X, !Y, !Z). The following variables get their initial values from IDL preferences:

!CPU	!DIR
!EDIT_INPUT	!ERROR_STATE.MSG_PREFIX
!EXCEPT	!HELP_PATH
!MORE	!PATH
!PROMPT	!QUIET

---

**Note**

For more information on the preferences associated with these system variables, see “IDL Preferences” on page 4841.

---

- Resets the current direct-graphics device, which returns to the startup default, based on the `IDL_DEVICE` preference.
- Resets the status of the path cache (enabled or disabled), based on the `IDL_PATH_CACHE_DISABLE` preference.
- Resets the state of the IDL profiler module (for more information, see “PROFILER” on page 1762).

The command does not do the following:

- The saved commands and output log are not erased.
- Graphics drivers are not reset to their full uninitialized state. However, all windows and pixmaps for the current window system device are closed.
- The following files are not closed:
  - Stdin (LUN 0)
  - Stdout (LUN -1)
  - Stderr (LUN -2)
  - The journal file (!JOURNAL) if one is open
  - Any files in use by graphics drivers (e.g., PostScript)

- Dynamically loaded graphics drivers (LINKIMAGE) are not removed, nor are any dynamic sharable libraries containing such drivers, even if the same library was also used for another purpose such as CALL\_EXTERNAL, LINKIMAGE system routines, or DLMs. See the [.FULL\\_RESET\\_SESSION](#) executive command to unload dynamic libraries.
- Message blocks are not removed. See the [.FULL\\_RESET\\_SESSION](#) executive command to remove message blocks loaded by DLMs or created using the [DEFINE\\_MSGBLK](#) or [DEFINE\\_MSGBLK\\_FROM\\_FILE](#) routines.

**Note**

---

[.RESET\\_SESSION](#) is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

[.RESET\\_SESSION](#)

## See Also

[.FULL\\_RESET\\_SESSION](#)

# .RETURN

The `.RETURN` command continues execution of a program until encountering a `RETURN` statement. This is convenient for debugging programs since it allows the whole program to run, stopping before returning to the next-higher program level so you can examine local variables.

Also see the [RETURN](#) command.

---

**Note**

`.RETURN` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

`.RETURN`

# .RNEW

The .RNEW command compiles and saves procedures and functions in the same manner as .RUN. In addition, all variables in the main program unit, except those in common blocks, are erased. The -T and -L filename switches have the same effect as with .RUN.

## Note

.RNEW is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

## Syntax

```
.RNEW [File1, ..., Filen]
```

To save listing in a file:

```
.RNEW -L ListFile.lis File1 [, File2, ..., Filen]
```

To display listing on screen:

```
.RNEW -T File1 [, File2, ..., Filen]
```

## Example

Some statements using the .RUN and .RNEW commands are shown below.

Statement	Description
.RUN	Accept a program from the keyboard. Retain the present variables.
.RUN myfile	Compile the file myfile.pro. If it is not found in the current directory, try to find it in the directory search path.
.RUN -T A, B, C	Compile the files a.pro, b.pro and c.pro. List the files on the terminal.

Table 2-1: Examples using .RUN and .RNEW

Statement	Description
<code>.RNEW -L myfile.lis myfile, yourfile</code>	Erase all variables and compile the files <code>myfile.pro</code> and <code>yourfile.pro</code> . Produce a listing on <code>myfile.lis</code> .

*Table 2-1: Examples using .RUN and .RNEW (Continued)*

## See Also

[.COMPILE](#), [.RUN](#)

# .RUN

The `.RUN` command compiles procedures, functions, and/or main programs in memory. Main programs are executed immediately. The command can be followed by a list of files to be compiled. Filenames are separated by blanks, tabs, or commas.

If a file specification is included in the command, IDL searches for the file first in the current directory, then in the directories specified by the system variable `!PATH`. See “[Creating \\$MAINS\\$ Programs](#)” in Chapter 2 of the *Building IDL Applications* manual for more information on IDL’s search strategy.

If a main program unit is encountered, execution of the program will begin after all files have been read if there were no errors. The values of all of the variables are retained. If the file isn’t found, input is accepted from the keyboard until a complete program unit is entered.

Files containing IDL procedures, programs, and functions are assumed to have the file extension (suffix) `.pro`. Files created with the `SAVE` procedure are assumed to have the extension `.sav`. See [Chapter 2, “Creating and Running Programs in IDL”](#) in the *Building IDL Applications* manual for further information.

---

**Note**

`.RUN` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

```
.RUN [File1, ..., Filen]
```

To save listing in a file:

```
.RUN -L ListFile.lis File1 [, File2, ..., Filen]
```

To display listing on screen:

```
.RUN -T File1 [, File2, ..., Filen]
```

---

**Note**

Subsequent calls to `.RUN` compile the procedure again.

---

## Using .RUN to Make Program Listings

The command arguments `-T` for terminal listing or `-L filename` for listing to a named file can appear after the command name and before the program filenames to produce a numbered program listing directed to the terminal or to a file.

For instance, to see a listing on the screen as a result of compiling a procedure contained in a file named `analyze.pro`, use the following command:

```
.RUN -T analyze
```

To compile the same procedure and save the listing in a file named `analyze.lis`, use the following command:

```
.RUN -L analyze.lis analyze
```

In listings produced by IDL, the line number of each statement is printed at the left margin. This number is the same as that printed in IDL error statements, simplifying location of the statement causing the error.

### Note

---

If the compiled file contains more than one procedure or function, line numbering is reset to “1” each time the end of a program segment is detected.

---

Each level of block nesting is indented four spaces to the right of the preceding block level to improve the legibility of the program’s structure.

## See Also

[.COMPILE](#), [.RNEW](#)

## .SKIP

The `.SKIP` command skips one or more statements. It is useful for moving past a program statement that caused an error. If the optional argument  $n$  is present, it gives the number of statements to skip; otherwise, a single statement is skipped.

Note that `.SKIP` does not execute or evaluate the code it is skipping. Rather, it arbitrarily alters the current program counter to the  $n$ th physical statement following the current point. This has implications that may not be obvious on initial consideration:

- `.SKIP` does not skip into a called routine.
- `.SKIP` moves to the  $n$ th physical statement following the current program location. This may not be the statement that execution would have actually have moved to if you had allowed the program to run normally.
- Arbitrarily moving the program counter in this way may leave your program in an unrunnable state, depending on resulting state of the local variables and the statements that the newly positioned program counter attempts to execute next.

In contrast, the `.STEP` executive command has none of the above drawbacks and can be used instead in many situations. The advantage of `.SKIP` over `.STEP` is that `.SKIP` can move past statements that `.STEP` cannot, such as:

- Statements with errors that cause execution to halt.
- Infinite loops, and similar logic errors.

For example, consider the following program segment:

```
..... ..
OPENR, 1, 'missing'
READF, 1, xxx, ..., ...
... ..
```

If the `OPENR` statement fails because the specified file does not exist, program execution will halt with the `OPENR` statement as the current statement. Execution can not be resumed with the executive command `.CONTINUE` because it attempts to re-execute the offending `OPENR` statement, causing the same error. The remainder of the program can be executed by entering `.SKIP`, which skips over the incorrect `OPEN` statement.

---

### Note

`.SKIP` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

`.SKIP [n]`

## .STEP

The `.STEP` command executes one or more statements in the current program starting at the current position, stops, and returns control to the interactive mode. This command is useful in debugging programs. The optional argument  $n$  indicates the number of statements to execute. If  $n$  is omitted, a single statement is executed.

---

**Note**

`.STEP` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

`.STEP [n]` or `.S [n]`

# .STEPOVER

The `.STEPOVER` command executes one or more statements in the current program starting at the current position, stops, and returns control to the interactive mode. Unlike `.STEP`, if `.STEPOVER` executes a statement that calls another routine, the called routine runs until it ends before control returns to interactive mode. That is, a statement calling another routine is treated as a single statement.

The optional argument `n` indicates the number of statements to execute. If `n` is omitted, a single statement (or called routine) is executed.

**Note**

---

`.STEPOVER` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

`.STEPOVER [n]` or `.SO [n]`

# .TRACE

The .TRACE command continues execution of a program that has stopped because of an error, a stop statement, or a keyboard interrupt.

**Note**

---

.TRACE is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

---

## Syntax

.TRACE

Chapter 3

# Procedures and Functions

# A\_CORRELATE

The A\_CORRELATE function computes the autocorrelation  $P_x(L)$  or autocovariance  $R_x(L)$  of a sample population  $X$  as a function of the lag  $L$ .

$$P_x(L) = P_x(-L) = \frac{\sum_{k=0}^{N-L-1} (x_k - \bar{x})(x_{k+L} - \bar{x})}{\sum_{k=0}^{N-1} (x_k - \bar{x})^2}$$

$$R_x(L) = R_x(-L) = \frac{1}{N} \sum_{k=0}^{N-L-1} (x_k - \bar{x})(x_{k+L} - \bar{x})$$

where  $\bar{x}$  is the mean of the sample population  $x = (x_0, x_1, x_2, \dots, x_{N-1})$ .

## Note

This routine is primarily designed for use in 1-D time-series analysis. The mean is subtracted before correlating. For image processing, methods based on FFT should be used instead if more than a few tens of points exist. For example:

```
Function AutoCorrelate, X
  Temp = FFT(X, -1)
  RETURN, FFT(Temp * CONJ(Temp), 1)
END
```

This routine is written in the IDL language. Its source code can be found in the file `a_correlate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = A\_CORRELATE(*X*, *Lag* [, /COVARIANCE] [, /DOUBLE] )

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector.

### Lag

An  $n$ -element integer vector in the interval  $[-(n-2), (n-2)]$ , specifying the signed distances between indexed elements of  $X$ .

## Keywords

### COVARIANCE

Set this keyword to compute the sample autocovariance rather than the sample autocorrelation.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an n-element sample population:
X = [3.73, 3.67, 3.77, 3.83, 4.67, 5.87, 6.70, 6.97, 6.40, 5.57]
; Compute the autocorrelation of X for LAG = -3, 0, 1, 3, 4, 8:
lag = [-3, 0, 1, 3, 4, 8]
result = A_CORRELATE(X, lag)
PRINT, result
```

IDL prints:

```
0.0146185  1.00000  0.810879  0.0146185  -0.325279  -0.151684
```

# ABS

The ABS function returns the absolute value of its argument.

## Syntax

*Result* = ABS(*X*)

## Return Value

Returns the absolute value of its argument.

## Arguments

### X

The value for which the absolute value is desired. If *X* is of complex type, ABS returns the magnitude of the complex number:

$$\sqrt{\text{Real}^2 + \text{Imaginary}^2}$$

If *X* is of complex type, the result is returned as the corresponding floating point type. For all other types, the result has the same type as *X*. If *X* is an array, the result has the same structure, with each element containing the absolute value of the corresponding element of *X*.

ABS applied to any of the unsigned integer types results in the unaltered value of *X* being returned.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To print the absolute value of -25, enter:

```
PRINT, ABS (-25)
```

IDL prints:

```
25
```

# ACOS

The ACOS function returns the angle, expressed in radians, whose cosine is  $X$  (i.e., the arc-cosine). For real input, the range of ACOS is between 0 and  $\pi$ .

For input of a complex number,  $Z = X + iY$ , the complex arccosine is given by,

$$\text{acos}(Z) = \text{acos}(B) - i \log(A + \sqrt{A^2 - 1}) \quad \text{if } Y \geq 0$$

$$\text{acos}(Z) = \text{acos}(B) + i \log(A + \sqrt{A^2 - 1}) \quad \text{if } Y < 0$$

where

$$A = 0.5 \sqrt{(X + 1)^2 + Y^2} + 0.5 \sqrt{(X - 1)^2 + Y^2}$$

$$B = 0.5 \sqrt{(X + 1)^2 + Y^2} - 0.5 \sqrt{(X - 1)^2 + Y^2}$$

The separation of the two formulas at  $Y = 0$  takes into account the branch-cut discontinuity along the real axis from  $-\infty$  to  $-1$  and  $+1$  to  $+\infty$ , and ensures that  $\cos(\text{acos}(Z))$  is equal to  $Z$ . For reference, see formulas 4.4.37-39 in Abramowitz, M. and Stegun, I.A., 1964: Handbook of Mathematical Functions (Washington: National Bureau of Standards).

## Syntax

*Result* = ACOS(*X*)

## Return Value

Returns the angle, expressed in radians, whose cosine is  $X$  (i.e., the arc-cosine).

## Arguments

### X

The cosine of the desired angle. For real input,  $X$  should be in the range  $-1$  to  $+1$ . If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If  $X$  is an array, the result has the same structure, with each element containing the arc-cosine of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Find the angle whose cosine is 0.707 and print the result in degrees by entering:

```
PRINT, 180/!PI*ACOS(0.707)
IDL prints:
45.0086
```

Find the complex arccosine of  $2 + i$  and print the result by entering:

```
PRINT, ACOS(COMPLEX(2,1))
IDL prints:
( 0.507356, -1.46935)
```

See the ATAN function for an example of visualizing the complex arccosine.

# ADAPT\_HIST\_EQUAL

The ADAPT\_HIST\_EQUAL function performs adaptive histogram equalization, a form of automatic image contrast enhancement. The algorithm is described in Pizer et. al., “Adaptive Histogram Equalization and its Variations.”, Computer Vision, Graphics and Image Processing, 39:355-368. Adaptive histogram equalization involves applying contrast enhancement based on the local region surrounding each pixel. Each pixel is mapped to an intensity proportional to its rank within the surrounding neighborhood. This method of automatic contrast enhancement has proven to be broadly applicable to a wide range of images and to have demonstrated effectiveness.

This routine is written in the IDL language. Its source code can be found in the file `adapt_hist_equal.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = ADAPT_HIST_EQUAL (Image [, CLIP=value] [, FCN=vector]  
    [, NREGIONS=nregions] [, TOP=value] )
```

## Return Value

The result of the function is a byte image with the same dimensions as the input image parameter.

## Arguments

### Image

A two-dimensional array representing the image for which adaptive histogram equalization is to be performed. This parameter is interpreted as unsigned 8-bit data, so be sure that the input values are properly scaled into the range of 0 to 255.

## Keywords

### CLIP

Set this keyword to a nonzero value to clip the histogram by limiting its slope to the given CLIP value, thereby limiting contrast. For example, if CLIP is set to 3, the slope of the histogram is limited to 3. By default, the slope and/or contrast is not

limited. Noise over-enhancement in nearly homogeneous regions is reduced by setting this parameter to values larger than 1.0.

## FCN

Set this keyword to the desired cumulative probability distribution function in the form of a 256 element vector. If omitted, a linear ramp, which yields equal probability bins results. This function is later normalized, so magnitude is inconsequential, though should increase monotonically.

## NREGIONS

Set this keyword to the size of the overlapped tiles, as a fraction of the largest dimensions of the image size. The default is 12, which makes each tile 1/12 the size of the largest image dimension.

## TOP

Set this keyword to the maximum value of the scaled output array. The default is 255.

## Examples

The following code snippet reads a data file in the `examples/data` subdirectory of the IDL distribution containing a cerebral angiogram, and then displays both the original image and the adaptive histogram equalized image:

```

OPENR, 1, FILEPATH('cereb.dat', $
    SUBDIRECTORY=['examples', 'data'])

;Image size = 512 x 512
a = BYTARR(512,512, /NOZERO)

;Read it
READU, 1, a
CLOSE, 1

; Reduce size of image for comparison
a = CONGRID(a, 256,256)

;Show original
TVSCL, a, 0

;Show processed
TV, ADAPT_HIST_EQUAL(a, TOP=!D.TABLE_SIZE-1), 1

```

**Note**

# ALOG

The ALOG function returns the natural logarithm of  $X$ .

For input of a complex number,  $Z = X + iY$ , the complex number can be rewritten as  $Z = R \exp(i\theta)$ , where  $R = \text{abs}(Z)$  and  $\theta = \text{atan}(y,x)$ . The complex natural log is then given by,

$$\text{alog}(Z) = \text{alog}(R) + i\theta$$

In the above formula, the use of the two-argument arctangent separates the solutions at  $Y = 0$  and takes into account the branch-cut discontinuity along the real axis from  $-\infty$  to  $0$ , and ensures that  $\exp(\text{alog}(Z))$  is equal to  $Z$ . For reference, see formulas 4.4.1-3 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

## Syntax

*Result* = ALOG( $X$ )

## Return Value

Returns the natural logarithm of  $X$ .

## Arguments

### X

The value for which the natural log is desired. For real input,  $X$  should be greater than or equal to zero. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If  $X$  is an array, the result has the same structure, with each element containing the natural log of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS,

TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Find the natural logarithm of 2 and print the result by entering:

```
PRINT, ALOG(2)
IDL prints:
0.693147
```

Find the complex natural log of  $\sqrt{2} + i\sqrt{2}$  and print the result by entering:

```
PRINT, ALOG(COMPLEX(sqrt(2), sqrt(2)))
IDL prints:
( 0.693147, 0.785398)
```

### Note

---

The real part of the result is just  $\text{ALOG}(2)$  and the imaginary part gives the angle (in radians) of the complex number relative to the real axis.

---

See the ATAN function for an example of visualizing the complex natural log.

[ALOG10](#), [ATAN](#)

# ALOG10

The ALOG10 function returns the logarithm to the base 10 of  $X$ .

For input of a complex number,  $Z = X + iY$ , the complex number can be rewritten as  $Z = R \exp(iq)$ , where  $R = \text{abs}(Z)$  and  $q = \text{atan}(y,x)$ . The complex log base 10 is then given by,

$$\text{alog10}(Z) = \text{alog10}(R) + i q/\text{alog}(10)$$

In the above formula, the use of the two-argument arctangent separates the solutions at  $Y = 0$  and takes into account the branch-cut discontinuity along the real axis from  $-\infty$  to 0, and ensures that  $10^{\text{alog10}(Z)}$  is equal to  $Z$ . For reference, see formulas 4.4.1-3 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

## Syntax

*Result* = ALOG10( $X$ )

## Return Value

Returns the logarithm to the base 10 of  $X$ .

## Arguments

### $X$

The value for which the base 10 log is desired. For real input,  $X$  should be greater than or equal to zero. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If  $X$  is an array, the result has the same structure, with each element containing the base 10 log of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS,

TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Find the base 10 logarithm of 100 and print the result by entering:

```
PRINT, ALOG10(100)
IDL prints:
2.00000
```

See the ATAN function for an example of visualizing the complex logarithm.

# AMOEBA

The AMOEBA function performs multidimensional minimization of a function  $Func(x)$ , where  $x$  is an  $n$ -dimensional vector, using the downhill simplex method of Nelder and Mead, 1965, *Computer Journal*, Vol 7, pp 308-313.

The downhill simplex method is not as efficient as Powell's method, and usually requires more function evaluations. However, the simplex method requires only function evaluations—not derivatives—and may be more reliable than Powell's method.

This routine is written in the IDL language. Its source code can be found in the file `amoeba.pro` in the `lib` subdirectory of the IDL distribution. AMOEBA is based on the routine `amoeba` described in section 10.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = AMOEBA( Ftol [, FUNCTION_NAME=string]
                [, FUNCTION_VALUE=variable] [, NCALLS=value] [, NMAX=value]
                [, P0=vector, SCALE=vector | , SIMPLEX=array] )
```

## Return Value

If the minimum is found, AMOEBA returns an  $n$ -element vector corresponding to the function's minimum value. If a minimum within the given tolerance is not found within the specified number of iterations, AMOEBA returns a scalar value of -1. Results are returned with the same precision (single- or double-precision floating-point) as is returned by the user-supplied function to be minimized.

## Arguments

### Ftol

The fractional tolerance to be achieved in the function value—that is, the fractional decrease in the function value in the terminating step. If the function you supply returns a single-precision result, *Ftol* should never be less than your machine's floating-point precision—the value contained in the EPS field of the structure returned by the `MACHAR` function. If the function you supply returns a double-precision floating-point value, *Ftol* should not be less than your machine's double-precision floating-point precision. See `MACHAR` for details.

## Keywords

### FUNCTION\_NAME

Set this keyword equal to a string containing the name of the function to be minimized. If this keyword is omitted, AMOEBA assumes that an IDL function named “FUNC” is to be used.

The function to be minimized must be written as an IDL function and compiled prior to calling AMOEBA. This function must accept an  $n$ -element vector as its only parameter and return a scalar single- or double precision floating-point value as its result.

See the *Example* section below for an example function.

### FUNCTION\_VALUE

Set this keyword equal to a named variable that will contain an  $(n+1)$ -element vector of the function values at the simplex points. The first element contains the function minimum.

### NCALLS

Set this keyword equal to a named variable that will contain a count of the number of times the function was evaluated.

### NMAX

Set this keyword equal to a scalar value specifying the maximum number of function evaluations allowed before terminating. The default is 5000.

### P0

Set this keyword equal to an  $n$ -element single- or double-precision floating-point vector specifying the initial starting point. Note that if you specify P0, you must also specify SCALE.

For example, in a 3-dimensional problem, if the initial guess is the point [0,0,0], and you know that the function’s minimum value occurs in the interval:

$$-10 < X[0] < 10, \quad -100 < X[1] < 100, \quad -200 < X[2] < 200,$$

specify: P0=[0,0,0] and SCALE=[10, 100, 200].

Alternately, you can omit P0 and SCALE and specify SIMPLEX.

## SCALE

Set this keyword equal to a scalar or  $n$ -element vector containing the problem's characteristic length scale for each dimension. SCALE is used with P0 to form an initial  $(n+1)$  point simplex. If all dimensions have the same scale, set SCALE equal to a scalar.

If SCALE is specified as a scalar, the function's minimum lies within a distance of SCALE from P0. If SCALE is an  $N$ -dimensional vector, the function's minimum lies within the  $Ndim+1$  simplex with the vertices P0,  $P0 + [1,0,\dots,0] * SCALE$ ,  $P0 + [0,1,0,\dots,0] * SCALE$ , ..., and  $P0+[0,0,\dots,1] * SCALE$ .

## SIMPLEX

Set this keyword equal to an  $n$  by  $n+1$  single- or double-precision floating-point array containing the starting simplex. After AMOEBA has returned, the SIMPLEX array contains the simplex enclosing the function minimum. The first point in the array, SIMPLEX[\*],0], corresponds to the function's minimum. This keyword is ignored if the P0 and SCALE keywords are set.

## Examples

Use AMOEBA to find the slope and intercept of a straight line that fits a given set of points, minimizing the maximum error. The function to be minimized (FUNC, in this case) returns the maximum error, given  $p[0] = \text{intercept}$ , and  $p[1] = \text{slope}$ .

```
; First define the function FUNC:
FUNCTION FUNC, P
COMMON FUNC_XY, X, Y
RETURN, MAX(ABS(Y - (P[0] + P[1] * X)))
END

; Put the data points into a common block so they are accessible to
; the function:
COMMON FUNC_XY, X, Y

; Define the data points:
X = FINDGEN(17)*5
Y = [ 12.0, 24.3, 39.6, 51.0, 66.5, 78.4, 92.7, 107.8, $
      120.0, 135.5, 147.5, 161.0, 175.4, 187.4, 202.5, 215.4, 229.9]

; Call the function. Set the fractional tolerance to 1 part in
; 10^5, the initial guess to [0,0], and specify that the minimum
; should be found within a distance of 100 of that point:
R = AMOEBA(1.0e-5, SCALE=1.0e2, P0 = [0, 0], FUNCTION_VALUE=fval)
```

```
; Check for convergence:
IF N_ELEMENTS(R) EQ 1 THEN MESSAGE, 'AMOEBA failed to converge'

; Print results:
PRINT, 'Intercept, Slope:', r, $
      'Function value (max error): ', fval[0]
```

IDL prints:

```
Intercept, Slope:      11.4100      2.72800
Function value:      1.33000
```

# ANNOTATE

The ANNOTATE procedure starts an IDL widget program that allows you to interactively annotate images and plots with text and drawings. Drawing objects include lines, arrows, polygons, rectangles, circles, and ellipses. Annotation files can be saved and restored, and annotated displays can be written to TIFF or PostScript files. The Annotation widget will work on any IDL graphics window or draw widget.

This routine is written in the IDL language. Its source code can be found in the file `annotate.pro` in the `lib` subdirectory of the IDL distribution.

## Using the Annotation Widget

Before calling the Annotation widget, plot or display your data in an IDL graphics window or draw widget. Unless you specify otherwise (using the `DRAWABLE` or `WINDOW` keywords), annotations will be made in the current graphics window.

For information on using the Annotation widget, click on the widget's "Help" button.

## Syntax

```
ANNOTATE [, COLOR_INDICES=array] [, DRAWABLE=widget_id | ,  
        WINDOW=index] [, LOAD_FILE=filename] [, /TEK_COLORS]
```

## Arguments

None.

## Keywords

### COLOR\_INDICES

An array of color indices from which the user can choose colors. For example, to allow the user to choose 10 colors, spread evenly over the available indices, set the keyword as follows:

```
COLOR_INDICES = INDGEN(10) * (!D.N_COLORS-1) / 9
```

If neither `TEK_COLORS` or `COLOR_INDICES` are specified, the default is to load 10 colors, evenly distributed over those available.

## DRAWABLE

The widget ID of the draw widget for the annotations. Do not set both `DRAWABLE` and `WINDOW`. If neither `WINDOW` or `DRAWABLE` are specified, the current window is used.

## LOAD\_FILE

The name of an annotation format file to load after initialization.

## TEK\_COLORS

Set this keyword and the Tektronix color table is loaded starting at color index `TEK_COLORS(0)`, with `TEK_COLORS(1)` color indices. The Tektronix color table contains up to 32 distinct colors suitable for graphics. If neither `TEK_COLORS` or `COLOR_INDICES` are specified, the default is to load 10 colors, evenly distributed over those available.

## WINDOW

The window index number of the window to receive the annotations. Do not set both `DRAWABLE` and `WINDOW`. If neither `WINDOW` or `DRAWABLE` are specified, the current window is used.

## Examples

```
; Output an image in the current window:
TVSCL, HANNING(300,200)
; Annotate it:
ANNOTATE
```

# APP\_USER\_DIR

The APP\_USER\_DIR function provides access to the IDL *application user directory*. The application user directory is a location where IDL, and applications written in IDL, can store user-specific data that will persist between IDL sessions. For example, the IDL iTools store user-specified preferences, styles, and macros in the application user directory.

The application user directory is created automatically by IDL as a subdirectory (named `.idl`) of the user's *home directory*. (For additional information on the location of the user's home directory on different platforms, see “HOME” in [Chapter 1](#), “Environment Variables Used by IDL” in the *Using IDL* manual.)

To prevent unrelated applications from encountering each other's files, the `.idl` directory is organized into subdirectories with names specified by the application author. For example, files used by applications created by RSI are stored in subdirectories of the `.idl` directory named `rsi` and `idl`. Inside each author's subdirectory, files are organized by application and (optionally) by a combination of attributes of the IDL version that creates the directory.

## Note

---

The organization of the `.idl` directory is opaque to both users and authors of IDL applications. Application authors are expected to manage the directory exclusively using the APP\_USER\_DIR function, and application users generally do not need to manually modify the files it contains.

---

APP\_USER\_DIR simplifies cross-platform application development by providing a well-defined location for IDL applications to store their resource files, regardless of the platform or version of IDL. The uniform organization it enforces is also a benefit for IDL users, since it makes it easier for them to understand the meaning and importance of the files found in their `.idl` directory.

Directories created by APP\_USER\_DIR have the following features:

- Each author of IDL applications has a unique area underneath the `.idl` directory. Different authors do not share space with each other, or with RSI.
- By default, an application directory is shared by all instances of the application. The application author can use RESTRICT keywords to specify that the directory only be used by a specified version of the application, or when running on a version of IDL with specified attributes such as release, operating system, hardware platform, *etc.* See “RESTRICT Keywords” on page 88 for additional details.

- A README file is automatically generated for each author and application directory, following a standard format. The application author is required to supply the body text for the application README file. (Text for the author README file is optional, but recommended.) The text is expected to explain the purpose of the directory, and supply contact information for the author. Each README file has a version associated with it, allowing APP\_USER\_DIR to automatically update the file as necessary.

APP\_USER\_DIR performs the following operations, in order:

1. If the specified author directory does not exist, it is created.
2. If the specified author directory does not have a standard README file, it is created. If there is an existing README file with a version number that is lower than the specified number, the file is replaced.
3. If the specified application subdirectory does not exist within the author directory, it is created.
4. If the specified application directory does not have a standard README file, it is created. If there is an existing README file with a version number that is lower than the specified number, the file is replaced.
5. The path to the application directory is returned as the value of the APP\_USER\_DIR function.

Other than the README file, the contents of an application directory are entirely up to the application author. The APP\_USER\_DIR function does not manage the content, only its location. The FILEPATH function can be used to construct filenames within the application directory, and IDL's many input/output and file manipulation routines can be used to create and manage application specific content within it.

## Syntax

```
Result = APP_USER_DIR(AuthorDirname, AuthorDesc, AppDirname, AppDesc,
  AppReadmeText, AppReadmeVersion
  [, AUTHOR_README_TEXT=string array]
  [, AUTHOR_README_VERSION=integer]
  [, RESTRICT_APPVERSION=string] [, /RESTRICT_ARCH]
  [, /RESTRICT_FAMILY | /RESTRICT_OS]
  [, /RESTRICT_FILE_OFFSET_BITS] [, /RESTRICT_IDL_RELEASE]
  [, /RESTRICT_MEMORY_BITS] )
```

## Return Value

Returns a string containing the path to the directory to be used by the calling application.

### Note

---

The directory and all associated README files are created if they do not exist. If the README files exist, they will be updated if the values of *AppReadmeVersion* and the `AUTHOR_README_VERSION` keyword are greater than those of the existing README files.

---

## Arguments

### AuthorDirname

A string specifying the name of the *author directory* to be used by the calling application. The author directory names `rsl` and `idl` are reserved for use by IDL and IDL applications created by RSI. Other authors should be careful to pick a unique name unlikely to conflict with others. (See “[Advice for Library Authors](#)” in Chapter 6 of the *Building IDL Applications* manual for advice on selecting a unique prefix for a library; the same advice applies when selecting an author directory name.)

In choosing *AuthorDirname*, be aware of the following:

1. *AuthorDirname* is case insensitive, regardless of the operating system platform. `APP_USER_DIR` will convert the name to lower case before creating the directory or returning its path string.
2. You should attempt to keep the name short, to minimize the chance that the full directory name is longer than the maximum supported length on the current platform.
3. The following characters are automatically converted to underscores (`_`) when creating the directory name: `-` `)` `(` `.` `:` `>` `<` as well as *space* and *tab*.

### AuthorDesc

A string containing a one-line description of the author in human-readable form. This string is used for the header of the README file within the author directory. For example, the *AuthorDesc* for IDL applications written by RSI is “Research Systems, Inc.”

## AppDirname

A string specifying the name of the application directory to be used by the calling application. For example, the IDL *iTools* application uses the application directory name “*itools*”.

### Note

---

`APP_USER_DIR` modifies the *AppDirname* string you specify in the same way it modifies the *AuthorDirname* string. See [AuthorDirname](#), above.

---

## AppDesc

A string giving a brief description of the application in human-readable form. This string is used for the header of the README file within the application directory. For example, the *AppDesc* for the IDL *iTools* application is “IDL Intelligent Tools (*iTools*)”.

## AppReadmeText

A string or string array containing the text used as the body of the README file within the application directory. The README text is for the benefit of IDL users who are trying to understand what the directory is for, and is expected to supply the following information:

- The identity of the author, and author contact information.
- A brief description of what the application is, and what it does.
- Any special rules governing if and when the user is allowed to delete the directory and its contents.

## AppReadmeVersion

An integer specifying the version number to be associated with the README file. *AppReadmeVersion* must be greater than zero.

Initially, *AppReadmeVersion* should be set to one. Every time you modify the text supplied as the *AppReadmeText* argument, you should increment the value of *AppReadmeVersion* by one. `APP_USER_DIR` uses this information to ensure that existing README files are automatically updated to the latest version.

**Note**

---

The application README file version is different from, and unrelated to, the application version (as specified via the `RESTRICT_APPVERSION` keyword). The README version applies only to the contents of the README file. You might want to change the text in a README file without changing the version of the application; perhaps to clarify existing information or update your contact information.

---

## Keywords

### **AUTHOR\_README\_TEXT**

Set the `AUTHOR_README_TEXT` keyword equal to a string or string array to supply README text for the author directory. Authors with multiple IDL applications should consider providing application-independent contact information here.

**Note**

---

`APP_USER_DIR` requires you to supply text for the body of the application directory README file. You are not required to supply text for the author directory README file, but supplying such text is strongly recommended.

---

If you include this keyword, use the `AUTHOR_README_VERSION` keyword to supply a version number for the README file.

### **AUTHOR\_README\_VERSION**

Set this keyword equal to an integer that specifies the version number for the author README file. The specified value must be greater than zero.

Initially, `AUTHOR_README_VERSION` should be set equal to one. Every time you modify the text supplied as the `AUTHOR_README_TEXT` keyword, you should increment the value of `AUTHOR_README_VERSION` by one. `APP_USER_DIR` uses this information to ensure that existing author README files are automatically updated to the latest version. If `AUTHOR_README_VERSION` is not supplied, a default version of 1 is used. However, RSI recommends that you explicitly specify this keyword whenever `AUTHOR_README_TEXT` is used.

**Note**

The author README file version is different from, and unrelated to, the application version (as specified via the `RESTRICT_APPVERSION` keyword). The README version applies only to the contents of the README file. You might want to change the text in a README file without changing the version of the application; perhaps to clarify existing information or update your contact information.

## RESTRICT Keywords

By default, `APP_USER_DIR` creates an application user directory that will be shared by *all* instances of the application. You can use `RESTRICT` keywords to specify that the directory only be used by a specified version of the application, or when running on a version of IDL with specified attributes such as release, operating system, hardware platform, *etc.* The `RESTRICT` keywords allow you to ensure that instances of your application running in different IDL, hardware, and operating system environments store their user data separately, when appropriate.

In deciding whether to use the `RESTRICT` keywords for your application, you should consider the following issues:

### Network Installations

In many environments, user home directories are kept on network accessible devices, and are mounted on many different systems. These systems may be running different IDL versions, different operating systems, and different hardware.

The advantages of the networked home directory are easier system administration, and the fact that no matter which computer you use, your files are always available without the need to copy them between systems. `APP_USER_DIR` is designed to work in such an environment. Concerning yourself with such heterogeneous network environments may seem like overkill if you are using a system with its own dedicated home directory, but you should remember that your users may be using a highly networked environment, and as such your application needs to take these issues into consideration.

### Application Version Compatibility

Experience shows that many application authors do not plan adequately for cross-version compatibility. This lack of planning may cause few problems at first, but as

new versions of the application are released, incompatibilities surface. Consider the following when designing your application to simplify later upgrades:

1. Can you imagine that a future version of your application might want to structure its data in a different way, or that changes for a new version might confuse older versions that also use the same data? If so, you should specify the `RESTRICT_APPVERSION` keyword to give your application a version. If in doubt, specify a version of '1.0'. You will never be required to change the version number, but you will have the flexibility to do so if your application user directories include application version information.
2. Carefully consider how platform-specific your application is, and apply any of the other `RESTRICT` keywords that are necessary.
3. If versioning is important to your application, you will eventually face the situation in which your users are upgrading to a new version. In such cases, you may want to offer them the option of migrating their configuration data from the older version. The `APP_USER_DIR_QUERY` function can be used to locate the application user directories for these older versions. Note that your application data must be designed in such a way that such migrations are possible. In particular, any versioning information needed to select the best migration candidate must be present.

## RESTRICT\_APPVERSION

Set this keyword to a string specifying the application version. Different application user directories will be created for different values of this keyword.

### Note

---

The application version can be any arbitrary string. In choosing your version string, be aware that the same rules and considerations described for the *AppDirname* argument apply to `RESTRICT_APPVERSION`.

---

## RESTRICT\_ARCH

Set this keyword to specify that different application user directories be created when your application runs on systems with different hardware architectures, as reported by the `!VERSION.ARCH` system variable field.

## RESTRICT\_FAMILY

Set this keyword to specify that different application user directories be created when your application runs on systems running different operating system families, as reported by the `!VERSION.OS_FAMILY` system variable field.

**Note**

If `RESTRICT_OS` is also specified, `RESTRICT_FAMILY` is ignored and has no effect.

## RESTRICT\_FILE\_OFFSET\_BITS

Set this keyword to specify that different application user directories be created when your application runs on versions of IDL that use a different number of file offset bits, as reported by the `!VERSION.FILE_OFFSET_BITS` system variable field.

## RESTRICT\_IDL\_RELEASE

Set this keyword to specify that different application user directories be created when your application runs under different versions of IDL, as specified by the `!VERSION.RELEASE` system variable field.

## RESTRICT\_MEMORY\_BITS

Set this keyword to specify that different application user directories be created when your application runs on versions of IDL that use a different number of memory address bits, as reported by the `!VERSION.MEMORY_BITS` system variable field.

## RESTRICT\_OS

Set this keyword to specify that different application user directories be created when your application runs on systems running different operating systems, as reported by the `!VERSION.OS` system variable field.

## Examples

The following function demonstrates how `APP_USER_DIR` can be used efficiently to create an application user directory for an IDL application supporting the “Amazing” Grill System (AGS), a product of the fictional Acme Widgets, Inc. We assume that each AGS application user directory should only be shared between instances of the same version of the application that are running under the same operating system family. The use of the `RESTRICT` keywords causes the AGS software to create a different application user directory for each unique combination of these two attributes. The rest of the application can call this function as many times as desired. It ensures that the necessary directory exists on the first call, and then simply returns the path string on subsequent calls:

```
FUNCTION acme_grill_config_dir
```

```

COMMON acme_grill_common, config_dir

IF (N_ELEMENTS(config_dir) NE 1) THEN BEGIN

    ; Increment if author_readme_text is changed
    author_readme_version = 1

    author_readme_text = $
        ['This is the user configuration directory for', $
        'IDL based products from Acme Widgets, Inc:', $
        '', $
        '    Acme Widgets, Inc.', $
        '    1234 Amazing Way', $
        '    Grill Valley, NV, 12345', $
        '    USA', $
        '', $
        'Thank you for using products from Acme Widgets, Inc.' ]

    ; Increment if app_readme_text is changed
    app_readme_version = 1

    app_readme_text = $
        ['This is the configuration directory for the', $
        'Acme "Amazing" Grill System. It is used to', $
        'remember grill settings in between grill', $
        'invocations.', $
        '', $
        'It is safe to remove this directory, as it', $
        'will be recreated on demand. Note that all', $
        'settings (e.g. smoke injection depth, juicitron', $
        'angle, etc.) will revert to their default settings.', $
        '', $
        'Thank you for using the Acme "Amazing" Grill System.'].

    config_dir = APP_USER_DIR('acme', 'Acme Widgets, Inc.', $
        'acme_grill', 'The Acme "Amazing" Grill System', $
        app_readme_text, app_readme_version, $
        AUTHOR_README_TEXT=author_readme_text, $
        AUTHOR_README_VERSION=author_readme_version, $
        RESTRICT_APPVERSION='1.0', /RESTRICT_FAMILY)

ENDIF

RETURN, config_dir

END

```

[APP\\_USER\\_DIR\\_QUERY](#), [FILE\\_MKDIR](#), [FILE\\_TEST](#), [FILEPATH](#),  
[OPENR/OPENU/OPENW](#), [!VERSION](#) system variable

# APP\_USER\_DIR\_QUERY

The APP\_USER\_DIR\_QUERY function is used to locate existing *application user directories* previously created by the APP\_USER\_DIR function. An IDL application can use APP\_USER\_DIR\_QUERY to locate the directories that were used by other (presumably older) versions of itself. A newly installed version can use this information to migrate application settings or data from another version in order to preserve the user's customizations.

To use APP\_USER\_DIR\_QUERY, your application should call it with the same values of the *AuthorDirname* and *AppDirname* arguments, and the exact set of RESTRICT keywords, used to call APP\_USER\_DIR. In this configuration, APP\_USER\_DIR\_QUERY will return the same application user directory returned by APP\_USER\_DIR. To search for other *related* application user directories, use the QUERY keywords to specify which of the attributes specified in the call to APP\_USER\_DIR should be allowed to take on any value.

As an example, suppose your application creates user application directories that depend on the version of the application and on the operating system in use. You might want to locate all directories created for a specific application version, regardless of the operating system in use when the directory was created.

## Tip

The application user directory for the current system is always one of the values returned by APP\_USER\_DIR\_QUERY. In the common example of an application that wants to migrate data from a different version, the path for the current system is not desired. Use the EXCLUDE\_CURRENT keyword to suppress it from the results.

## Syntax

```
Result = APP_USER_DIR_QUERY(AuthorDirname, AppDirname
    [, COUNT=variable] [, /EXCLUDE_CURRENT][, /QUERY_APPVERSION]
    [, /QUERY_ARCH] [, /QUERY_FAMILY] [, /QUERY_FILE_OFFSET_BITS]
    [, /QUERY_IDL_RELEASE] [, /QUERY_MEMORY_BITS] [, /QUERY_OS]
    [RESTRICT Keywords] )
```

## Return Value

Returns a string array containing all application user directories that match the query criteria. If no matching application user directories exist, a null scalar string is returned.

## Arguments

### AuthorDirname

A string specifying the name of the *author directory* to be used by the calling application. For APP\_USER\_DIR\_QUERY to work correctly, *AuthorDirname* must be set to the same value used in the call to APP\_USER\_DIR. See [APP\\_USER\\_DIR](#) for details.

### AppDirname

A string specifying the name of the application directory to be used by the calling application. For APP\_USER\_DIR\_QUERY to work correctly, *AppDirname* must be set to the same value used in the call to APP\_USER\_DIR. See [APP\\_USER\\_DIR](#) for details.

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of matching application user directories found. If no matching directories are found, the specified variable will contain the value 0 (zero).

### EXCLUDE\_CURRENT

By default, APP\_USER\_DIR\_QUERY includes the application user directory that matches the current system (the directory that would be returned by APP\_USER\_DIR) in *Result*. Set this keyword to exclude the directory returned by APP\_USER\_DIR from the *Result*.

## RESTRICT Keywords

APP\_USER\_DIR\_QUERY accepts the same RESTRICT keywords documented for [APP\\_USER\\_DIR](#). For APP\_USER\_DIR\_QUERY to work correctly, you must

specify the same `RESTRICT` keywords as were specified to `APP_USER_DIR`. See the documentation for `APP_USER_DIR` for full details.

There is a subtle difference in the meaning of the `RESTRICT` keywords between `APP_USER_DIR` and `APP_USER_DIR_QUERY`. In the case of `APP_USER_DIR`, specifying one of the `RESTRICT` keywords causes IDL to create a directory whose name incorporates information about the value of the specified attribute *on the current platform*. In the case of `APP_USER_DIR_QUERY`, specifying one of the `RESTRICT` keywords tells IDL that the directory name must contain information about the specified attribute; if the corresponding `QUERY` keyword is also specified, directory names that contain *any* value for the specified attribute will be matched.

## QUERY Keywords

A minimally correct call to `APP_USER_DIR_QUERY` consists of specifying the same *AuthorDirname* argument, *AppDirname* argument, and `RESTRICT` keywords as the corresponding call to `APP_USER_DIR`. Such a call will return a single string containing the path returned by `APP_USER_DIR`. Using `APP_USER_DIR_QUERY` in this manner is not particularly interesting; in order to locate *other* application user directories in addition to the one that applies to the current platform, you must add one or more `QUERY` keywords.

Each `QUERY` keyword corresponds to one of the `RESTRICT` keywords. The presence of a `QUERY` keyword tells `APP_USER_DIR_QUERY` to search for application user directories that satisfy all of the `RESTRICT` keywords while allowing any value for the attribute specified by the `QUERY` keyword.

### QUERY\_APPVERSION

Set this keyword to match application user directories that have any value for the application version. This keyword is quietly ignored if the `RESTRICT_APPVERSION` keyword is not set.

### QUERY\_ARCH

Set this keyword to match application user directories that have any value for the hardware architecture. This keyword is quietly ignored if the `RESTRICT_ARCH` keyword is not set.

### QUERY\_FAMILY

Set this keyword to match application user directories that have any value for the operating system family. This keyword is quietly ignored if the `RESTRICT_FAMILY` keyword is not set.

## QUERY\_FILE\_OFFSET\_BITS

Set this keyword to match application user directories that have any value for the number of bits used for file offsets. This keyword is quietly ignored if the `RESTRICT_FILE_OFFSET_BITS` keyword is not set.

## QUERY\_IDL\_RELEASE

Set this keyword to match application user directories that have any value for the IDL version string. This keyword is quietly ignored if the `RESTRICT_IDL_RELEASE` keyword is not set.

## QUERY\_MEMORY\_BITS

Set this keyword to match application user directories that have any value for the number of bits used for memory addresses. This keyword is quietly ignored if the `RESTRICT_MEMORY_BITS` keyword is not set.

## QUERY\_OS

Set this keyword to match application user directories that have any value for the operating system. This keyword is quietly ignored if the `RESTRICT_OS` keyword is not set.

## Example

In the discussion of the `APP_USER_DIR` function, we give the example of an IDL application supporting the “Amazing” Grill System, a product of the fictional Acme Widgets, Inc. The application user directory created for that application is dependent on two attributes:

1. Application version (`RESTRICT_APPVERSION`)
2. Operating system family (`RESTRICT_FAMILY`)

When a new version of IDL runs this application for the first time, the application code will find that its newly created application directory is empty. In such a situation, the application might wish to offer the user a choice between starting over with the application defaults or migrating settings and data from an older version of the application.

The following call to `APP_USER_DIR_QUERY` can be used to locate application user directories that are for other versions of the application, but for the same operating system family. The `QUERY_APPVERSION` keyword causes the function

to match all application versions, while the `EXCLUDE_CURRENT` keyword tells it to exclude the application user directory for the current system:

```
old_appdirs = APP_USER_DIR_QUERY('acme', 'acme_grill', $
    RESTRICT_APPVERSION='1.0', /RESTRICT_FAMILY, $
    /QUERY_APPVERSION, /EXCLUDE_CURRENT)
```

Note that `APP_USER_DIR_QUERY` may return more than one directory. It is up to the application to decide which one to use. Applications that intend to migrate information between versions should include information in their application user directories that will facilitate such migration.

[APP\\_USER\\_DIR](#), [FILE\\_SEARCH](#)

# ARG\_PRESENT

The ARG\_PRESENT function is useful in user-written procedures that need to know if the lifetime of a value they are creating extends beyond the current routine's lifetime. This can be important for two reasons:

1. To avoid expensive computations that the caller is not interested in.
2. To prevent heap variable leakage that would result if the routine creates pointers or object references and assigns them to arguments that are *not* passed back to the caller.

## Syntax

*Result* = ARG\_PRESENT(*Variable*)

## Return Value

Returns a nonzero value if the following conditions are met:

- The argument to ARG\_PRESENT was passed as a plain argument or keyword to the current routine by its caller, and
- The argument to ARG\_PRESENT is a named variable into which a value will be copied when the current routine exits.

In other words, ARG\_PRESENT returns TRUE if the value of the specified variable will be passed back to the caller.

## Arguments

### Variable

The variable to be tested.

## Example

Suppose that you are writing an IDL procedure that has the following procedure definition line:

```
PRO myproc, RET_PTR = ret_ptr
```

The intent of the `RET_PTR` keyword is to pass back a pointer to a new pointer heap variable. The following command could be used to avoid creating (and possibly losing) a pointer if no named variable is provided by the caller:

```
IF ARG_PRESENT(ret_ptr) THEN BEGIN
```

The commands that follow would only be executed if `ret_ptr` is supplied and will be copied into a variable in the scope of the calling routine.

[KEYWORD\\_SET](#), [N\\_ELEMENTS](#), [N\\_PARAMS](#)

# ARRAY\_EQUAL

The `ARRAY_EQUAL` function is a fast way to compare data for equality in situations where the index of the elements that differ are not of interest. This operation is much faster than using `TOTAL(A NE B)`, because it stops the comparison as soon as the first inequality is found, an intermediate array is not created, and only one pass is made through the data. For best speed, ensure that the operands are of the same data type.

Arrays may be compared to scalars, in which case each element is compared to the scalar. For two arrays to be equal, they must have the same number of elements. If the types of the operands differ, the type of the least precise is converted to that of the most precise, unless the `NO_TYPECONV` keyword is specified to prevent it. This function works on all numeric types, strings, pointer references, and object references. In the case of pointer and object references, `ARRAY_EQUAL` compares the *references* (which are long integers), not the heap variables to which the references point.

## Syntax

```
Result = ARRAY_EQUAL( Op1 , Op2 [, /NO_TYPECONV ] )
```

## Return Value

Returns 1 (true) if, and only if, all elements of *Op1* are equal to *Op2*; returns 0 (false) at the first instance of inequality.

## Arguments

### Op1, Op2

The variables to be compared.

## Keywords

### NO\_TYPECONV

By default, `ARRAY_EQUAL` converts operands of different types to a common type before performing the equality comparison. Set `NO_TYPECONV` to disallow this implicit type conversion. If `NO_TYPECONV` is specified, operands of different types are never considered to be equal, even if their numeric values are the same.

## Examples

```
; Return True (1) if all elements of a are equal to a 0 byte:  
IF ARRAY_EQUAL(a, 0b) THEN ...  
; Return True (1) if all elements of a are equal all elements of b:

# ARRAY\_INDICES

The ARRAY\_INDICES function converts one-dimensional subscripts of an array into corresponding multi-dimensional subscripts.

This routine is written in the IDL language. Its source code can be found in the file `array_indices.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = ARRAY\_INDICES(*Array*, *Index* [, /DIMENSIONS] )

## Return Value

If *Index* is a scalar, returns a vector containing *m* dimensional subscripts, where *m* is the number of dimensions of *Array*.

If *Index* is a vector containing *n* elements, returns an (*m* x *n*) array, with each row containing the multi-dimensional subscripts corresponding to that index.

## Arguments

### Array

An array of any type, whose dimensions should be used in converting the subscripts. If DIMENSIONS is set then Array should be a vector containing the dimensions.

### Index

A scalar or vector containing the one-dimensional subscripts to be converted.

## Keywords

### DIMENSIONS

If this keyword is set, then Array is assumed to be a vector containing the dimensions.

### Tip

---

This keyword is useful when you don't have the actual Array, and want to avoid allocating the array just to find the indices.

---

## Examples

### Example 1

This example finds the location of the maximum value of a random 10 by 10 array:

```
seed = 111
array = RANDOMU(seed, 10, 10)
mx = MAX(array, location)
ind = ARRAY_INDICES(array, location)
PRINT, ind, array[ind[0],ind[1]], $
      FORMAT = '(%"Value at [%d, %d] is %f")'
```

IDL prints:

```
Value at [3, 6] is 0.973381
```

### Example 2

This example is the same as the previous example, but uses the `/DIMENSIONS` keyword.

```
seed = 111
array = RANDOMU(seed, 10, 10)
mx = MAX(array, location)
dims = SIZE(array, /DIMENSIONS)
ind = ARRAY_INDICES(dims, location, /DIMENSIONS)
print, ind, array[ind[0],ind[1]], $
      format = '(%"Value at [%d, %d] is %f")'
```

IDL prints:

```
Value at [3, 6] is 0.973381
```

### Example 3

This example routine locates the highest point in the example Maroon Bells data set and places a flag at that point.

Enter the following code in the IDL editor:

```
PRO ExARRAY_INDICES

; Import Maroon Bells data.
file = FILEPATH('surface.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [350, 450], $
  DATA_TYPE = 2, ENDIAN='little')

; Display data.
```

```

ISURFACE, data

; Calculate the value and one-dimensional
; array location of the highest point.
maxValue = MAX(data, maxPoint)

; Using ARRAY_INDICES to convert the one-
; dimensional array location to a two-
; dimensional array location.
maxLocation = ARRAY_INDICES(data, maxPoint)

; Print the results.
PRINT, 'Highest Point Location: ', maxLocation
PRINT, 'Highest Point Value: ', maxValue

; Create flag for the highest point.
x = maxLocation[0]
y = maxLocation[1]
z = maxValue
xFlag = [x, x, x + 50., x]
yFlag = [y, y, y + 50., y]
zFlag = [z, z + 1000., z + 750., z + 500.]

; Display flag at the highest point.
IPLOT, xFlag, yFlag, zFlag, /OVERPLOT

END

```

Save the code as `ExARRAY_INDICES.pro`, compile it and run it. The following figure displays the output of this example:

*Figure 3-1: Maroon Bells Surface Plot with Flag at Highest Point Before Rotation (Left) and After Rotation (Right)*

For a better view of the flag, use the Rotate tool to rotate the surface.

[MAX, MIN, WHERE](#)

# ARROW

The ARROW procedure draws one or more vectors with arrow heads.

This routine is written in the IDL language. Its source code can be found in the file `arrow.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
ARROW, X0, Y0, X1, Y1 [, /DATA | , /NORMALIZED] [, HSIZE=length]  
[, COLOR=index] [, HTHICK=value] [, /SOLID] [, THICK=value]
```

## Arguments

### X0, Y0

Arrays or scalars containing the coordinates of the tail end of the vector or vectors. Coordinates are in DEVICE coordinates unless otherwise specified.

### X1, Y1

Arrays or scalars containing the coordinates of the arrowhead end of the vector or vectors. *X1* and *Y1* must have the same number of elements as *X0* and *Y0*.

## Keywords

### DATA

Set this keyword if vector coordinates are DATA coordinates.

### NORMALIZED

Set this keyword if vector coordinates are NORMALIZED coordinates.

### HSIZE

Use this keyword to set the length of the lines used to draw the arrowhead. The default is 1/64th the width of the display (!D.X\_SIZE / 64.). If the HSIZE is positive, the value is assumed to be in device coordinate units. If HSIZE is negative, the arrowhead length is set to the vector length \* ABS(HSIZE). The lines are separated by 60 degrees to make the arrowhead.

## COLOR

The color of the arrow. The default is the highest color index.

## HTHICK

The thickness of the arrowheads. The default is 1.0.

## SOLID

Set this keyword to make a solid arrow, using polygon fills, looks better for thick arrows.

## THICK

The thickness of the body. The default is 1.0.

## Examples

Draw an arrow from (100,150) to (300,350) in DEVICE units:

```
ARROW, 100, 150, 300, 350
```

Draw a sine wave with arrows from the line  $Y = 0$  to  $\text{SIN}(X/4)$ :

```
X = FINDGEN(50)
Y = SIN(x/4)
PLOT, X, Y
ARROW, X, REPLICATE(0,50), X, Y, /DATA
```

# ASCII\_TEMPLATE

The ASCII\_TEMPLATE function presents a graphical user interface (GUI) which generates a template defining an ASCII file format. Templates are IDL structure variables that may be used when reading ASCII files with the READ\_ASCII routine. See [READ\\_ASCII](#) for details on reading ASCII files.

This routine is written in the IDL language. Its source code can be found in the file `ascii_template.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = ASCII_TEMPLATE( [Filename] [, BROWSE_LINES=lines]  
                        [, CANCEL=variable] [, GROUP=widget_id] )
```

## Return Value

Returns a template defining an ASCII file format.

## Arguments

### Filename

A string containing the name of a file to base the template on. If *Filename* is not specified, a dialog allows you to choose a file.

## Keywords

### BROWSE\_LINES

Set this keyword equal to the number of lines that will be read in at a time when the “Browse” button is selected. The default is 50 lines.

### CANCEL

Set this keyword to a named variable that will contain the byte value 1 if the user clicked the “Cancel” button, or 0 otherwise.

## GROUP

The widget ID of an existing widget that serves as “group leader” for the ASCII\_TEMPLATE graphical user interface. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

## Examples

Use the following command to generate a template structure from the file “myFile”:

```
myTemplate = ASCII_TEMPLATE(myFile)
```

### Note

---

If no filename is supplied in the call to the ASCII\_TEMPLATE function, a file selection dialog is displayed prior to the first ASCII\_TEMPLATE screen.

---

## Using the ASCII Template Dialog

The ASCII\_TEMPLATE function lets you describe the data organization of an ASCII file and generates a template that describes how to correctly import the ASCII data. The READ\_ASCII function accesses the data in an ASCII file, using the template to determine how to import the data correctly. (You only have to explicitly call READ\_ASCII when you call ASCII\_TEMPLATE from the command line. When you start the **ASCII Template** dialog from an iTool or the IDLDE, the READ\_ASCII routine is called for you.) The template is an IDL variable that you can use to read other files with the same organization.

After starting the **ASCII Template** dialog using one of the methods described in [“Launching the ASCII Template Dialog”](#) in Chapter 6 of the *Using IDL* manual, complete the following steps to create the template:

1. **Select the ASCII file.** In the **Select File to Open** dialog, select `sine_waves.txt` from the `examples\data` subdirectory of your IDL distribution. The ASCII Template window is displayed.
2. **Define ASCII data type and range.** For this data set, make sure the following options are selected and then click **Next**:
  - **Field Type of Delimited**
  - **Comment String to Ignore** is blank as there are no file comments
  - **Data Starts at Line** value of 1

The following table describes each of these options.

Field Type	Choose from fixed width or delimited.
Comment String to Ignore	Enter any character that indicates text sections to ignore.
Data Starts at Line	Enter the line number containing the first line of data to be read.
Selected Text File	Shows the real data from the selected text file. The option is also given to <b>Get next 50 Lines</b> .

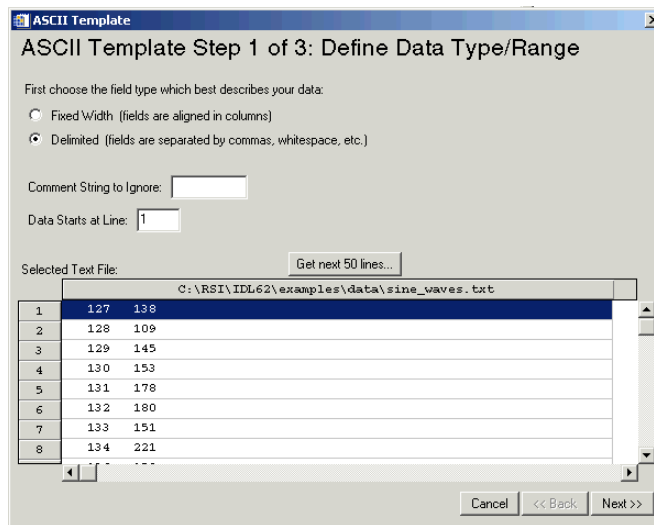

Figure 3-2: The ASCII Template Step 1, Defining Data Type and Range

3. **Define ASCII data field characteristics.** For this data set, select the following options and then click **Next**:
  - **Number of Fields Per Line** equals 2
  - **Delimiter Between Data Elements** equals **White space**
  - **Value to Assign to Missing Data** option is **IEEE NaN**

- **Selected Records** shows data in the file.

The following table describes each of these options:

Number of Fields Per Line	Specify how many fields should appear per line.
Delimiter Between Data Elements	Define the delimiter type between data elements. <b>Note</b> - If you selected a <b>Field Type</b> of <b>Fixed Width</b> on the previous dialog screen, this field is not visible.
Value to Assign Missing Data	Choose a value to assign any missing data. Select <b>IEEE Nan</b> or define a custom value.
Selected Records	Shows the data itself in its desired column-delimited format.

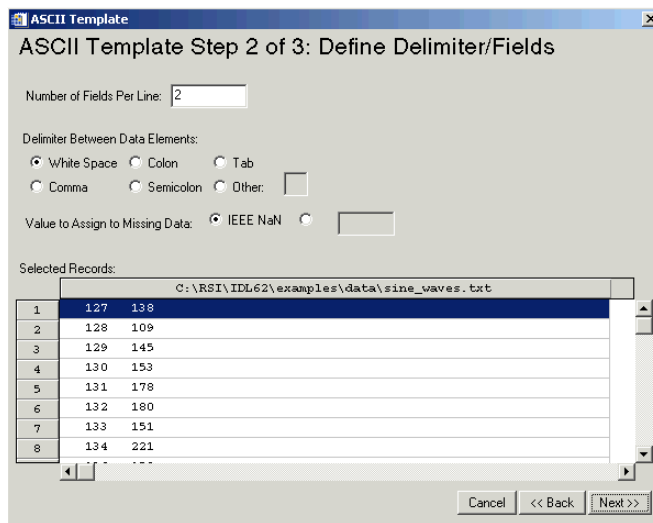

Figure 3-3: The ASCII Template Step 2, Defining Delimiters/Fields

4. **Specify field characteristics.** For this data set, define the following:
- Name **Field1** `SmoothSine` and **Field2** `NoisySine` by selecting each field and entering the names in the **Name** field. The **Type** fields are correct and do not need to be changed.
  - Accept the default **Grouping** (none).

The following table describes each of these options:

Name	Allows you to name your fields. Default values are <b>Field1</b> , <b>Field2</b> , and so on. You can enter the name into the <b>Name</b> field to the right.
Data Type	Allows you to set the data type for your fields. You can enter a different type by selecting it from the <b>Type</b> drop-down menu.
Grouping	Lets you join selected fields into a single field that is to be manipulated or displayed as a group. The default is no grouping.
Selected Records	Shows a sample of the data with your defined configuration parameters.

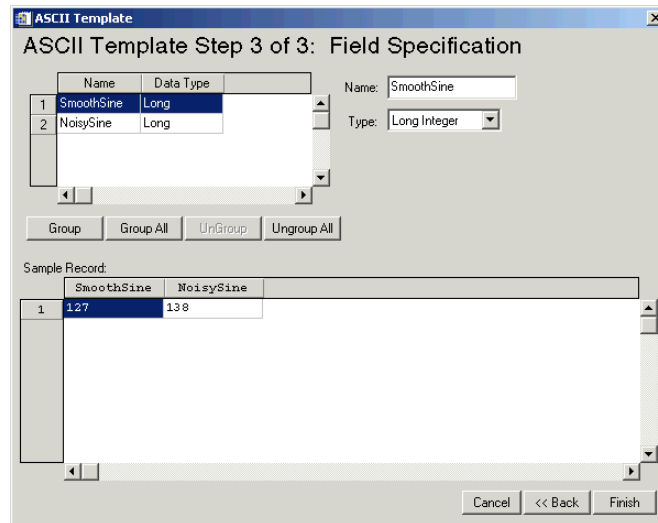

Figure 3-4: ASCII Template Step 3, Field Specifications

5. **Create the template.** Click **Finish**.

The result of these actions depends on the location from which you launched the **ASCII Template** dialog. The `READ_ASCII` function, which reads data from a file according to the template specification, is automatically called when you access the **ASCII Template** dialog from *iTools* or from the **Import ASCII** macro. From the command line, you must explicitly read the ASCII data with the template specification. After defining the structure of your ASCII data using the **ASCII Template** dialog, refer to the appropriate section:

- ***iTools* ASCII data access** — the ASCII data is read and placed in the Data Manager. You can display single or multiple fields of the data using the **Insert Visualization** dialog. See “[Inserting Visualizations](#)” in Chapter 3 of the *iTool User’s Guide* manual for details.
- **Import ASCII macro data access** — the ASCII data is placed in a structure. You can access fields of the data using a `StructureName.FieldName` syntax. See “[Using Macros to Import ASCII Files](#)” in Chapter 6 of the *Using IDL* manual.
- **Command line ASCII data access** — the template is a structure defining the format of the ASCII data. Access the data using `READ_ASCII`, and specify

the template (or other characteristics) as parameters of the data access operation. See “[Working with a READ\\_ASCII Data Structure](#)” on page 1879 for details.

## Example: Create a SAVE File of a Custom ASCII Template

When importing an ASCII data file into IDL, you must first describe the format of the data using the interactive ASCII\_TEMPLATE function. If you have a number of ASCII files that have the same format, you can create and save a customized ASCII template using the [SAVE](#) procedure. After creating a SAVE file of your custom template, you can avoid having to repeatedly define the same fields and records when reading in ASCII files that have the same structure.

1. At the IDL command line, enter the following to create the variable `plotTemplate`, which will contain your custom ASCII template:

```
plotTemplate = ASCII_TEMPLATE( )
```

A dialog box appears, prompting you to select a file.

2. Select the `plot.txt` file in the `examples/data` subdirectory of the IDL distribution.

---

### Note

Another way to import ASCII data is to use the **Import ASCII File** toolbar button on the IDLDE toolbar. To use this feature, simply click the button and select `plot.txt` from the file selection dialog.

---

3. After selecting the file, the **Define Data Type/Range** dialog appears. First, choose the field type. Since the data file is delimited by tabs (or whitespace) select the **Delimited** button. In the **Data Starts at Line** field, specify to begin reading the data at line 3, not line 1, since there are two comment lines at the beginning of the file. Click **Next** to continue.
4. In the **Define Delimiter/Fields** dialog box, select **Tab** as the delimiter between data elements since it is known that tabs were used in the original file. Click **Next**.
5. In the **Field Specification** dialog box, name each field as follows:
  - Click on the first row (row 1). In the **Name** field, enter `time`.
  - Select the second row and enter `temperature1`.
  - Select the third row and enter `temperature2`.
6. Click **Finish**.

7. Type the following line at the IDL command line to read in the `plot.txt` file using the custom template, `plotTemplate`:

```
PLOT_ASCII = READ_ASCII(FILEPATH('plot.txt', SUBDIRECTORY = $
    ['examples', 'data']), TEMPLATE = plotTemplate)
```

8. Enter the following line to print the `plot.txt` file data:

```
PRINT, PLOT_ASCII
```

The file contents are printed in the Output Log window. Your output will resemble the following display.

Figure 3-5: PLOT\_ASCII Printout

9. Create a SAVE file of your custom template by entering the following:

```
SAVE, plotTemplate, FILENAME='myPlotTemplate.sav'
```

10. To restore the template so that you can read another ASCII file, enter:

```
RESTORE, 'myPlotTemplate.sav'
```

This file contains your custom ASCII template information stored in the structure variable, `plotTemplate`.

### Note

If you are attempting to restore a file that is not in your current working directory, you will need to specify a path to the file.

11. After restoring your custom template, you can read another ASCII file that is delimited in the same way as the original file by using the `READ_ASCII` function and specifying `plotTemplate` for the `TEMPLATE`:

```
PLOT_ASCII = READ_ASCII(FILEPATH('plot.txt', $
    SUBDIRECTORY = ['examples', 'data']), $
    TEMPLATE = plotTemplate)
```

12. Enter the following to display the contents of the file using the customized ASCII template structure previously defined using the dialog.

```
PRINT, PLOT_ASCII
```

## Version History

[QUERY\\_ASCII](#), [READ\\_ASCII](#), [BINARY\\_TEMPLATE](#)

# ASIN

The ASIN function returns the angle, expressed in radians, whose sine is  $X$  (i.e., the arc-sine).

For real input, the range of ASIN is between  $-\pi/2$  and  $\pi/2$ .

For input of a complex number,  $Z = X + iY$ , the complex arcsine is given by,

$$\text{asin}(Z) = \text{asin}(B) + i \text{alog}(A + \sqrt{A^2 - 1}) \quad \text{if } Y \geq 0$$

$$\text{asin}(Z) = \text{asin}(B) - i \text{alog}(A + \sqrt{A^2 - 1}) \quad \text{if } Y < 0$$

where

$$A = 0.5 \sqrt{(X + 1)^2 + Y^2} + 0.5 \sqrt{(X - 1)^2 + Y^2}$$

$$B = 0.5 \sqrt{(X + 1)^2 + Y^2} - 0.5 \sqrt{(X - 1)^2 + Y^2}$$

The separation of the two formulas at  $Y = 0$  takes into account the branch-cut discontinuity along the real axis from  $-\infty$  to  $-1$  and  $+1$  to  $+\infty$ , and ensures that  $\sin(\text{asin}(Z))$  is equal to  $Z$ . For reference, see formulas 4.4.37-39 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

## Syntax

*Result* = ASIN( $X$ )

## Return Value

Returns the angle, expressed in radians, whose sine is  $X$  (i.e., the arc-sine).

## Arguments

### X

The sine of the desired angle. For real input,  $X$  should be in the range  $-1$  to  $+1$ . If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If  $X$  is an array, the result has the same structure, with each element containing the arcsine of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Find the angle whose sine is 0.707 and print the result in degrees by entering:

```
PRINT, 180!/PI*ASIN(0.707)
IDL prints:
44.9913
```

Find the complex arcsine of  $2 + i$  and print the result by entering:

```
PRINT, ASIN(COMPLEX(2,1))
IDL prints:
( 1.06344, 1.46935)
```

See the ATAN function for an example of visualizing the complex arcsine.

# ASSOC

The ASSOC function associates an array structure with a file. It provides a basic method of random access input/output in IDL.

---

**Note**

Unformatted data files generated by FORTRAN programs under UNIX contain an extra long word before and after each logical record in the file. ASSOC does not interpret these extra bytes but considers them to be part of the data. This is true even if the F77\_UNFORMATTED keyword is specified in the [OPENR/OPENU/OPENW](#) statement. Therefore, ASSOC should not be used with such files. Instead, such files should be processed using [READU](#) and [WRITEU](#). An example of using IDL to read such data is given in “[Using Unformatted Input/Output](#)” in Chapter 18 of the *Building IDL Applications* manual.

---

---

**Note**

Associated file variables cannot be used for output with files opened using the COMPRESS keyword to OPEN. This is due to the fact that it is not possible to move the current file position backwards in a compressed file that is currently open for writing. ASSOC is allowed with compressed files opened for input only. However, such operations may be slow due to the large amount of work required to change the file position in a compressed file.

Effective use of ASSOC requires the ability to rapidly position the file to arbitrary positions. In general, files that require random access may not be good candidates for compression. If this is necessary however, such files can be processed using [READU](#) and [WRITEU](#).

---

## Syntax

*Result* = ASSOC( *Unit*, *Array\_Structure* [, *Offset*] [, [PACKED](#)] )

## Return Value

Returns a value that when assigned to a variable, stores the association between an array structure and a file in an *associated variable*. This variable provides a means of mapping a file into vectors or arrays of a specified type and size.

## Arguments

### Unit

The IDL file unit to associate with *Array\_Structure*.

### Array\_Structure

An expression of the data type and structure to be associated with *Unit* are taken from *Array\_Structure*. The actual value of *Array\_Structure* is not used.

### Offset

The offset in the file to the start of the data in the file, in bytes.

## Keywords

### PACKED

When ASSOC is applied to structures, the default action is to map the actual definition of the structure for the current machine, including any holes required to properly align the fields. (IDL uses the same rules for laying out structures as the C language). If the PACKED keyword is specified, I/O using the resulting variable instead works in the same manner as READU and WRITEU, and data is moved one field at a time and there are no alignment gaps between the fields.

## Examples

Suppose that the file `images.dat` holds 5 images as 256-element by 256-element arrays of bytes. Open the file for reading and create an associated variable by entering:

```
OPENR, 1, 'images.dat' ;Open the file as file unit 1.
A = ASSOC(1, BYTARR(256, 256)) ;Make an associated variable.
```

Now `A[0]` corresponds to the first image in the file, `A[1]` is the second element, etc. To display the first image in the file, you could enter:

```
TV, A[0]
```

The data for the first image is read and then displayed. Note that the data associated with `A[0]` is not held in memory. It is read in every time there is a reference to `A[0]`. To store the image in the memory-resident array `B`, you could enter:

```
B = A[0]
```

**Note**

It is also possible to refer to individual elements within an associated array directly, using multiple subscripts. See [“Multiple Subscripts With Associated File Variables”](#) in Chapter 18 of the *Building IDL Applications* manual for details and examples.

# ATAN

The ATAN function returns the angle, expressed in radians, whose tangent is  $X$  (i.e., the arc-tangent). If two parameters are supplied, the angle whose tangent is equal to  $Y/X$  is returned.

For real input, the range of ATAN is between  $-\pi/2$  and  $\pi/2$  for the single argument case, and between  $-\pi$  and  $\pi$  if two arguments are given.

In the single argument case with a complex number,  $Z = X + iY$ , the complex arctangent is given by,

$$\text{atan}(Z) = 0.5 \text{atan}(2x, 1 - x^2 - y^2) + 0.25 i \log((x^2 + (y+1)^2)/(x^2 + (y-1)^2))$$

In the above formula, the use of the two-argument arctangent separates the solutions at  $X = 0$  and takes into account the branch-cut discontinuity along the imaginary axis from  $-i\infty$  to  $-i$  and  $+i$  to  $+i\infty$ , and ensures that  $\tan(\text{atan}(Z))$  is equal to  $Z$ . For reference, see formulas 4.4.37-39 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

In the two argument case with two complex numbers  $Zy$  and  $Zx$ , the complex arctangent is given by,

$$\text{atan}(Zy, Zx) = -i \log((Zx + iZy)/\sqrt{Zx^2 + Zy^2})$$

In the two-argument case (either real or complex), if both arguments are zero, the result returned is platform-dependent but typically 0.

## Syntax

*Result* = ATAN( $X$  [, /PHASE] )

or

*Result* = ATAN( $Y, X$ )

## Return Value

Returns the angle, expressed in radians, whose tangent is  $X$  (i.e., the arc-tangent). If two parameters are supplied, the angle whose tangent is equal to  $Y/X$  is returned.

## Arguments

### X

The tangent of the desired angle. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the arctangent of the corresponding element of X.

### Y

An optional argument. If this argument is supplied, ATAN returns the angle whose tangent is equal to Y/X. If both arguments are arrays, the function matches up the corresponding elements of X and Y, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

## Keywords

### PHASE

If this keyword is set, and the argument is a complex number Z, then the complex phase angle is computed as  $\text{ATAN}(\text{Imaginary}(Z), \text{Real\_part}(Z))$ . If this keyword is not set, then the complex arctangent is computed as described above. If the argument is not complex or if two arguments are present, then this keyword is ignored.

#### Tip

---

Using the PHASE keyword is equivalent to computing  $\text{ATAN}(\text{Imaginary}(Z), \text{Real\_part}(Z))$ , but uses less memory and is faster.

---

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Example

Find the angle whose tangent is 0.5 and print the result in degrees by entering:

```
PRINT, 180/!PI*ATAN(0.5)
IDL prints:
26.5651
```

Find the angle whose tangent is 0.5, taking into account that the tangent came from the ratio -0.25/-0.5:

```
PRINT, 180/!PI*ATAN(-0.25, -0.5)
IDL prints:
-153.435
```

Find the complex arccosine of  $2 + i$  and print the result by entering:

```
PRINT, ATAN(COMPLEX(2,1))
IDL prints:
(      1.17810,      0.173287)
```

Create a visualization of the complex arctangent:

```
; Create a grid of complex numbers.
n = 100
x = (FINDGEN(n) - (n-1)/2.0) / (n/4)
z = DCOMPLEX(REBIN(x,n,n), REBIN(TRANSPOSE(x),n,n))

; Try any of these transcendental functions:
;   ACOS, COS, COSH, ASIN, SIN, SINH,
;   ATAN, TAN, TANH, ALOG, EXP
fn = ATAN(z)

ISURFACE, FLOAT(fn), x, x, COLOR=[255, 180, 0]
ISURFACE, IMAGINARY(fn), x, x, COLOR=[0, 150, 255], /OVERPLOT
```

# AXIS

The `AXIS` procedure draws an axis of the specified type and scale at a given position. It can be used to add additional axes to plots or to draw axes at a specified position. The new scale is saved for use by subsequent overplots if the `SAVE` keyword parameter is set. By default, `AXIS` draws an X axis. The `XAXIS`, `YAXIS`, and `ZAXIS` keywords can be used to select a specific axis type and position.

## Syntax

```
AXIS [, X [, Y [, Z]]] [, /SAVE] [, XAXIS={0 | 1} | YAXIS={0 | 1} | ZAXIS={0 | 1 | 2 | 3}] [, /XLOG] [, /YNOZERO] [, /YLOG]
```

**Graphics Keywords:** [, CHARSIZE=*value*] [, CHARTHICK=*integer*] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, FONT=*integer*] [, /NODATA] [, /NOERASE] [, SUBTITLE=*string*] [, /T3D] [, TICKLEN=*value*] [, {X | Y | Z}CHARSIZE=*value*] [, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}] [, {X | Y | Z}MARGIN=[*left, right*] [, {X | Y | Z}MINOR=*integer*] [, {X | Y | Z}RANGE=[*min, max*] [, {X | Y | Z}STYLE=*value*] [, {X | Y | Z}THICK=*value*] [, {X | Y | Z}TICKFORMAT=*string*] [, {X | Y | Z}TICKINTERVAL=*value*] [, {X | Y | Z}TICKLAYOUT=*scalar*] [, {X | Y | Z}TICKLEN=*value*] [, {X | Y | Z}TICKNAME=*string\_array*] [, {X | Y | Z}TICKS=*integer*] [, {X | Y | Z}TICKUNITS=*string*] [, {X | Y | Z}TICKV=*array*] [, {X | Y | Z}TICK\_GET=*variable*] [, {X | Y | Z}TITLE=*string*] [, ZVALUE=*value*{0 to 1}]

## Arguments

### X, Y, and Z

Scalars giving the starting coordinates of the new axis. If no coordinates are specified, the axis is drawn in its default position as given by the [XYZ]AXIS keyword. When drawing an X axis, the X coordinate is ignored, similarly the Y and Z arguments are ignored when drawing their respective axes (i.e., new axes will always point in the correct direction).

## Keywords

### SAVE

Set this keyword to indicate that the scaling to and from data coordinates established by the call to AXIS is to be saved in the appropriate axis system variable, !X, !Y, or !Z. If this keyword is not present, the scaling is not changed.

### XAXIS

Set this keyword to draw an X axis. If the X argument *is not* present, setting XAXIS equal to 0 draws an axis under the plot window with the tick marks pointing up, and setting XAXIS equal to one draws an axis above the plot window with the tick marks pointing down. If the X argument *is* present, the X axis is positioned accordingly, and setting XAXIS equal to 0 or 1 causes the tick marks to point up or down, respectively.

### XLOG

Set this keyword to specify a logarithmic X axis

### YAXIS

Set this keyword to draw a Y axis. If the Y argument *is not* present, setting YAXIS equal to 0 draws an axis on the left side of the plot window with the tick marks pointing right, and setting YAXIS equal to one draws an axis on the right side of the plot window with the tick marks pointing left. If the Y argument *is* present, the Y axis is positioned accordingly, and setting YAXIS equal to 0 or 1 causes the tick marks to point right or left, respectively.

### Note

---

The YAXIS keyword must be specified in order use any Y\* graphics keywords. See the note under [“Graphics Keywords Accepted”](#) on page 128 for more information.

---

## YLOG

Set this keyword to specify a logarithmic Y axis.

## YNOZERO

Set this keyword to inhibit setting the minimum Y axis value to zero when the Y data are all positive and non-zero, and no explicit minimum Y value is specified (using YRANGE, or !Y.RANGE). By default, the Y axis spans the range of 0 to the maximum value of Y, in the case of positive Y data. Set bit 4 in !Y.STYLE to make this option the default.

## ZAXIS

Set this keyword to draw a Z axis. If the Z argument is *not* present, setting ZAXIS has the following meanings:

- 0 = lower (front) right, with tickmarks pointing left
- 1 = lower (front) left, with tickmarks pointing right
- 2 = upper (back) left, with tickmarks pointing right
- 3 = upper (back) right, with tickmarks pointing left

If the Z argument *is* present, the Z axis is positioned accordingly, and setting ZAXIS equal to 0 or 1 causes the tick marks to point left or right, respectively.

Note that AXIS uses the 3D plotting transformation stored in the system variable field !P.T.

---

### Note

The ZAXIS keyword must be specified in order use any Z\* graphics keywords. See the note under [Graphics Keywords Accepted](#) for more information.

---

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

CHARSIZE, CHARTHICK, COLOR, DATA, DEVICE, FONT, NODATA, NOERASE, NORMAL, SUBTITLE, T3D, TICKLEN, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK\_GET, [XYZ]TITLE, ZVALUE

**Note**

In order for the Y\* or Z\* graphics keywords to work with the AXIS procedure, the corresponding YAXIS or ZAXIS keyword must be specified. For example, the following code will *not* draw a title for the Y axis:

```
AXIS, YTITLE = 'Y-axis Title'
```

To use the YTITLE graphics keyword, you must specify the YAXIS keyword to AXIS:

```
AXIS, YAXIS = 0, YTITLE = 'Y-axis Title'
```

Because the AXIS procedure draws an X axis by default, it is not necessary to specify the XAXIS keyword in order to use the X\* graphics keywords.

## Examples

The AXIS procedure accepts the set of plotting keyword parameters that govern the scaling and appearance of the axes. Additionally, the keyword parameters XAXIS, YAXIS, and ZAXIS specify the orientation and position (if no position coordinates are present) of the axis. The value of these parameters are 0 for the bottom or left axis and 1 for the top or right. The tick marks and their annotation extend away from the plot window. For example, specify YAXIS = 1 to draw a y-axis on the right of the window.

The optional keyword parameter SAVE saves the data-scaling parameters established for the axis in the appropriate axis system variable, !X, !Y, or !Z. Any of the coordinate systems can be used by including the appropriate coordinate keyword in the call. The coordinate corresponding to the axis direction is ignored. When specifying an x-axis, the x-coordinate parameter is ignored, but must be present if there is a y coordinate.

The following example shows how the AXIS procedure can be used with normal or polar plots to draw axes through the origin, dividing the plot window into four quadrants:

```
; Make the plot, polar in this example, and suppress the X and Y
; axes using the XSTYLE and YSTYLE keywords:
PLOT, /POLAR, XSTYLE=4, YSTYLE=4, TITLE='Polar Plot', r, theta

; Draw an X axis, through data Y coordinate of 0. Because the XAXIS
; keyword parameter has a value of 0, the tick marks point down:
AXIS, 0, 0, XAX=0, /DATA
```

```

; Similarly, draw the Y axis through data X = 0. The tick marks
; point left:
AXIS,0,0,0,YAX=0,/DATA

```

## Drawing Axes with a Different Scale

The figure shown below illustrates using `AXIS` to draw axes with a different scale, opposite the main  $x$ - and  $y$ -axes. The plot is produced using `PLOT` with the bottom and left axes annotated and scaled in units of days and degrees Fahrenheit. The `XMARGIN` and `YMARGIN` keyword parameters are specified to allow additional room around the plot window for the new axes. The keyword parameters `XSTYLE = 8` and `YSTYLE = 8` inhibit drawing the top and right axes.

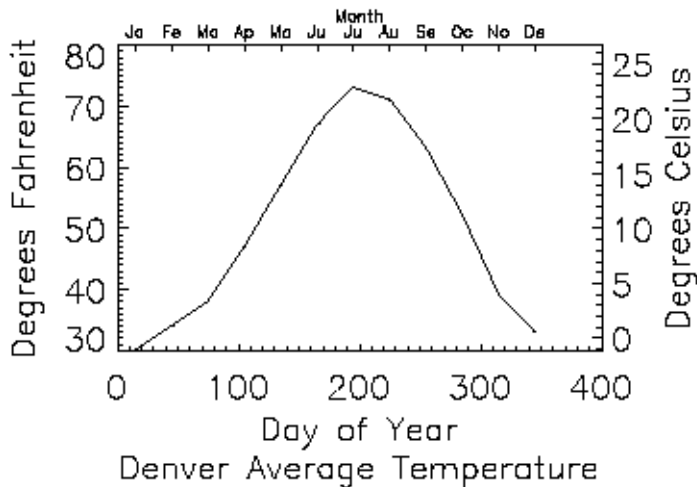

Figure 3-6: A plot created with the `AXIS` procedure

Next, the `AXIS` procedure is called to draw the top, `XAXIS = 1`, axis, labeled in months. Eleven tick intervals with 12 tick marks are drawn. The  $x$  value of each monthly tick mark is the day of the year that is approximately the middle of the month. Tick-mark names come from the `MONTH` string array.

The right  $y$ -axis, `YAXIS = 1`, is drawn in the same manner. The new  $y$ -axis range is set by converting the original  $y$ -axis minimum and maximum values, saved by `PLOT` in `!Y.CRANGE`, from Fahrenheit to Celsius, using the formula  $C = 5(F-32)/9$ . The

keyword parameter `YSTYLE = 1` forces the y-axis range to match the given range exactly. The program is as follows:

```

; Plot the data, omit right and top axes:
PLOT, DAY, TEMP, /YNOZERO, $
    SUBTITLE = 'Denver Average Temperature', $
    XTITLE = 'Day of Year', $
    YTITLE = 'Degrees Fahrenheit', $
    XSTYLE=8, YSTYLE=8, XMARGIN=[8, 8], YMARGIN=[4, 4]
; Draw the top x-axis, supplying labels, etc.
; Make the characters smaller so they will fit:
AXIS, XAXIS=1, XTICKS=11, XTICKV=DAY, XTICKN=MONTH, $
    XTITLE='Month', XCHARSIZE = 0.7
; Draw the right y-axis. Scale the current y-axis minimum
; values from Fahrenheit to Celsius and make them
; the new min and max values. Set YSTYLE=1 to make axis exact.
AXIS, YAXIS=1, YRANGE = (!Y.CRANGE-32)*5./9., YSTYLE = 1, $
    YTITLE = 'Degrees Celsius'
```

### Example Code

---

The code above is included in the batch file `plot09` in the `examples/doc/plot` subdirectory of the IDL distribution.

---

## Using AXIS with Polar Plots

If the `POLAR` keyword parameter is set, the IDL `PLOT` procedure converts its coordinates from polar to Cartesian coordinates when plotting. The first parameter to plot is the radius,  $R$ , and the second is the angle  $\theta$  (expressed in radians). Polar plots are produced using the standard axis and label styles, with box axes enclosing the plot area.

The following figure illustrates using `AXIS` to draw centered axes, dividing the plot window into the four quadrants centered about the origin. This method uses `PLOT` to plot the polar data and to establish the coordinate scaling, but suppresses the axes. Next, two calls to `AXIS` add the  $x$ - and  $y$ -axes, drawn through data coordinate  $(0, 0)$ .

Polar Plot

*Figure 3-7: Using AXIS for polar plots*

```

; Make a radius vector:
R = FINDGEN(100)
; Make a vector:
THETA = R/5
; Plot the data, suppressing the axes by setting their styles to 4:
PLOT, R, THETA, SUBTITLE='Polar Plot', XSTY=4, YSTY=4, /POLAR
AXIS, 0, 0, XAX=0
; Draw the x and y axes through (0, 0):
AXIS, 0, 0, YAX=0

```

**Example Code**

The code above is included in the batch file `plot09` in the `examples/doc/plot` subdirectory of the IDL distribution.

# BAR\_PLOT

The `BAR_PLOT` procedure creates a bar graph. This routine is written in the IDL language. Its source code can be found in the file `bar_plot.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
BAR_PLOT, Values [, BACKGROUND=color_index]
          [, BARNAMES=string_array] [, BAROFFSET=scalar] [, BARSPACE=scalar]
          [, BARWIDTH=value] [, BASELINES=vector] [, BASERANGE=scalar{0.0 to
          1.0}] [, COLORS=vector] [, /OUTLINE] [, /OVERPLOT] [, /ROTATE]
          [, TITLE=string] [, XTITLE=string] [, YTITLE=string]
```

## Arguments

### Values

A vector containing the values to be represented by the bars. Each element in *Values* corresponds to a single bar in the output.

## Keywords

### BACKGROUND

A scalar that specifies the color index to be used for the background color. By default, the normal IDL background color is used.

### BARNAMES

A string array, containing one string label per bar. If the bars are vertical, the labels are placed beneath them. If horizontal (rotated) bars are specified, the labels are placed to the left of the bars.

### BAROFFSET

A scalar that specifies the offset to be applied to the first bar, in units of “nominal bar width”. This keyword allows, for example, different groups of bars to be overplotted on the same graph. If not specified, the default offset is equal to `BARSPACE`.

## BARSPACE

A scalar that specifies, in units of “nominal bar width”, the spacing between bars. For example, if `BARSPACE` is 1.0, then all bars will have one bar-width of space between them. If not specified, the bars are spaced apart by 20% of the bar width.

## BARWIDTH

A floating-point value that specifies the width of the bars in units of “nominal bar width”. The nominal bar width is computed so that all the bars (and the space between them, set by default to 20% of the width of the bars) will fill the available space (optionally controlled with the `BASERANGE` keyword).

## BASELINES

A vector, the same size as *Values*, that contains the base value associated with each bar. If not specified, a base value of zero is used for all bars.

## BASERANGE

A floating-point scalar in the range 0.0 to 1.0, that determines the fraction of the total available plotting area (in the direction perpendicular to the bars) to be used. If not specified, the full available area is used.

## COLORS

A vector, the same size as *Values*, containing the color index to be used for each bar. If not specified, the colors are selected based on spacing the color indices as widely as possible within the range of available colors (specified by `!D.N_COLORS`).

## OUTLINE

If set, this keyword specifies that an outline should be drawn around each bar.

## OVERPLOT

If set, this keyword specifies that the bar plot should be overplotted on an existing graph.

## ROTATE

If set, this keyword indicates that horizontal rather than vertical bars should be drawn. The bases of horizontal bars are on the left, “Y” axis and the bars extend to the right.

**TITLE**

A string containing the main title for the bar plot.

**XTITLE**

A string containing the title for the X axis.

**YTITLE**

A string containing the title for the Y axis.

**Examples**

By using the overplotting capability, it is relatively easy to create stacked bar charts, or different groups of bars on the same graph.

The following example creates a two-dimensional array of 5 columns and 8 rows, and creates a plot with 5 bars, each of which is a “stacked” composite of 8 sections.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Load color table:
LOADCT, 5

;Make axes black:
!P.COLOR=0

;Create 5-column by 8-row array:
array = INDGEN(5,8)

;Create a 2D array, equal in size to array, that has identical
;color index values across each row to ensure that the same item is
;represented by the same color in all bars:
colors = INTARR(5,8)
FOR I = 0, 7 DO colors[* ,I]=(20*I)+20

;With arrays and colors defined, create stacked bars (note that
;the number of rows and columns is arbitrary):

;Scale range to accommodate the total bar lengths:
!Y.RANGE = [0, MAX(array)]
nrows = N_ELEMENTS(array[0,*])
base = INTARR(nrows)
FOR I = 0, nrows-1 DO BEGIN
    BAR_PLOT, array[* ,I], COLORS=colors[* ,I], BACKGROUND=255, $
        BASELINES=base, BARWIDTH=0.75, BARSPACE=0.25, OVER=(I GT 0)

```

```

    base = array[*,I]
  ENDFOR

```

;To plot each row of array as a clustered group of bars within the same graph, use the `BASERANGE` keyword to restrict the available plotting region for each set of bars, where `NCOLS` is the number of columns in array. (In this example, each group uses the same set of colors, but this could easily be changed.):

```

ncols = N_ELEMENTS(array[*,0])
FOR I = 0, nrows-1 DO BEGIN
  BAR_PLOT, array[*,I], COLORS=colors[*,I], BACKGROUND=255, $
    BARWIDTH=0.75, BARSPACE=0.25, BAROFFSET=I*(1.4*ncols), $
    OVER=(I GT 0), BASERANGE=0.12
ENDFOR

```

# BEGIN...END

The BEGIN...END statement defines a block of statements. A block of statements is a group of statements that is treated as a single statement. Blocks are necessary when more than one statement is the subject of a conditional or repetitive statement. For more information on using BEGIN...END and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

## Syntax

BEGIN

*statements*

END | ENDIF | ENDELSE | ENDFOR | ENDREP | ENDWHILE

The END identifier used to terminate the block should correspond to the type of statement in which BEGIN is used. The following table lists the correct END identifiers to use with each type of statement.

Statement	END Identifier	Example
ELSE BEGIN	ENDELSE	IF (0) THEN A=1 ELSE BEGIN A=2 ENDELSE
FOR <i>variable</i> = <i>init</i> , <i>limit</i> DO BEGIN	ENDFOR	FOR i=1,5 DO BEGIN PRINT, array[i] ENDFOR
IF <i>expression</i> THEN BEGIN	ENDIF	IF (0) THEN BEGIN A=1 ENDIF
REPEAT BEGIN	ENDREP	REPEAT BEGIN A = A * 2 ENDREP UNTIL A GT B
WHILE <i>expression</i> DO BEGIN	ENDWHILE	WHILE ~ EOF(1) DO BEGIN READF, 1, A, B, C ENDWHILE
<i>LABEL</i> : BEGIN	END	LABEL1: BEGIN PRINT, A END
<i>case_expression</i> : BEGIN	END	CASE name OF 'Moe': BEGIN PRINT, 'Stooge' END ENDCASE
<i>switch_expression</i> : BEGIN	END	SWITCH name OF 'Moe': BEGIN PRINT, 'Stooge' END ENDSWITCH

Table 3-1: Types of END Identifiers

**Note**

CASE and SWITCH also have their own END identifiers. CASE should always be ended with ENDCASE, and SWITCH should always be ended with ENDSWITCH.

# BESELI

The BESELI function returns the I Bessel function of order  $N$  for the argument  $X$ . The BESELI function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

## Syntax

*Result* = BESELI( $X$ ,  $N$  [, /DOUBLE] [, ITER=*variable*])

## Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $X$  and  $N$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

### Note

---

If the function does not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

---

## Arguments

### X

A scalar or array specifying the values for which the Bessel function is required. Values for  $X$  must be in the range -709 to 709.

### Note

---

If  $X$  is negative then  $N$  must be an integer (either positive or negative).

---

### N

A scalar or array specifying the order of the Bessel function to calculate. Values for  $N$  can be integers or real numbers. If  $N$  is negative then it must be an integer.

## Keywords

### DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

### ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order  $N$ . If  $X$  or  $N$  are arrays, ITER will contain a scalar representing the maximum number of iterations.

#### Note

---

If the routine did not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN, and ITER will contain the largest order that *would have converged* for that  $X$  value.

---

## Examples

The following example plots the I and K Bessel functions for orders 0, 1 and 2:

```
X = FINDGEN(40)/10

;Plot I and K Bessel Functions:
PLOT, X, BESELI(X, 0), MAX_VALUE=4, $
  TITLE = 'I and K Bessel Functions'
OPLOT, X, BESELI(X, 1)
OPLOT, X, BESELI(X, 2)
OPLOT, X, BESELK(X, 0), LINESSTYLE=2
OPLOT, X, BESELK(X, 1), LINESSTYLE=2
OPLOT, X, BESELK(X, 2), LINESSTYLE=2

;Annotate plot:
xcoords = [.18, .45, .95, 1.4, 1.8, 2.4]
ycoords = [2.1, 2.1, 2.1, 1.8, 1.6, 1.4]
labels = ['!8K!X!D0', '!8K!X!D1', '!8K!X!D2', '!8I!X!D0',
  '!8I!X!D1', '!8I!X!D2']
XYOUTS, xcoords, ycoords, labels, /DATA
```

This results in the following plot:

Figure 3-8: *I and K Bessel Functions.*

For an example calculating the accuracy of the Bessel function, see “[Example 2](#)” for the [BESELJ](#) routine.

[BESELJ](#), [BESELK](#), [BESELY](#)

# BESELJ

The BESELJ function returns the J Bessel function of order  $N$  for the argument  $X$ . The BESELJ function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

## Syntax

*Result* = BESELJ( $X$ ,  $N$  [, /DOUBLE] [, ITER=*variable*])

## Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $X$  and  $N$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

If  $X$  is double-precision, the result is double-precision, otherwise the result is single-precision.

### Note

---

If the function does not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

---

## Arguments

### X

A scalar or array specifying the values for which the Bessel function is required. Values for  $X$  must be in the range  $-10^8$  to  $10^8$ .

### Note

---

If  $X$  is negative then  $N$  must be an integer (either positive or negative).

---

### N

A scalar or array specifying the order of the Bessel function to calculate. Values for  $N$  can be integers or real numbers. If  $N$  is negative then it must be an integer.

## Keywords

### DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

### ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order  $N$ . If  $X$  or  $N$  are arrays, ITER will contain a scalar representing the maximum number of iterations.

#### Note

---

If the routine did not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN, and ITER will contain the largest order that *would have converged* for that  $X$  value.

---

## Examples

### Example 1

The following example plots the J and Y Bessel functions for orders 0, 1, and 2:

```
X = FINDGEN(100)/10

;Plot J and Y Bessel Functions:
PLOT, X, BESELJ(X, 0), TITLE = 'J and Y Bessel Functions'
OPLOT, X, BESELJ(X, 1)
OPLOT, X, BESELJ(X, 2)
OPLOT, X, BESELY(X, 0), LINESSTYLE=2
OPLOT, X, BESELY(X, 1), LINESSTYLE=2
OPLOT, X, BESELY(X, 2), LINESSTYLE=2

;Annotate plot:
xcoords = [1, 1.66, 3, .7, 1.7, 2.65]
ycoords = [.8, .62, .52, -.42, -.42, -.42]
labels = ['!8J!X!D0', '!8J!X!D1', '!8J!X!D2', '!8Y!X!D0',
          '!8Y!X!D1', '!8Y!X!D2']
XYOUTS, xcoords, ycoords, labels, /DATA
```

This results in the following plot:

Figure 3-9: The J and Y Bessel Functions.

## Example 2

Different order Bessel functions have *recurrence relationships* to each other. These relationships can be used to determine how accurately IDL is computing the Bessel functions. In the following example, the recurrence relationships for each order are set to zero and the left side of the equations are plotted. The plots show how close the left side of the equations are to zero, and therefore, how accurate IDL's computation of the Bessel functions are.

This example uses the following recurrence relationship:

$$x(J_{n-1}(x) + J_{n+1}(x)) - 2nJ_n(x) = 0$$

where  $J(x)$  is the Bessel function of the first kind of order  $n-1$ ,  $n$ , or  $n+1$ . (Similar recurrence relationships could be used for the other forms of the Bessel function.) Results are plotted for  $n$  equal to 1 through 6.

```

[BESELI](#), [BESELK](#), [BESELY](#)

# BESELK

The BESELK function returns the  $K$  Bessel function of order  $N$  for the argument  $X$ . The BESELK function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

## Syntax

*Result* = BESELK(  $X$ ,  $N$  [, /DOUBLE] [, ITER=*variable*])

## Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $X$  and  $N$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

If  $X$  is double-precision, the result is double-precision, otherwise the result is single-precision.

### Note

---

If the function does not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

---

## Arguments

### X

A scalar or array specifying the values for which the Bessel function is required. Values for  $X$  must be greater than or equal to zero.

### N

A scalar or array specifying the order of the Bessel function to calculate. Values for  $N$  can be integers or real numbers. If  $N$  is negative then it must be an integer.

## Keywords

### DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

### ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order  $N$ . If  $X$  or  $N$  are arrays, ITER will contain a scalar representing the maximum number of iterations.

#### Note

---

If the routine did not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN, and ITER will contain the largest order that *would have converged* for that  $X$  value.

---

## Examples

The following example plots the I and K Bessel functions for orders 0, 1 and 2:

```
X = FINDGEN(40)/10

;Plot I and K Bessel Functions:
PLOT, X, BESELI(X, 0), MAX_VALUE=4, $
  TITLE = 'I and K Bessel Functions'
OPLOT, X, BESELI(X, 1)
OPLOT, X, BESELI(X, 2)
OPLOT, X, BESELK(X, 0), LINESSTYLE=2
OPLOT, X, BESELK(X, 1), LINESSTYLE=2
OPLOT, X, BESELK(X, 2), LINESSTYLE=2

;Annotate plot:
xcoords = [.18, .45, .95, 1.4, 1.8, 2.4]
ycoords = [2.1, 2.1, 2.1, 1.8, 1.6, 1.4]
labels = ['!8K!X!D0', '!8K!X!D1', '!8K!X!D2', '!8I!X!D0',
  '!8I!X!D1', '!8I!X!D2']
XYOUTS, xcoords, ycoords, labels, /DATA
```

This results in the following plot:

Figure 3-11: *I and K Bessel Functions.*

## See Also

[BESELI](#), [BESELJ](#), [BESELY](#)

# BESELY

The BESELY function returns the Y Bessel function of order  $N$  for the argument  $X$ . The BESELY function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

## Syntax

*Result* = BESELY( $X$ ,  $N$  [, /DOUBLE] [, ITER=*variable*])

## Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $X$  and  $N$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

If  $X$  is double-precision, the result is double-precision, otherwise the result is single-precision.

### Note

---

If the function does not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

---

## Arguments

### X

A scalar or array specifying the values for which the Bessel function is required. Values for  $X$  must be in the range 0 to  $10^8$ .

### N

A scalar or array specifying the order of the Bessel function to calculate. Values for  $N$  can be integers or real numbers. If  $N$  is negative then it must be an integer.

## Keywords

### DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

### ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order  $N$ . If  $X$  or  $N$  are arrays, ITER will contain a scalar representing the maximum number of iterations.

#### Note

---

If the routine did not converge for an element of  $X$ , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN, and ITER will contain the largest order that *would have converged* for that  $X$  value.

---

## Examples

The following example plots the J and Y Bessel functions for orders 0, 1, and 2:

```
X = FINDGEN(100)/10

;Plot J and Y Bessel Functions:
PLOT, X, BESELJ(X, 0), TITLE = 'J and Y Bessel Functions'
OPLOT, X, BESELJ(X, 1)
OPLOT, X, BESELJ(X, 2)
OPLOT, X, BESELY(X, 0), LINESSTYLE=2
OPLOT, X, BESELY(X, 1), LINESSTYLE=2
OPLOT, X, BESELY(X, 2), LINESSTYLE=2

;Annotate plot:
xcoords = [1, 1.66, 3, .7, 1.7, 2.65]
ycoords = [.8, .62, .52, -.42, -.42, -.42]
labels = ['!8J!X!D0', '!8J!X!D1', '!8J!X!D2', '!8Y!X!D0',
         '!8Y!X!D1', '!8Y!X!D2']
XYOUTS, xcoords, ycoords, labels, /DATA
```

This results in the following plot:

Figure 3-12: The J and Y Bessel Functions.

For an example calculating the accuracy of the Bessel function, see “[Example 2](#)” for the [BESELJ](#) routine.

## Version History

# BETA

The BETA function returns the value of the beta function  $B(Z, W)$ . This routine is written in the IDL language. Its source code can be found in the file `beta.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = BETA( Z, W [, /DOUBLE] )
```

## Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $Z$  and  $W$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If both of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### Z, W

The point at which the beta function is to be evaluated.  $Z$  and  $W$  can be scalar or array.  $Z$  or  $W$  may be complex.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established

by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

To evaluate the beta function at the point (1.0, 1.1) and print the result:

```
PRINT, BETA(1.0, 1.1)
```

IDL prints:

```
0.909091
```

The exact solution is:

$$((1.00 * .95135077) / (1.10 * .95135077)) = 0.909091.$$

## Version History

4.0.1	Introduced
5.6	Added Z and W arguments to accept complex input

# BILINEAR

The BILINEAR function uses a bilinear interpolation algorithm to compute the value of a data array at each of a set of subscript values.

This routine is written in the IDL language. Its source code can be found in the file `bilinear.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = BILINEAR(*P*, *IX*, *JY* [, MISSING=*value*] )

## Return Value

This function returns a two-dimensional interpolated array of the same type as the input array.

## Arguments

### P

A two-dimensional data array.

### IX and JY

Arrays containing the X and Y “virtual subscripts” of *P* for which to interpolate values. *IX* and *JY* can be either of the following:

- One-dimensional, *n*-element floating-point arrays of subscripts to look up in *P*. One-dimensional arrays will be converted to two-dimensional arrays in such a way that *IX* contains *n* identical rows and *JY* contains *n* identical columns.
- Two-dimensional, *n*-element floating-point arrays that uniquely specify the X subscripts (the *IX* array) and the Y subscripts (the *JY* array) of the points to be computed from the input array *P*.

In either case, *IX* must satisfy the expressions

$$0 \leq \text{MIN}(\text{IX}) < \text{N0} \quad \text{and} \quad 0 < \text{MAX}(\text{IX}) \leq \text{N0}$$

where *N0* is the total number of columns in the array *P*.

*JY* must satisfy the expressions

$$0 \leq \text{MIN}(JY) < M0 \quad \text{and} \quad 0 < \text{MAX}(JY) \leq M0$$

where *M0* is the total number of rows in the array *P*.

It is better to use two-dimensional arrays for *IX* and *JY* because the algorithm is somewhat faster. If *IX* and *JY* are specified as one-dimensional, the returned two-dimensional arrays *IX* and *JY* can be re-used on subsequent calls to take advantage of the faster 2D algorithm.

## Keywords

### MISSING

The value to return for elements outside the bounds of *P*. If this keyword is not specified, interpolated positions that fall outside the bounds of the array *P* - that is, elements of the *IX* or *JY* arguments that are either less than zero or greater than the largest subscript in the corresponding dimension of *P* - are set equal to the value of the nearest element of *P*.

#### Note

---

If MISSING value is set to a complex number, IDL uses only the real part.

---

## Examples

Create a 3 x 3 floating point array *P*:

```
P = FINDGEN(3,3)
```

Suppose we wish to find the value of a point half way between the first and second elements of the first row of *P*. Create the subscript arrays *IX* and *JY*:

```
IX = 0.5 ;Define the X subscript.
JY = 0.0 ;Define the Y subscript.
Z = BILINEAR(P, IX, JY) ;Interpolate.
PRINT, Z ;Print the value at the point IX,JY within P.
```

IDL prints:

```
0.500000
```

Suppose we wish to find the values of a 2 x 2 array of points in *P*. Create the subscript arrays *IX* and *JY*:

```
IX = [[0.5, 1.9], [1.1, 2.2]] ;Define the X subscripts.
JY = [[0.1, 0.9], [1.2, 1.8]] ;Define the Y subscripts.
Z = BILINEAR(P, IX, JY) ;Interpolate.
```

```
PRINT, Z ;Print the array of values.
```

IDL prints:

```
0.800000    4.60000  
4.70000    7.40000
```

## Version History

# BIN\_DATE

The BIN\_DATE function converts a standard form ASCII date/time string to a binary string.

This routine is written in the IDL language. Its source code can be found in the file `bin_date.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = BIN\_DATE(*Ascii\_Time*)

## Return Value

The function returns a six-element integer array where:

- Element 0 is the year (e.g., 1994)
- Element 1 is the month (1-12)
- Element 2 is the day (1-31)
- Element 3 is the hour (0-23)
- Element 4 is minutes (0-59)
- Element 5 is seconds (0-59)

## Arguments

### Ascii\_Time

A string containing the date/time to convert in standard ASCII format. If this argument is omitted, the current date/time is used. Standard form is a 24 character string:

DOW MON DD HH:MM:SS YYYY

where DOW is the day of the week, MON is the month, DD is the day of month, HH:MM:SS is the time in hours, minutes, second, and YYYY is the year.

## Keywords

# BINARY\_TEMPLATE

The `BINARY_TEMPLATE` function presents a graphical user interface which allows the user to interactively generate a template structure for use with `READ_BINARY`.

The graphical user interface allows the user to define one or more fields in the binary file. The file may be big, little, or native byte ordering.

Individual fields can be edited by the user to define the dimensionality and type of data to be read. Where necessary, fields can be defined in terms of other previously defined fields using IDL expressions. Fields can also be designated as “Verify”. When a file is read using a template with “Verify” fields, those fields will be checked against a user defined value supplied via the template.

---

## Note

Greater than (“>”) and less than (“<”) symbols can appear in the “New Field” and the “Modify Field” dialogs where the offset value is displayed. The presence of either symbol indicates that the supplied offset value is “relative” from the end of the previous field or from the initial position in the file. Greater than means offset forward. Less than means offset backward. “>0” and “<0” are synonymous and mean “offset zero bytes”. You can delete these special symbols (thereby indicating that their corresponding offset value is not “relative”) by typing over them in the “New Field” or “Modify Field” dialogs.

---

## Syntax

```
Result = BINARY_TEMPLATE ( [Filename] [, CANCEL=variable]
    [, GROUP=widget_id] [, N_ROWS=rows] [, TEMPLATE=variable] )
```

## Return Value

This function returns an anonymous structure that contains the template. If the user cancels out of the graphical user interface and no initial template was supplied, it returns zero.

## Arguments

### Filename

A scalar string containing the name of a binary file which may be used to test the template. As the user interacts with the `BINARY_TEMPLATE` graphical user interface, the user's input will be tested for correctness against the binary data in the file. If *filename* is not specified, a dialog allows the user to choose the file.

## Keywords

### CANCEL

Set this keyword to a named variable that will contain the byte value 1 if the user clicked the “Cancel” button, or 0 otherwise.

### GROUP

The widget ID of an existing widget that serves as “group leader” for the `BINARY_TEMPLATE` interface. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

### N\_ROWS

Set this keyword to the number of rows to be visible in the `BINARY_TEMPLATE`'s table of fields.

#### Note

---

The `N_ROWS` keyword is analogous to the `WIDGET_TABLE` and the `Y_SCROLL_SIZE` keywords.

---

### TEMPLATE

Set this keyword to structure variable containing an initial template (usually from a previous call to `BINARY_TEMPLATE`). This template structure will be used to fill in the initial fields in the new `BINARY_TEMPLATE`. If `TEMPLATE` is specified and the user cancels out of the dialog, the specified template will be returned as the Result.

## Examples

Use the following command to launch the Binary Template dialog so that a structure can be defined for the file, `head.dat`:

```
sTemplate = BINARY_TEMPLATE(FILEPATH('head.dat', $
    SUBDIRECTORY=['examples', 'data']))
```

---

### Note

If no filename is supplied in the call to the `BINARY_TEMPLATE` function, a file selection dialog is displayed prior to the first `BINARY_TEMPLATE` screen.

---

## Using the `BINARY_TEMPLATE` Interface

A binary template describes the format of the data in a binary file, and can be used to successfully import binary data from any file that shares that structure. The **Binary Template** dialog allows you to specify characteristics of each field within a binary file, and returns a structure containing the template information. The `READ_BINARY` function accesses the data in a binary file, using the template to determine how to import the data correctly. (You only have to explicitly call `READ_BINARY` when you call `BINARY_TEMPLATE` from the command line. When you start the **Binary Template** dialog from an iTool or the IDLDE, the `READ_BINARY` routine is called for you.)

After starting the **Binary Template** dialog using one of the methods described in “[Launching the Binary Template Dialog](#)” in Chapter 6 of the *Using IDL* manual, complete the following steps to create the template:

1. **Select the binary file.** In the **Select File to Open** dialog, select `surface.dat` from the `examples\data` subdirectory of your IDL distribution. This file contains an integer array of elevation data of the Maroon Bells mountains, a group of mountains located among the Rocky Mountains of Colorado. The **Binary Template** window is displayed.
2. **Define template and data characteristics.** Define the following in this example before defining field information:
  - **Template Name** of `sMarBellsTemplate`
  - **File’s byte ordering** is set to **Little Endian**

The following table describes each of these options.

<b>Template name</b>	Enter a name that describes the template. This field is optional.
<b>File's byte ordering</b>	<p>Select the byte order of the data:</p> <p><b>Native</b> — the storage method is native to the machine you are currently running. Little Endian for Intel microprocessor-based machines and Big Endian for Motorola microprocessor-based machines. No byte swapping will be performed.</p> <p><b>Little Endian</b> — the storage method where the least significant byte appears first in the number. Given the hexadecimal number A02B, the Little Endian method stores it as 2BA0. Specify this if the original file was created on a machine that uses an Intel microprocessor.</p> <p><b>Big Endian</b> — the storage method where the most significant byte appears first in the number. Given the hexadecimal number A02B, the big endian method stores it as A02B. Specify this if the original file was created on a machine that uses a Motorola microprocessor.</p> <p>See “Files and I/O” in Chapter 9 of the <i>Building IDL Applications</i> manual for more information on byte ordering.</p>

Figure 3-13: Binary Template

3. **Open the New Field dialog.** Fields are read in the order in which they are listed in the main dialog for `BINARY_TEMPLATE`, with offsets being added to the current file position pointer before each field is read. Click **New Field...** to enter the description of a new field.

**Note**

If a field has already been defined, clicking in the **Return** column will toggle the value of the field between Yes and No. Fields that are not marked for return can be used for calculations by other fields in the template. At least one field must be marked Yes for return in order for the `BINARY_TEMPLATE` function to return a template.

4. **Define characteristics of the field.** Use the **New Field** dialog to define the data type and dimensions of the field as well as any offsets. In this example, configure the following:
  - **Field name** is `marbells`
  - **Type** is **Integer**
  - **Offset** is 0 **From beginning of file**
  - Field is **Returned in the result** when read

- **Number of dimensions** value is 2, and are defined as 350 and 450 respectively

The following table describes the **New Field** dialog options:

<b>Field name</b>	Enter a name that describes the data field.
<b>Type</b>	Select the data type of the field from a droplist that offers the following IDL types: byte, integer, long, float, double, complex, dcomplex, uint, ulong, long64 and ulong64. Strings are read as an array of bytes for later conversion to type STRING.
<b>Offset</b>	<p>Specify the data offset using integer values, field names, or any valid IDL expression.</p> <p><b>Absolute integer</b> — defines a fixed location (in bytes) from the beginning of the file or the initial file position for an externally opened file.</p> <p><b>Relative integer</b> — uses a preceding &gt; or &lt; character, to indicate a positive (&gt;) or negative (&lt;) byte offset relative to the current file position pointer after the previous field (if any) is read.</p> <p><b>Expression</b> — can include the names of fields that will be read <i>before</i> the current field — that is, the field number of the referenced field must be lower than the field number of the field being defined.</p> <p><b>From beginning of file</b> — read from the beginning of the file plus any offset.</p> <p><b>From initial position in file/From end of previous file</b> — read from the beginning of the file or from the end of the previous field plus any offset.</p>

<p><b>When file is read...</b></p>	<p><b>Returned in the result</b> — select this to return the field when the file is read</p> <p><b>Verified as being equal to</b> — select this and define the condition. The <b>Verify</b> field can contain an integer, field name, or any valid IDL expression. Only scalar fields can be verified. READ_BINARY reports an error if a verification fails.</p>
<p><b>Number of dimensions</b></p>	<p>Select the number of dimensions of the field ranging from 0 (scalar) to 8 (which is the maximum number of dimensions that an IDL variable can have.) The <b>Size</b> of each dimension can be an integer, field name, or any valid IDL expression. Select <b>Reverse</b> to read any of the first three dimensions of array data in reversed order.</p>

---

**Note**

If BINARY\_TEMPLATE is called by a program that is running in the IDL Virtual Machine, the **Offsets**, **Verify**, and **Size** fields can contain integers or field names, but *not* an IDL expression.

---

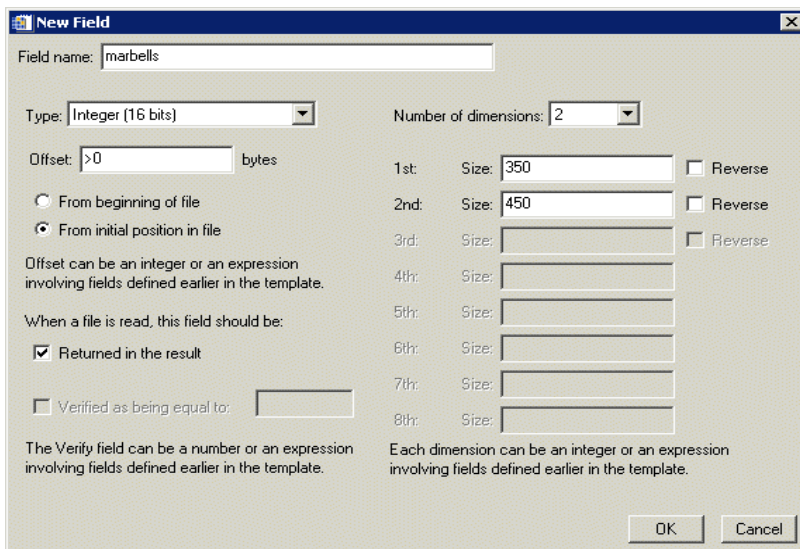

Figure 3-14: Binary Template - New Field

5. **Create the template.** Click **OK** to create the new field definition. This file contains a single field so click **OK** on the **Binary Template** dialog to create the template. If needed, you could click **New Field** to define additional data fields.

The `BINARY_TEMPLATE` function returns a structure variable containing the template. The result of the previous actions depends on the location from which you launched the **Binary Template** dialog. The `READ_BINARY` function, which reads data from a file according to the template specification, is automatically called when you access the **Binary Template** dialog from *iTools* or from the **Import Binary** macro. From the command line, you must explicitly read the binary data with the template specification.

After defining the structure of your binary data using the **Binary Template** dialog, refer to the appropriate section:

- ***iTools* binary data access** — the binary data is read and placed in the Data Manager. If it is not automatically displayed, use the **Insert Visualization** dialog to display fields of the data. See “[Inserting Visualizations](#)” in Chapter 3 of the *iTool User’s Guide* manual for details.

- **Import Binary macro data access** — the binary data is placed in a structure. You can access fields of the data using a *variable\_name.element\_name* syntax. See “[Using Macros to Import Binary Files](#)” in Chapter 6 of the *Using IDL* manual.
- **Command line binary data access** — the template is a structure defining the format of the binary data. Access the data using READ\_BINARY, and specify the template (or other characteristics) as parameters of the data access operation. See “[Working with a READ\\_ASCII Data Structure](#)” on page 1879 for details.

---

### Note

You can create a SAVE file of a template in order to use it from session to session. See “[Example: Create a SAVE File of a Custom ASCII Template](#)” on page 114 for a related example.

# BINDGEN

The BINDGEN function creates a byte array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$Result = \text{BINDGEN}(D_1 [, \dots, D_8])$$

## Return Value

This function returns a byte array with the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments or array elements are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create a four-element by four-element byte array, and store the result in the variable A, enter:

```
A = BINDGEN(4,4)
```

Each element in A holds the value of its one-dimensional subscript. That is, if you enter the command:

```
PRINT, A
```

IDL prints the result:

```
0  1  2  3
4  5  6  7
8  9 10 11
12 13 14 15
```

## Version History

# BINOMIAL

The BINOMIAL function computes the probability that in a cumulative binomial (Bernoulli) distribution, a random variable  $X$  is greater than or equal to a user-specified value  $V$ , given  $N$  independent performances and a probability of occurrence or success  $P$  in a single performance:

$$\text{Probability}(X \geq V) = \sum_{x=V}^N \frac{N!}{x!(N-x)!} P^x (1-P)^{(N-x)}$$

This routine is written in the IDL language. Its source code can be found in the file `binomial.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = BINOMIAL(*V*, *N*, *P* [, /DOUBLE] [, /GAUSSIAN] )

## Return Value

This function returns a single- or double-precision floating point scalar or array that contains the value of the probability.

## Arguments

### V

A non-negative integer specifying the minimum number of times the event occurs in  $N$  independent performances.

### N

A non-negative integer specifying the number of performances.

### P

A non-negative single- or double-precision floating-point scalar or array, in the interval  $[0.0, 1.0]$ , that specifies the probability of occurrence or success of a single independent performance.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### GAUSSIAN

Set this keyword to use the Gaussian approximation, by using the normalized variable  $Z = (V - NP)/\text{SQRT}(NP(1 - P))$ .

#### Note

---

The Gaussian approximation is useful when  $N$  is large and neither  $P$  nor  $(1-P)$  is close to zero, where the binomial summation may overflow. If GAUSSIAN is not explicitly set, and the binomial summation overflows, then BINOMIAL will automatically switch to using the Gaussian approximation.

---

## Examples

Compute the probability of obtaining at least two 6s in rolling a die four times. The result should be 0.131944.

```
result = BINOMIAL(2, 4, 1.0/6.0)
```

Compute the probability of obtaining exactly two 6s in rolling a die four times. The result should be 0.115741.

```
result = BINOMIAL(2, 4, 1./6.) - BINOMIAL(3, 4, 1./6.)
```

Compute the probability of obtaining three or fewer 6s in rolling a die four times. The result should be 0.999228.

```
result = BINOMIAL(0, 4, 1./6.) - BINOMIAL(4, 4, 1./6.)
```

# BIT\_FFS

The BIT\_FFS function returns the index of the first bit set (non-zero) in its integer argument.

## Syntax

*Result* = BIT\_FFS( *Value* )

## Return Value

BIT\_FFS returns the index of the first bit set in *Value*. Bits are numbered starting at one (the least significant bit). Zero (0) is returned if *Value* has no bits set. If *Value* is an array, the result is an array with the same structure, where each element contains the index of the first bit set in the corresponding element of *Value*.

## Arguments

### Value

A scalar or array of any integer type.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Example

Binary integer arithmetic has the property that any integer value with a single bit set is a power of 2. For example, the value 1024 is equivalent to  $2^{10}$ . The following

statement uses `BIT_FFS` to determine the power to which 2 must be raised to yield 1024:

```
p = BIT_FFS(1024) - 1
PRINT, FORMAT='(%"2^%d = %d")', p, 2^p
```

IDL prints:

```
2^10 = 1024
```

# BIT\_POPULATION

The BIT\_POPULATION function returns the number of set (non-zero) bits in its integer argument.

## Syntax

*Result* = BIT\_POPULATION( *Value* )

## Return Value

BIT\_POPULATION returns the number of set (non-zero) bits in *Value*. If *Value* is an array, the result is an array with the same structure, where each element contains the count of non-zero bits in the corresponding element of *Value*.

## Arguments

### Value

A scalar or array of any integer type.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Example

The following statement displays the number of bits in an IDL long integer:

```
PRINT, BIT_POPULATION('ffffffff'x1)
```

IDL prints:

```
32
```

## Version History

# BLAS\_AXPY

The `BLAS_AXPY` procedure updates an existing array by adding a multiple of another array. It can also be used to update one or more one-dimensional subvectors of an array according to the following vector operation:

$$Y = aX + Y$$

where  $a$  is a scale factor and  $X$  is an input vector.

`BLAS_AXPY` can be faster and use less memory than the usual IDL array notation (e.g. `Y=Y+A*X`) for updating existing arrays.

---

**Note**

`BLAS_AXPY` is much faster when operating on entire arrays and rows, than when used on columns or higher dimensions.

---

## Syntax

```
BLAS_AXPY, Y, A, X [, D1, Loc1 [, D2, Range]]
```

## Arguments

### Y

The array to be updated.  $Y$  can be of any numeric type. `BLAS_AXPY` does not change the size and type of  $Y$ .

### A

The scaling factor to be multiplied with  $X$ .  $A$  may be any scalar or one-element array that IDL can convert to the type of  $X$ . `BLAS_AXPY` does not change  $A$ .

### X

The array to be scaled and added to array  $Y$ , or the vector to be scaled and added to subvectors of  $Y$ .

### D1

An optional parameter indicating which dimension of  $Y$  is to be updated.

## Loc1

A variable with the same number of elements as the number of dimensions of *Y*. The *Loc1* and *D1* arguments together determine which one-dimensional subvector (or subvectors, if *D1* and *Range* are provided) of *Y* is to be updated.

## D2

An optional parameter, indicating in which dimension of *Y* a group of one-dimensional subvectors are to be updated. *D2* should be different from *D1*.

## Range

A variable containing *D2* indices indicating where to put one-dimensional updates of *Y*.

## Keywords

None

## Examples

The following examples show how to use the `BLAS_AXPY` procedure to add a multiple of an array, add a constant, and a group of subvectors.

```
seed = 5L
```

Create a multidimensional array:

```
A = FINDGEN(4, 5, 2)
```

Print A:

```
PRINT, A
```

IDL prints:

```
0.000000    1.00000    2.00000    3.00000
 4.00000    5.00000    6.00000    7.00000
 8.00000    9.00000   10.0000    11.0000
12.0000    13.0000    14.0000    15.0000
16.0000    17.0000    18.0000    19.0000

20.0000    21.0000    22.0000    23.0000
24.0000    25.0000    26.0000    27.0000
28.0000    29.0000    30.0000    31.0000
32.0000    33.0000    34.0000    35.0000
36.0000    37.0000    38.0000    39.0000
```

Create a random update:

```
B = RANDOMU(seed, 4, 5, 2)
```

Print B

```
PRINT, B
```

IDL prints:

```

0.172861    0.680409    0.917078    0.917510
0.766779    0.648501    0.334211    0.505953
0.652182    0.158174    0.912751    0.257593
0.810990    0.267308    0.188872    0.237323
0.312265    0.551604    0.944883    0.673464

0.613302    0.0874299    0.782052    0.374534
0.0799968   0.581460    0.433864    0.459824

40.1994    38.7490    39.2132    42.5835

```

Add a constant to a subvector of A (i.e.  $A[* , 3, 1] = A[* , 3, 1] + 4.3$ ):

```
BLAS_AXPY, A, 1., REPLICATE(4.3, 4), 1, [0, 3, 1]
```

Print A:

```
PRINT, A
```

IDL prints:

```

0.777872    4.06184    6.12685    7.12880

```

```

7.45051      7.91825      7.50395      9.27679
10.9348      9.71178      14.1074      12.1592
15.6495      14.2029      14.8499      16.0680
17.4052      19.4822      22.2520      22.0306

22.7599      21.3934      25.5192      24.6854
24.3600      27.6166      27.9524      29.0692
30.8559      29.8193      33.7461      32.0584
38.2466      39.3415      41.6247      40.9009
40.1994      38.7490      39.2132      42.5835

```

Create a vector update and print:

```

C = FINDGEN(5)
PRINT, C

```

IDL prints:

```

0.000000      1.00000      2.00000      3.00000      4.00000

```

Add C to a group of subvectors of A (i.e. FOR i = 0, 1 DO A[1, \*, i] = A[1, \*, i] + C) and print:

```

BLAS_AXPY, A, 1., C, 2, [1, 0, 0], 3, LINDGEN(2)
PRINT, A

```

IDL prints:

```

0.777872      4.06184      6.12685      7.12880
7.45051      8.91825      7.50395      9.27679

[REPLICATE\\_INPLACE](#)

# BLK\_CON

The `BLK_CON` function computes a “fast convolution” of a digital signal and an impulse-response sequence. It returns the filtered signal.

This routine is written in the IDL language. Its source code can be found in the file `blk_con.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = BLK_CON( Filter, Signal [, B_LENGTH=scalar] [, /DOUBLE] )
```

## Return Value

This function returns a vector with the same length as *Signal*. If either of the input arguments are double-precision or the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### Filter

A  $P$ -element floating-point vector containing the impulse-response sequence of the digital filter.

### Signal

An  $n$ -element floating-point vector containing the discrete signal samples.

## Keywords

### B\_LENGTH

A scalar specifying the *block length* of the subdivided signal segments. If this parameter is not specified, a near-optimal value is chosen by the algorithm based upon the length  $P$  of the impulse-response sequence. If  $P$  is a value less than 11 or greater than 377, then `B_LENGTH` must be specified.

`B_LENGTH` must be greater than the filter length,  $P$ , and less than the number of signal samples.

## DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

### Examples

```
; Create a filter of length P = 32:
filter = REPLICATE(1.0,32) ;Set all points to 1.0
filter(2*INDGEN(16)) = 0.5 ;Set even points to 0.5

; Create a sampled signal with random noise:
signal = SIN((FINDGEN(1000)/35.0)^2.5)
noise = (RANDOMU(SEED,1000) - .5)/2.
signal = signal + noise

; Convolve the filter and signal using block convolution:
result = BLK_CON(filter, signal)
```

[CONVOL](#)

# BOX\_CURSOR

The BOX\_CURSOR procedure emulates the operation of a variable-sized box cursor (also known as a “marquee” selector).

## Warning

---

BOX\_CURSOR does not function properly when used within a draw widget. See the BUTTON\_EVENTS and MOTION\_EVENTS keywords in [WIDGET\\_DRAW](#).

---

This routine is written in the IDL language. Its source code can be found in the file `box_cursor.pro` in the `lib` subdirectory of the IDL distribution.

## Using BOX\_CURSOR

Once the box cursor has been realized, hold down the left mouse button to move the box by dragging. Hold down the middle mouse button to resize the box by dragging. (The corner nearest the initial mouse position is moved.) Press the right mouse button to exit the procedure and return the current box parameters.

On machines with only two mouse buttons, hold down the left and right buttons simultaneously to resize the box.

## Syntax

```
BOX_CURSOR, [ X0, Y0, NX, NY [, /INIT] [, /FIXED_SIZE]] [, /MESSAGE]
```

## Arguments

### X0, Y0

Named variables that will contain the coordinates of the lower left corner of the box cursor.

### NX, NY

Named variables that will contain the width and height of the cursor, in pixels.

## Keywords

### INIT

If this keyword is set, the arguments *X0*, *Y0*, *NX*, and *NY* contain the initial position and size of the box.

### FIXED\_SIZE

If this keyword is set, *NX* and *NY* contain the initial size of the box. This size may not be changed by the user.

### MESSAGE

If this keyword is set, IDL prints a message describing operation of the cursor.

# BREAK

The BREAK statement provides a convenient way to immediately exit from a loop (FOR, WHILE, REPEAT), CASE, or SWITCH statement without resorting to GOTO statements.

---

**Note**

BREAK is an IDL statement. For information on using statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

---

## Syntax

BREAK

## Examples

This example exits the enclosing WHILE loop when the value of i hits 5.

```
I = 0
WHILE (1) DO BEGIN
    i = i + 1
    IF (i eq 5) THEN BREAK
ENDWHILE
```

## Version History

---

5.4	Introduced

---

# BREAKPOINT

The BREAKPOINT procedure allows you to insert and remove breakpoints in programs for debugging. A breakpoint causes program execution to stop after the designated statement is executed. Breakpoints are specified using the source file name and line number. For multiple-line statements (statements containing “\$”, the continuation character), specify the line number of the last line of the statement.

You can insert breakpoints in programs without editing the source file. Enter the following :

```
HELP, /BREAKPOINT
```

to display the breakpoint table which gives the index, module and source file locations of each breakpoint.

## Syntax

```
BREAKPOINT [, File], Index [, AFTER=integer] [, /CLEAR]
  [, /CONDITION='expression'] [, /DISABLE] [, /ENABLE]
  [, /ON_RECOMPILE] [, /ONCE] [, /SET]
```

## Arguments

### File

An optional string argument that contains the name of the source file. Note that if *File* is not in the current directory, the full path name must be specified even if *File* is in one of the directories specified by !PATH.

### Index

The line number at which to clear or set a breakpoint.

## Keywords

### AFTER

Set this keyword equal to an integer *n*. Execution will stop only after the *n*th time the breakpoint is hit. For example:

```
BREAKPOINT, /SET, 'test.pro', 8, AFTER=3
```

This sets a breakpoint at the eighth line of the file `test.pro`, but only stops execution after the breakpoint has been encountered three times.

## CLEAR

Set this keyword to remove a breakpoint. The breakpoint to be removed is specified either by index, or by the source file and line number. Use command `HELP, /BREAKPOINT` to display the indices of existing breakpoints. For example:

```
; Clear breakpoint with an index of 3:
BREAKPOINT, /CLEAR, 3

; Clear the breakpoint corresponding to the statement in the file
; test.pro, line number 8:
BREAKPOINT, /CLEAR, 'test.pro',8
```

## CONDITION

Set this keyword to a string containing an IDL expression. When a breakpoint is encountered, the expression is evaluated. If the expression is true (if it returns a non-zero value), program execution is interrupted. The expression is evaluated in the context of the program containing the breakpoint. For example:

```
BREAKPOINT, 'myfile.pro', 6, CONDITION='i gt 2'
```

If `i` is greater than 2 at line 6 of `myfile.pro`, the program is interrupted.

## DISABLE

Set this keyword to disable the specified breakpoint, if it exists. The breakpoint can be specified using the breakpoint index or file and line number:

```
; Disable breakpoint with an index of 3:
BREAKPOINT, /DISABLE, 3

; Disable the breakpoint corresponding to the statement in the file
; test.pro, line number 8:
BREAKPOINT, /DISABLE, 'test.pro',8
```

## ENABLE

Set this keyword to enable the specified breakpoint if it exists. The breakpoint can be specified using the breakpoint index or file and line number:

```
; Enable breakpoint with an index of 3:
BREAKPOINT, /ENABLE, 3

; Enable the breakpoint at line 8 of the file test.pro
BREAKPOINT, /ENABLE, 'test.pro',8
```

## ON\_RECOMPILE

Set this keyword to specify that the breakpoint will not take effect until the next time the file containing it is compiled.

## ONCE

Set this keyword to make the breakpoint temporary. If ONCE is set, the breakpoint is cleared as soon as it is hit. For example:

```
BREAKPOINT, /SET, 'file.pro', 12, AFTER=3, /ONCE
```

sets a breakpoint at line 12 of `file.pro`. Execution stops when line 12 is encountered the third time, and the breakpoint is automatically cleared.

## SET

Set this keyword to set a breakpoint at the designated source file line. If this keyword is set, the first input parameter, *File* must be a string expression that contains the name of the source file. The second input parameter must be an integer that represents the source line number.

For example, to set a breakpoint at line 23 in the source file `xyz.pro`, enter:

```
BREAKPOINT, /SET, 'xyz.pro', 23
```

## Version History

Pre 4.0	Introduced
---------	------------

# BROYDEN

The BROYDEN function solves a system of  $n$  nonlinear equations (where  $n \geq 2$ ) in  $n$  dimensions using a globally-convergent Broyden's method.

BROYDEN is based on the routine `broyn` described in section 9.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = BROYDEN( X, Vecfunc [, CHECK=variable] [, /DOUBLE] [, EPS=value]
  [, ITMAX=value] [, STEPMAX=value] [, TOLF=value] [, TOLMIN=value]
  [, TOLX=value] )
```

## Return Value

This function returns an  $n$ -element vector containing the solution.

## Arguments

### X

An  $n$ -element vector (where  $n \geq 2$ ) containing an initial guess at the solution of the system.

### Note

---

If BROYDEN is complex then only the real part is used for the computation.

---

### Vecfunc

A scalar string specifying the name of a user-supplied IDL function that defines the system of non-linear equations. This function must accept a vector argument  $X$  and return a vector result.

For example, suppose we wish to solve the following system:

$$\begin{bmatrix} 3x - \cos(yz) - 1/2 \\ x^2 - 81(y + 0.1)^2 + \sin(z) + 1.06 \\ e^{-xy} + 20z + \frac{10\pi - 3}{3} \end{bmatrix} = 0$$

To represent this system, we define an IDL function named BROYFUNC:

```
FUNCTION broyfunc, X
  RETURN, [3.0 * X[0] - COS(X[1]*X[2]) - 0.5,$
    X[0]^2 - 81.0*(X[1] + 0.1)^2 + SIN(X[2]) + 1.06,$
    EXP(-X[0]*X[1]) + 20.0 * X[2] + (10.0*!PI - 3.0)/3.0]
END
```

## Keywords

### CHECK

BROYDEN calls an internal function named `fmin()` to determine whether the routine has converged to a local rather than a global minimum (see *Numerical Recipes*, section 9.7). Use the CHECK keyword to specify a named variable which will be set to 1 if the routine has converged to a local minimum or to 0 if not. If the routine does converge to a local minimum, try restarting from a different initial guess to obtain the global minimum.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### EPS

Set this keyword to a number close to machine accuracy, used to remove noise from each iteration. The default is  $10^{-7}$  for single precision, and  $10^{-14}$  for double precision.

### ITMAX

Use this keyword to specify the maximum allowed number of iterations. The default is 200.

## STEPMAX

Use this keyword to specify the scaled maximum step length allowed in line searches. The default value is 100.0.

## TOLF

Set the convergence criterion on the function values. The default value is  $1.0 \times 10^{-4}$ .

## TOLMIN

Set the criterion for deciding whether spurious convergence to a minimum of the function `fmin()` has occurred. The default value is  $1.0 \times 10^{-6}$ .

## TOLX

Set the convergence criterion on  $X$ . The default value is  $1.0 \times 10^{-7}$ .

## Examples

We can use `BROYDEN` to solve the non-linear system of equations defined by the `BROYFUNC` function above:

```
;Provide an initial guess as the algorithm's starting point:
X = [-1.0, 1.0, 2.0]

;Compute the solution:
result = BROYDEN(X, 'BROYFUNC')

;Print the result:
PRINT, result
```

IDL prints:

```
0.500000 -1.10731e-07 -0.523599
```

The exact solution (to eight-decimal accuracy) is [0.5, 0.0, -0.52359877].

# BYTARR

The BYTARR function creates a byte vector or array.

## Syntax

$$Result = BYTARR( D_1[, \dots, D_8] [, /NOZERO] )$$

## Return Value

This function returns a byte vector or array.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, BYTARR sets every element of the result to zero. If the NOZERO keyword is set, this zeroing is not performed (array elements contain random values) and BYTARR executes faster.

## Examples

To create B as a 3 by 3 by 5 byte array where each element is set to zero, enter:

```
B = BYTARR(3, 3, 5)
```

## Version History

# BYTE

The BYTE function returns a result equal to *Expression* converted to byte type. If *Expression* is a string, each string is converted to a byte vector of the same length as the string. Each element of the vector is the character code of the corresponding character in the string. The BYTE function can also be used to extract data from *Expression* and place it in a byte scalar or array without modification, if more than one parameter is present. See “[Type Conversion Functions](#)” on page 275 for details.

## Syntax

$$Result = \text{BYTE}( Expression[, Offset [, D_1[, \dots, D_8]]] )$$

## Return Value

This function returns the result of the *Expression* converted to byte type.

## Arguments

### Expression

The expression to be converted to type byte.

### Offset

The byte offset from the beginning of *Expression*. Specifying this argument allows fields of data extracted from *Expression* to be treated as byte data without conversion.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

### Example

If the variable A contains the floating-point value 10.0, it can be converted to byte type and saved in the variable B by entering:

```
B = BYTE(A)
```

# BYTEORDER

The `BYTEORDER` procedure converts integers between host and network byte ordering or floating-point values between the native format and XDR (IEEE) format. This routine can also be used to swap the order of bytes within both short and long integers. If the type of byte swapping is not specified via one of the keywords below, bytes within short integers are swapped (even and odd bytes are interchanged).

The size of the parameter, in bytes, must be evenly divisible by two for short integer swaps, and by four for long integer swaps. `BYTEORDER` operates on both scalars and arrays. The parameter must be a variable, not an expression or constant, and may not contain strings. The contents of *Variable* are overwritten by the result.

Network byte ordering is “big endian”. That is, multiple byte integers are stored in memory beginning with the most significant byte.

## Syntax

```

BYTEORDER, Variable1, ..., Variablen [, /DTOVAX] [, /DTOXDR] [, /FTOVAX]
  [, /FTOXDR] [, /HTONL] [, /HTONS] [, /L64SWAP] [, /LSWAP] [, /NTOHL]
  [, /NTOHS] [, /SSWAP] [, /SWAP_IF_BIG_ENDIAN]
  [, /SWAP_IF_LITTLE_ENDIAN] [, /VAXTOD] [, /VAXTOF] [, /XDRTOD]
  [, /XDRTOF]

```

## Arguments

### Variable<sub>n</sub>

A named variable (not an expression or constant) that contains the data to be converted. The contents of *Variable* are overwritten by the new values.

## Keywords

### D<sub>T</sub>O<sub>V</sub>A<sub>X</sub>

Set this keyword to convert native (IEEE) double-precision floating-point format to VAX D float format. See “[Note on Accessing Data in VAX Floating Point Format](#)” on page 201.

## **DTOXDR**

Set this keyword to convert native double-precision floating-point format to XDR (IEEE) format.

## **FTOVAX**

Set this keyword to convert native (IEEE) single-precision floating-point format to VAX F float format. See [“Note on Accessing Data in VAX Floating Point Format”](#) on page 201.

## **FTOXDR**

Set this keyword to convert native single-precision floating-point format to XDR (IEEE) format.

## **HTONL**

Set this keyword to perform host to network conversion, longwords.

## **HTONS**

Set this keyword to perform host to network conversion, short integers.

## **L64SWAP**

Set this keyword to perform a 64-bit swap (8 bytes). Swap the order of the bytes within each 64-bit word. For example, the eight bytes within a 64-bit word are changed from  $(B_0, B_1, B_2, B_3, B_4, B_5, B_6, B_7)$ , to  $(B_7, B_6, B_5, B_4, B_3, B_2, B_1, B_0)$ .

## **LSWAP**

Set this keyword to perform a 32-bit longword swap. Swap the order of the bytes within each longword. For example, the four bytes within a longword are changed from  $(B_0, B_1, B_2, B_3)$ , to  $(B_3, B_2, B_1, B_0)$ .

## **NTOHL**

Set this keyword to perform network to host conversion, longwords.

## **NTOHS**

Set this keyword to perform network to host conversion, short integers.

## SSWAP

Set this keyword to perform a short word swap. Swap the bytes within short integers. The even and odd numbered bytes are interchanged. This is the default action, if no other keyword is set.

## SWAP\_IF\_BIG\_ENDIAN

If this keyword is set, the BYTEORDER request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the BYTEORDER request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## SWAP\_IF\_LITTLE\_ENDIAN

If this keyword is set, the BYTEORDER request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the BYTEORDER request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## VAXTOD

Set this keyword to convert VAX D float format to native (IEEE) double-precision floating-point format. See [“Note on Accessing Data in VAX Floating Point Format”](#) on page 201.

## VAXTOF

Set this keyword to convert VAX F float format to native (IEEE) single-precision floating-point format. See [“Note on Accessing Data in VAX Floating Point Format”](#) on page 201.

## XDRTOD

Set this keyword to convert XDR (IEEE) format to native double-precision floating-point.

## XDRTOF

Set this keyword to convert XDR (IEEE) format to native single-precision floating-point.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Note on Accessing Data in VAX Floating Point Format

When converting between VAX and IEEE formats, you should be aware of the following basic numerical issues in order to get the best results. Translation of floating-point values from IDL's native IEEE format to the VAX format and back (that is, VAX to IEEE to VAX) is not a completely reversible operation, and should be avoided when possible. There are many cases where the recovered values will differ from the original values, including:

- The VAX floating-point format lacks support for the IEEE special values (*NaN* and *Infinity*). Hence, their special meaning is lost when they are converted to VAX format and cannot be recovered.
- The IEEE and VAX floating formats have intrinsic differences in precision and range, which can cause information to be lost in both directions. When converting from one format to another, IDL rounds the value to the nearest representable value in the target format.

As a practical matter, an initial conversion of existing VAX format data to IEEE cannot be avoided if the data is to be used on modern machines. However, each format conversion can add a small amount of error to the resulting values, so it is important to minimize the number of such conversions. RSI recommends using IEEE/VAX conversions only to read existing VAX format data, and strongly recommends that all new files be created using the native IEEE format. This introduces only a single unavoidable conversion, and minimizes the resulting conversion error.

# BYTSCL

The BYTSCL function scales all values of *Array* that lie in the range ( $Min \leq x \leq Max$ ) into the range ( $0 \leq x \leq Top$ ). For floating-point input, each value is scaled using the formula  $(Top + 0.9999) * (x - Min) / (Max - Min)$ . For integer input, each value is scaled using the formula  $((Top + 1) * (x - Min) - 1) / (Max - Min)$ .

## Syntax

*Result* = BYTSCL( *Array* [, **MAX**=value] [, **MIN**=value] [, **/NAN**] [, **TOP**=value] )

## Return Value

The returned result has the same structure as the original parameter and is of byte type.

## Arguments

### Array

The array to be scaled and converted to bytes.

## Keywords

### MAX

Set this keyword to the maximum value of *Array* to be considered. If MAX is not provided, *Array* is searched for its maximum value. All values greater or equal to MAX are set equal to TOP in the result.

### Note

---

The data type of the value specified for MAX should match the data type of the input array. Since MAX is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

---

### MIN

Set this keyword to the minimum value of *Array* to be considered. If MIN is not provided, *Array* is searched for its minimum value. All values less than or equal to MIN are set equal to 0 in the result.

**Note**

---

The data type of the value specified for MIN should match the data type of the input array. Since MIN is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

---

**NAN**

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

**TOP**

Set this keyword to the maximum value of the scaled result. If TOP is not specified, 255 is used. Note that the minimum value of the scaled result is always 0.

**Thread Pool Keywords**

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

**Examples****Note**

---

Also see “[Byte-Scaling](#)” in Chapter 8 of the *Image Processing in IDL* manual.

---

BYTSCL is often used to scale images into the appropriate range for 8-bit displays. As an example, enter the following commands:

```
; Create a simple image array and display:
IM = DIST(200)
TV, IM

; Scale the image into the full range of bytes (0 to 255) and
; re-display it:
IM = BYTSCL(IM)
```

```
    ; Display the new image:  
    TV, IM
```

# C\_CORRELATE

The C\_CORRELATE function computes the cross correlation  $P_{xy}(L)$  or cross covariance  $R_{xy}(L)$  of two sample populations  $X$  and  $Y$  as a function of the lag  $L$

$$P_{xy}(L) = \begin{cases} \frac{\sum_{k=0}^{N-|L|-1} (x_{k+|L|} - \bar{x})(y_k - \bar{y})}{\sqrt{\left[ \sum_{k=0}^{N-1} (x_k - \bar{x})^2 \right] \left[ \sum_{k=0}^{N-1} (y_k - \bar{y})^2 \right]}} & \text{For } L < 0 \\ \frac{\sum_{k=0}^{N-L-1} (x_k - \bar{x})(y_{k+L} - \bar{y})}{\sqrt{\left[ \sum_{k=0}^{N-1} (x_k - \bar{x})^2 \right] \left[ \sum_{k=0}^{N-1} (y_k - \bar{y})^2 \right]}} & \text{For } L \geq 0 \end{cases}$$

$$R_{xy}(L) = \begin{cases} \frac{1}{N} \sum_{k=0}^{N-|L|-1} (x_{k+|L|} - \bar{x})(y_k - \bar{y}) & \text{For } L < 0 \\ \frac{1}{N} \sum_{k=0}^{N-L-1} (x_k - \bar{x})(y_{k+L} - \bar{y}) & \text{For } L \geq 0 \end{cases}$$

where  $\bar{x}$  and  $\bar{y}$  are the means of the sample populations  $x = (x_0, x_1, x_2, \dots, x_{N-1})$  and  $y = (y_0, y_1, y_2, \dots, y_{N-1})$ , respectively.

This routine is written in the IDL language. Its source code can be found in the file `c_correlate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = C\_CORRELATE( *X*, *Y*, *Lag* [, /COVARIANCE] [, /DOUBLE] )

## Return Value

Returns the cross correlation  $P_{xy}(L)$  or cross covariance  $R_{xy}(L)$  of two sample populations  $X$  and  $Y$  as a function of the lag  $L$ .

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector.

### Lag

A scalar or  $n$ -element integer vector in the interval  $[-(n-2), (n-2)]$ , specifying the signed distances between indexed elements of  $X$ .

## Keywords

### COVARIANCE

Set this keyword to compute the sample cross covariance rather than the sample cross correlation.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define two n-element sample populations:
X = [3.73, 3.67, 3.77, 3.83, 4.67, 5.87, 6.70, 6.97, 6.40, 5.57]
Y = [2.31, 2.76, 3.02, 3.13, 3.72, 3.88, 3.97, 4.39, 4.34, 3.95]

; Compute the cross correlation of X and Y for LAG = -5, 0, 1, 5,
; 6, 7:
lag = [-5, 0, 1, 5, 6, 7]
```

```
result = C_CORRELATE(X, Y, lag)
PRINT, result
```

IDL prints:

```
-0.428246  0.914755  0.674547  -0.405140  -0.403100  -0.339685
```

# CALDAT

The CALDAT procedure computes the month, day, year, hour, minute, or second corresponding to a given Julian date. The inverse of this procedure is JULDAY.

---

**Note**

The Julian calendar, established by Julius Caesar in the year 45 BCE, was corrected by Pope Gregory XIII in 1582, excising ten days from the calendar. The CALDAT procedure reflects the adjustment for dates after October 4, 1582. See the example below for an illustration.

---

This routine is written in the IDL language. Its source code can be found in the file `caldat.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

`CALDAT, Julian, Month [, Day [, Year [, Hour [, Minute [, Second]]]]]`

## Arguments

### Julian

A numeric value or array that specifies the Julian Day Number (which begins at noon) to be converted to a calendar date.

---

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

---

---

**Note**

Julian Day Numbers should be maintained as double-precision floating-point data when the numbers are used to determine hours, minutes, and seconds.

---

### Month

A named variable that, on output, contains a longword integer or longword integer array representing the number of the desired month (1 = January, ..., 12 = December).

## Day

A named variable that, on output, contains a longword integer or longword integer array representing the number of the day of the month (1-31).

## Year

A named variable that, on output, contains a longword integer or longword integer array representing the number of the desired year (e.g., 1994).

## Hour

A named variable that, on output, contains a longword integer or longword integer array representing the number of the hour of the day (0-23).

## Minute

A named variable that, on output, contains a longword integer or longword integer array representing the number of the minute of the hour (0-59).

## Second

A named variable that, on output, contains a double-precision floating-point value or a double-precision floating-point array representing the number of the second of the minute (0-59).

## Keywords

None.

## Examples

In 1582, Pope Gregory XIII adjusted the Julian calendar to correct for its inaccuracy of slightly more than 11 minutes per year. As a result, the day following October 4, 1582 was October 15, 1582. CALDAT follows this convention, as illustrated by the following commands:

```
CALDAT, 2299160, Month1, Day1, Year1
CALDAT, 2299161, Month2, Day2, Year2
PRINT, Month1, Day1, Year1
PRINT, Month2, Day2, Year2
```

IDL prints:

```
10    4    1582
10   15    1582
```

### Warning

You should be aware of this discrepancy between the original and revised Julian calendar reckonings if you calculate dates before October 15, 1582.

Be sure to distinguish between *Month* and *Minute* when assigning variable names. For example, the following code would cause the Month value to be the same as the Minute value:

```
;Find date corresponding to Julian day 2529161.36:
CALDAT, 2529161.36, M, D, Y, H, M, S
PRINT, M, D, Y, H, M, S
```

IDL prints:

```
0          4          2212          18          0          0.00000000
```

Moreover, Julian Day Numbers should be maintained as double-precision floating-point data when the numbers are used to determine hours, minutes, and seconds.

So, instead of the previous call to CALDAT, use something like:

```
CALDAT, 2529161.36D, Month, Day, Year, Hour, Minute, Second
PRINT, Month, Day, Year, Hour, Minute, Second
```

IDL prints:

```
7          4          2212          20          38          23.999989
```

You can also use arrays for the *Julian* argument:

```
CALDAT, DINDGEN(4) + 2449587.0D, m, d, y
PRINT, m, d, y
```

IDL prints:

```
          8          8          8          8
          22          23          24          25
1994      1994      1994      1994
```

# CALENDAR

The CALENDAR procedure displays a calendar for a month or an entire year on the current plotting device. This IDL routine imitates the UNIX `cal` command.

This routine is written in the IDL language. Its source code can be found in the file `calendar.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
CALENDAR [, Month , Year]
```

## Arguments

### Month

The number of the month for which a calendar is desired (1 is January, 2 is February, ..., 12 is December). If called without arguments, CALENDAR draws a calendar for the current month.

### Year

The number of the year for which a calendar should be drawn. If YEAR is provided without MONTH, a calendar for the entire year is drawn. If called without arguments, CALENDAR draws a calendar for the current month.

## Example

```
; Display a calendar for the year 2038.  
CALENDAR, 2038  
; Display the calendar for October, 1582.  
CALENDAR, 10, 1582
```

[SYSTIME](#)

# CALL\_EXTERNAL

The `CALL_EXTERNAL` function calls a function in an external sharable object and returns a scalar value. Parameters can be passed by reference (the default) or by value. See [Chapter 9, “Using CALL\\_EXTERNAL”](#) in the *External Development Guide* manual for examples.

`CALL_EXTERNAL` is supported under all operating systems supported by IDL, although there are system specific details of which you must be aware. This function requires no interface routines and is much simpler and easier to use than the `LINKIMAGE` procedure. However, `CALL_EXTERNAL` performs no checking of the type and number of parameters. Programming errors are likely to cause IDL to crash or to corrupt your data.

## Warning

---

Input and output actions should be performed within IDL code, using IDL’s built-in input/output facilities, or by using the internal `IDL_Message()` function. Performing input or output from external code, especially to the user console or tty (e.g. using `printf()` or equivalent functionality in other languages to send text to `stdout`) may create errors or generate unexpected results.

---

`CALL_EXTERNAL` supports the IDL Portable Convention, a portable calling convention that works on all platforms. This convention passes two arguments to the called routine, an argument count (`argc`) and an array of arguments (`argv`).

`CALL_EXTERNAL` also offers a feature called [Auto Glue](#) that can greatly simplify use of the `CALL_EXTERNAL` portable convention if you have the appropriate C compiler installed on your system. Auto glue automatically writes the glue function required to convert the (`argc`, `argv`) arguments to the actual function call, and then compiles and loads the glue function transparently. If you want IDL to simply write the glue function for you, but not compile it, the `WRITE_WRAPPER` keyword can be used.

The result of the `CALL_EXTERNAL` function is a scalar value returned by the external function. By default, this is a scalar long (32-bit) integer. This default can be changed by specifying one of the keywords described below that alter the result type.

## Syntax

```
Result = CALL_EXTERNAL(Image, Entry [, P0, ..., PN-1] [, /ALL_VALUE]
    [, /B_VALUE | /D_VALUE | /F_VALUE | /I_VALUE | /L64_VALUE |
    , /S_VALUE | /UI_VALUE | /UL_VALUE | /UL64_VALUE] [, /CDECL]
```

```
[, RETURN_TYPE=value] [, /UNLOAD] [, VALUE=byte_array]
[, WRITE_WRAPPER=wrapper_file] )
```

**Auto Glue keywords:** [, /AUTO\_GLUE] [, CC=string]  
 [, COMPILE\_DIRECTORY=string] [, EXTRA\_CFLAGS=string]  
 [, EXTRA\_LFLAGS=string] [, /IGNORE\_EXISTING\_GLUE] [, LD=string]  
 [, /NOCLEANUP] [, /SHOW\_ALL\_OUTPUT] [, /VERBOSE]

## Return Value

This function calls a function in an external sharable object and returns a scalar value.

## Arguments

### Image

The name of the file, which must be a sharable library (UNIX), or DLL (Windows), which contains the routine to be called.

### Entry

A string containing the name of the symbol in the library which is the entry point of the routine to be called.

### $P_0, \dots, P_{N-1}$

The parameters to be passed to the external routine. All array and structure arguments are passed by reference (address). The default is to also pass scalars by reference, but the ALL\_VALUE or VALUE keywords can be used to pass them by value. Care must be taken to ensure that the type, structure, and passing mechanism of the parameters passed to the external routine match what it expects. There are some restrictions on data types that can be passed by value, and the user needs to be aware of how IDL passes strings. Both issues discussed in further detail below.

## Keywords

### ALL\_VALUE

Set this keyword to indicate that all parameters are passed by value. There are some restrictions on data types that should be considered when using this keyword, as discussed below.

## **B\_VALUE**

If set, this keyword indicates that the called function returns a byte value.

## **CDECL**

The Microsoft Windows operating system has two distinct system defined standards that govern how routines pass arguments: `stdcall`, which is used by much of the operating system as well as languages such as Visual Basic, and `cdecl`, which is used widely for programming in the C language. These standards differ in how and when arguments are pushed and removed from the system stack. The standard used by a given function is determined when the function is compiled, and can usually be controlled by the programmer. If you call a function using the wrong standard (e.g. calling a `stdcall` function as if it were `cdecl`, or the reverse), you could get incorrect results, corrupted memory, or you could crash IDL. Unfortunately, there is no way for IDL to know which convention a given function uses; this information must be supplied by the user of `CALL_EXTERNAL`. If the `CDECL` keyword is present, IDL will use the `cdecl` convention to call the function. Otherwise, `stdcall` is used.

## **D\_VALUE**

If set, this keyword indicates that the called function returns a double-precision floating value.

## **F\_VALUE**

If set, this keyword indicates that the called function returns a single-precision floating value.

## **I\_VALUE**

If set, this keyword indicates that the called function returns an integer value.

## **L64\_VALUE**

If set, this keyword indicates that the called function returns a 64-bit integer value.

## **RETURN\_TYPE**

The type code to set the type of the result. See the description of the [SIZE](#) function for a list of the IDL type codes.

## S\_VALUE

If set, this keyword indicates that the called function returns a pointer to a null-terminated string.

## UI\_VALUE

If set, this keyword indicates that the called function returns an unsigned integer value.

## UL\_VALUE

If set, this keyword indicates that the called function returns an unsigned long integer value.

## UL64\_VALUE

If set, this keyword indicates that the called function returns an unsigned 64-bit integer value.

## UNLOAD

Normally, IDL keeps *Image* loaded in memory after the call to `CALL_EXTERNAL` completes. This is done for efficiency—loading a sharable object can be a slow operation. Setting the `UNLOAD` keyword will cause IDL to unload *Image* after the call to it is complete. This is useful if you are debugging code in *Image*, as it allows you to iterate on your code without having to exit IDL between tests. It can also be a good idea if you do not intend to make any subsequent calls to routines within *Image*.

If IDL is unable to unload the sharable object, it will issue an error to that effect. In addition to any operating system reported problem that might occur, there are 2 situations in which IDL cannot perform the `UNLOAD` operation:

- If the sharable library has been used for any other purpose in addition to `CALL_EXTERNAL` (e.g. `LINKIMAGE`).

## VALUE

A byte array, with as many elements as there are optional parameters, indicating the method of parameter passing. Arrays are always passed by reference. If parameter `Pi` is a scalar, it is passed by reference if `VALUE[i]` is 0; and by value if it is non-zero. There are some restrictions on data types that should be considered when using this keyword, as discussed below.

## WRITE\_WRAPPER

If set, `WRITE_WRAPPER` supplies the name of a file for `CALL_EXTERNAL` to create containing the C function required to convert the `(argc, argv)` interface used by the `CALL_EXTERNAL` portable calling convention to the interface of the target function. If `WRITE_WRAPPER` is specified, `CALL_EXTERNAL` writes the specified file, but does not attempt to actually call the function specified by `Entry`. The result from `CALL_EXTERNAL` is an integer 0 in this case, and has no special meaning. Use of `WRITE_WRAPPER` implies the `PORTABLE` keyword.

---

### Note

This is similar to Auto Glue only in that `CALL_EXTERNAL` writes a function on your behalf. Unlike Auto Glue, `WRITE_WRAPPER` does not attempt to compile the resulting function or to use it. You might want to use `WRITE_WRAPPER` to generate IDL interfaces for an external library in cases where you intend to combine the interfaces with other code or otherwise modify it before using it with IDL.

---

## Auto Glue Keywords

Auto Glue, discussed in the section “[Auto Glue](#)” on page 221, offers a simplified way to use the `CALL_EXTERNAL` portable calling convention. The following keywords control its use. Many of these keywords correspond to the same keywords to the `MAKE_DLL` procedure, and are covered in more detail in the documentation for that routine.

## AUTO\_GLUE

Set this keyword to enable the `CALL_EXTERNAL` Auto Glue feature.

## CC

If present, a template string to be used in generating the C compiler command(s) to compile the automatically generated glue function. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## COMPILE\_DIRECTORY

Specifies the directory to use for creating the necessary intermediate files and the final glue function sharable library. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## EXTRA\_CFLAGS

If present, a string supplying extra options to the command used to execute the C compiler. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## EXTRA\_LFLAGS

If present, a string supplying extra options to the command used to execute the linker. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## IGNORE\_EXISTING\_GLUE

Normally, if Auto Glue finds a pre-existing glue function, it will use it without attempting to build it again. Set `IGNORE_EXISTING_GLUE` to override this caching behavior and force `CALL_EXTERNAL` to rebuild the glue function sharable library.

## LD

If present, a template string to be used in generating the linker command to build the glue function sharable library. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## NOCLEANUP

If set, `CALL_EXTERNAL` will not remove intermediate files generated in order to build the glue function sharable library after the library has been built. This keyword can be used to preserve information for debugging in case of error, or for additional information on how Auto Glue works. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## SHOW\_ALL\_OUTPUT

Auto Glue normally produces no output unless an error prevents successful building of the glue function sharable library. Set `SHOW_ALL_OUTPUT` to see all output produced by the process of building the library. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## VERBOSE

If set, `VERBOSE` causes `CALL_EXTERNAL` to issue informational messages as it carries out the task of locating, building, and executing the glue function. For a more complete description of this keyword, see [MAKE\\_DLL](#).

## String Parameters

IDL represents strings internally as `IDL_STRING` descriptors, which are defined in the C language as:

```
typedef struct {
    unsigned short slen;
    unsigned short stype;
    char *s;
} IDL_STRING;
```

To pass a string by reference, IDL passes the address of its `IDL_STRING` descriptor. To pass a string by value the string pointer (the `s` field of the descriptor) is passed. Programmers should be aware of the following when manipulating IDL strings:

- Called code should treat the information in the passed `IDL_STRING` descriptor and the string itself as read-only, and should not modify these values.
- The `slen` field contains the length of the string without including the NULL termination that is required at the end of all C strings.
- The `stype` field is used internally by IDL to know keep track of how the memory for the string was obtained, and should be ignored by `CALL_EXTERNAL` users.
- `s` is the pointer to the actual C string represented by the descriptor. If the string is NULL, IDL represents it as a NULL (0) pointer, not as a pointer to an empty null terminated string. Hence, called code that expects a string pointer should check for a NULL pointer before dereferencing it.

These issues are examined in greater detail in the IDL *External Development Guide*.

## Calling Convention

`CALL_EXTERNAL` uses the IDL Portable convention for calling user-supplied routines. The IDL Portable calling convention can be simplified by using the Auto Glue extension, described below.

The portable interface convention passes all arguments as elements of an array of C void pointers (`void *`). The C language prototype for a user function called this way looks like one of the following:

```
RET_TYPE xxx(int argc, void *argv[])
```

Where `RET_TYPE` is one of the following: `UCHAR`, `short`, `IDL_UINT`, `IDL_LONG`, `IDL_ULONG`, `IDL_LONG64`, `IDL_ULONG64`, `float`, `double`, or `char *`. The return

type used must agree with the type assumed by `CALL_EXTERNAL` as specified via the keywords described above.

`argc` is the number of arguments, and the vector `argv` contains the arguments themselves, one argument per element. Arguments passed by reference map directly to these `(void *)` pointers, and can be cast to the proper type and then dereferenced directly by the called function. Passing arguments by value is allowed, but since the values are passed in `(void *)` pointers, there are some limitations and restrictions on what is possible:

- Types that are larger than a pointer cannot be passed by value, and `CALL_EXTERNAL` will issue an error if this is attempted. This limitation applies only to the standard portable calling convention. Auto Glue does not have this limitation, and is able to pass such variables by value.
- Integer values can be easily passed by value. IDL widens any of the integer types to the C `int` type and they are then converted to a `(void *)` pointer using a C cast operation.
- There is no C language-defined conversion between pointers and floating point types, so IDL copies the data for the value directly into the pointer element. Although such values can be retrieved by the called routine with the correct C casting operations, this is inconvenient and error prone. It is best to pass non-integer data by reference.

## Auto Glue

Auto Glue is an extension to the IDL Portable Calling Convention that makes it easier to use.

The portable calling convention requires your function to use the IDL defined `(argc, argv)` interface for passing arguments. However, functions not explicitly written for use with `CALL_EXTERNAL` may not have this interface. A common solution using the portable convention is for the IDL user to write a *glue* function that serves as an interface between IDL and the called function. The entire purpose of this glue function, which is usually very simple, is to convert the IDL `(argc, argv)` method of passing parameters to a form acceptable to the called function. Writing this wrapper function is easy for programmers who understand the C language, the system C compiler and linker, and how sharable libraries work on their target operating system. However, it is also tedious and error prone, and can be difficult for users that do not already have these skills.

Auto Glue uses the `MAKE_DLL` procedure to automate the process of using glue code to call functions via the `CALL_EXTERNAL` portable calling convention. Since

it depends so closely on MAKE\_DLL, an understanding of how MAKE\_DLL works is necessary to fully understand Auto Glue. As with MAKE\_DLL, Auto Glue requires that your system have a suitable C compiler installed. Please refer to the documentation for MAKE\_DLL.

Auto Glue maintains a cache of previously built glue functions, and will reuse them on subsequent requests, even between IDL sessions. Glue function libraries can be recognized by their name, which starts with the prefix `idl_ce`, and ends with the proper suffix for a sharable library on the target system (most UNIX: `.so`, AIX: `.a`, HP-UX: `.sl`, Windows: `.dll`). CALL\_EXTERNAL finds a suitable glue function by performing the following steps in order, stopping after the first one that works:

1. Look for a `ce_glue` subdirectory within the IDL distribution `bin` subdirectory for the current platform. (For example, on a Windows system the subdirectory would be located in `<IDL_DEFAULT>\bin\bin.x86`.) If this directory exists, it looks there for a sharable library containing the appropriate glue function.

---

### Note

For customer security reasons, the `ce_glue` subdirectory does not exist in the IDL distribution as shipped by RSI, and IDL does not use it to create glue functions. However, if an individual site creates this directory and places glue library files within it, IDL will use them. Multiple IDL sessions on a given system can all share these same glue files, even when run by different users on a multi-user system. If you keep your IDL distribution on a network based file server shared by multiple clients, and if you provide a sufficient selection of glue files, it is possible that your users will not require a locally installed C compiler to use Auto Glue.

---

If you do create the `ce_glue` subdirectory on a multi-user system, we recommend that you make it along with all files contained within belong to the owner of the IDL distribution, and apply file protections that prevent non-privileged users from creating files in the directory or modifying them.

2. Look in the directory given by the `COMPILE_DIRECTORY` keyword, or if `COMPILE_DIRECTORY` is not present, in the directory given by the `!MAKE_DLL.COMPILE_DIRECTORY` system variable for the appropriate glue function.
3. If this step is reached, there is no pre-existing glue function available. CALL\_EXTERNAL will create one in the same directory searched in the previous step by generating a C language file containing the needed glue function, and then compiling and linking it into a sharable library using the functionality of the MAKE\_DLL procedure.

- IDL loads the sharable library containing the glue function found in the previous step, as well as the library you specified with the Image argument.
- `CALL_EXTERNAL` calls the glue function, causing your function to be called with the correct parameters.

The first time `CALL_EXTERNAL` encounters the need for a glue function that does not already exist, it will automatically build it, and then use it without any external indication that this has happened. You may notice a brief hesitation in IDL's execution as it waits for this process to occur. Once a glue function exists, IDL can load it immediately on subsequent calls (even in unrelated later IDL sessions), and no delay will occur.

### Example: Using Auto Glue To Call System Library Routines

Under Sun Solaris, there is a function in the system math library called `hypot()` that computes the length of the hypotenuse of a right-angled triangle:

```
sqrt(x*x + y*y)
```

This function has the C prototype:

```
double hypot(double x, double y)
```

The following IDL function uses Auto Glue to call this routine:

```
FUNCTION HYPOT, X, Y
; Use the 32-bit or the 64-bit math library?
LIBM=(!VERSION.MEMORY_BITS EQ 64) $
? '/usr/lib/sparcv9/libm.so' : '/usr/lib/libm.so'
RETURN, CALL_EXTERNAL(LIBM, 'hypot', double(x), double(y), $
/ALL_VALUE, /D_VALUE, /AUTO_GLUE)
END
```

## Important Changes Since IDL 5.0

The current version of `CALL_EXTERNAL` differs from IDL versions up to and including IDL 5.0 in a few ways that are important to users moving code to the current version:

- Under Windows, `CALL_EXTERNAL` would pass IDL strings by value no matter how the `ALL_VALUE` or `VALUE` keywords were set. This was inconsistent with all the other platforms and created unnecessary confusion. IDL now uses these keywords to decide how to pass strings on all platforms. Windows users with existing code that expects strings to be passed by value without having specified it via one of these keywords will need to adjust their use of `CALL_EXTERNAL` or their code.

- Older versions of IDL would quietly pass by value arguments that are larger than a pointer without issuing an error when using the portable calling convention. Although this might work on some hardware, it is error prone and can cause IDL to crash. IDL now issues an error in this case. Programmers with existing code moving to a current version of IDL should change their code to pass such data by reference.

## Examples

See [Chapter 9, “Using CALL\\_EXTERNAL”](#) in the *External Development Guide* manual.

## Version History

Pre 4.0	Introduced
Pre 6.1	Deprecated the DEFAULT, PORTABLE, and VAX_FLOAT keywords

# CALL\_FUNCTION

CALL\_FUNCTION function calls the IDL function specified by the string *Name*, passing any additional parameters as its arguments.

Although not as flexible as the EXECUTE function, CALL\_FUNCTION is much faster. Therefore, CALL\_FUNCTION should be used in preference to EXECUTE whenever possible.

## Syntax

$$Result = CALL\_FUNCTION(Name [, P_1, \dots, P_n])$$

## Return Value

The result of the called function (specified by the string *Name*) is passed back as the result of this routine.

## Arguments

### Name

A string containing the name of the function to be called. This argument can be a variable, which allows the called function to be determined at runtime.

### $P_i$

The arguments to be passed to the function given by *Name*. These arguments are the positional and keyword arguments documented for the called function, and are passed to the called function exactly as if it had been called directly.

## Keywords

None.

## Examples

The following command indirectly calls the IDL function SQRT (the square root function) with an argument of 4 and stores the result in the variable R:

```
R = CALL_FUNCTION('SQRT', 4)
```

## Version History

[CALL\\_PROCEDURE](#), [CALL\\_METHOD](#), [EXECUTE](#)

# CALL\_METHOD

The CALL\_METHOD function or procedure calls the object method specified by *Name*, passing any additional parameters as its arguments.

## Note

---

CALL\_METHOD can also be used as a function or a procedure.

---

Although not as flexible as the EXECUTE function, CALL\_METHOD is much faster. Therefore, CALL\_METHOD should be used in preference to EXECUTE whenever possible.

## Syntax

*Result* = CALL\_METHOD(*Name*, *ObjRef*, [, *P*<sub>1</sub>, ..., *P*<sub>*n*</sub>])

or

CALL\_METHOD, *Name*, *ObjRef*, [, *P*<sub>1</sub>, ..., *P*<sub>*n*</sub>]

## Return Value

Returns the results generated by the named function method when applicable.

## Arguments

### Name

A string containing the name of the method to be called. This argument can be a variable, which allows the called method to be determined at runtime.

### ObjRef

A scalar object reference that will be passed to the method as the *Self* argument.

### *P*<sub>*i*</sub>

The arguments to be passed to the method given by *Name*. These arguments are the positional and keyword arguments documented for the called method, and are passed to the called method exactly as if it had been called directly.

## Keywords

None.

[CALL\\_FUNCTION](#), [CALL\\_PROCEDURE](#), [EXECUTE](#)

# CALL\_PROCEDURE

CALL\_PROCEDURE calls the procedure specified by *Name*, passing any additional parameters as its arguments.

Although not as flexible as the EXECUTE function, CALL\_PROCEDURE is much faster. Therefore, CALL\_PROCEDURE should be used in preference to EXECUTE whenever possible.

## Syntax

```
CALL_PROCEDURE, Name [, P1, ..., Pn]
```

## Arguments

### Name

A string containing the name of the procedure to be called. This argument can be a variable, which allows the called procedure to be determined at runtime.

### *P*<sub>*i*</sub>

The arguments to be passed to the procedure given by *Name*. These arguments are the positional and keyword arguments documented for the called procedure, and are passed to the called procedure exactly as if it had been called directly.

## Example

The following example shows how to call the PLOT procedure indirectly with a number of arguments. First, create a dataset for plotting by entering:

```
B = FINDGEN(100)
```

Call PLOT indirectly to create a polar plot by entering:

```
CALL_PROCEDURE, 'PLOT', B, B, /POLAR
```

A “spiral” plot should appear.

# CASE

The CASE statement selects one, and only one, statement for execution, depending on the value of an expression. This expression is called the case selector expression. Each statement that is part of a CASE statement is preceded by an expression that is compared to the value of the selector expression. CASE executes by comparing the CASE expression with each selector expression in the order written. If a match is found, the statement is executed and control resumes directly below the CASE statement.

The ELSE clause of the CASE statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the CASE statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, an error occurs and program execution stops.

The BREAK statement can be used within CASE statements to force an immediate exit from the CASE.

In this CASE statement, only one clause is selected, and that clause is the first one whose value is equal to the value of the case selector expression.

---

**Tip**

Each clause is tested in order, so it is most efficient to order the most frequently selected clauses first.

---

CASE is similar to the SWITCH statement. For more information on using CASE and other IDL program control statements, as well as the differences between CASE and SWITCH, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

## Syntax

```
CASE expression OF
    expression: statement
    ...
    expression: statement
[ ELSE: statement ]
ENDCASE
```

## Examples

This example illustrates how the CASE statement, unlike SWITCH, executes only the one statement that matches the case expression:

```
x=2  
  
CASE x OF  
  1: PRINT, 'one'  
  2: PRINT, 'two'  
  3: PRINT, 'three'  
  4: PRINT, 'four'  
ENDCASE
```

IDL Prints:

```
two
```

# CATCH

The CATCH procedure provides a generalized mechanism for the handling of exceptions and errors within IDL. Calling CATCH establishes an error handler for the current procedure that intercepts all errors that can be handled by IDL, excluding non-fatal warnings such as math errors (e.g., floating-point underflow).

When an error occurs, each active procedure, beginning with the offending procedure and proceeding up the call stack to the main program level, is examined for an error handler (established by a call to CATCH). If an error handler is found, control resumes at the statement after the call to CATCH. The index of the error is returned in the argument to CATCH. The `!ERROR_STATE` system variable is also set. The associated error message is stored in `!ERROR_STATE.MSG`. If no error handlers are found, program execution stops, an error message is issued, and control reverts to the interactive mode. A call to `ON_IOERROR` in the procedure that causes an I/O error supersedes CATCH, and takes the branch to the label defined by `ON_IOERROR`.

This mechanism is similar, but not identical to, the `setjmp/longjmp` facilities in C and the `catch/throw` facilities in C++.

Error handling is discussed in more detail in [“Controlling and Recovering from Errors”](#) in Chapter 8 of the *Building IDL Applications* manual.

## Syntax

```
CATCH, [Variable] [, /CANCEL]
```

## Arguments

### Variable

A named variable in which the error index is returned. When an error handler is established by a call to CATCH, *Variable* is set to zero. If an error occurs, *Variable* is set to the error index, and control is transferred to the statement after the call to CATCH. The error index is also returned in the CODE field of the `!ERROR_STATE` system variable, i.e., `!ERROR_STATE.CODE`.

## Keywords

### CANCEL

Set this keyword to cancel the error handler for the current procedure. This cancellation does not affect other error handlers that may be established in other active procedures.

---

#### Note

If the CANCEL keyword is set, the *Variable* argument must not be present.

---

## Examples

The following procedure illustrates the use of CATCH:

```

PRO CATCH_EXAMPLE

    ; Define variable A:
    A = FLTARR(10)

    ; Establish error handler. When errors occur, the index of the
    ; error is returned in the variable Error_status:
    CATCH, Error_status

    ;This statement begins the error handler:
    IF Error_status NE 0 THEN BEGIN
        PRINT, 'Error index: ', Error_status
        PRINT, 'Error message: ', !ERROR_STATE.MSG
        ; Handle the error by extending A:
        A=FLTARR(12)
        CATCH, /CANCEL
    ENDIF

    ; Cause an error:
    A[11]=12

    ; Even though an error occurs in the line above, program
    ; execution continues to this point because the event handler
    ; extended the definition of A so that the statement can be
    ; re-executed.
    HELP, A
END

```

Running the `CATCH_EXAMPLE` procedure causes IDL to produce the following output and control returns to the interactive prompt:

```
Error index:          -144
Error message:
Attempt to subscript A with <INT (      11)> is out of range.
A                FLOAT      = Array[12]
```

# CD

The CD procedure is used to set and/or change the current working directory. This routine changes the working directory for the IDL session and any child processes started from IDL during that session after the directory change is made. Under UNIX, CD does not affect the working directory of the process that started IDL. The PUSH, POP, and PRINTD procedures provide a convenient interface to CD.

IDL's *default* current working directory depends on the platform and method used to invoke IDL:

- Under Microsoft Windows, the default current working directory is controlled by the value of the `IDL_WDE_START_DIR` preference.
- Under UNIX with the command-line interface (`idl`), the default current working directory is the directory from which IDL was started.
- Under UNIX with the graphical interface (`idlde`), the default current working directory is controlled by the value of the `IDL_MDE_START_DIR` preference.

## Syntax

```
CD [, Directory] [, CURRENT=variable]
```

## Arguments

### Directory

A scalar string specifying the path of the new working directory. If *Directory* is specified as a null string, the working directory is changed to the user's home directory (UNIX) or to the directory specified by !DIR (Windows). If this argument is not specified, the working directory is not changed.

## Keywords

### CURRENT

If CURRENT is present, it specifies a named variable into which the current working directory is stored as a scalar string. The returned directory is the working directory before the directory is changed. Thus, you can obtain the current working directory and change it in a single statement:

```
CD, new_dir, CURRENT=old_dir
```

**Note**

The return value of the `CURRENT` keyword does not include a directory separator at the end of the string.

## Examples

### Windows

To change drives:

```
CD, 'C:'
```

To specify a full path:

```
CD, 'C:\MyData\January'
```

To change from the `C:\MyData` directory to the `C:\MyData\January` directory:

```
CD, 'January'
```

To go back up a directory, use `..`. For example, if the current directory is `C:\MyData\January`, you could go up to the `C:\MyData` directory with the following command:

```
CD, '..'
```

If the current directory is `C:\MyData\January`, you could change to the `C:\MyData\February` directory with the following command:

```
CD, '..\February'
```

### Unix

To specify a full path:

```
CD, '/home/data/'
```

To change to the `january` subdirectory of the current directory:

```
CD, 'january'
```

To go back up a directory, use `..`. For example, if the current directory is `/home/data/january`, you could go up to the `/home/data/` directory with the following command:

```
CD, '..'
```

If the current directory is `/home/data/january`, you could change to the `/home/data/february` directory with the following command:

```
CD, '../february'
```

# CDF Routines

For information, see [Chapter 2, “Common Data Format”](#) in the *IDL Scientific Data Formats* manual.

# CEIL

The CEIL function returns the closest integer greater than or equal to its argument.

## Syntax

$$Result = CEIL(X [, /L64] )$$

## Return Value

If the input value  $X$  is integer type,  $Result$  has the same value and type as  $X$ . Otherwise,  $Result$  is a 32-bit longword integer with the same structure as  $X$ .

## Arguments

### $X$

The value for which the ceiling function is to be evaluated. This value can be any numeric type (integer, floating, or complex).

## Keywords

### L64

If set, the result type is 64-bit integer regardless of the input type. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To print the ceiling function of 5.1, enter:

```
PRINT, CEIL(5.1)
; IDL prints:
6
```

To print the ceiling function of 3000000000.1, the result of which is too large to represent in a 32-bit integer:

```
PRINT, CEIL(3000000000.1D, /L64)
; IDL prints:
30000000001
```

# CHEBYSHEV

The CHEBYSHEV function returns the forward or reverse Chebyshev polynomial expansion of a set of data. Note: Results from this function are subject to roundoff error given discontinuous data.

This routine is written in the IDL language. Its source code can be found in the file `chebyshev.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$$Result = CHEBYSHEV(D, N)$$

## Return Value

Returns the forward or reverse Chebyshev polynomial expansion of a set of data.

## Arguments

### D

A vector containing the values at the zeros of Chebyshev polynomial.

### N

A flag that, if set to -1, returns a set of Chebyshev polynomials. If set to +1, the original data is returned.

## Keywords

None.

# CHECK\_MATH

The CHECK\_MATH function returns and clears the accumulated math error status.

## Syntax

```
Result = CHECK_MATH( [, MASK=bitmask] [, /NOCLEAR] [, /PRINT] )
```

## Return Value

The returned value is the sum of the bit values (described in the following table) of the accumulated errors.

Value	Condition
0	No errors detected since the last interactive prompt or call to CHECK_MATH
1	Integer divided by zero
2	Integer overflow
16	Floating-point divided by zero
32	Floating-point underflow
64	Floating-point overflow
128	Floating-point operand error. An illegal operand was encountered, such as a negative operand to the SQRT or ALOG functions, or an attempt to convert to integer a number whose absolute value is greater than $2^{31} - 1$

*Table 3-2: Math Error Status Values*

### Note

CHECK\_MATH can only relay information reported by the underlying hardware. Some hardware/operating system combinations may not report all of the math errors listed.

Each type of error is only represented once in the return value—any number of “Integer divided by zero” errors will result in a return value of 1.

The math error status is cleared (reset to zero) when CHECK\_MATH is called, or when errors are reported. Math errors are reported either never, when the interpreter returns to an interactive prompt, or after execution of each IDL statement, depending on the value of the !EXCEPT system variable (see “!EXCEPT” on page 4809). See “Examples” below for further discussion.

## Keywords

### MASK

If present, the mask of exceptions to check. Otherwise, all exceptions are checked. Exceptions that are pending but not specified by MASK are not reported, and not cleared. Set this keyword equal to the sum of the bit values for each exception to be checked. For a list of the bit values corresponding to various exceptions, see [CHECK\\_MATH](#).

### NOCLEAR

By default, CHECK\_MATH returns the pending exceptions (as specified via the MASK keyword) and clears them from its list of pending exceptions. If NOCLEAR is set, the exceptions are not cleared and remain pending.

### PRINT

Set this keyword to print an error message to the IDL command log if any accumulated math errors exist. If this keyword is not present, CHECK\_MATH executes silently.

## Examples

To simply check and clear the accumulated math error status using all the defaults, enter:

```
PRINT, CHECK_MATH()
```

IDL prints the accumulated math error status code and resets to zero.

### CHECK\_MATH and !EXCEPT

Because the accumulated math error status is cleared when it is reported, the behavior and appropriate use of CHECK\_MATH depends on the value of the system variable !EXCEPT.

- If !EXCEPT is set equal to 0, math exceptions are not reported automatically, and thus CHECK\_MATH will always return the error status accumulated since the last time it was called.
- If !EXCEPT is set equal to 1, math exceptions are reported when IDL returns to the interactive command prompt. In this case, CHECK\_MATH will return appropriate error codes when used *within* an IDL procedure, but will always return zero when called at the IDL prompt.
- If !EXCEPT is set equal to 2, math exceptions are reported after each IDL statement. In this case, CHECK\_MATH will return appropriate error codes only when used *within an IDL statement*, and will always return zero otherwise.

For example:

```
;Set value of !EXCEPT to zero.
!EXCEPT=0

;Both of these operations cause errors.
PRINT, 1./0., 1/0
```

IDL prints:

```
Inf    1
```

The special floating-point value Inf is returned for 1./0. There is no integer analogue to the floating-point Inf.

```
;Check the accumulated error status.
PRINT, CHECK_MATH()
```

IDL prints:

```
17
```

CHECK\_MATH reports floating-point and integer divide-by-zero errors.

```
;Set value of !EXCEPT to one.
!EXCEPT=1

;Both of these operations cause errors.
PRINT, 1./0., 1/0
```

IDL prints:

```
Inf    1
% Program caused arithmetic error: Integer divide by 0
% Program caused arithmetic error: Floating divide by 0
```

This time IDL also prints error messages.

```
;Check the accumulated error status.
PRINT, CHECK_MATH()
```

IDL prints:

```
0
```

The status was reset.

However, if we do not allow IDL to return to an interactive prompt before checking the math error status:

```
;Set value of !EXCEPT to one.
!EXCEPT=1

;Call to CHECK_MATH happens before returning to the
;IDL command prompt.
PRINT, 1./0., 1/0 & PRINT, CHECK_MATH()
```

IDL prints:

```
Inf    1
17
```

In this case, the math error status code (17) is printed, but because the error status has been cleared by the call to `CHECK_MATH`, no error messages are printed when IDL returns to the interactive command prompt. Finally,

```
;Set value of !EXCEPT to two.
!EXCEPT=2

;Call to CHECK_MATH happens before returning to the
;IDL command prompt.
PRINT, 1./0., 1/0 & PRINT, CHECK_MATH()
```

IDL prints:

```
Inf    1
% Program caused arithmetic error: Integer divide by 0
% Program caused arithmetic error: Floating divide by 0
% Detected at $MAIN$
0
```

Errors are printed before executing the `CHECK_MATH` function, so `CHECK_MATH` reports no errors. However, if we include the call to `CHECK_MATH` in the first `PRINT` command, we see the following:

```
;Call to CHECK_MATH is part of a single IDL statement.
PRINT, 1./0., 1/0, CHECK_MATH()
```

IDL prints:

```
Inf    1    17
```

## Printing Error Messages

The following code fragment prints abbreviated names of errors that have occurred:

```
;Create a string array of error names.
ERRS = ['Divide by 0', 'Underflow', 'Overflow', $
        'Illegal Operand']

;Get math error status.
J = CHECK_MATH()
FOR I = 4, 7 DO IF ISHFT(J, -I) AND 1 THEN $

;Check to see if an error occurred and print the corresponding
;error message.
PRINT, ERRS(I-4), ' Occurred'
```

## Testing Critical Code

### Example 1

Assume you have a critical section of code that is likely to produce an error. The following example shows how to check for errors, and if one is detected, how to repeat the code with different parameters.

```
; Clear error status from previous operations, and print error
; messages if an error exists:
JUNK = CHECK_MATH(/PRINT)

; Disable automatic printing of subsequent math errors:
!EXCEPT=0

;Critical section goes here.
AGAIN: ...

; Did an arithmetic error occur? If so, print error message and
; request new values:
IF CHECK_MATH() NE 0 THEN BEGIN
PRINT, 'Math error occurred in critical section.'

; Get new parameters from user:
READ, 'Enter new values.',...

; Enable automatic printing of math errors:
!EXCEPT=2
```

```

;And retry:
GOTO, AGAIN
ENDIF

```

## Example 2

This example demonstrates the use of the MASK keyword to check for a specific error, and the NOCLEAR keyword to prevent exceptions from being cleared:

```

PRO EXAMPLE2_CHECKMATH

    PRINT, 1./0
    PRINT, CHECK_MATH (MASK=16, /NOCLEAR)
    PRINT, CHECK_MATH (MASK=2, /NOCLEAR)

END

```

IDL prints:

```

Inf
16
0
% Program caused arithmetic error: Floating divide by 0

```

# CHISQR\_CVF

The CHISQR\_CVF function computes the cutoff value  $V$  in a chi-square distribution with  $Df$  degrees of freedom such that the probability that a random variable  $X$  is greater than  $V$  is equal to a user-supplied probability  $P$ .

This routine is written in the IDL language. Its source code can be found in the file `chisqr_cvf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = CHISQR\_CVF(*P*, *Df*)

## Return Value

Returns computes the cutoff value  $V$  in a chi-square distribution with  $Df$  degrees of freedom such that the probability that a random variable  $X$  is greater than  $V$  is equal to a user-supplied probability  $P$ .

## Arguments

### P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

### Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the chi-square distribution.

## Keywords

None.

## Examples

Use the following command to compute the cutoff value in a chi-square distribution with three degrees of freedom such that the probability that a random variable  $X$  is greater than the cutoff value is 0.100. The result should be 6.25139.

```
PRINT, CHISQR_CVF(0.100, 3)
```

IDL prints:

6.25139

# CHISQR\_PDF

The CHISQR\_PDF function computes the probability  $P$  that, in a chi-square distribution with  $Df$  degrees of freedom, a random variable  $X$  is less than or equal to a user-specified cutoff value  $V$ .

This routine is written in the IDL language. Its source code can be found in the file `chisqr_pdf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = CHISQR\_PDF(*V*, *Df*)

## Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $V$  and  $Df$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

## Arguments

### **V**

A scalar or array that specifies the cutoff value(s).

### **Df**

A positive scalar or array that specifies the number of degrees of freedom of the chi-square distribution.

## Keywords

None.

## Examples

Use the following command to compute the probability that a random variable  $X$ , from the chi-square distribution with three degrees of freedom, is less than or equal to 6.25. The result should be 0.899939.

```
result = CHISQR_PDF(6.25, 3)
PRINT, result
```

IDL prints:

```
0.899939
```

Compute the probability that a random variable  $X$  from the chi-square distribution with three degrees of freedom, is greater than 6.25. The result should be 0.100061.

```
PRINT, 1 - chisqr_pdf(6.25, 3)
```

IDL prints:

```
0.100061
```

# CHOLDC

Given a positive-definite symmetric  $n$  by  $n$  array  $A$ , the CHOLDC procedure constructs its Cholesky decomposition  $A = LL^T$ , where  $L$  is a lower triangular array and  $L^T$  is the transpose of  $L$ .

CHOLDC is based on the routine `choldc` described in section 2.9 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the `LA_CHOLDC` procedure instead.

---

## Syntax

CHOLDC,  $A$ ,  $P$  [, /DOUBLE]

## Arguments

### A

An  $n$  by  $n$  array. On input, only the upper triangle of  $A$  need be given. On output,  $L$  is returned in the lower triangle of  $A$ , except for the diagonal elements, which are returned in the vector  $P$ .

---

**Note**

If CHOLDC is complex then only the real part is used for the computation.

---

### P

An  $n$ -element vector containing the diagonal elements of  $L$ .

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

See “[CHOLSOL](#)” on page 255.

## Version History

---

4.0	Introduced
-----	------------

---

# CHOLSOL

The CHOLSOL function returns an  $n$ -element vector containing the solution to the set of linear equations  $Ax = b$ , where  $A$  is the positive-definite symmetric array returned by the CHOLDC procedure.

CHOLSOL is based on the routine `cholsl` described in section 2.9 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the LA\_CHOLSOL procedure instead.

---

## Syntax

*Result* = CHOLSOL( *A*, *P*, *B* [, /DOUBLE] )

## Return Value

Returns an  $n$ -element vector containing the solution to the set of linear equations  $Ax = b$ , where  $A$  is the positive-definite symmetric array returned by the [CHOLDC](#).

## Arguments

### A

An  $n$  by  $n$  positive-definite symmetric array, as output by CHOLDC. Only the lower triangle of  $A$  is accessed.

---

**Note**

If CHOLSOL is complex then only the real part is used for the computation.

---

### P

The diagonal elements of the Cholesky factor  $L$ , as computed by CHOLDC.

### B

An  $n$ -element vector containing the right-hand side of the equation.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To solve a positive-definite symmetric system  $Ax = b$ :

```

;Define the coefficient array:
A = [[ 6.0, 15.0, 55.0], $
      [15.0, 55.0, 225.0], $
      [55.0, 225.0, 979.0]]

;Define the right-hand side vector B:
B = [9.5, 50.0, 237.0]

;Compute Cholesky decomposition of A:
CHOLDC, A, P

;Compute and print the solution:
PRINT, CHOLSOL(A, P, B)

```

IDL prints:

```
-0.499998  -1.00000  0.500000
```

The exact solution vector is [-0.5, -1.0, 0.5].

# CINDGEN

The CINDGEN function returns a complex, single-precision, floating-point array with the specified dimensions.

## Syntax

$$Result = CINDGEN(D_1[, \dots, D_8])$$

## Return Value

Returns a complex, single-precision, floating-point array with the specified dimensions. Each element of the array has its real part set to the value of its one-dimensional subscript. The imaginary part is set to zero.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create C, a 4-element vector of complex values with the real parts set to the value of their subscripts, enter:

```
C = CINDGEN(4)
```

# CIR\_3PNT

The CIR\_3PNT procedure returns the radius and center of a circle, given 3 points on the circle. This is analogous to finding the circumradius and circumcircle of a triangle; the center of the circumcircle is the point at which the three perpendicular bisectors of the triangle formed by the points meet.

This routine is written in the IDL language. Its source code can be found in the file `cir_3pnt.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
CIR_3PNT, X, Y, R, X0, Y0
```

## Arguments

### X

A three-element vector containing the X-coordinates of the points.

### Y

A three-element vector containing the Y-coordinates of the points.

### R

A named variable that will contain the radius of the circle. The procedure returns 0.0 if the points are co-linear.

### X0

A named variable that will contain the X-coordinate of the center of the circle. The procedure returns 0.0 if the points are co-linear.

### Y0

A named variable that will contain the Y-coordinate of the center of the circle. The procedure returns 0.0 if the points are co-linear.

## Keywords

None.

## Examples

```
X = [1.0, 2.0, 3.0]
Y = [1.0, 2.0, 1.0]
CIR_3PNT, X, Y, R, X0, Y0
PRINT, 'The radius is: ', R
PRINT, 'The center of the circle is at: ', X0, Y0
```

# CLOSE

The CLOSE procedure closes the file units specified as arguments. All open files are also closed when IDL exits.

## Syntax

```
CLOSE[, Unit1, ..., Unitn] [, /ALL] [, EXIT_STATUS=variable] [, /FILE]  
[, /FORCE]
```

## Arguments

### Unit<sub>*i*</sub>

The IDL file units to close.

## Keywords

### ALL

Set this keyword to close all open file units. In addition, any file units that were allocated via GET\_LUN are freed.

### EXIT\_STATUS

Set this keyword to a named variable that will contain the exit status reported by a UNIX child process started via the UNIT keyword to SPAWN. This value is the exit value reported by the process by calling EXIT, and is analogous to the value returned by \$? under most UNIX shells. If used with any other type of file, 0 is returned. EXIT\_STATUS is not allowed in conjunction with the ALL or FILE keywords.

### FILE

Set this keyword to close all file units from 1 to 99. File units greater than 99, which are associated with the GET\_LUN and FREE\_LUN procedures, are not affected.

### FORCE

Overrides the IDL file output buffer and forces the file to be closed no matter what errors occur in the process.

IDL buffers file output for performance reasons. If it is not possible to properly flush this data when a file close is requested, an error is normally issued and the file

remains open. An example of this might be that your disk does not have room to write the remaining data. This default behavior prevents data from being lost. To override it and force the file to be closed no matter what errors occur in the process, specify `FORCE`.

## Examples

If file units 1 and 3 are open, they can both be closed at the same time by entering the command:

```
CLOSE, 1, 3
```

## Version History

# CLUST\_WTS

The CLUST\_WTS function computes the weights (the cluster centers) of an  $n$ -column,  $m$ -row array, where  $n$  is the number of variables and  $m$  is the number of observations or samples. CLUST\_WTS uses  $k$ -means clustering. With this technique, CLUST\_WTS starts with  $k$  random clusters and then iteratively moves items between clusters, minimizing variability within each cluster and maximizing variability between clusters.

---

**Note**

Because the initial clusters are chosen randomly, your results may differ slightly each time the CLUST\_WTS routine is invoked, even for the same input data. For data with well-defined clusters the differences should be slight. For randomly-scattered data (no distinguishable clusters), the results may be significantly different, which may indicate that  $k$ -means clustering is not appropriate for your data.

---

---

**Tip**

For hierarchical tree clustering, see the [CLUSTER\\_TREE](#) function.

---

For more information on cluster analysis, see:

Everitt, Brian S. *Cluster Analysis*. New York: Halsted Press, 1993. ISBN 0-470-22043-0

## Syntax

```
Result = CLUST_WTS( Array [, /DOUBLE] [, N_CLUSTERS=value]  
                  [, N_ITERATIONS=integer] [, VARIABLE_WTS=vector] )
```

## Return Value

Returns an  $m$ -column,  $N\_CLUSTERS$ -row array of cluster centers by computing the weights (the cluster centers) of an  $n$ -column,  $m$ -row array, where  $n$  is the number of variables and  $m$  is the number of observations or samples.

## Arguments

### Array

An  $n$ -column,  $m$ -row array of any data type except string, single- or double-precision complex.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### N\_CLUSTERS

Set this keyword equal to the number of cluster centers. The default is to compute  $m$  cluster centers.

### N\_ITERATIONS

Set this keyword equal to the number of iterations used when in computing the cluster centers. The default is to use 20 iterations.

### VARIABLE\_WTS

Set this keyword equal to an  $m$ -element vector of floating-point variable weights. The elements of this vector are used to give greater or lesser importance to each variable (each column) in determining the cluster centers. The default is to give all variables equal weighting using a value of 1.0.

## Examples

See “[CLUSTER](#)” on page 266.

## Version History

5.0	Introduced

# CLUSTER

The CLUSTER function computes the classification of an  $n$ -column,  $m$ -row array, where  $n$  is the number of variables and  $m$  is the number of observations or samples. CLUST\_WTS uses  $k$ -means clustering. With this technique, CLUST\_WTS starts with  $k$  random clusters and then iteratively moves items between clusters, minimizing variability within each cluster and maximizing variability between clusters.

---

**Note**

Because the initial clusters are chosen randomly, your results may differ slightly each time the CLUST\_WTS routine is invoked, even for the same input data. For data with well-defined clusters the differences should be slight. For randomly-scattered data (no distinguishable clusters), the results may be significantly different, which may indicate that  $k$ -means clustering is not appropriate for your data.

---

**Tip**

For hierarchical tree clustering, see the [CLUSTER\\_TREE](#) function.

---

For more information on cluster analysis, see:

Everitt, Brian S. *Cluster Analysis*. New York: Halsted Press, 1993. ISBN 0-470-22043-0

## Syntax

*Result* = CLUSTER( *Array*, *Weights* [, /DOUBLE] [, N\_CLUSTERS=*value*] )

## Return Value

Results in a 1-column,  $m$ -row array of cluster number assignments that correspond to each sample.

## Arguments

### Array

An  $n$ -column,  $m$ -row array of type float or double.

## Weights

An array of weights (the cluster centers) computed using the `CLUST_WTS` function. The dimensions of this array vary according to keyword values.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### N\_CLUSTERS

Set this keyword equal to the number of clusters. The default is based upon the row dimension of the *Weights* array.

## Examples

```

; Construct 3 separate clusters in a 3D space:
n = 50
c1 = RANDOMN(seed, 3, n)
c1[0:1,*] -= 3
c2 = RANDOMN(seed, 3, n)
c2[0,*] += 3
c2[1,*] -= 3
c3 = RANDOMN(seed, 3, n)
c3[1:2,*] += 3
array = [[c1], [c2], [c3]]

; Compute cluster weights, using three clusters:
weights = CLUST_WTS(array, N_CLUSTERS = 3)

; Compute the classification of each sample:
result = CLUSTER(array, weights, N_CLUSTERS = 3)

; Plot each cluster using a different symbol:
IPLOT, array[*], WHERE(result eq 0)], $
    LINESTYLE = 6, SYM_INDEX = 2
IPLOT, array[*], WHERE(result eq 1)], /OVERPLOT, $
    LINESTYLE = 6, SYM_INDEX = 4
IPLOT, array[*], WHERE(result eq 2)], /OVERPLOT, $
    LINESTYLE = 6, SYM_INDEX = 1

```

[CLUST\\_WTS](#), [CLUSTER\\_TREE](#), [PCOMP](#), [STANDARDIZE](#), “Multivariate Analysis” in Chapter 11 of the *Using IDL* manual.

# CLUSTER\_TREE

The CLUSTER\_TREE function computes the hierarchical clustering for a set of  $m$  items in an  $n$ -dimensional space. The CLUSTER\_TREE function is designed to be used with the DENDROGRAM or DENDRO\_PLOT procedures.

This routine is written in the IDL language. Its source code can be found in the file `cluster_tree.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = CLUSTER\_TREE( *Pairdistance*, *Linkdistance* [, LINKAGE = *value*] )

or for LINKAGE = 3 (centroid):

*Result* = CLUSTER\_TREE( *Pairdistance*, *Linkdistance*, LINKAGE = 3,  
[, DATA = *array*] [, MEASURE=*value*] [, POWER\_MEASURE=*value*] )

## Return Value

The *Result* is a 2-by- $(m-1)$  integer array containing the cluster indices. Each row of *Result* contains the indices of the two items that were clustered together. The distance between the two items is contained in the corresponding element of the *Linkdistance* output argument.

### Note

The original  $m$  items are given indices 0... $m-1$ , while each newly-created cluster is given a new index starting at  $m$  and incrementing.

## Arguments

### Pairdistance

An input array containing the pairwise distances as either a compact vector or as a symmetric matrix, usually created by the DISTANCE\_MEASURE function. For the compact vector form, *Pairdistance* should be an  $m*(m-1)/2$  element vector, ordered as:  $[D_{0,1}, D_{0,2}, \dots, D_{0,m-1}, D_{1,2}, \dots, D_{m-2,m-1}]$ , where  $D_{i,j}$  denotes the distance between items  $i$  and  $j$ . For the matrix form, *Pairdistance* should be an  $m$ -by- $m$  symmetric matrix with zeroes down the diagonal.

## Linkdistance

Set this argument to a named variable in which the cluster distances will be returned as an  $(m-1)$ -element single or double-precision vector. Each element of *Linkdistance* corresponds to the distance between the two items of the corresponding row in *Result*. If *Pairdistance* is double-precision then *Linkdistance* will be double-precision, otherwise *Linkdistance* will be single-precision.

## Keywords

### DATA

If the LINKAGE keyword is set equal to 3 (centroid), then the DATA keyword must be set to the array of original data as input to the DISTANCE\_MEASURE function. The data array is necessary for computing the centroid of newly-created clusters.

#### Note

---

DATA does not need to be supplied if LINKAGE is not equal to 3.

---

### LINKAGE

Set this keyword to an integer giving the method used for linking clusters together. Possible values are:

Value	Method Used
0	(Default) Use single linkage (nearest neighbor). The distance between two clusters is defined as the smallest distance between items in the two clusters. This method tends to string items together and is useful for non-homogeneous clusters.
1	Use complete linkage (furthest neighbor). The distance between two clusters is defined as the largest distance between items. This method is useful for homogeneous, compact, clusters but is not useful for long chain-like clusters.
2	Use weighted pairwise average. The distance between two clusters is defined as the average distance for all pairs of objects between each cluster, weighted by the number of objects in each cluster. This method works well for both homogeneous clusters and for chain-like clusters.

Table 3-3: LINKAGE Values and Methods

Value	Method Used
3	Use weighted centroid. The distance between two clusters is defined as the distance between the centroids of each cluster. The centroid of a cluster is the average position of all the subclusters, weighted by the number of objects in each subcluster.

*Table 3-3: LINKAGE Values and Methods (Continued)*

**Note**

If the LINKAGE keyword is equal to 3, the distance between two clusters may be less than the distance between items within one of the clusters. In a dendrogram plot this will cause the node lines to overlap.

## MEASURE

If the LINKAGE keyword is equal to 3 (centroid), set this keyword to an integer giving the distance measure (the metric) to use. Possible values are:

Value	Type
0	(Default) Euclidean distance
1	CityBlock (Manhattan) distance
2	Chebyshev distance
3	Correlative distance
4	Percent disagreement

*Table 3-4: MEASURE Values*

For consistent results, the MEASURE value should match the value used in the original call to DISTANCE\_MEASURE. This keyword is ignored if LINKAGE is not equal to 3, or if POWER\_MEASURE is set.

**Note**

See DISTANCE\_MEASURE for a detailed description of the various metrics.

## POWER\_MEASURE

If the LINKAGE keyword is equal to 3 (centroid), set this keyword to a scalar or a two-element vector giving the parameters  $p$  and  $r$  to be used in the power distance metric. If POWER\_MEASURE is a scalar then the same value is used for both  $p$  and  $r$ . For consistent results, the POWER\_MEASURE value should match the value used in the original call to DISTANCE\_MEASURE. This keyword is ignored if LINKAGE is not equal to 3.

---

### Note

See DISTANCE\_MEASURE for a detailed description of the power distance metric.

---

## Example

```

; Given a set of points in two-dimensional space.
DATA = [ $
[1, 1], $
[1, 3], $
[2, 2.2], $
[4, 1.75], $
[4, 4], $
[5, 1], $
[5.5, 3]]

; Compute the Euclidean distance between each point.
DISTANCE = DISTANCE_MEASURE(data)

; Now compute the cluster analysis.
CLUSTERS = CLUSTER_TREE(distance, linkdistance)

PRINT, 'Item# Item# Distance'
PRINT, [clusters, TRANSPOSE(linkdistance)], $
      FORMAT='(I3, I7, F10.2)'
```

When this code is run, IDL prints:

```

Item#  Item#  Distance
5      3      1.25
2      1      1.28
8      0      1.56
6      4      1.80
7      10     1.95
11     9      2.05
```

Items 5 and 3 are joined to create a new cluster, which is given the item number of 7. Items 2 and 1 are joined to create a cluster with item number 8. The process continues until all items have been joined together. A graphical representation is shown below (for clarity the last cluster, between items 9 and 11, has been omitted):

Figure 3-16: Graphical Representation of Hierarchical Clustering

# CMYK\_CONVERT

The `CMYK_CONVERT` procedure converts from the CMYK (cyan-magenta-yellow-black) color model to RGB (red-green-blue) and vice versa.

The procedure uses the following method to convert from CMYK to RGB:

$$R = (255 - C) (1 - K/255)$$

$$G = (255 - M) (1 - K/255)$$

$$B = (255 - Y) (1 - K/255)$$

To convert from RGB to CMYK, the procedure uses the following method:

$$K = \text{minimum of } (R, G, B)$$

$$C = 255 [1 - R/(255 - K)] \quad (\text{if } K=255 \text{ then } C=0)$$

$$M = 255 [1 - G/(255 - K)] \quad (\text{if } K=255 \text{ then } M=0)$$

$$Y = 255 [1 - B/(255 - K)] \quad (\text{if } K=255 \text{ then } Y=0)$$

In both cases the CMYK and RGB values are assumed to be in the range 0 to 255.

---

## Note

There is no single method that is used for CMYK/RGB conversion. The method used by `CMYK_CONVERT` is the simplest and, depending on printing inks and screen colors, might not be optimal in all situations.

---

This routine is written in the IDL language. Its source code can be found in the file `cmyk_convert.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

`CMYK_CONVERT, C, M, Y, K, R, G, B [, /TO_CMYK]`

## Arguments

### C, M, Y, K

To convert from CMYK to RGB, set these arguments to scalars or arrays containing the CMYK values in the range 0-255. To convert from RGB to CMYK (with the `TO_CMYK` keyword set), set these arguments to named variables that will contain the converted values.

## R, G, B

To convert from CMYK to RGB, set these arguments to named variables that will contain the converted values. To convert from RGB to CMYK (with the [TO\\_CMYK](#) keyword set), set these arguments to scalars or arrays containing the RGB values.

## Keywords

### TO\_CMYK

If this keyword is set, the values contained in the RGB arguments are converted to CMYK. The default is to convert from CMYK to RGB.

## Example

This example converts an image file's RGB data to CMYK, displays the image using different color tables, converts CMYK back to RGB, and displays the image again.

```
file = FILEPATH( 'rose.jpg', SUBDIRECTORY=['examples','data'] )
READ_JPEG, file, image
red = REFORM( image[0,*,*] )
green = REFORM( image[1,*,*] )
blue = REFORM( image[2,*,*] )

; Convert from RGB to CMYK
CMYK_CONVERT, c, m, y, k, red, green, blue, /TO_CMYK

; Display using cyan (green + blue) color table
IIMAGE, GREEN=c, BLUE=c, VIEW_GRID=[2,3], DIM=[600,800]
; Display using magenta (red + blue) color table
IIMAGE, RED=m, BLUE=m, /VIEW_NEXT
; Display using yellow (red + green) color table
IIMAGE, RED=y, GREEN=y, /VIEW_NEXT
; Display using inverted grayscale (like ink)
IIMAGE, 255b-k, /VIEW_NEXT

; Convert from CMYK back to RGB
CMYK_CONVERT, c, m, y, k, r, g, b
IIMAGE, image, /VIEW_NEXT
IIMAGE, RED=r, GREEN=g, BLUE=b, /VIEW_NEXT
```

[COLOR\\_CONVERT](#)

# COLOR\_CONVERT

The COLOR\_CONVERT procedure converts colors to and from the RGB (Red Green Blue), HLS (Hue Lightness Saturation), and HSV (Hue Saturation Value) color systems. A keyword parameter indicates the type of conversion to be performed (one of the keywords must be specified). The first three parameters contain the input color triple(s) which may be scalars or arrays of the same size. The result is returned in the last three parameters,  $O_0$ ,  $O_1$ , and  $O_2$ . RGB values are bytes in the range 0 to 255.

Hue is measured in degrees, from 0 to 360. Saturation, Lightness, and Value are floating-point numbers in the range 0 to 1. A Hue of 0 degrees is the color red. Green is 120 degrees. Blue is 240 degrees. A reference containing a discussion of the various color systems is: Foley and Van Dam, *Fundamentals of Interactive Computer Graphics*, Addison-Wesley Publishing Co., 1982.

## Syntax

```
COLOR_CONVERT,  $I_0$ ,  $I_1$ ,  $I_2$ ,  $O_0$ ,  $O_1$ ,  $O_2$  [, /HLS_RGB | , /HSV_RGB | ,  
/RGB_HLS | , /RGB_HSV]
```

## Arguments

$I_0$ ,  $I_1$ ,  $I_2$

The input color triple(s). These arguments may be either scalars or arrays of the same length.

$O_0$ ,  $O_1$ ,  $O_2$

The variables to receive the result. Their structure is copied from the input parameters.

## Keywords

**HLS\_RGB**

Set this keyword to convert from HLS to RGB.

**HSV\_RGB**

Set this keyword to convert from HSV to RGB.

## RGB\_HLS

Set this keyword to convert from RGB to HLS.

## RGB\_HSV

Set this keyword to convert from RGB to HSV.

## Examples

The command:

```
COLOR_CONVERT, 255, 255, 0, h, s, v, /RGB_HSV
```

converts the RGB color triple (255, 255, 0), which is the color yellow at full intensity and saturation, to the HSV system. The resulting hue in the variable h is 60.0 degrees. The saturation and value, s and v, are set to 1.0.

# COLOR\_QUAN

The COLOR\_QUAN function quantizes a TrueColor image and returns a pseudo-color image and palette to display the image on standard pseudo-color displays. The output image and palette can have from 2 to 256 colors.

COLOR\_QUAN solves the general problem of accurately displaying decomposed, TrueColor images, that contain a palette of up to  $2^{24}$  colors, on pseudo-color displays that can only display 256 (or fewer) simultaneous colors.

## Using COLOR\_QUAN

One of two color quantization methods can be used:

- Method 1 is a statistical method that attempts to find the N colors that most accurately represent the original color distribution. This algorithm uses a variation of the Median Cut Algorithm, described in “Color Image Quantization for Frame Buffer Display”, from *Computer Graphics*, Volume 16, Number 3 (July, 1982), Page 297. It repeatedly subdivides the color space into smaller and smaller rectangular boxes, until the requested number of colors are obtained.

The original colors are then mapped to the nearest output color, and the original image is resampled to the new palette with optional Floyd-Steinberg color dithering. The resulting pseudo-color image and palette are usually a good approximation of the original image.

The number of colors in the output palette defaults to the number of colors supported by the currently-selected graphics output device. The number of colors can also be specified by the COLOR keyword parameter.

- Method 2, selected by setting the keyword parameter CUBE, divides the three-dimensional color space into equal-volume cubes. Each color axis is divided into CUBE segments, resulting in  $CUBE^3$  volumes. The original input image is sampled to this color space using Floyd-Steinberg dithering, which distributes the quantization error to adjacent pixels.

The CUBE method has the advantage that the color tables it produces are independent of the input image, so that multiple quantized images can be viewed simultaneously. The statistical method usually provides a better-looking result and a smaller global error.

COLOR\_QUAN can use the same color mapping for a series of images. See the descriptions of the GET\_TRANSLATION, MAP\_ALL, and TRANSLATION keywords, below.

## Syntax

*Result* = COLOR\_QUAN( *Image\_R*, *Image\_G*, *Image\_B*, *R*, *G*, *B* )

or

*Result* = COLOR\_QUAN( *Image*, *Dim*, *R*, *G*, *B* )

**Keywords:** [, **COLORS**=*integer*{2 to 256}] [, **CUBE**={2 | 3 | 4 | 5 | 6} | ,  
**GET\_TRANSLATION**=*variable* [, /MAP\_ALL]] [, /DITHER]  
 [, **ERROR**=*variable*] [, **TRANSLATION**=*vector*]

The input image parameter can be passed as either three, separate color-component arrays (*Image\_R*, *Image\_G*, *Image\_B*) or as a three-dimensional array containing all three components, *Image*, and a scalar, *Dim*, indicating the dimension over which the colors are interleaved.

## Return Value

Returns a pseudo-color image composed of 2 to 256 colors.

## Arguments

### Image\_R, Image\_G, Image\_B

Arrays containing the red, green, and blue components of the decomposed TrueColor image. For best results, the input image(s) should be scaled to the range of 0 to 255.

### Image

A three-dimensional array containing all three components of the TrueColor image.

### Dim

A scalar that indicates the method of color interleaving in the *Image* parameter. A value of 1 indicates interleaving by pixel: (3, *n*, *m*). A value of 2 indicates interleaving by row: (*n*, 3, *m*). A value of 3 indicates interleaving by image: (*n*, *m*, 3).

### R, G, B

Three output byte arrays containing the red, green, and blue components of the output palette.

## Keywords

### **COLORS**

The number of colors in the output palette. This value must be at least 2 and not greater than 256. The default is the number of colors supported by the current graphics output device.

### **CUBE**

If this keyword is set, the color space is divided into  $CUBE^3$  volumes, to which the input image is quantized. This result is always Floyd-Steinberg dithered. The value of CUBE can range from 2 to 6; providing from  $2^3 = 8$ , to  $6^3 = 216$  output colors. If this keyword is set, the COLORS, DITHER, and ERROR keywords are ignored.

### **DITHER**

Set this keyword to dither the output image. Dithering can improve the appearance of the output image, especially when using relatively few colors.

### **ERROR**

Set this optional keyword to a named variable. A measure of the quantization error is returned. This error is proportional to the square of the Euclidean distance, in RGB space, between corresponding colors in the original and output images.

### **GET\_TRANSLATION**

Set this keyword to a named variable in which the mapping between the original RGB triples (in the TrueColor image) and the resulting pseudo-color indices is returned as a vector. Do not use this keyword if CUBE is set.

### **MAP\_ALL**

Set this keyword to establish a mapping for all possible RGB triples into pseudo-color indices. Set this keyword only if GET\_TRANSLATION is also present. Note that mapping all possible colors requires more compute time and slightly degrades the quality of the resultant color matching.

### **TRANSLATION**

Set this keyword to a vector of translation indices obtained by a previous call to COLOR\_QUAN using the GET\_TRANSLATION keyword. The resulting image is quantized using this vector.

## Examples

The following code segment reads a TrueColor, row interleaved, image from a disk file, and displays it on the current graphics display, using a palette of 128 colors:

```
;Open an input file:
OPENR, unit, 'XXX.DAT', /GET_LUN

;Dimensions of the input image:
a = BYTARR(512, 3, 480)

;Read the image:
READU, unit, a

;Close the file:
FREE LUN, unit

;Show the quantized image. The 2 indicates that the colors are
;interleaved by row:
TV, COLOR_QUAN(a, 2, r, g, b, COLORS=128)

;Load the new palette:
TVLCT, r, g, b
```

To quantize the image into 216 equal-volume color cubes, replace the call to `COLOR_QUAN` with the following:

```
TV, COLOR_QUAN(a, 2, r, g, b, CUBE=6)
```

## Converting RGB Images to Indexed Images

Although it is a relatively simple process to convert an RGB image to a grayscale image, the process needed to convert an RGB image to an indexed image is more complex. This process is more complex because the millions of possible colors provided by an RGB image must be decomposed into the 256 colors used by an indexed image. IDL's `COLOR_QUAN` function may be used to perform this process.

The following example shows how to use the `COLOR_QUAN` function to convert an RGB image to an indexed image. The `elev_t.jpg` file contains a pixel interleaved RGB image, which has its own color information. This example converts the image to an indexed image with an associated color table. Complete the following steps for a detailed description of the process.

### Example Code

See `rgbtoindexed.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `elev_t.jpg` file:

```
elev_tFile = FILEPATH('elev_t.jpg', $  
    SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image from the `elev_t.jpg` file into IDL:

```
READ_JPEG, elev_tFile, elev_tImage
```

3. Determine the size of the imported image:

```
elev_tSize = SIZE(elev_tImage, /DIMENSIONS)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to one before your first RGB image is displayed within an IDL session or program.

```
DEVICE, DECOMPOSED = 1
```

5. Initialize the display:

```
WINDOW, 0, TITLE = 'elev_t.jpg', $  
    XSIZE = elev_tSize[1], YSIZE = elev_tSize[2]
```

6. Display the imported image:

```
TV, elev_tImage, TRUE = 1
```

The following figure shows the original RGB image.

*Figure 3-17: Example of an RGB Image*

**Note**

---

If you are running IDL on a PseudoColor display, the RGB image will not be displayed correctly. A PseudoColor display only allows the display of indexed images. You can change the RGB image to an indexed image with the `COLOR_QUAN` routine. An example of this method is shown in this section.

---

The RGB image is converted to an indexed image with the `COLOR_QUAN` routine, but the `DECOMPOSED` keyword to the `DEVICE` command must be set to zero (for TrueColor displays) before using `COLOR_QUAN` because it is a color table related routine. See [COLOR\\_QUAN](#) for more information.

**Note**

---

`COLOR_QUAN` may result in some loss of color information since it quantizes the image to a fixed number of colors (stored in the color table).

---

7. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

8. Convert the RGB image to an indexed image with an associated color table:

```
imageIndexed = COLOR_QUAN(elev_tImage, 1, red, green, $
    blue)
```

9. Export the resulting indexed image and its associated color table to a PNG file:

```
WRITE_PNG, 'elev_t.png', imageIndexed, red, green, blue
```

# COLORMAP\_APPLICABLE

The COLORMAP\_APPLICABLE function determines whether the current visual class supports the use of a colormap, and if so, whether colormap changes affect pre-displayed Direct Graphics or if the graphics must be redrawn to pick up colormap changes.

This routine is written in the IDL language. Its source code can be found in the file `colormap_applicable.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = COLORMAP\_APPLICABLE( *redrawRequired* )

## Return Value

The function returns a long value of 1 if the current visual class allows modification of the color table, and 0 otherwise.

## Arguments

### **redrawRequired**

A named variable to retrieve a value indicating whether the visual class supports automatic updating of graphics. The value is 0 if the graphics are updated automatically, or 1 if the graphics must be redrawn to pick up changes to the colormap.

## Keywords

None.

## Examples

To determine whether to redisplay an image after a colormap change:

```
result = COLORMAP_APPLICABLE(redrawRequired)
IF ((result GT 0) AND (redrawRequired GT 0)) THEN BEGIN
    my_redraw
ENDIF
```

# COMFIT

The COMFIT function fits the paired data  $\{x_i, y_i\}$  to one of six common types of approximating models using a gradient-expansion least-squares method.

This routine is written in the IDL language. Its source code can be found in the file `comfit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = COMFIT( X, Y, A [, /EXPONENTIAL | /GEOMETRIC | /GOMPERTZ |  
/HYPERBOLIC | /LOGISTIC | /LOGSQUARE] [, SIGMA=variable]  
[, WEIGHTS=vector] [, YFIT=variable] )
```

## Return Value

Results in a vector containing the model parameters  $a_0, a_1, a_2$ , etc.

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector.

### A

A vector of initial estimates for each model parameter. The length of this vector depends upon the type of model selected.

## Keywords

### Note

---

One of the following keywords specifying a type of model must be set when using COMFIT. If you do not specify a model, IDL will display a warning message when COMFIT is called.

---

## EXPONENTIAL

Set this keyword to compute the parameters of the exponential model.

$$y = a_0 a_1^x + a_2$$

## GEOMETRIC

Set this keyword to compute the parameters of the geometric model.

$$y = a_0 x^{a_1} + a_2$$

## GOMPertz

Set this keyword to compute the parameters of the Gompertz model.

$$y = a_0 a_1^{a_2 x} + a_3$$

## HYPERBOLIC

Set this keyword to compute the parameters of the hyperbolic model.

$$y = \frac{1}{a_0 + a_1 x}$$

## LOGISTIC

Set this keyword to compute the parameters of the logistic model.

$$y = \frac{1}{a_0 a_1^x + a_2}$$

## LOGSQUARE

Set this keyword to compute the parameters of the logsquare model.

$$y = a_0 + a_1 \log(x) + a_2 \log(x)^2$$

## SIGMA

Set this keyword to a named variable that will contain a vector of standard deviations for the computed model parameters.

## WEIGHTS

Set this keyword equal to a vector of weights for  $Y_i$ . This vector should be the same length as  $X$  and  $Y$ . The error for each term is weighted by  $WEIGHTS_i$  when computing the fit. Frequently,  $WEIGHTS_i = 1.0/\sigma_i^2$ , where  $\sigma$  is the measurement error or standard deviation of  $Y_i$  (Gaussian or instrumental weighting), or  $WEIGHTS = 1/Y$  (Poisson or statistical weighting). If  $WEIGHTS$  is not specified,  $WEIGHTS_i$  is assumed to be 1.0.

## YFIT

Set this keyword to a named variable that will contain an  $n$ -element vector of y-data corresponding to the computed model parameters.

## Examples

```
; Define two n-element vectors of paired data:
X = [ 2.27, 15.01, 34.74, 36.01, 43.65, 50.02, 53.84, 58.30, $
      62.12, 64.66, 71.66, 79.94, 85.67, 114.95]
Y = [ 5.16, 22.63, 34.36, 34.92, 37.98, 40.22, 41.46, 42.81, $
      43.91, 44.62, 46.44, 48.43, 49.70, 55.31]

; Define a 3-element vector of initial estimates for the logsquare
; model:
A = [1.5, 1.5, 1.5]

; Compute the model parameters of the logsquare model, A[0], A[1],
; & A[2]:
result = COMFIT(X, Y, A, /LOGSQUARE)
```

The result should be the 3-element vector: [1.42494, 7.21900, 9.18794].

# COMMAND\_LINE\_ARGS

The `COMMAND_LINE_ARGS` function returns strings supplied by the user when IDL was started with the `-arg` or `-args` command line options. If either of these options is specified at the command line when IDL is started, IDL saves them without examining their values or attaching any special meaning to them.

---

## Note

The shell performs its normal interpretation of wildcards and shell metacharacters *before* the values of the `-arg` or `-args` command line options are passed to IDL.

---

Strings specified at the command line can be retrieved at any time within the IDL session via the `COMMAND_LINE_ARGS` function. This mechanism can be used to pass special application-defined values to a program written in the IDL language.

## Syntax

*Result* = `COMMAND_LINE_ARGS`( [, `COUNT`=*variable*] )

## Return Value

If any `-arg` or `-args` options were specified at the command line when IDL was started, `COMMAND_LINE_ARGS` returns a string array containing the specified values, one value per element. The values are returned in the order specified by the user on the command line. If no such options were specified, a `NULL` scalar string is returned.

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of retrieved arguments. If no arguments were specified, the variable will contain 0.

## Version History

6.2	Introduced

# COMMON

The `COMMON` statement creates or references a common block. Common blocks are useful when there are variables that need to be accessed by several IDL procedures or when the value of a variable within a procedure must be preserved across calls. Once a common block has been defined, any program unit referencing that common block can access variables in the block as though they were local variables. Variables in a common statement have a global scope within procedures defining the same common block. Unlike local variables, variables in common blocks are not destroyed when a procedure is exited.

There are two types of common block statements: definition statements and reference statements. See the Examples section for details.

## Note on Common Block Variable Names

Variables in IDL `COMMON` blocks do not actually have names. Rather, IDL represents `COMMON` blocks internally as an array of variables, and these variables are referenced by their positional index. Hence, the first variable is at position 0, the second at position 1, and so forth. When you specify a `COMMON` block declaration in an IDL routine, you specify names to be used for these variables *within the scope of that routine*.

The first routine in which a `COMMON` block is defined is remembered by IDL as part of the state of that block. When another routine defines the same `COMMON` block, it is allowed to omit the variable names. In this case, IDL uses the same names used in the original defining routine. Since good programming practice dictates that the same names be used everywhere, this result usually causes no confusion. However, different routines are *allowed* to use entirely different names to refer to a given variable. For example, the `DIV` routine above could have been written like this:

```
PRO DIV2, D
  COMMON SHARE2, X, Y, Z
  D = X / Y
  PRINT, D, X, Y, Z
  RETURN
END
```

In this scenario, the variable referred to by the name `E` in the `MULT` routine is referred to by the name `X` in the `DIV2` routine. Similarly, the variable name `F` is replaced by `Y`, and the name `G` is replaced by `Z`. Note that only the names by which the variables are called has changed — the underlying variables are the same. While this type of `COMMON` block reference is legal, it can quickly become confusing, and most programmers use the same names in every case.

## Syntax

COMMON *Block\_Name*, *Variable*<sub>1</sub>, ..., *Variable*<sub>*n*</sub>

## Examples

### Common Block Definition Statements

The common block definition statement creates a common block with the designated name and places the variables whose names follow into that block. Variables defined in a common block can be referenced by any program unit that declares that common block. The general form of the COMMON block definition statement is as follows:

```
COMMON Block_Name, Variable1, Variable2, ..., Variablen
```

The number of variables appearing in the common block cannot change after the common block has been defined. The first program unit (main program, function, or procedure) to define the common block sets the number of included variables; other program units can *reference* the common block with any number of variables up to the number originally specified. Different program units can give the variables different names, as shown in the example below.

Common blocks share the same space for all procedures. In IDL, common block variables are matched variable to variable, unlike FORTRAN, where storage locations are matched. The third variable in a given IDL common block will always be the same as the third variable in all declarations of the common block regardless of the size, type, or structure of the preceding variables.

Note that common blocks must appear before any of the variables they define are referenced in the procedure.

Variables in common blocks can be of any type and can be used in the same manner as normal variables. Variables appearing as parameters cannot be used in common blocks. There are no restrictions on the number of common blocks used, although each common block uses dynamic memory.

### Example

The two procedures in the following example show how variables defined in common blocks are shared.

```
PRO ADD, A
  COMMON SHARE1, X, Y, Z, Q, R
  A = X + Y + Z + Q + R
  PRINT, X, Y, Z, Q, R, A
  RETURN
```

```

END

PRO SUB, T
  COMMON SHARE1, A, B, C, D
  T = A - B - C - D
  PRINT, A, B, C, D, T
  RETURN
END

```

The variables X, Y, Z, and Q in the procedure ADD are the same as the variables A, B, C, and D, respectively, in procedure SUB. The variable R in ADD is not used in SUB. If the procedure SUB were to be compiled before the procedure ADD, an error would occur when the COMMON definition in ADD was compiled. This is because SUB has already declared the size of the COMMON block, SHARE1, which cannot be extended.

## Common Block Reference Statements

The common block reference statement duplicates the COMMON block and variable names from a previous definition. The COMMON block need only be defined in the first routine to be compiled that references the block.

### Example

The two procedures in the following example share the COMMON block SHARE2 and all its variables.

```

PRO MULT, M
  COMMON SHARE2, E, F, G
  M = E * F * G
  PRINT, M, E, F, G
  RETURN
END

PRO DIV, D
  COMMON SHARE2
  D = E / F
  PRINT, D, E, F, G
  RETURN
END

```

The MULT procedure uses a common block *definition* statement to define the block SHARE2. The DIV procedure then uses a COMMON block *reference* statement to gain access to all the variables defined in SHARE2. (Note that MULT must be defined before DIV in order for the COMMON block *reference* to succeed.)

# COMPILE\_OPT

The `COMPILE_OPT` statement allows you to give the IDL compiler information that changes some of the default rules for compiling the function or procedure within which the `COMPILE_OPT` statement appears.

RSI recommends the use of

```
COMPILE_OPT IDL2
```

in all new code intended for use in a reusable library. We further recommend the use of

```
COMPILE_OPT idl2, HIDDEN
```

in all such routines that are not intended to be called directly by regular users (e.g. helper routines that are part of a larger package).

## Syntax

```
COMPILE_OPT opt1 [, opt2, ..., optn]
```

## Arguments

### *opt*<sub>*n*</sub>

This argument can be any of the following:

- **IDL2** — A shorthand way of saying:
 

```
COMPILE_OPT DEFINT32, STRICTARR
```
- **DEFINT32** — IDL should assume that lexical integer constants default to the 32-bit type rather than the usual default of 16-bit integers. This takes effect from the point where the `COMPILE_OPT` statement appears in the routine being compiled and remains in effect until the end of the routine. The following table illustrates how the `DEFINT32` argument changes the interpretation of integer constants.

Constant	Normal Type	DEFINT32 Type
<b>Without type specifier:</b>		
42	INT	LONG
'2a'x	INT	LONG
42u	UINT	ULONG
'2a'xu	UINT	ULONG
<b>With type specifier:</b>		
0b	BYTE	BYTE
0s	INT	INT
0l	LONG	LONG
42.0	FLOAT	FLOAT
42d	DOUBLE	DOUBLE
42us	UINT	UINT
42ul	ULONG	ULONG
42ll	LONG64	LONG64
42ull	ULONG64	ULONG64

*Table 3-5: Examples of the Effect of the DEFINT32 Argument*

- **HIDDEN** — This routine should not be displayed by HELP, unless the FULL keyword to HELP is used. This directive can be used to hide helper routines that regular IDL users are not interested in seeing.

A side-effect of making a routine hidden is that IDL will not print a “Compile module” message for it when it is compiled from the library to satisfy a call to it. This makes hidden routines appear built-in to the user.

- **LOGICAL\_PREDICATE** — When running this routine, from the point where the COMPILE\_OPT statement appears until the end of the routine, treat any non-zero or non-NULL predicate value as “true,” and any zero or NULL predicate value as “false.”

## Background

A predicate expression is an expression that is evaluated as being “true” or “false” as part of a statement that controls program execution. IDL evaluates such expressions in the following contexts:

- IF . . . THEN . . . ELSE statements
- ? : inline conditional expressions
- WHILE . . . DO statements
- REPEAT . . . UNTIL statements
- when evaluating the result from an INIT function method to determine if a call to OBJ\_NEW successfully created a new object

By default, IDL uses the following rules to determine whether an expression is true or false:

- **Integer** — An integer is considered true if its least significant bit is 1, and false otherwise. Hence, odd integers are true and even integers (including zero) are false. This interpretation of integer truth values is sometimes referred to as “bitwise,” reflecting the fact that the value of the least significant bit determines the result.
- **Other** — Non-integer numeric types are true if they are non-zero, and false otherwise. String and heap variables (pointers and object references) are true if they are non-NULL, and false otherwise.

The LOGICAL\_PREDICATE option alters the way IDL evaluates predicate expressions. When LOGICAL\_PREDICATE is set for a routine, IDL uses the following rules to determine whether an expression is true or false:

- **Numeric Types** — A number is considered true if its value is non-zero, and false otherwise.
- **Other Types** — Strings and heap variables (pointers and object references) are considered true if they are non-NULL, or false otherwise.

### Note on the NOT Operator

When using the LOGICAL\_PREDICATE compile option, you must be aware of the fact that applying the IDL NOT operator to integer data computes a *bitwise* negation (1’s complement), and is generally not applicable for use in logical computations. Consider the common construction:

```
WHILE (NOT EOF(1un)) DO BEGIN
  . . .
ENDWHILE
```

The EOF function returns 0 while the file specified by LUN has data left, and returns 1 when hits the end of file. However, the expression “NOT 1” has the numeric value -2. When the LOGICAL\_PREDICATE option is not in use, the WHILE statement sees -2 as false; if the LOGICAL\_PREDICATE is in use, -2 is a true value and the above loop will not terminate as desired.

The proper way to write the above loop uses the ~ logical negation operator:

```
WHILE (~ EOF(lun)) DO BEGIN
  ...
ENDWHILE
```

It is worth noting that this version will work properly whether or not the LOGICAL\_PREDICATE compile option is in use. Logical negation operations should always use the ~ operator in preference to the NOT operator, reserving NOT exclusively for bitwise computations.

- **OBSOLETE** — If the user has !WARN.OBS\_ROUTINES set to True, attempts to compile a call to this routine will generate warning messages that this routine is obsolete. This directive can be used to warn people that there may be better ways to perform the desired task.
- **STRICTARR** — While compiling this routine, IDL will not allow the use of parentheses to index arrays, reserving their use only for functions. Square brackets are then the only way to index arrays. Use of this directive will prevent the addition of a new function in future versions of IDL, or new libraries of IDL code from any source, from changing the meaning of your code, and is an especially good idea for library functions.

Use of STRICTARR can eliminate many uses of the FORWARD\_FUNCTION definition.

---

### Note

STRICTARR has no effect on the use of parentheses to reference structure tags using the tag index, which is not an array indexing operation. For example, no syntax error will occur when compiling the following code:

```
COMPILE_OPT STRICTARR
mystruct = {a:0, b:1}
byindex_0 = mystruct.(0)
```

For more on referencing structure tags by index, see [“Advanced Structure Usage”](#) in Chapter 16 of the *Building IDL Applications* manual.

---

- **STRICTARRSUBS** — When IDL subscripts one array using another array as the source of array indices, the default behavior is to clip any out-of-range indices into range and then quietly use the resulting data without error. This behavior is described in “[Understanding Array Subscripts](#)” in Chapter 15 of the *Building IDL Applications* manual. Specifying STRICTARRSUBS will instead cause IDL to treat such out-of-range array subscripts within the body of the routine containing the COMPILE\_OPT statement as an error. The position of the STRICTARRSUBS option within the module is not important: All subscripting operations within the entire body of the specified routine will be treated this way.

## Version History

5.3	Introduced
5.6	Added STRICTARRSUBS option
6.0	Added LOGICAL_PREDICATE option

# COMPLEX

The COMPLEX function returns complex scalars or arrays given one or two scalars or arrays.

## Syntax

*Result* = COMPLEX(*Real* [, *Imaginary*] [, /DOUBLE])

or

*Result* = COMPLEX(*Expression*, *Offset*, *D<sub>1</sub>* [, ..., *D<sub>8</sub>*] [, /DOUBLE])

## Return Value

Returns complex scalars or arrays given one or two scalars or arrays. If only one parameter is supplied, the imaginary part of the result is zero, otherwise it is set to the value of the *Imaginary* parameter. Parameters are first converted to single-precision floating-point. If either or both of the parameters are arrays, the result is an array, following the same rules as standard IDL operators. If three parameters are supplied, COMPLEX extracts fields of data from *Expression*.

## Arguments

### Real

Scalar or array to be used as the real part of the complex result.

### Imaginary

Scalar or array to be used as the imaginary part of the complex result.

### Expression

The expression from which data is to be extracted.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as complex data. See the description in [Chapter 13, “Working with Data in IDL”](#) in the *Building IDL Applications* manual for details.

## $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON\_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

## Keywords

### DOUBLE

Set this keyword to return a double-precision complex result. Setting this keyword is equivalent to using the DCOMPLEX function, and is provided as a programming convenience.

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Create a complex array from two integer arrays by entering the following commands:

```
; Create the first integer array:
A = [1,2,3]

; Create the second integer array:
B = [4,5,6]
```

```

; Make A the real parts and B the imaginary parts of the new
; complex array:
C = COMPLEX(A, B)

; See how the two arrays were combined:
PRINT, C

```

IDL prints:

```

( 1.00000, 4.00000) ( 2.00000, 5.00000)
( 3.00000, 6.00000)

```

The real and imaginary parts of the complex array can be extracted as follows:

```

; Print the real part of the complex array C:
PRINT, 'Real Part: ', REAL_PART(C)

; Print the imaginary part of the complex array C:
PRINT, 'Imaginary Part: ', IMAGINARY(C)

```

IDL prints:

```

Real Part:          1.00000    2.00000    3.00000
Imaginary Part:    4.00000    5.00000    6.00000

```

# COMPLEXARR

The COMPLEXARR function returns a complex, single-precision, floating-point vector or array.

## Syntax

$$\text{Result} = \text{COMPLEXARR}( D_1[, \dots, D_8] [, \text{/NOZERO}] )$$

## Return Value

Returns a complex, single-precision, floating-point vector or array.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, COMPLEXARR sets every element of the result to zero. If the NOZERO keyword is set, this zeroing is not performed, and COMPLEXARR executes faster.

## Examples

To create an empty, 5-element by 5-element, complex array C, enter:

```
C = COMPLEXARR(5, 5)
```

# COMPLEXROUND

The COMPLEXROUND function rounds real and imaginary components of a complex array.

This routine is written in the IDL language. Its source code can be found in the file `complexround.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = COMPLEXROUND(*Input*)

## Return Value

Returns the result of rounding the real and imaginary components of the input array. If the array is double-precision complex, then the result is also double-precision complex.

## Arguments

### Input

The complex array to be rounded.

## Keywords

None.

## Examples

```
X = [COMPLEX(1.245, 3.88), COMPLEX(9.1, 0.3345)]  
PRINT, COMPLEXROUND(X)
```

IDL prints:

```
( 1.00000, 4.00000) ( 9.00000, 0.00000)
```

# COMPUTE\_MESH\_NORMALS

The COMPUTE\_MESH\_NORMALS function computes normal vectors for a set of polygons described by the input array.

## Syntax

```
Result = COMPUTE_MESH_NORMALS(fVerts [, iConn] )
```

## Return Value

Returns a 3 x *M* array containing a unit normal for each vertex in the input array.

## Arguments

### fVerts

A 3 x *M* array of vertices.

### iConn

A connectivity array (see the POLYGONS keyword to IDLgrPolygon::Init). If no *iConn* array is provided, it is assumed that the vertices in *fVerts* constitute a single polygon.

## Keywords

None.

5.1	Introduced
-----	------------

# COND

The COND function returns the condition number of a real or complex two-dimensional array  $A$ .

By default, COND uses the  $L_\infty$  norm to compute the condition number. You may use the LNORM keyword to specify the  $L_1$ ,  $L_2$ , or  $L_\infty$  norm.

For the  $L_1$  and  $L_\infty$  norms, the condition number is computed from  $\text{NORM}(A) \cdot \text{NORM}(\text{INVERT}(A))$ . If the inverse of  $A$  is invalid (due to the singularity of  $A$  or floating-point errors in the INVERT function), COND returns -1.

For the  $L_2$  norm, the condition number is defined as the ratio of the largest singular value to the smallest. The singular values are computed using [LA\\_SVD](#).

This routine is written in the IDL language. Its source code can be found in the file `cond.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = COND( A [, /DOUBLE] [, LNORM={0 | 1 | 2}] )
```

## Return Value

Returns the condition number of an  $n$  by  $n$  real or complex array  $A$  by explicitly computing  $\text{NORM}(A) \cdot \text{NORM}(A^{-1})$ . If  $A^{-1}$  is invalid (due to the singularity of  $A$  or floating-point errors in the INVERT function), COND returns -1.

## Arguments

### **A**

The two-dimensional array. For LNORM = 0 or 1, the array  $A$  must be a square and can be either real or complex. For LNORM = 2, the array  $A$  may be rectangular and can only be real.

## Keywords

### **DOUBLE**

Set this keyword to force the result to be returned as double-precision. The default is to return a single-precision result if the input is single precision, or a double-precision

result otherwise. Internally, IDL performs all computations using double-precision arithmetic.

## LNORM

Set this keyword to an integer value to indicate which norm to use for the computation. The possible values of this keyword are:

Value	Description
0	Use the $L_\infty$ norm (the maximum absolute row sum norm). This is the default.
1	Use the $L_1$ norm (the maximum absolute column sum norm).
2	Use the $L_2$ norm (the spectral norm).

Table 3-6: LNORM Keyword Values

## Examples

```

; Define a complex array A:
A = [[COMPLEX(1, 0), COMPLEX(2, -2), COMPLEX(-3, 1)], $
      [COMPLEX(1, -2), COMPLEX(2, 2), COMPLEX(1, 0)], $
      [COMPLEX(1, 1), COMPLEX(0, 1), COMPLEX(1, 5)]]

; Compute the condition number of the array using internal
; double-precision arithmetic:
PRINT, COND(A, /DOUBLE)

```

IDL prints:

```
5.93773
```

[DETERM](#), [INVERT](#), [NORM](#), [LA\\_SVD](#)

# CONGRID

The CONGRID function shrinks or expands the size of an array by an arbitrary amount. CONGRID is similar to REBIN in that it can resize a one, two, or three dimensional array, but where REBIN requires that the new array size must be an integer multiple of the original size, CONGRID will resize an array to any arbitrary size. (REBIN is somewhat faster, however.) REBIN averages multiple points when shrinking an array, while CONGRID just resamples the array.

This routine is written in the IDL language. Its source code can be found in the file `congrid.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CONGRID( Array, X, Y, Z [, /CENTER] [, CUBIC=value{-1 to 0}]  
[, /INTERP] [, /MINUS_ONE] )
```

## Return Value

Returns the resized array. The returned array has the same number of dimensions as the original array and is of the same data type.

## Arguments

### Array

A 1-, 2-, or 3-dimensional array to resize. *Array* can be any type except string or structure.

### X

The new X-dimension of the resized array. *X* must be an integer or a long integer, and must be greater than or equal to 2.

### Y

The new Y-dimension of the resized array. If the original array has only 1 dimension, *Y* is ignored. If the original array has 2 or 3 dimensions *Y* MUST be present.

## Z

The new Z-dimension of the resized array. If the original array has only 1 or 2 dimensions, Z is ignored. If the original array has 3 dimensions then Z MUST be present.

## Keywords

### CENTER

Set this keyword to shift the interpolation so that points in the input and output arrays are assumed to lie at the midpoint of their coordinates rather than at their lower-left corner.

### CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm. This keyword has no effect when used with 3-dimensional arrays.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal,  $f$ , is a band-limited signal, with no frequency component larger than  $\omega_0$ , and  $f$  is sampled with spacing less than or equal to  $1/(2\omega_0)$ , then  $f$  can be reconstructed by convolving with a sinc function:  $\text{sinc}(x) = \sin(\pi x) / (\pi x)$ .

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used. Note that cubic convolution interpolation is significantly slower than bilinear interpolation.

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 "Image Reconstruction by Parametric Cubic Convolution", Computer Vision, Graphics & Image Processing 23, 256.

## INTERP

Set this keyword to force CONGRID to use linear interpolation when resizing a 1- or 2-dimensional array. CONGRID automatically uses linear interpolation if the input array is 3-dimensional. When the input array is 1- or 2-dimensional, the default is to employ nearest-neighbor sampling.

## MINUS\_ONE

Set this keyword to prevent CONGRID from extrapolating one row or column beyond the bounds of the input array. For example, if the input array has the dimensions  $(i, j)$  and the output array has the dimensions  $(x, y)$ , then by default the array is resampled by a factor of  $(i/x)$  in the X direction and  $(j/y)$  in the Y direction. If MINUS\_ONE is set, the array will be resampled by the factors  $(i-1)/(x-1)$  and  $(j-1)/(y-1)$ .

## Examples

Given `vol` is a 3-D array with the dimensions (80, 100, 57), resize it to be a (90, 90, 80) array

```
vol = CONGRID(vol, 90, 90, 80)
```

### Note

Also see [“Resizing Images”](#) in Chapter 2 of the *Image Processing in IDL* manual for a more extensive example.

# CONJ

The CONJ function returns the complex conjugate of  $X$ . The complex conjugate of the real-imaginary pair  $(x, y)$  is  $(x, -y)$ . If  $X$  is not complex, a complex-valued copy of  $X$  is used.

## Syntax

$Result = CONJ(X)$

## Return Value

Returns the complex conjugate of  $X$ .

## Arguments

### $X$

The value for which the complex conjugate is desired. If  $X$  is an array, the result has the same structure, with each element containing the complex conjugate of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Print the conjugate of the complex pair (4.0, 5.0) by entering:

```
PRINT, CONJ(COMPLEX(4.0, 5.0))
```

IDL prints:

```
( 4.00000, -5.00000)
```

# CONSTRAINED\_MIN

The CONSTRAINED\_MIN procedure solves nonlinear optimization problems of the following form:

Minimize or maximize  $gp(X)$ , subject to:

$$glb_i \leq g_i(X) \leq gub_i \quad \text{for } i = 0, \dots, nfun-1, i \neq p$$

$$xlb_j \leq x_j \leq xub_j \quad \text{for } j = 0, \dots, nvars-1$$

$X$  is a vector of  $nvars$  variables,  $x_0, \dots, x_{nvars-1}$ , and  $G$  is a vector of  $nfun$  functions  $g_0, \dots, g_{nfun-1}$ , which all depend on  $X$ . Any of these functions may be nonlinear. Any of the bounds may be infinite and any of the constraints may be absent. If there are no constraints, the problem is solved as an unconstrained optimization problem. The program solves problems of this form by the Generalized Reduced Gradient Method. See References 1-4.

CONSTRAINED\_MIN uses first partial derivatives of each function  $g_i$  with respect to each variable  $x_j$ . These are automatically computed by finite difference approximation (either forward or central differences).

CONSTRAINED\_MIN is based on an implementation of the GRG algorithm supplied by Windward Technologies, Inc. See Reference 11.

## Syntax

```
CONSTRAINED_MIN, X, Xbnd, Gbnd, Nobj, Gcomp, Inform [, EPSTOP=value]
  [, LIMSER=value] [, /MAXIMIZE] [, NSTOP=value] [, REPORT=filename]
  [, TITLE=string]
```

## Arguments

### X

An  $nvars$ -element vector. On input,  $X$  contains initial values for the variables. On output,  $X$  contains final values of the variable settings determined by CONSTRAINED\_MIN.

## Xbnd

Bounds on variables. *Xbnd* is an *nvars* x 2 element array.

- *Xbnd[j,0]* is the lower bound for variable *x[j]*.
- *Xbnd[j,1]* is the upper bound for variable *x[j]*.
- Use -1.0e30 to denote no lower bound and 1.0e30 for no upper bound.

## Gbnd

Bounds on constraint functions. *Gbnd* is an *nfuncs* x 2 element array.

- *Gbnd[i,0]* is the lower bound for function *g[i]*.
- *Gbnd[i,1]* is the upper bound for function *g[i]*.
- use -1.0e30 to denote no lower bound and 1.0e30 for no upper bound.

Bounds on the objective function are ignored; set them to 0.

## Nobj

Index of the objective function.

## Gcomp

A scalar string specifying the name of a user-supplied IDL function. This function must accept an *nvars*-element vector argument *x* of variable values and return an *nfuncs*-element vector *G* of function values.

## Inform

Termination status returned from `CONSTRAINED_MIN`.

<i>Inform</i> value	Message
0	Kuhn-Tucker conditions satisfied. This is the best possible indicator that an optimal point has been found.
1	Fractional change in objective less than EPSTOP for NSTOP consecutive iterations. See Keywords below. This is not as good as <i>Inform</i> =0, but still indicates the likelihood that an optimal point has been found.

Table 3-7: *Inform* Argument Values

<b>Inform value</b>	<b>Message</b>
2	All remedies have failed to find a better point. User should check functions and bounds for consistency and, perhaps, try other starting values.
3	Number of completed 1-dimensional searches exceeded LIMSER. See Keywords below. User should check functions and bounds for consistency and, perhaps, try other starting values. It might help to increase LIMSER. Use <code>LIMSER=larger_value</code> to do this.
4	Objective function is unbounded. CONSTRAINED_MIN has observed dramatic change in the objective function over several steps. This is a good indication that the objective function is unbounded. If this is not the case, the user should check functions and bounds for consistency.
5	Feasible point not found. CONSTRAINED_MIN was not able to find a feasible point. If the problem is believed to be feasible, the user should check functions and bounds for consistency and perhaps try other starting values.
6	Degeneracy has been encountered. The point returned may be close to optimal. The user should check functions and bounds for consistency and perhaps try other starting values.
7	Noisy and nonsmooth function values. Possible singularity or error in the function evaluations.
8	Optimization process terminated by user request.
9	Maximum number of function evaluations exceeded.
-1	Fatal Error. Some condition, such as <code>nvars &lt; 0</code> , was encountered. CONSTRAINED_MIN documented the condition in the report and terminated. In this case, the user needs to correct the input and rerun CONSTRAINED_MIN.

Table 3-7: Inform Argument Values (Continued)

<i>Inform value</i>	<b>Message</b>
-2	Fatal Error. The report file could not be opened. Check the filename specified via the REPORT keyword, and make sure you have write privileges to the specified path.
-3	Fatal Error. Same as <i>Inform</i> = -1. In this case, the REPORT keyword was not specified. Specify the REPORT keyword and rerun CONSTRAINED_MIN, then check the report file for more detail on the error.

Table 3-7: *Inform Argument Values (Continued)*

## Keywords

### EPSTOP

Set this keyword to specify the CONSTRAINED\_MIN convergence criteria. If the fractional change in the objective function is less than EPSTOP for NSTOP consecutive iterations, the program will accept the current point as optimal. CONSTRAINED\_MIN will accept the current point as optimal if the Kuhn-Tucker optimality conditions are satisfied to EPSTOP. By default, EPSTOP = 1.0e-4.

### LIMSER

If the number of completed one dimensional searches exceeds LIMSER, CONSTRAINED\_MIN terminates and returns inform = 3. By default: LIMSER = 10000.

### MAXIMIZE

By default, the CONSTRAINED\_MIN procedure performs a minimization. Set the MAXIMIZE keyword to perform a maximization instead.

### NSTOP

Set this keyword to specify the CONSTRAINED\_MIN convergence criteria. If the fractional change in the objective function is less than EPSTOP for NSTOP consecutive iterations, CONSTRAINED\_MIN will accept the current point as optimal. By default, NSTOP = 3.

## REPORT

Set this keyword to specify a name for the CONSTRAINED\_MIN report file. If the specified file does not exist, it will be created. Note that if the file cannot be created, no error message will be generated. If the specified file already exists, it will be overwritten. By default, CONSTRAINED\_MIN does not create a report file.

## TITLE

Set this keyword to specify a title for the problem in the CONSTRAINED\_MIN report.

## Examples

This example has 5 variables {X0, X1, ..., X4}, bounded above and below, a quadratic objective function {G3}, and three quadratic constraints {G0, G1, G2}, with both upper and lower bounds. See the Himmelblau text [7], problem 11.

Minimize:

$$G3 = 5.3578547X2X2 + 0.8356891X0X4 + 37.293239X0 - 40792.141$$

Subject to:

$$0 < G0 = 85.334407 + 0.0056858X1X4 + 0.0006262X0X3 - 0.0022053X2X4 < 92$$

$$90 < G1 = 80.51249 + 0.0071317X1X4 + 0.0029955X0X1 + 0.0021813X2X2 < 110$$

$$20 < G2 = 9.300961 + 0.0047026X2X4 + 0.0012547X0X2 + 0.0019085X2X3 < 25$$

and,

$$78 < X0 < 102$$

$$33 < X1 < 45$$

$$27 < X2 < 45$$

$$27 < X3 < 45$$

$$27 < X4 < 45$$

This problem is solved starting from  $X = \{78, 33, 27, 27, 27\}$  which is infeasible because constraint G2 is not satisfied at this point.

The constraint functions and objective function are evaluated by HMBL11:

```
; Himmelblau Problem 11
; 5 variables and 4 functions
FUNCTION HMBL11, x

g = DBLARR(4)
g[0] = 85.334407 + 0.0056858*x[1]*x[4] + 0.0006262*x[0] $
      *x[3] - 0.0022053*x[2]*x[4]
```

```

g[1] = 80.51249 + 0.0071317*x[1]*x[4] + 0.0029955*x[0] $
      *x[1] + 0.0021813*x[2]*x[2]
g[2] = 9.300961 + 0.0047026*x[2]*x[4] + 0.0012547*x[0]* $
      x[2] + 0.0019085*x[2]*x[3]
g[3] = 5.3578547*x[2]*x[2] + 0.8356891*x[0]*x[4] $
      + 37.293239*x[0] - 40792.141
RETURN, g

-----	------------

# CONTINUE

The CONTINUE statement provides a convenient way to immediately start the next iteration of the enclosing FOR, WHILE, or REPEAT loop.

---

**Note**

Do not confuse the CONTINUE statement described here with the .CONTINUE executive command. The two constructs are not related, and serve completely different purposes.

---

---

**Note**

CONTINUE is not allowed within CASE or SWITCH statements. This is in contrast with the C language, which does allow this.

---

For more information on using CONTINUE and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

## Syntax

CONTINUE

## Examples

This example presents one way (not necessarily the best) to print the even numbers between 1 and 10.

```
FOR I = 1,10 DO BEGIN
  ; If odd, start next iteration:
  IF (I AND 1) THEN CONTINUE
  PRINT, I
ENDFOR
```

# CONTOUR

The CONTOUR procedure draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created. Note that outline and fill contours cannot be drawn at the same time. To create a contour plot with both filled contours and outlines, first create the filled contour plot, then add the outline contours by calling CONTOUR a second time with the OVERPLOT keyword.

In its simplest form, CONTOUR makes a contour plot given a two-dimensional array of  $z$  values. In more complicated forms, CONTOUR accepts, in addition to  $z$ , arrays containing the  $x$  and  $y$  locations of each column, row, or point, plus many keyword parameters. In more sophisticated applications, the output of CONTOUR can be projected from three dimensions to two dimensions, superimposed over an image, or combined with the output of SURFACE.

Using various keywords, described below, it is possible to specify contour levels, labeling, colors, line styles, and other options. CONTOUR draws contours by searching for each contour line and then following the line until it reaches a boundary or closes.

## Smoothing Contours

Contours can be smoothed by using the [MIN\\_CURVE\\_SURF](#) function on the contour data before contouring. The MIN\_CURVE\_SURF function can be used to smoothly interpolate both regularly and irregularly sampled surfaces before contouring. This function replaces the older SPLINE keyword to CONTOUR, which was inaccurate and is no longer supported. MIN\_CURVE\_SURF interpolates the entire surface to a relatively fine grid before drawing the contours.

## Syntax

```
CONTOUR, Z [, X, Y] [, C_ANNOTATION=vector_of_strings]
  [, C_CHARSIZE=value] [, C_CHARTHICK=integer] [, C_COLORS=vector]
  [, C_LABELS=vector{each element 0 or 1}] [, C_LINestyle=vector]
  [{, /CELL_FILL |, /FILL}] [, C_ORIENTATION=degrees]
  [, C_SPACING=value] [, C_THICK=vector] [, /CLOSED] [, /DOWNHILL]
  [, /FOLLOW] [, /IRREGULAR] [, /ISOTROPIC] [, LEVELS=vector] [,
  NLEVELS=integer{1 to 60}] [, MAX_VALUE=value] [, MIN_VALUE=value]
  [, /OVERPLOT] [{, /PATH_DATA_COORDS, PATH_FILENAME=string,
  PATH_INFO=variable, PATH_XY=variable} |, TRIANGULATION=variable]
  [, /PATH_DOUBLE] [, /XLOG] [, /YLOG] [, ZAXIS={0 | 1 | 2 | 3 | 4}]
```

**Graphics Keywords:** Accepts all graphics keywords accepted by PLOT except for: LINSTYLE, PSYM, SYMSIZE. See “[Graphics Keywords Accepted](#)” on page 335.

---

**Note**

Many of the keyword parameters correspond directly to fields in the system variables !P, !X, !Y, or !Z. When specifying a keyword parameter name and value in a call that value affects only the current call, the corresponding system-variable field is not changed. Changing the value of a system-variable field changes the default for that particular parameter and remains in effect until explicitly changed. The system variables involving graphics and their corresponding keywords are detailed in “!P” in Appendix D.

---

## Arguments

### Z

A one- or two-dimensional array containing the values that make up the contour surface. If arguments *X* and *Y* are provided, the contour is plotted as a function of the (*X*, *Y*) locations specified by their contents. Otherwise, the contour is generated as a function of the two-dimensional array index of each element of *Z*.

If the IRREGULAR keyword is set, *X*, *Y*, *Z* are all required, and are treated as vectors. Each point has a value of  $Z[i]$  and a location of ( $X[i]$ ,  $Y[i]$ ).

This argument is converted to double-precision floating-point before plotting. Plots created with CONTOUR are limited to the range and precision of double-precision floating-point values.

### X

A vector or two-dimensional array specifying the *X* coordinates for the contour surface. If *X* is a vector, each element of *X* specifies the *X* coordinate for a column of *Z* (e.g.,  $X[0]$  specifies the *X* coordinate for  $Z[0,*]$ ). If *X* is a two-dimensional array, each element of *X* specifies the *X* coordinate of the corresponding point in *Z* (i.e.,  $X_{ij}$  specifies the *X* coordinate for  $Z_{ij}$ ).

### Y

A vector or two-dimensional array specifying the *Y* coordinates for the contour surface. If *Y* a vector, each element of *Y* specifies the *Y* coordinate for a row of *Z* (e.g.,  $Y[0]$  specifies the *Y* coordinate for  $Z[* ,0]$ ). If *Y* is a two-dimensional array,

each element of  $Y$  specifies the  $Y$  coordinate of the corresponding point in  $Z$  ( $Y_{ij}$  specifies the  $Y$  coordinate for  $Z_{ij}$ ).

## Keywords

### C\_ANNOTATION

The label to be drawn on each contour. Usually, contours are labeled with their value. This parameter, a vector of strings, allows any text to be specified. The first label is used for the first contour drawn, and so forth. If the LEVELS keyword is specified, the elements of C\_ANNOTATION correspond directly to the levels specified, otherwise, they correspond to the default levels chosen by the CONTOUR procedure. If there are more contour levels than elements in C\_ANNOTATION, the remaining levels are labeled with their values.

Use of this keyword implies use of the FOLLOW keyword.

#### Note

---

This keyword has no effect if the FILL or CELL\_FILL keyword is set (i.e., if the contours are drawn with solid-filled or line-filled polygons).

---

#### Example

To produce a contour plot with three levels labeled “low”, “medium”, and “high”:

```
CONTOUR, Z, LEVELS = [0.0, 0.5, 1.0], $
    C_ANNOTATION = ['low', 'medium', 'high']
```

### C\_CHARSIZE

The size of the characters used to annotate contour labels. Normally, contour labels are drawn at 3/4 of the size used for the axis labels (specified by the CHARSIZE keyword or !P.CHARSIZE system variable. This keyword allows the contour label size to be specified directly. Use of this keyword implies use of the FOLLOW keyword.

### C\_CHARTHICK

The thickness of the characters used to annotate contour labels. Set this keyword equal to an integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1. Use of this keyword implies use of the FOLLOW keyword.

## C\_COLORS

The color index used to draw each contour. This parameter is a vector, converted to integer type if necessary. If there are more contour levels than elements in C\_COLORS, the elements of the color vector are cyclically repeated.

### Example

If C\_COLORS contains three elements, and there are seven contour levels to be drawn, the colors  $c_0, c_1, c_2, c_0, c_1, c_2, c_0$  will be used for the seven levels. To call CONTOUR and set the colors to [100,150,200], use the command:

```
CONTOUR, Z, C_COLORS = [100,150,200]
```

## C\_LABELS

Specifies which contour levels should be labeled. By default, every other contour level is labeled. C\_LABELS allows you to override this default and explicitly specify the levels to label. This parameter is a vector, converted to integer type if necessary. If the LEVELS keyword is specified, the elements of C\_LABELS correspond directly to the levels specified, otherwise, they correspond to the default levels chosen by the CONTOUR procedure. Setting an element of the vector to zero causes that contour label to not be labeled. A nonzero value forces labeling.

Use of this keyword implies use of the FOLLOW keyword.

### Example

To produce a contour plot with four levels where all but the third level is labeled:

```
CONTOUR, Z, LEVELS = [0.0, 0.25, 0.75, 1.0], $
  C_LABELS = [1, 1, 0, 1]
```

## C\_LINestyle

The line style used to draw each contour. As with C\_COLORS, C\_LINestyle is a vector of line style indices. If there are more contour levels than line styles, the line styles are cyclically repeated. See [“LINestyle”](#) on page 4782 for a list of available styles.

### Note

---

The cell drawing contouring algorithm draws all the contours in each cell, rather than following contours. Since an entire contour is not drawn as a single operation, the appearance of the more complicated linestyles will suffer. Use of the contour following method (selected with the FOLLOW keyword) will give better looking results in such cases.

---

**Example**

To produce a contour plot, with the contour levels directly specified in a vector `V`, with all negative contours drawn with dotted lines, and with positive levels in solid lines:

```
CONTOUR, Z, LEVELS = V, C_LINestyle = (V LT 0.0)
```

**C\_ORIENTATION**

If the `FILL` keyword is set, this keyword can be set to the angle, in degrees counterclockwise from the horizontal, of the lines used to fill contours. If neither `C_ORIENTATION` nor `C_SPACING` are specified, the contours are solid filled.

**C\_SPACING**

If the `FILL` keyword is set, this keyword can be used to control the distance, in centimeters, between the lines used to fill the contours.

**C\_THICK**

The line used to draw each contour level. As with `C_COLORS`, `C_THICK` is a vector of line thickness values, although the values are floating point. If there are more contours than thickness elements, elements are repeated. If omitted, the overall line thickness specified by the `THICK` keyword parameter or `!P.THICK` is used for all contours.

**CELL\_FILL**

Set this keyword to produce a filled contour plot using a “cell filling” algorithm. Use this keyword instead of `FILL` when you are drawing filled contours over a map, when you have missing data, or when contours that extend off the edges of the contour plot. `CELL_FILL` is less efficient than `FILL` because it makes one or more polygons for each data cell. It also gives poor results when used with patterned (line) fills, because each cell is assigned its own pattern. Otherwise, this keyword operates identically to the `FILL` keyword, described below.

**Tip**

---

In order for `CONTOUR` to fill the contours properly when using a map projection, the `X` and `Y` arrays (if supplied) must be arranged in increasing order. This ensures that the polygons generated will be in counterclockwise order, as required by the mapping graphics pipeline.

---

**Warning**

Do not draw filled contours over the poles on Cylindrical map projections. In this case, the polar points map to lines on the map, and the interpolation becomes ambiguous, causing errors in filling. One possible work-around is to limit the latitudes to the range of -89.9 degrees to + 89.9 degrees, avoiding the poles.

**CLOSED**

Set this keyword to a nonzero value to close contours that intersect the plot boundaries. After a contour hits a boundary, it follows the plot boundary until it connects with its other boundary intersection. Set `CLOSED=0` along with `PATH_INFO` and/or `PATH_XY` to return path information for contours that are not closed.

**DOWNHILL**

Set this keyword to label each contour with short, perpendicular tick marks that point in the “downhill” direction, making the direction of the grade readily apparent. If this keyword is set, the contour following method is used in drawing the contours. For example:

```
CONTOUR, data, /DOWNHILL
```

**FILL**

Set this keyword to produce a filled contour plot. The contours are filled with solid or line-filled polygons. For solid polygons, use the `C_COLOR` keyword to specify the color index of the polygons for each contour level. For line fills, use `C_ORIENTATION`, `C_SPACING`, `C_COLOR`, `C_LINestyle`, and/or `C_THICK` to specify attributes for the lines.

If the current device is not a pen plotter, each polygon is erased to the background color before the fill lines are drawn, to avoid superimposing one pattern over another.

Contours that are not closed cannot be filled because their interior and exterior are undefined. Contours created from data sets with missing data may not be closed; many map projections can also produce contours that are not closed. You should not use filled contours in these cases.

You should not use this keyword when you are drawing filled contours over a map, when you have missing data, or when contours extend off the edges of the contour plot. In these cases, you should use `CELL_FILL` instead.

**Note**

---

If the current graphics device is the Z-buffer, the algorithm used when the FILL keyword is specified will not work when a Z value is also specified with the graphics keyword ZVALUE. In this situation, use the CELL\_FILL keyword instead of the FILL keyword.

---

**FOLLOW**

In IDL version 5, CONTOUR always uses a line-following method. The FOLLOW keyword remains available for compatibility with existing code, but is no longer necessary. As in previous versions of IDL, setting FOLLOW will cause CONTOUR to draw contour labels.

**IRREGULAR**

Set this keyword to indicate that the input data is irregularly gridded. Setting IRREGULAR is the same as performing an explicit triangulation. That is:

```
CONTOUR, Z, X, Y, /IRREGULAR
```

is the same as

```
TRIANGULATE, X, Y, tri ;Get triangulation
CONTOUR, Z, X, Y, TRIANGULATION=tri
```

**ISOTROPIC**

Set this keyword to force the scaling of the X and Y axes to be equal.

**Note**

---

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See [“POSITION”](#) on page 4784 for more information.

---

**LEVELS**

Specifies a vector containing the contour levels drawn by the CONTOUR procedure. A contour is drawn at each level in LEVELS.

**Example**

To draw a contour plot with levels at 1, 100, 1000, and 10000:

```
CONTOUR, Z, LEVELS = [1, 100, 1000, 10000]
```

To draw a contour plot with levels at 50, 60, ..., 90, 100:

```
CONTOUR, Z, LEVELS = FINDGEN(6) * 10 + 50
```

## MAX\_VALUE

Data points with values above this value are ignored (i.e., treated as missing data) when contouring. Cells containing one or more corners with values above MAX\_VALUE will have no contours drawn through them. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## MIN\_VALUE

Data points with values less than this value are ignored (i.e., treated as missing data) when contouring. Cells containing one or more corners with values below MIN\_VALUE will have no contours drawn through them. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## NLEVELS

The number of equally spaced contour levels that are produced by CONTOUR. If the LEVELS parameter, which explicitly specifies the value of the contour levels, is present, this keyword has no effect. If neither parameter is present, approximately six levels are drawn. NLEVELS should be a positive integer.

## OVERPLOT

Set this keyword to make CONTOUR “overplot”. That is, the current graphics screen is not erased, no axes are drawn and the previously established scaling remains in effect. You must explicitly specify either the values of the contour levels or the number of levels (via the NLEVELS keyword) when using this option, unless geographic mapping coordinates are in effect.

### Note

---

When specifying overplot levels with the NLEVELS keyword, keep in mind that the levels are calculated according to the range set by the original CONTOUR call. If the overplot dataset has a different range, you might want to set your levels more explicitly with the LEVELS keyword.

---

## PATH\_DATA\_COORDS

Set this keyword to cause the output contour positions to be measured in data units rather than the default normalized units. This keyword is useful only if the `PATH_XY` or `PATH_FILENAME` keywords are set.

## PATH\_DOUBLE

Set this keyword to indicate that the `PATH_FILENAME`, `PATH_INFO`, and `PATH_XY` keywords should return vertex and contour value information as double-precision floating-point values. The default is to return this information as single-precision floating-point values.

## PATH\_FILENAME

Specifies the name of a file to contain the contour positions. If `PATH_FILENAME` is present, `CONTOUR` does not draw the contours, but rather, opens the specified file and writes the coordinates of the contours, into it. The file consists of a series of logical records containing binary data. Each record is preceded with a header structure defining the contour as follows:

If the `PATH_DOUBLE` keyword is not set:

```
{CONTOUR_HEADER, TYPE:0B, HIGH:0B, LEVEL:0, NUM:0L, VALUE:0.0}
```

If the `PATH_DOUBLE` keyword is set:

```
{CONTOUR_DBL_HEADER, TYPE:0B, HIGH:0B, LEVEL:0, NUM:0L,
VALUE:0.0D}
```

The fields are:

Field	Description
TYPE	A byte that is zero if the contour is open, and one if it is closed.
HIGH	A byte that is 1 if the contour is closed and above its surroundings, and is 0 if the contour is below. This field is meaningless if the contour is not closed.
LEVEL	A short integer with value greater or equal to zero (It is an index into the LEVELS array).
NUM	The longword number of data points in the contour.

Table 3-8: CONTOUR Fields

Field	Description
VALUE	The contour value. If the PATH_DOUBLE keyword is not set, this is a single-precision floating-point value; if the PATH_DOUBLE keyword is set, this is a double-precision floating-point value.

*Table 3-8: CONTOUR Fields (Continued)*

Following the header in each record are NUM X-coordinate values followed by NUM Y-coordinate values. By default, these values are specified in normalized coordinates unless the PATH\_DATA\_COORDS keyword is set.

## PATH\_INFO

Set this keyword to a named variable that will return path information for the contours. This information can be used, along with data stored in a variable named by the PATH\_XY keyword, to trace closed contours. To get PATH\_INFO and PATH\_XY with contours that are not closed, set the CLOSED keyword to 0. If PATH\_INFO is present, CONTOUR does not draw the contours, but rather records the path information in an array of structures of the following type:

If the PATH\_DOUBLE keyword is not set:

```
{CONTOUR_PATH_STRUCTURE, TYPE:0B, HIGH_LOW:0B, $
  LEVEL:0, N:0L, OFFSET:0L, VALUE:0.0}
```

If the PATH\_DOUBLE keyword is set:

```
{COUNTOUR_DBL_PATH_STRUCTURE, TYPE:0B, HIGH_LOW:0B, LEVEL:0,
  N: 0L, OFFSET:0L, VALUE:0.0D}
```

The fields are:

Field	Description
TYPE	A byte that is zero if the contour is open, and one if it is closed. <b>Note</b> - If the CLOSED keyword is not explicitly set equal to zero, all contours will be closed.
HIGH_LOW	A byte that is 1 if the contour is above its surroundings, and is 0 if the contour is below.

*Table 3-9: PATH\_INFO Fields*

Field	Description
LEVEL	A short integer indicating the index of the contour level, from zero to the number of levels minus one.
N	A long integer indicating the number of XY pairs in the contour's path.
OFFSET	A long integer that is the offset into the array defined by PATH_XY, representing the first XY coordinate for this contour.
VALUE	The contour value. If the PATH_DOUBLE keyword is not set, this is a single-precision floating-point value; if the PATH_DOUBLE keyword is set, this is a double-precision floating-point value.

*Table 3-9: PATH\_INFO Fields (Continued)*

See the examples section below for an example using the PATH\_INFO and PATH\_XY keywords to return contour path information.

## PATH\_XY

Set this keyword to a named variable that returns the coordinates of a set of closed polygons defining the closed paths of the contours. This information can be used, along with data stored in a variable named by the PATH\_INFO keyword, to trace closed contours. To get PATH\_XY and PATH\_INFO with contours that are not closed, set the CLOSED keyword to 0. If PATH\_XY is present, CONTOUR does not draw the contours, but rather records the path coordinates in the named array. If the PATH\_DOUBLE keyword is not set, the array will contain single-precision floating point values; if the PATH\_DOUBLE keyword is set, the array will contain double-precision floating point values. By default, the values in the array are specified in normalized coordinates unless the PATH\_DATA\_COORDS keyword is set.

See the examples section below for an example using the PATH\_INFO and PATH\_XY keywords to return contour path information.

## TRIANGULATION

Set this keyword to a variable that contains an array of triangles returned from the TRIANGULATE procedure. Providing triangulation data allows you to contour irregularly gridded data directly, without gridding.

## XLOG

Set this keyword to specify a logarithmic X axis.

## YLOG

Set this keyword to specify a logarithmic Y axis.

## ZAXIS

Set this keyword to an integer value to draw a Z axis for the CONTOUR plot. CONTOUR draws no Z axis by default. This keyword is of use only if a three-dimensional transformation is established. Possible values are:

- 0 - No Z axis is drawn (the default).
- 1 - Draws Z axis from the lower right-hand corner of the plot
- 2 - Draws Z axis from the lower left-hand corner of the plot
- 3 - Draws Z axis from the upper left-hand corner of the plot
- 4 - Draws Z axis from the upper right-hand corner of the plot

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[BACKGROUND](#), [CHARSIZE](#), [CHARTHICK](#), [CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [NOCLIP](#), [NODATA](#), [NOERASE](#), [NORMAL](#), [POSITION](#), [SUBTITLE](#), [T3D](#), [THICK](#), [TICKLEN](#), [TITLE](#), [\[XYZ\]CHARSIZE](#), [\[XYZ\]GRIDSTYLE](#), [\[XYZ\]MARGIN](#), [\[XYZ\]MINOR](#), [\[XYZ\]RANGE](#), [\[XYZ\]STYLE](#), [\[XYZ\]THICK](#), [\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKINTERVAL](#), [\[XYZ\]TICKLAYOUT](#), [\[XYZ\]TICKLEN](#), [\[XYZ\]TICKNAME](#), [\[XYZ\]TICKS](#), [\[XYZ\]TICKUNITS](#), [\[XYZ\]TICKV](#), [\[XYZ\]TICK\\_GET](#), [\[XYZ\]TITLE](#), [ZVALUE](#)

## Examples

In addition to the following examples, also see the PLOT routine “[Examples](#)” on page 1663 for samples that control plot position, configure axes and position multiple plots on a page. This section includes the following information:

“[Using CONTOUR](#)” on page 336

<a href="#">“Filling Contours”</a> on page 339	

**Note**

---

Several of the following examples use batch files. See [“Running the Example Code”](#) on page 40 if IDL does not find the referenced batch file.

---

**Using CONTOUR**

The basic call to CONTOUR is as follows:

```
CONTOUR, Z
```

where  $Z$  is a two-dimensional array. This call labels the  $x$ - and  $y$ -axes with the subscript along each dimension. For example, when contouring a  $10 \times 20$  array, the  $x$ -axis ranges from 0 to 9, and the  $y$ -axis ranges from 0 to 19.

You can explicitly specify the  $x$  and  $y$  locations of each cell as follows:

```
CONTOUR, Z, X, Y
```

where the  $X$  and  $Y$  arrays can be either vectors or two-dimensional arrays of the same size as  $Z$ . If they are vectors, the element  $z_{i,j}$  has a coordinate location of  $(x_i, y_j)$ . Otherwise, if the  $x$  and  $y$  arrays are two-dimensional, the element  $z_{i,j}$  has the location  $(x_{i,j}, y_{i,j})$ . Thus, vectors should be used if the  $x$  location of  $z_{i,j}$  does not depend upon  $j$  and the  $y$  location of  $z_{i,j}$  does not depend upon  $i$ .

Dimensions must be compatible. In the one-dimensional case,  $X$  must have a dimension equal to the number of columns in  $Z$ , and  $Y$  must have a dimension equal to the number of rows in  $Z$ . In the two-dimensional case, all three arrays must have the same dimensions.

IDL uses linear interpolation to determine the  $x$  and  $y$  locations of the contour lines that pass between grid elements. The cells must be regular in that the  $x$  and  $y$  arrays must be monotonic over rows and columns, respectively. The lines describing the quadrilateral enclosing each cell and whose vertices are  $(x_{i,j}, y_{i,j})$ ,  $(x_{i+1,j}, y_{i+1,j})$ ,  $(x_{i+1,j+1}, y_{i+1,j+1})$ , and  $(x_{i,j+1}, y_{i,j+1})$  must intersect only at the four corners and the quadrilateral must not contain other nodes.

## Contouring Methods

In order to provide a wide range of options, CONTOUR uses one of two contouring algorithms. The algorithm used depends on the keywords specified, and is one of the two following methods.

### Cell Drawing

The first algorithm, used by default, examines each array cell and draws all contours emanating from that cell before proceeding to the next cell. This method is efficient in terms of computer resources, but does not allow options such as contour labeling or smoothing.

### Contour Following

The second method searches for each contour line, then follows the line until it reaches a boundary or closes. This method gives better looking results with dashed linestyles and allows contour labeling and bi-cubic spline interpolation, but requires more computer time. The contour following method is used if any of these keywords are specified: C\_ANNOTATION, C\_CHARSIZE, C\_LABELS, CLOSED, FOLLOW, PATH\_FILENAME, or DOWNHILL.

### Note

---

Due to their differing algorithms, these two methods will often draw slightly different, yet correct, contour maps for the same data. This difference is a direct result of the fact that there is often more than one valid way to draw contours and should not be a cause for concern.

---

## Label Ten Contour Levels

This example creates a contour plot with 10 contour levels where every other contour is labeled:

```

; Create a simple dataset to plot:
Z = DIST(100)

; Draw the plot:
CONTOUR, Z, NLEVELS=10, /FOLLOW, TITLE='Simple Contour Plot'
```

## Polygon Filling and Smoothing

This example shows the use of polygon filling and smoothing.

```

; Handle TrueColor displays:
DEVICE, DECOMPOSED=0

; Create a surface to contour (2D array of random numbers):
A = RANDOMU(seed, 5, 6)

; Smooth the dataset before contouring:
B = MIN_CURVE_SURF(A)

; Load discrete colors for contours:
TEK_COLOR

; Draw filled contours:
CONTOUR, B, /FILL, NLEVELS=5, C_COLOR=INDGEN(5)+2

; Overplot the contour lines with tickmarks:
CONTOUR, B, NLEVELS=5, /DOWNHILL, /OVERPLOT

```

Alternatively, we could draw line-filled contours by replacing the last two commands with:

```

CONTOUR, B, C_ORIENTATION=[0, 22, 45]

CONTOUR, B, /OVERPLOT, NLEVELS=5

```

The following short example shows the difference between a smoothed and an unsmoothed contour plot:

```

; Create a simple dataset:
data = RANDOMU(seed, 7, 7)
; Plot the unsmoothed data:
CONTOUR, data
; Plot the smoothed data:
CONTOUR, MIN_CURVE_SURF(data)

```

## Plotting Closed Contour Paths

The following example saves the closed path information of a set of contours and plots the result:

```

; Create a 2D array of random numbers:
A = RANDOMU(seed, 8, 10)

; Smooth the dataset before contouring:
B = MIN_CURVE_SURF(A)

```

```

; Compute contour paths:
CONTOUR, B, PATH_XY=xy, PATH_INFO=info
FOR I = 0, (N_ELEMENTS(info) - 1) DO BEGIN
    S = [INDGEN(info(I).N), 0]

; Plot the closed paths:
    PLOTS, xy(*,INFO(I).OFFSET + S), /NORM
ENDFOR

```

## Filling Contours

Set the FILL keyword to produce a filled contour plot. The contours are filled with solid or line-filled polygons. For solid polygons, use the C\_COLOR keyword to specify the color index of the polygons for each contour level. For line fills, use C\_ORIENTATION, C\_SPACING, C\_COLOR, C\_LINestyle, and/or C\_THICK to specify attributes for the lines.

If the current device is not a pen plotter, each polygon is erased to the background color before the fill lines are drawn, to avoid superimposing one pattern over another.

The FILL keyword replaces the use of the PATH\_FILENAME keyword and POLYFILL procedure from previous versions of IDL. Setting the FILL keyword also closes any open contours before filling.

The following example illustrates various filled contour plot options.

```

; Create a simple, random dataset for contouring:
data = RANDOMU(seed, 7, 7)
; Create a basic, solid-color, filled CONTOUR plot
; with 6 evenly-spaced levels.
CONTOUR, data, NLEVELS=6, /FILL
; Overplot contour outlines:
CONTOUR, data, NLEVELS=6, /NOERASE

```

Instead of solid colors, contours can be filled with lines:

```

; Create a vector of orientations for the fill lines:
ANGLES = [0, 45, -45]
; Create a vector of colors to use:
C = [70, 120, 200, 255]
; Create contours filled with lines.
CONTOUR, data, NLEVELS=10, C_ORIENT=ANGLES, C_COLORS=C
; Overplot contour outlines:
CONTOUR, data, NLEVELS=10, /NOERASE

```

There are many other controls for filled contour plots. The C\_COLORS, C\_LINestyle, C\_SPACING, and C\_THICK keywords can also be used to control the type of fill.

## Contour Irregularly-gridded with TRIANGULATE

This example contours irregularly-gridded data without having to call TRIGRID. First, use the TRIANGULATE procedure to get the Delaunay triangulation of your data, then pass the triangulation array to CONTOUR:

```

; Make 50 normal X, Y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)

; Make the Gaussian:
Z = EXP(-(x^2 + y^2))

; Get triangulation:
TRIANGULATE, X, Y, tri

; Draw the contours:
CONTOUR, Z, X, Y, TRIANGULATION = tri

```

## Contour of Digital Elevation Data

Digital elevation data of the Maroon Bells area, near Aspen, Colorado, are used to illustrate the CONTOUR procedure. The data set was obtained from a United States Geological Survey Digital Elevation Model tape. This data provides terrain elevation data over a 7.5-minute square (approximately  $11 \times 13.7$  kilometers at the latitude of Maroon Bells), with 30-meter sampling.

The data are contained in a  $360 \times 460$  array A, sampled in 30-meter square intervals, measured in Universal Transverse Mercator (UTM) coordinates. The rectangular array is not completely filled with data because the 7.5-minute square is not perfectly oriented to the UTM grid system. Missing data are represented as zeroes. Elevation measurements range from 2658 to 4241 meters or from 8720 to 13,914 feet.

The Maroon Bells data are used in a number of examples in this section, and is included in an IDL SAVE file called `marbells.dat` in the `examples/data` subdirectory of the IDL distribution. To restore the save file, issue the following commands at the IDL prompt (change the path separator characters as necessary for your platform):

```

CD, !DIR+'/'examples/data'
RESTORE, 'marbells.dat'

```

### Example Code

The batch file `cntour01`, located in the `examples/doc/plot` subdirectory of the IDL distribution, restores this data and defines several variables used in the following examples. Typing `@cntour01` at the IDL command prompt creates an IDL variable named `elev` that contains the 360 x 460 integer array.

The figure below is the result of applying the `CONTOUR` procedure to the data, using the default settings:

```
CONTOUR, elev
```

*Figure 3-18: Simple Contour Plot of Maroon Bells*

A number of problems are apparent with this simple contour plot.

- IDL selected six contour levels, by default, for the elevation from 0 to 4241; that's roughly 4241 divided into 7 intervals or approximately 605 meters in elevation between contour levels. The levels are 605, 1250, ..., 3635 meters, even though the range of valid data is from 2658 to 4241 meters. This is because the missing data values of 0 were considered when selecting the intervals. It is generally more appropriate to select contour levels only within the range of valid data.
- The vertical contours along the left edge are an invalid artifact due to contouring missing data and should not be present.

- For most display systems and for contour intervals of approximately 200 meters, the data has too many samples in the  $x$ - $y$  direction. This oversampling has two adverse effects: the contours appear jagged, and a large number of short vectors are produced.
- The axes are labeled by point number, but should be in UTM coordinates.
- It is difficult to visualize the terrain and to discern maxima from minima because each contour is drawn with the same type of line.

The above problems are readily solved using the following simple techniques:

- Specify the contour levels directly using the LEVELS keyword parameter. Selecting contour intervals of 250 meters, at elevation levels of [2750, 3000, 3250, 3500, 3750, 4000], results in six levels within the range of valid data.
- Change the missing data value to a value well above the maximum valid data value, then use the MAX\_VALUE keyword parameter to exclude missing points. In this example, we set missing data values to one million with the following statement:

```
elev(WHERE(elev EQ 0)) = 32767
```

---

**Note**

32767 is the maximum allowable 16-bit integer.

---

- Use the REBIN function to decrease the sampling in  $x$  and  $y$  by a factor of 5:

```
new = REBIN(elev, 360/5, 460/5)
```

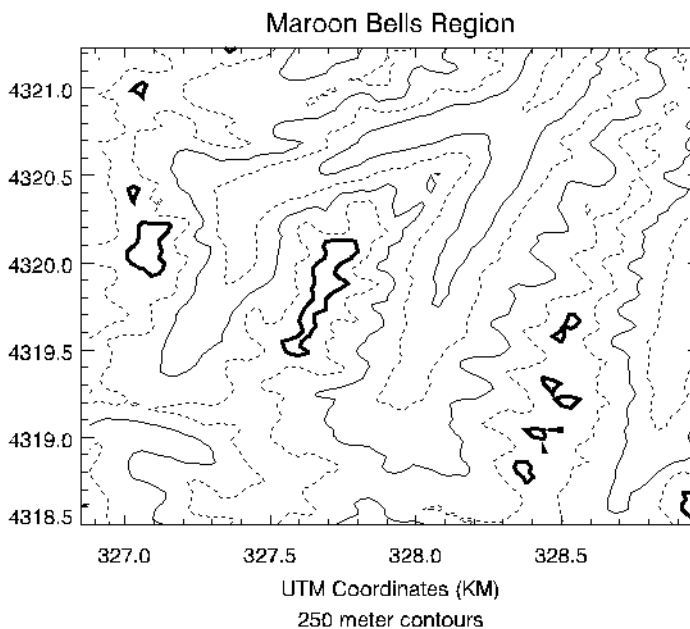

This smooths the contours, because the call to REBIN averages  $5^2=25$  bins when resampling. The number of vectors transmitted to the display also are decreased by a factor of approximately 25. The variable B is now a  $72 \times 92$  array.

Care is taken in the second step to ensure that the missing data are not confused with valid data after REBIN is applied. As in this example, REBIN averages bins of  $5^2=25$  elements, the missing data value must be set to a value of at least 25 times the maximum valid data value. After applying REBIN, any cell with a missing original data point will have a value of at least  $106/25 = 40000$ , well over the largest valid data value of approximately 4,500.

The  $x$  and  $y$  vectors are constructed containing the UTM coordinates for each row and column. From the USGS data tape, the UTM coordinate of the lower-left corner of the array is (326,850: 4,318,500) meters. As the data spacing is 30 meters in both directions, the  $x$  and  $y$  vectors, in kilometers, are easily formed using the FINDGEN function, as shown in the example below.

Contour levels at each multiple of 500 meters (every other level) are drawn with a solid line style, while levels that fall between are drawn with a dotted line. In addition, the 4000-meter contour is drawn with a triple thick line, emphasizing the top contour.

The result of these improvements is shown in the figure below.

*Figure 3-19: Improved Contour Plot*

This figure was produced with the `cntour02` batch file.

```

; Restore variables:
@cntour01
; Set missing data points to a large value:
elev (WHERE (elev EQ 0)) = 1E6
; REBIN down to a 72 x 92 matrix:
new = REBIN(elev, 360/5, 460/5)
; Make the x and y vectors specifying the position
; of each column and row.
X = 326.850 + .030 * FINDGEN(72)
Y = 4318.500 + .030 * FINDGEN(92)
; Make the plot, specifying the contour levels,
; missing data value, linestyles, etc.

```

```
; Set the STYLE keywords to 1, obtaining exact axes.  
CONTOUR, new, X, Y, LEVELS = 2750 + FINDGEN(6) * 250., $  
  XSTYLE = 1, YSTYLE = 1, YMARGIN = 5, MAX_VALUE = 5000, $  
  C_LINestyle = [1, 0], $  
  C_THICK = [1, 1, 1, 1, 1, 3], $  
  TITLE = 'Maroon Bells Region', $  
  SUBTITLE = '250 meter contours', $  
  XTITLE = 'UTM Coordinates (KM)'
```

---

### Example Code

See `cntour02` located in the `examples/doc/plot` subdirectory of the IDL installation directory for the example code. You can also run the batch file `cntour02` by entering the following command at the IDL prompt:

```
@cntour02
```

---

See [“Running the Example Code”](#) on page 40 if IDL does not find the batch file.

The figure below illustrates the data displayed as a grayscale image. Higher elevations are white. This image demonstrates that contour plots do not always provide the best qualitative visualization of many two-dimensional data sets.

*Figure 3-20: Maroon Bells Data Displayed as an Image*

## Labeling Contours

The `C_ANNOTATION`, `C_CHARSIZE`, and `C_LABELS` keywords are used to control contour labeling. Using them, possibly in conjunction with the `LEVELS` keyword, it is possible to specify which contours should be labeled, the size of the labels, and the actual labels that should be used.

In the following discussion, a variable named `DATA` is contoured. This variable contains uniformly distributed random numbers obtained using the following statement:

```
SEED = 20 & DATA = RANDOMU(SEED, 6, 6)
```

To label contours using the defaults for label size and contours to label, it is sufficient to select the `FOLLOW` keyword. In this case, `CONTOUR` labels every other contour using the default label size (three-fourths of the plot axis label size). Each contour is labeled with its value.

Figure 3-21: Simple Labeled Contour Plot

The preceding figure was produced using the following statement:

```
CONTOUR, /FOLLOW, DATA
```

The `C_CHARSIZE` keyword is used to specify the size of the characters used for labeling in the same manner that `SIZE` is used to control plot axis label size. The `C_LABELS` keyword can be used to select the contours to be labeled. For example, suppose that we want to contour the variable `DATA` at 0.2, 0.5, and 0.8, and we want all three levels labeled. In addition, we wish to make each label larger, and use hardware fonts. This can be accomplished with the statement below.

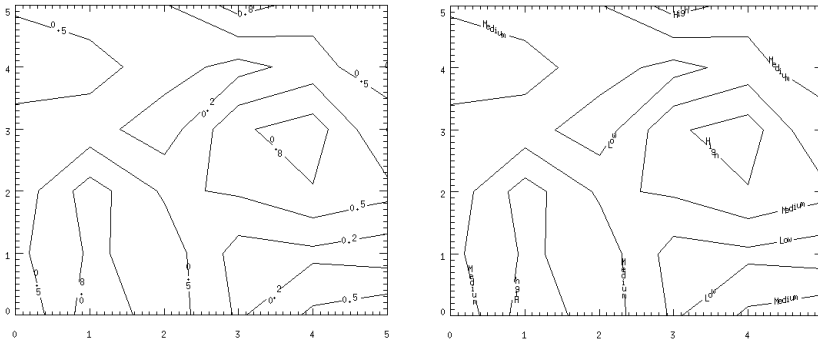

```
CONTOUR, LEVEL=[0.2, 0.5, 0.8], C_LABELS=[1, 1, 1], $
C_CHARSIZE = 1.25, DATA, FONT = 0
```

The result is the plot on the left in the figure below.

Finally, it is possible to specify the text to be used for the contour labels using the `C_ANNOTATION` keyword, as shown in the statements below.

```
CONTOUR, LEVEL=[0.2, 0.5, 0.8], C_LABELS=[1, 1, 1], $
C_ANNOTATION = ["Low", "Medium", "High"], DATA, FONT=0
```

The result is the plot on the right in the figure below.

*Figure 3-22: Label Size and Levels Specified (left), Explicitly Specified Labels (right)*

## Overlaying Images and Contour Plots

Superimposing an image and its contour plot combines the best of both worlds: the image allows easy visualization and the contour lines provide a semi-quantitative display. The programs presented in the rest of this section are for advanced computing only.

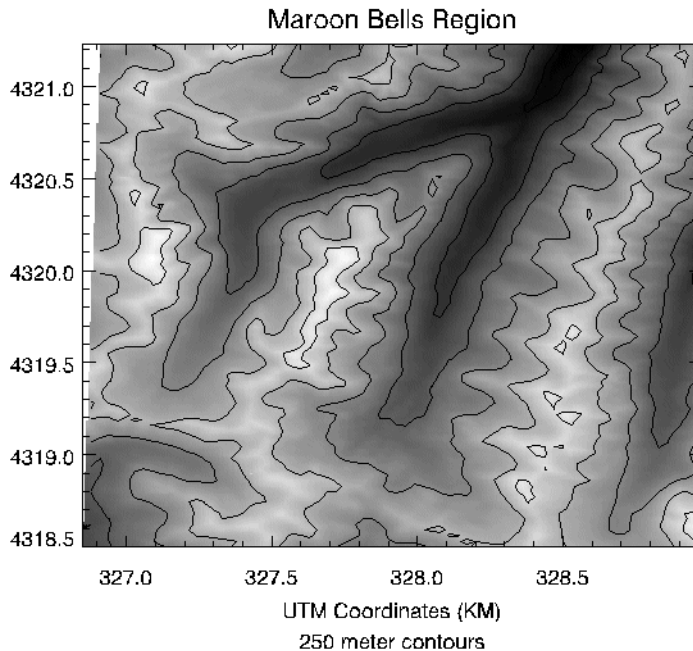

A combined contour and image display, such as that discussed in this section, can be created with the `IMAGE_CONT` procedure. The following material is intended to illustrate the ways in which images and graphics can be combined using IDL.

The technique used to overlay plots and images depends on whether or not the device is able to represent pixels of variable size, as does PostScript, or if it has pixels of a fixed size. If the device does not have scalable pixels, the image must be resized to fit within the plotting area if it is not already of a size suitable for viewing. This leads to three separate cases that are illustrated in the following examples.

- [“Overlaying with Scalable Pixels”](#) below
- [“Overlaying with Fixed Pixels”](#) on page 349

## Overlaying with Scalable Pixels

Certain devices, notably PostScript, can display pixels of varying sizes. With these devices, it is easy to set the size and position of an image so that it exactly overlays the plot window. In creating the next figure, the actual dimensions of the contour plot window (contained in the `!X.WINDOW` and `!Y.WINDOW` system variables) were used to calculate the new size of the image.

*Figure 3-23: Overlay of Image and Contour Plots*

---

**Note**

In order to do this successfully, you must establish the size of the plot window before scaling the image. This means that you must make a call to `CONTOUR` before displaying the image, to set the window size, and another call to `CONTOUR` after displaying the image, to draw the contour lines on top of the image data.

---

**Example Code**

Inspect the batch file `cntour03` located in the `examples/doc/plot` subdirectory of the IDL distribution to see how the figure was created.

---

Note that the aspect ratio of the image was changed to fit that of the plot window. To retain the original image aspect ratio, the plot window must be resized to an identical aspect ratio using the `POSITION` keyword parameter.

## Overlaying with Fixed Pixels

If the pixel size is fixed (as is true on most displays), we can either resize the image to fit the plotting window or size the plotting window to fit the image dimensions.

### Method 1: Scale the Image to Fit the Display

We can use the CONGRID function to create an image of the same size as the plotting window. The REBIN function also can be used to resample the original image if the plot window dimensions are an integer multiple or factor of the original image dimensions. REBIN is always faster than CONGRID. The following IDL procedure creates an image of the same size as the window, displays it, then overlays the contour plot.

```

; Restore variables:
@cntour01
; Set missing data points to a large value:
elev (WHERE (elev EQ 0)) = 1E6
; REBIN down to a 72 x 92 matrix.
new = REBIN(elev, 360/5, 460/5)
; Scale image intensities:
image = BYTACL(elev, MIN=2658, MAX=4241)
; Before displaying the image, use the CONTOUR command
; to create the appropriate plot window.
; The plot window must be created before re-sizing
; the image data.
; Use the NODATA keyword to inhibit actually drawing
; the contour plot.
CONTOUR, new, X, Y, LEVELS = 2750 + FINDGEN(6) * 250., $
    MAX_VALUE = 5000, XSTYLE = 1, YSTYLE = 1, $
    TITLE = 'Maroon Bells Region', $
    SUBTITLE = '250 meter contours', $
    XTITLE = 'UTM Coordinates (KM)', /NODATA
; Get size of plot window in device pixels.
PX = !X.WINDOW * !D.X_VSIZE
PY = !Y.WINDOW * !D.Y_VSIZE
; Desired size of image in pixels.
SX = PX[1] - PX[0] + 1
SY = PY[1] - PY[0] + 1
; Display the image with its lower-left corner at
; the origin of the plot window and with its size
; scaled to fit the plot window.
TVSCL, CONGRID(image, SX, SY), PX[0], PY[0])
CONTOUR, new, X, Y, LEVELS = 2750 + FINDGEN(6) * 250., $
    MAX_VALUE = 5000, XSTYLE = 1, YSTYLE = 1, $
    TITLE = 'Maroon Bells Region', $
    SUBTITLE = '250 meter contours', $
    XTITLE = 'UTM Coordinates (KM)', /NOERASE

```

```

; Write the contours over the image, being sure
; to use the exact axis styles so that the contours
; fill the plot window. Inhibit erasing.

```

### Example Code

---

See the `cntour04` batch file located in the `examples/doc/plot` subdirectory of the IDL distribution for the example code. You can also run the batch file `cntour04` with the following command at the IDL prompt:

```
@cntour04
```

---

See “[Running the Example Code](#)” on page 40 if IDL does not find the batch file.

### Method 2: Scale the Display to Fit the Image

If the image is already close to the proper display size, it is simpler and more efficient to change the plot window size to that of the image. The following procedure displays the image at the window origin, then sets the plot window to the image size, leaving its origin unchanged.

```

; Restore variables:
@cntour01
; Set missing data points to a large value:
elev (WHERE (elev EQ 0)) = 1E6
; REBIN down to a 72 x 92 matrix.
new = REBIN(elev, 360/5, 460/5)
; Scale image intensities.
image = BYTSCL(elev, MIN=2658, MAX=4241)
; Get size of plot window in device pixels.
PX = !X.WINDOW * !D.X_VSIZE
PY = !Y.WINDOW * !D.Y_VSIZE
; Get the size of the image.
SZ = SIZE(image)
; Display the image with its lower-left corner
; at the origin of the plot window.
TVSCL, image, PX[0], PY[0]
; Write the contours over the image, being sure to use
; the exact axis styles so that the contours fill the plot
; window. Inhibit erasing.
CONTOUR, new, X, Y, XSTYLE = 1, YSTYLE = 1, $
  POSITION = [PX[0], PY[0], PX[0]+SZ[1]-1, PY[0]+SZ[2]-1], $
  LEVELS = 2750 + FINDGEN(6) * 250., MAX_VALUE = 5000, $
  TITLE = 'Maroon Bells Region', $
  SUBTITLE = '250 meter contours', $
  XTITLE = 'UTM Coordinates (KM)', /NOERASE, /DEVICE

```

**Example Code**

See the `cntour05` batch file located in the `examples/doc/plot` subdirectory of the IDL distribution for the example code. You can also run the batch file `cntour05` with the following command at the IDL prompt:

```
@cntour05
```

See [“Running the Example Code”](#) on page 40 if IDL does not find the batch file.

**Displaying Date/Time Data on a Contour Display**

Another possible example may be the surface temperature (in degrees Celsius) of each degree of a single circle on a sphere recorded at every second for 37 seconds after the initial recording of 59 minutes and 30 seconds after 2 o'clock pm (14 hundred hours) on the 30th day of March in the year 2000:

```
number_samples = 37
date_time = TIMEGEN(number_samples, UNITS = 'Seconds', $
    START = JULDAY(3, 30, 2000, 14, 59, 30))
angle = 10.*FINDGEN(number_samples)
temperature = BYTSC(SIN(10.*!DTOR* $
    FINDGEN(number_samples))) # COS(!DTOR*angle))
```

Since the final contour display will be filled, we should define a color table:

```
DEVICE, DECOMPOSED = 0
LOADCT, 5
```

The call to the `DEVICE` command with the `DECOMPOSED` keyword set to zero allows color tables to be used on TrueColor displays, which may be the default setting on some systems. The call to the `LOADCT` routine loads the Standard Gamma-II (number 5) color table, which is a part of IDL's libraries.

As with the one-dimensional case, the format of the date/time values is specified through the `LABEL_DATE` routine as follows

```
date_label = LABEL_DATE(DATE_FORMAT = $
    ['%I:%S', '%H', '%D %M, %Y'])
```

where `%I` represents minutes, `%S` represents seconds, `%H` represents hours, `%D` represents days, `%M` represents months, and `%Y` represents years.

The first level (closest to the axis) will contain minute and second values separated by a colon (`%I:%S`). The second level (just below the first level) will contain the hour values(`%H`). The third level (the final level farthest from the axis) will contain the day and month values separated by a space and year value separated from the day and month values by a comma (`%D %M, %Y`).

The resulting format is specified by using the CONTOUR routine with the XTICKFORMAT keyword:

```

CONTOUR, temperature, angle, date_time, $
    ; specifying contour levels and fill colors.
LEVELS = BYTSCL(INDGEN(8)), /XSTYLE, /YSTYLE, $
C_COLORS = BYTSCL(INDGEN(8)), /FILL, $
    ; displaying titles.
TITLE = 'Measured Temperature (degrees Celsius)', $
XTITLE = 'Angle (degrees)', $
YTITLE = 'Time (seconds)', $
    ; applying date/time formats to X-axis labels.
POSITION = [0.25, 0.2, 0.9, 0.9], $
YTICKFORMAT = ['LABEL_DATE', 'LABEL_DATE', 'LABEL_DATE'], $
YTICKUNITS = ['Time', 'Hour', 'Day'], $
YTICKINTERVAL = 5, $
YTICKLAYOUT = 2
    ; Applying contour lines over the original contour display.
CONTOUR, temperature, angle, date_time, /OVERPLOT, $
    LEVELS = BYTSCL(INDGEN(8))

```

As in the plot example, the POSITION keyword is set to allow the resulting display to contain all three levels and the title of the date/time axis. The YTICKUNITS keyword is set to note the unit of each level. And the YTICKINTERVAL keyword is set to place the major tick marks at every five second interval.

This example also contains the YTICKLAYOUT keyword. By default, this keyword is set to 0, which provides the date/time layout shown in the plot example.

In this example, YTICKLAYOUT is set to 2, which rotates and boxes the tick labels to provide the following results:

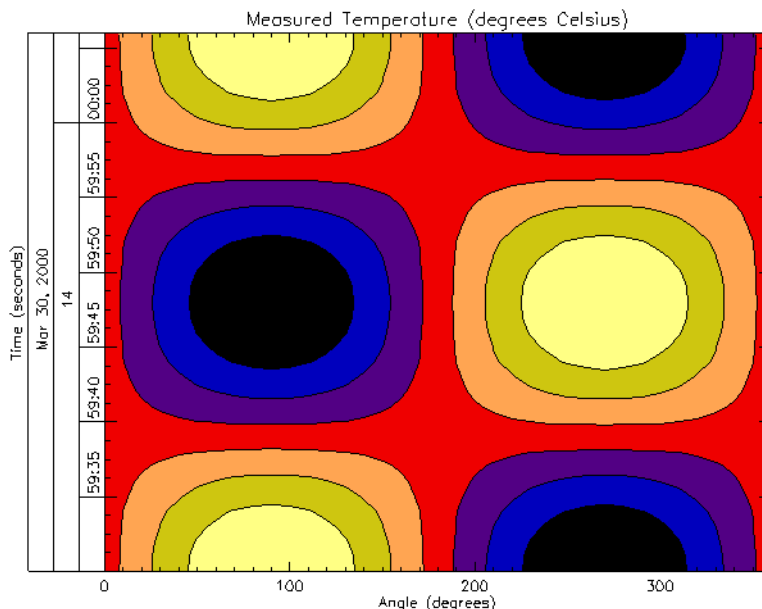

Figure 3-24: Displaying Date/Time Data with CONTOUR

### Note

You could set system variables instead of graphic keywords in the previous example. See [“Using System Variables to Display Date/Time Data”](#) on page 1296 for details.

# CONVERT\_COORD

The `CONVERT_COORD` function transforms one or more sets of coordinates to and from the coordinate systems supported by IDL.

The input coordinates  $X$  and, optionally,  $Y$  and/or  $Z$  can be given in data, device, or normalized form by using the `DATA`, `DEVICE`, or `NORMAL` keywords. The default input coordinate system is `DATA`. The keywords `TO_DATA`, `TO_DEVICE`, and `TO_NORMAL` specify the output coordinate system.

If the input points are in 3D data coordinates, be sure to set the `T3D` keyword.

---

## Note

`CONVERT_COORD` utilizes values currently stored in the `!X`, `!Y`, `!Z` and `!P` system variables to compute coordinate conversion factors. See [“Two-Dimensional Coordinate Conversion”](#) on page 4823 for more information.

---

## Warning

For devices that support windows, `CONVERT_COORD` can only provide valid results if a window is open and current. Also, `CONVERT_COORD` only applies to Direct Graphics devices.

---

## Syntax

```
Result = CONVERT_COORD( X [, Y [, Z]] [, /DATA | /DEVICE | /NORMAL]
    [, /DOUBLE][, /T3D] [, /TO_DATA | /TO_DEVICE | /TO_NORMAL] )
```

## Return Value

The result of the function is a  $(3, n)$  vector containing the  $(x, y, z)$  components of the  $n$  output coordinates.

## Arguments

### X

A vector or scalar argument providing the  $X$  components of the input coordinates. If only one argument is specified,  $X$  must be an array of either two or three vectors (i.e.,  $(2, *)$  or  $(3, *)$ ). In this special case, `X[0, *]` are taken as the  $X$  values, `X[1, *]` are taken as the  $Y$  values, and, if present, `X[2, *]` are taken as the  $Z$  values.

**Y**

An optional argument providing the Y input coordinate(s).

**Z**

An optional argument providing the Z input coordinate(s).

**Keywords****DATA**

Set this keyword if the input coordinates are in data space (the default).

**DEVICE**

Set this keyword if the input coordinates are in device space.

**DOUBLE**

Set this keyword to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the returned coordinates will be double-precision).

**NORMAL**

Set this keyword if the input coordinates are in normalized space.

**T3D**

Set this keyword if the 3D transformation !P.T is to be applied.

**TO\_DATA**

Set this keyword if the output coordinates are to be in data space.

**TO\_DEVICE**

Set this keyword if the output coordinates are to be in device space.

**TO\_NORMAL**

Set this keyword if the output coordinates are to be in normalized space.

## Examples

Convert, using the currently established viewing transformation, 11 points along the parametric line  $x = t$ ,  $y = 2t$ ,  $z = t^2$ , along the interval  $[0, 1]$  from data coordinates to device coordinates:

```
; Establish a valid transformation matrix:
SURFACE, DIST(20), /SAVE

; Make a vector of X values:
X = FINDGEN(11)/10.

; Convert the coordinates. D will be a (3,11) element array:
D = CONVERT_COORD(X, 2*X, X^2, /T3D, /TO_DEVICE)
```

To convert the endpoints of a line from data coordinates (0, 1) to (5, 7) to device coordinates, use the following statement:

```
D = CONVERT_COORD([0, 5], [1, 7], /DATA, /TO_DEVICE)
```

On completion, the variable  $D$  is a (3, 2) vector, containing the  $x$ ,  $y$ , and  $z$  coordinates of the two endpoints.

## Three-Dimensional Direct Graphic Coordinate Conversion

The `CONVERT_COORD` function performs the three-dimensional coordinate conversion process (described in [“Three-Dimensional Coordinate Conversion”](#) in Chapter 8 of the *Using IDL* manual) when converting to and from coordinate systems when the `T3D` keyword is specified. For example, if a three-dimensional coordinate system is established, then the device coordinates of the data point (0, 1, 2) can be computed as follows:

```
D = CONVERT_COORD(0, 1, 2, /TO_DEVICE, /T3D, /DATA)
```

On completion, the three-element vector  $D$  will contain the desired device coordinates. The process of converting from three-dimensional to two-dimensional coordinates also can be written as an IDL function. This function accepts a three-dimensional data coordinate, returns a two-element vector containing the coordinate transformed to two-dimensional normalized coordinates using the current transformation matrix:

```
FUNCTION CVT_TO_2D, X, Y, Z
; Make a homogeneous vector of normalized 3D coordinates:
P = [!X.S[0] + !X.S[1] * X, !Y.S[0] + !Y.S[1] * Y, $
     !Z.S[0] + !Z.S[1] * Z, 1]
; Transform by !P.T:
P = P # !P.T
```

```
        ; Return the scaled result as a two-element,  
        ; two-dimensional, xy vector:  
    RETURN, [P[0] / P[3], P[1] / P[3]]  
END
```

# CONVOL

The CONVOL function convolves an array with a kernel, and returns the result. Convolution is a general process that can be used for various types of smoothing, signal processing, shifting, differentiation, edge detection, etc. The CENTER keyword controls the alignment of the kernel with the array and the ordering of the kernel elements. If CENTER is explicitly set to 0, convolution is performed in the strict mathematical sense; otherwise, the kernel is centered over each data point.

## Using CONVOL

Assume  $R = \text{CONVOL}(A, K, S)$ , where  $A$  is an  $n$ -element vector,  $K$  is a  $k$ -element vector ( $k \leq n$ ), and  $S$  is the scale factor. If the CENTER keyword is omitted or set to 1:

$$R_t = \begin{cases} \frac{1}{S} \sum_{i=0}^{k-1} A_{t+i-k/2} K_i & \text{if } k/2 \leq t \leq n - \frac{k}{2} - 1 \\ 0 & \text{otherwise} \end{cases}$$

where the value  $k/2$  is determined by *integer division*. This means that the result of the division is the largest *integer* value less than or equal to the fractional number.

If CENTER is explicitly set to 0:

$$R_t = \begin{cases} \frac{1}{S} \sum_{i=0}^{k-1} A_{t-i} K_i & \text{if } t \geq k - 1 \\ 0 & \text{otherwise} \end{cases}$$

In the two-dimensional, zero CENTER case where  $A$  is an  $m$ -by- $n$ -element array, and  $K$  is the  $k$ -by- $k$  element kernel; the result  $R$  is an  $m$  by  $n$ -element array:

$$R_{t,u} = \begin{cases} \frac{1}{S} \sum_{i=0}^{k-1} \sum_{j=0}^{k-1} A_{t-i, u-j} K_{i,j} & \text{if } t \geq k - 1 \quad \text{and} \quad u \geq k - 1 \\ 0 & \text{otherwise} \end{cases}$$

The centered case is similar, except the  $t-i$  and  $u-j$  subscripts are replaced by  $t+i-k/2$  and  $u+j-k/2$ .

## Syntax

```
Result = CONVOL( Array, Kernel [, Scale_Factor] [, BIAS=value] [, /CENTER]
[, /EDGE_TRUNCATE] [, /EDGE_WRAP] [, /EDGE_ZERO]
[, INVALID=value] [, MISSING=value] [, /NAN] [, /NORMALIZE] )
```

## Return Value

Returns the result of the array convolution. Depending on *Array*'s type, the computation might be performed using a different type, although the result will always have the same type as *Array*. The following table shows the types used, as well as any clipping of the result values. The calculation type is also used for *Kernel*, *Scale\_Factor*, and **BIAS**.

Array Type	Kernal and Calculation Type	Clipping
BYTE	LONG	[0,255]
INT	LONG	[-32768,32767]
LONG	LONG	None
FLOAT	FLOAT	None
DOUBLE	DOUBLE	None
COMPLEX	COMPLEX	None
DCOMPLEX	DCOMPLEX	None
UINT	LONG	[0,65535]
ULONG	LONG	None
LONG64	LONG64	None
ULONG64	LONG64	None

Table 3-10: Calculation Types and Clipping for CONVOL's Return Value

## Arguments

### Array

An array of any basic type except string. The result of CONVOL has the same type and dimensions as *Array*.

### Kernel

An array of any type except string. If the type of *Kernel* is not the same as *Array*, a copy of *Kernel* is made and converted to the appropriate type before use (for byte data, the kernel is converted to type LONG). The size of the kernel dimensions must be less than or equal to those of *Array*.

---

**Note**

CONVOL accepts non-square kernels including one-dimensional kernels.

---

### Scale\_Factor

A scale factor that is divided into each resulting value. This argument should be of the same type as the calculation type in [Table 3-10](#), and is automatically converted if necessary. For byte or integer input arrays, the argument allows the use of fractional kernel values and avoids overflow of the result. If omitted or set to zero, a scale factor of 1 is used.

---

**Note**

The same *Scale\_Factor* is always divided into each result value, regardless of any missing data as specified by the [INVALID](#) or [NAN](#) keywords. It is usually not appropriate to divide the result value by the full scale factor if portions of the kernel were not applied due to missing data. In this case, you might want to use the [NORMALIZE](#) keyword instead.

---

## Keywords

### BIAS

Set this keyword to the bias offset to be added to each result value, after any *Scale\_Factor* has been applied. BIAS should be of the same type as the calculation type in [Table 3-10](#), and will be automatically converted if necessary. If you have negative kernel values and a byte or unsigned integer input array, you can use this keyword to ensure that the result values are within the range of your data type.

**Note**

The same BIAS is always added to each result value, regardless of any missing data as specified by the **INVALID** or **NAN** keywords. It is usually not appropriate to add the full BIAS if portions of the kernel were not applied due to missing data. In this case, you might want to use the **NORMALIZE** keyword instead.

**CENTER**

Set or omit this keyword to center the kernel over each array point. If **CENTER** is explicitly set to zero, the **CONVOL** function works in the conventional mathematical sense. In many signal and image processing applications, it is useful to center a symmetric kernel over the data, thereby aligning the result with the original array.

Note that for the kernel to be centered, it must be symmetric about the point  $K(\text{FLOOR}(m/2))$ , where  $m$  is the number of elements in the kernel.

**EDGE\_TRUNCATE**

Set this keyword to make **CONVOL** compute the values of elements at the edge of *Array* by repeating the subscripts of *Array* at the edge. For example, if **CENTER** is set to zero:

$$R_t = \frac{1}{S} \sum_{i=0}^k A_{((t-i) > 0 < (n-1))} K_i$$

where  $n$  is the number of elements in *Array*. The “<” and “>” operators in the above formula return the smaller and larger of their operands, respectively.

If none of the **EDGE\_\*** keywords are set, **CONVOL** sets the values of *Result* to zero (or the value of **BIAS**) where the kernel extends beyond the edge.

**EDGE\_WRAP**

Set this keyword to make **CONVOL** compute the values of elements at the edge of *Array* by “wrapping” the subscripts of *Array* at the edge. For example, if **CENTER** is set to zero:

$$R_t = \frac{1}{S} \sum_{i=0}^{k-1} A_{((t-i) \bmod (n))} K_i$$

where  $n$  is the number of elements in *Array*. The mod operator in the formula above is defined as  $a \bmod b = a - b * \text{floor}(a/b)$ . For example,  $-1 \bmod 5$  is 4.

If none of the `EDGE_*` keywords are set, `CONVOL` sets the values of *Result* to zero (or the value of `BIAS`) where the kernel extends beyond the edge.

## EDGE\_ZERO

Set this keyword to make `CONVOL` compute the values of elements at the edge of *Array* as if the array were padded with zeroes. For example, if `CENTER` is set to zero:

$$R_t = \begin{cases} \frac{1}{S} \sum_{i=0}^{k-1} A_{t-i} K_i & \text{if } t \geq k-1 \\ \frac{1}{S} \sum_{i=0}^t A_{t-i} K_i & \text{otherwise} \end{cases}$$

If none of the `EDGE_*` keywords are set, `CONVOL` sets the values of *Result* to zero (or the value of `BIAS`) where the kernel extends beyond the edge.

## INVALID

Set this keyword to a scalar value of the same type as *Array* that should be used to indicate missing or invalid data within *Array*. Missing data are ignored when computing the convolution for neighboring elements. In *Result*, missing elements are replaced by the convolution of all other valid points within the kernel. If all points within the kernel are missing, the result at that point is given by the value of the `MISSING` keyword.

### Tip

The `INVALID` keyword has the same effect as the `NAN` keyword, but is useful for byte or integer data which have missing values.

### Note

The `INVALID` keyword uses a simple comparison to ignore values and should not be set to NaN. For floating-point data, you can use the `INVALID` and `NAN` keywords simultaneously to filter out both user-defined values and NaN or Infinity values.

## MISSING

Set this keyword to the numeric value to return for elements that contain no valid points within the kernel. The default is zero for byte or integer input, and NaN for floating-point input. This keyword is only used if the INVALID or NAN keyword is set.

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.) Missing data are ignored when computing the convolution for neighboring elements. In the *Result*, missing elements are replaced by the convolution of all other valid points within the kernel. If all points within the kernel are missing, then the result at that point is given by the MISSING keyword.

### Note

---

CONVOL should never be called without the NAN keyword if the input array may possibly contain *NaN* or *Infinity* values.

---

## NORMALIZE

Set this keyword to automatically compute a scale factor and bias and apply them to the result values. If this keyword is set, the *Scale\_Factor* argument and the **BIAS** keyword are ignored. For all input types, the scale factor is defined as the sum of the absolute values of *Kernel*. For BYTE or UINT, the bias is defined as the sum of the absolute values of the negative *Kernel* values, multiplied by either  $(255/Scale)$  for BYTE or  $(65535/Scale)$  for UINT, where *Scale* is the computed scale factor. For all other types, the bias is zero.

### Tip

---

If NORMALIZE is set and your input array has missing data (the **INVALID** or **NAN** keywords are set), for each result value the scale factor and bias are computed using only those kernel values that contributed to that result value. This ensures that all result values are comparable in magnitude, regardless of any missing data.

---

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

### Note

Also see [“Filtering an Image”](#) and [“Sharpening an Image”](#) in Chapter 8 of the *Image Processing in IDL* manual.

The first example uses a kernel to detect diagonal lines in an image. The code uses *Scale\_Factor* and *BIAS* to ensure that the result values are still within the range of byte values.

```

; Sample image
array = READ_PNG( FILEPATH('mineral.png', $
    SUBDIRECTORY=['examples','data']) )

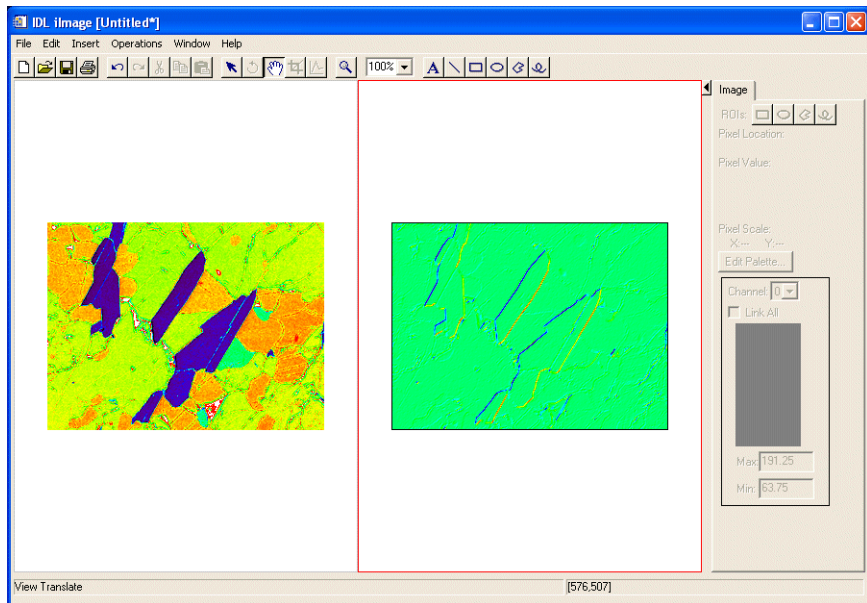

; Edge detection kernel
kernel = [ [0,1,0], [-1,0,1], [0,-1,0] ]

; Convolution with scale factor = total(abs(kernel))
; bias = (sum of abs of negative kernels)*(255/Scale)
result = CONVOL( array, kernel, 4, BIAS=2.0*255/4 )

LOADCT, 39, /SILENT
TVLCT, r, g, b, /GET
IIMAGE, array, VIEW_GRID=[2,1], RGB_TABLE=[[r],[g],[b]]
IIMAGE, result, /VIEW_NEXT, RGB_TABLE=[[r],[g],[b]]

```

[Figure 3-25](#) shows the result of running this code.

*Figure 3-25: CONVOL Example of Detecting Diagonal Lines*

The second example smooths a noisy image that has missing data and use the **NORMALIZE** keyword to automatically remove much of the missing data.

```

; Array with noise
array = HANNING(300,300) + 0.1*RANDOMN(s,300,300)

; Convert to bytes from [1, 255]
array = BYTSCL( array, TOP=254 )

; Add some missing scanlines, plus a large region
array[* , RANDOMU(s,40)*300] = 255
array[* , 10:20] = 255

; Simple Gaussian kernel
kernel = [ $
  [ 1, 8, 15, 8, 1], $
  [ 8, 63,127, 63, 8], $
  [15,127,255,127,15], $
  [ 8, 63,127, 63, 8], $
  [ 1, 8, 15, 8, 1]]

```

```

; Values of 255 are flagged as invalid (missing)
; and replaced by 0 if there are no valid values
; within the kernel
result = CONVOL( array, kernel, INVALID=255, MISSING=0, $
/NORMALIZE, /EDGE_ZERO )

LOADCT, 39, /SILENT
TVLCT, r, g, b, /GET
IIMAGE, array, VIEW_GRID=[2,1], RGB_TABLE=[[r],[g],[b]]
IIMAGE, result, /VIEW_NEXT, RGB_TABLE=[[r],[g],[b]]

```

Figure 3-26 shows the result of running this code.

# COORD2TO3

The COORD2TO3 function converts normalized X and Y screen coordinates to 3D data coordinates.

---

**Note**

A valid 3D transform must exist in !P.T or be specified by the PTI keyword. The axis scaling variables, !X.S, !Y.S and !Z.S must be valid.

---

This routine is written in the IDL language. Its source code can be found in the file `coord2to3.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = COORD2TO3( *Mx*, *My*, *Dim*, *D0* [, *PTI*] )

## Return Value

Returns a three-element vector containing 3D data coordinates given the normalized X and Y screen coordinates and one of the three data coordinates.

## Arguments

### **Mx, My**

The normalized X and Y screen coordinates.

### **Dim**

A parameter used to specify which data coordinate is fixed. Use 0 for a fixed X data coordinate, 1 for a fixed Y data coordinate, or 2 for a fixed Z data coordinate.

### **D0**

The value of the fixed data coordinate.

### **PTI**

The inverse of !P.T. If this parameter is not supplied, or set to 0, COORD2TO3 computes the inverse. If this routine is to be used in a loop, the caller should supply PTI for highest efficiency.

## Keywords

None.

## Examples

To return the data coordinates of the mouse, fixing the data Z value at 10, enter the commands:

```
;Make sure a transformation matrix exists.  
CREATE_VIEW  
  
;Get the normalized mouse coords.  
CURSOR, X, Y, /NORM  
  
;Print the 3D coordinates.  
PRINT, COORD2TO3 (X, Y, 2, 10.0)
```

# COPY\_LUN

The COPY\_LUN procedure copies data between two open files. It allows you to transfer a known amount of data from one file to another without needing to have the data available in an IDL variable. COPY\_LUN can copy a fixed amount of data, specified in bytes or lines of text, or it can copy from the current position of the file pointer in the input file to the end of that file.

COPY\_LUN copies data between open files. To copy entire files based on their names, see the [FILE\\_COPY](#) procedure. To read and discard a known amount of data from a file, see the [SKIP\\_LUN](#).

## Syntax

```
COPY_LUN, FromUnit, ToUnit [, Num] [, /EOF] [, /LINES]  
[ , /TRANSFER_COUNT]
```

## Arguments

### FromUnit

An integer that specifies the file unit for the file from which data is to be taken (the *source* file). Data is copied from *FromUnit*, starting at the current position of the file pointer. The file pointer is advanced as data is read. The file specified by *FromUnit* must be open, and must not have been opened with the RAWIO keyword to OPEN.

### ToUnit

An integer that specifies the file unit for the file to which data is to be written (the *destination* file). Data is written to *ToUnit*, starting at the current position of the file pointer. The file pointer is advanced as data is written. The file specified by *ToUnit* must be open for output (OPENW or OPENU), and must not have been opened with the RAWIO keyword to OPEN.

### Num

The amount of data to transfer between the two files. This value is specified in bytes, unless the LINES keyword is specified, in which case it is taken to be the number of text lines. If *Num* is not specified, COPY\_LUN acts as if the EOF keyword has been set, and copies all data in *FromUnit* (the source file) from the current position of the file pointer to the end of the file.

If *Num* is specified and the source file comes to end of file before the specified amount of data is transferred, COPY\_LUN issues an end-of-file error. The EOF keyword alters this behavior.

## Keywords

### EOF

Set this keyword to ignore the value given by *Num* (if present) and instead transfer all data between the current position of the file pointer in *FromUnit* and the end of the file.

#### Note

---

If EOF is set, no end-of-file error is issued even if the amount of data transferred does not match the amount specified by *Num*. The TRANSFER\_COUNT keyword can be used with EOF to determine how much data was transferred.

---

### LINES

Set this keyword to indicate that the *Num* argument specifies the number of lines of text to be transferred. By default, the *Num* argument specifies the number of bytes of data to transfer.

### TRANSFER\_COUNT

Set this keyword equal to a named variable that will contain the amount of data transferred. If LINES is specified, this value is the number of lines of text. Otherwise, it is the number of bytes. TRANSFER\_COUNT is primarily useful when the *Num* argument is not specified or the EOF keyword is present. If *Num* is specified and the EOF keyword is not present, TRANSFER\_COUNT will be the same as the value specified for *Num*.

## Examples

Copy the next 100000 bytes of data between two files:

```
COPY_LUN, FromUnit, ToUnit, 100000
```

Copy the next 8 lines of text between two files:

```
COPY_LUN, FromUnit, ToUnit, 8, /LINES
```

Copy the remainder of the data in one file to another, and use the `TRANSFER_COUNT` keyword to determine how much data was copied:

```
COPY_LUN, FromUnit, ToUnit, /EOF, TRANSFER_COUNT=n
```

Copy the remaining lines of text from one file to another, and use the `TRANSFER_COUNT` keyword to determine how many lines were transferred.

```
COPY_LUN, FromUnit, ToUnit, /EOF, /LINES, TRANSFER_COUNT=n
```

# CORRELATE

The CORRELATE function computes the linear Pearson correlation coefficient of two vectors or the correlation matrix of an  $m \times n$  array. Alternatively, this function computes the covariance of two vectors or the covariance matrix of an  $m \times n$  array.

This routine is written in the IDL language. Its source code can be found in the file `correlate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CORRELATE( X [, Y] [, /COVARIANCE] [, /DOUBLE] )
```

## Return Value

If vectors of unequal lengths are specified, the longer vector is truncated to the length of the shorter vector and a single correlation coefficient is returned. If an  $m \times n$  array is specified, the result will be an  $m \times m$  array of linear Pearson correlation coefficients, with the element  $i,j$  corresponding to correlation of the  $i$ th and  $j$ th columns of the input array.

## Arguments

### X

A vector or an  $m \times n$  array.  $X$  can be integer, single-, or double-precision floating-point.

### Y

An integer, single-, or double-precision floating-point vector. If  $X$  is an  $m \times n$  array,  $Y$  should not be supplied.

## Keywords

### COVARIANCE

Set this keyword to compute the sample covariance rather than the correlation coefficient.

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### Examples

Define the data vectors.

```
X = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71]
Y = [68, 66, 68, 65, 69, 66, 68, 65, 71, 67, 68, 70]
```

Compute the linear Pearson correlation coefficient of x and y. The result should be 0.702652:

```
PRINT, CORRELATE (X, Y)
```

IDL prints:

```
0.702652
```

Compute the covariance of x and y. The result should be 3.66667.

```
PRINT, CORRELATE (X, Y, /COVARIANCE)
```

IDL prints:

```
3.66667
```

Define an array with x and y as its columns.

```
A = TRANSPOSE ( [[X], [Y] ] )
```

Compute the correlation matrix.

```
PRINT, CORRELATE (A)
```

IDL prints:

```
1.00000    0.702652
0.702652    1.00000
```

# COS

The periodic function COS returns the trigonometric cosine of X.

## Syntax

*Result* = COS(*X*)

## Return Value

Returns the trigonometric cosine of X.

## Arguments

### X

The angle for which the cosine is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers:

$$\text{COS}(x) = (\text{EXP}(i*x) + 1/\text{EXP}(i*x))/2$$

where *i* is defined as COMPLEX(0, 1).

If *X* is an array, the result has the same structure, with each element containing the cosine of the corresponding element of *X*.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Find the cosine of 0.5 radians and print the result by entering:

```
PRINT, COS (.5)
```

IDL prints:

```
0.877583
```

## Version History

Original	Introduced

# COSH

The COSH function returns the hyperbolic cosine of  $X$ .

## Syntax

*Result* = COSH( $X$ )

## Return Value

Returns the hyperbolic cosine of  $X$ .

## Arguments

### $X$

The value for which the hyperbolic cosine is desired, specified in radians. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. COSH is defined as:

$$\text{COSH}(u) = (e^u + e^{-u}) / 2$$

If  $X$  is an array, the result has the same structure, with each element containing the hyperbolic cosine of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Find the hyperbolic cosine of 0.5 radians and print the result by entering:

```
PRINT, COSH(.5)
```

IDL prints:

1.12763

[ACOS](#), [COS](#)

# CPU

The CPU procedure is used to change the values stored in the read-only !CPU system variable, which in turn controls the way IDL uses the system processor or processors.

## Note

---

Not all routines are affected by changes to the !CPU system variable. Those routines that *are* affected can override some of the values in the !CPU system variable by setting *thread pool keywords*, which change the way IDL uses the system processor(s) during a single invocation of the routine. A list of thread pool keywords appears at the end of the keywords list for each routine that is affected by the state of the !CPU system variable.

---

## Syntax

```
CPU [, /RESET] [, RESTORE = structure] [, TPOOL_MAX_ELTS = NumMaxElts]  
    [, TPOOL_MIN_ELTS = NumMinElts] [, TPOOL_NTHREADS = NumThreads]  
    [, /VECTOR_ENABLE]
```

## Arguments

None.

## Keywords

### RESET

Set this keyword to cause the CPU procedure to reset the values contained in the !CPU system variable to the values it had when IDL was started. See [“Restoring !CPU Values”](#) on page 381 for more information on this topic. The RESET and RESTORE keywords are mutually exclusive; only one of them can be specified in a given call to CPU.

### RESTORE

Set this keyword equal to a structure of type !CPU to set the !CPU system variable with the values contained in the structure. See [“Restoring !CPU Values”](#) on page 381 for more information on this topic. The RESET and RESTORE keywords are mutually exclusive; only one of them can be specified in a given call to CPU.

## TPOOL\_MAX\_ELTS

This keyword changes the value returned by `!CPU.TPOOL_MAX_ELTS`.

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number contained in `!CPU.TPOOL_MAX_ELTS`, IDL will not use the thread pool for the computation. Setting this value to 0 removes any limit on maximum number of elements, and any computation with at least `!CPU.TPOOL_MIN_ELTS` will use the thread pool.

See “[Possible Drawbacks to the Use of the IDL Thread Pool](#)” in Chapter 11 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a maximum number of elements for computations that use the thread pool.

## TPOOL\_MIN\_ELTS

This keyword changes the value returned by `!CPU.TPOOL_MIN_ELTS`.

Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number contained in `!CPU.TPOOL_MIN_ELTS`, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

See “[Possible Drawbacks to the Use of the IDL Thread Pool](#)” in Chapter 11 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a minimum number of elements for computations that use the thread pool.

## TPOOL\_NTHREADS

This keyword changes the value returned by `!CPU.TPOOL_NTHREADS`.

Set this keyword to the number of threads IDL should use when performing computations that take advantage of the thread pool. By default, IDL will use `!CPU.HW_NCPU` threads, so that each thread will have the potential to run in parallel with the others. Set this keyword equal to 0 (zero) to ensure that `!CPU.HW_NCPU` threads will be used. Set this keyword equal to 1 (one) to disable use of the thread pool.

**Note**

For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to using *fewer* CPUs. See “[Possible Drawbacks to the Use of the IDL Thread Pool](#)” in Chapter 11 of the *Building IDL Applications* manual for a discussion of the circumstances under which using fewer than the maximum number of CPUs makes sense.

`!CPU.TPOOL_NTHREADS` is initialized with the value of the `IDL_CPU_TPOOL_NTHREADS` preference at startup. On systems shared by multiple users, you may wish to set this preference so that IDL uses the specified number of threads instead of defaulting to the number of CPUs present in the underlying hardware. For more information, see “[!CPU Settings Preferences](#)” in Appendix E of the *IDL Reference Guide* manual.

**VECTOR\_ENABLE**

This keyword changes the value returned by `!CPU.VECTOR_ENABLE`.

Set this keyword to enable use of the system’s vector unit (e.g. Macintosh Altivec/Velocity Engine) if one is present. Set this keyword equal to 0 (zero) explicitly disable such use. This keyword is ignored if the current system does not support a vector unit (that is, if `!CPU.HW_VECTOR = 0`).

**Restoring !CPU Values**

It is sometimes necessary to alter the way IDL uses the system processor or processors for a section of code, and then to restore IDL to the settings in effect before the code section was executed. It is often possible to accomplish this using the thread pool keywords to specific routines; in some circumstances, however, this approach may be inconvenient or ineffective. For example:

- If the section of code includes many routines for which alterations are required, the repetition of the keywords is inconvenient and error prone.
- Binary and unary operators that use the thread pool do not accept keywords.
- There is no keyword equivalent to the `!CPU.VECTOR_ENABLE` field.
- Future versions of IDL may provide additional CPU options; adding keywords to your code to invoke these options could pose maintenance problems.
- You may be working with IDL routines you did not write.

In all of these cases, the answer is to use the CPU procedure to alter the value of the !CPU system variable to suit the needs of your code, execute the code, and then reset !CPU to the state it had initially. It is possible to do this by using the individual keywords to CPU, as shown below:

```

save_cpu = !CPU           ; Save the current configuration
CPU, TPOOL_NTHREADS=2, ... ; Change the current configuration
...                       ; Carry out a computation
; Restore the CPU state
CPU, TPOOL_MAXELTS=save_cpu.tpool_max_elts, $
    TPOOL_MINELTS=save_cpu.tpool_min_elts, $
    TPOOL_NTHREADS=save_cpu.tpool_nthreads

```

There are two obvious problems with this approach: it is tedious and error prone, and if new versions of IDL add new CPU attributes, your code will require updates in order to reset them.

The RESTORE keyword to CPU solves both of these problems. When a structure of type !CPU is supplied using the RESTORE keyword, IDL adjusts the !CPU system variable to match the structure. Using RESTORE, the above example becomes:

```

save_cpu = !CPU
CPU, TPOOL_NTHREADS=2, ...
...
CPU, RESTORE=save_cpu

```

The RESET keyword is similar to RESTORE, but it resets the !CPU system variable to the values it had when IDL first started. The syntax is:

```

CPU, /RESET

```

The RESET keyword is useful in *ad hoc* analysis, when you've made changes to the !CPU system variable manually (perhaps as an experiment), and you wish to bring !CPU back to its default state for your machine without exiting and restarting IDL.

RESET and RESTORE are mutually exclusive — only one of them can be used in a given call to the CPU procedure. However, they are allowed in conjunction with the other keywords to CPU. In such cases, the explicit keywords take precedence over the values from the RESET or RESTORE keywords. For example, the following statement changes the number of threads used by the IDL thread pool to 3, and sets all other CPU parameters to the values contained in a variable named `save_cpu`:

```

CPU, TPOOL_NTHREADS=3, RESTORE=save_cpu

```

## Example

Configure !CPU so that by default, IDL will use two threads for computations that involve more than 5000 data values.

```
CPU, TPOOL_MIN_ELTS=5000, TPOOL_NTHREADS=2
```

## Version History

5.5	Introduced
6.1	Added RESET and RESTORE keywords

# CRAMER

The CRAMER function solves an  $n$  by  $n$  linear system of equations using Cramer's rule.

This routine is written in the IDL language. Its source code can be found in the file `cramer.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = CRAMER( *A*, *B* [, /DOUBLE] [, ZERO=*value*] )

## Return Value

Returns the solution of an  $n$  by  $n$  linear system of equations using Cramer's rule.

## Arguments

### A

An  $n$  by  $n$  single- or double-precision floating-point array.

### B

An  $n$ -element single- or double-precision floating-point vector.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ZERO

Use this keyword to set the value of the floating-point zero. A floating-point zero on the main diagonal of a triangular array results in a zero determinant. A zero determinant results in a "Singular matrix" error and stops the execution of CRAMER. For single-precision inputs, the default value is  $1.0 \times 10^{-6}$ . For double-precision inputs, the default value is  $1.0 \times 10^{-12}$ .

## Examples

Define an array A and right-hand side vector B.

```
A = [[ 2.0,  1.0,  1.0], $  
     [ 4.0, -6.0,  0.0], $  
     [-2.0,  7.0,  2.0]]  
B = [3.0, 10.0, -5.0]
```

```
;Compute the solution and print.  
PRINT, CRAMER(A,B)
```

IDL prints:

```
1.00000      -1.00000      2.00000
```

# CREATE\_CURSOR

The `CREATE_CURSOR` function creates an image array from a string array that represents a 16 by 16 cursor. The returned image array can be passed to the `REGISTER_CURSOR` procedure *Image* argument. This allows you to quickly design a cursor using a simple string array.

## Syntax

```
Result = CREATE_CURSOR( StringArray [, HOTSPOT=variable]
                        [, MASK=variable])
```

## Return Value

Translates the input string array into an image that satisfies the *Image* argument of the `REGISTER_CURSOR` procedure.

## Arguments

### StringArray

This must be a 16 element string array of 16 characters each that represents a window cursor. The array can consist of the "#" character, space and non-space characters, and optionally, a "\$" character as follows:

- The "#" characters define the black outline of the cursor.
- Any non-space characters define the shape of the white mask. Adding a mask ensures the cursor's visibility in light and dark areas of a visualization. Use the `MASK` keyword to return the array of masked out values.
- The "\$" defines a hot spot. Use the `HOTSPOT` keyword to return the location of this character within the string array.

## Keywords

### HOTSPOT

Set this keyword to a variable that will contain a two-element vector indicating the location of the "\$" character in the *StringArray*. This is considered to be the mouse position of the cursor. If there is no "\$" present, then [0,0] is returned. This variable can be directly passed to the `HOTSPOT` keyword of `REGISTER_CURSOR`.

## MASK

Set this keyword to return a 16 by 16 byte array containing any non-space characters, which indicates the area to be masked out. This variable can be passed to the MASK keyword of [REGISTER\\_CURSOR](#).

## Examples

The following code creates a simple cursor. Define a string array representing the body and mask portions of the cursor. Notice the hotspot ("\$\$") in the cursor structure.

```
strArray = [ $
      | . | $
      | .# | $
      | .### | $
      | .#### | $
      | . . . # . . . | $
      | .# . # . # | $
      | .## . . # . . ## | $
      | .#####$##### | $
      | .## . . # . . ## | $
      | .# . # . # | $
      | . . . # . . . | $
      | .#### | $
      | .### | $
      | .# | $
      | . | $
      | ]
cursor_image = CREATE_CURSOR(strArray, HOTSPOT=hotspot, MASK=mask)
REGISTER_CURSOR, 'translate', cursor_image, HOTSPOT=hotspot, $
    MASK=mask
```

After registering a cursor, you can set the current cursor using the [IDLgrWindow::SetCurrentCursor](#) method. The previous string results in the following cursor.

*Figure 3-27: String Array Translated into a Cursor*

## Version History

6.1	Introduced
-----	------------

# CREATE\_STRUCT

The `CREATE_STRUCT` function creates a structure given pairs of tag names and values. `CREATE_STRUCT` can also be used to concatenate structures.

## Syntax

```
Result = CREATE_STRUCT( [Tag1, Values1, ..., Tagn, Valuesn] [, Structuresn]  
                        [, NAME=string])
```

or

```
Result = CREATE_STRUCT( [Tags, Values1, ..., Valuesn] [, Structuresn]  
                        [, NAME=string])
```

## Return Value

Returns a structure composed of given pairs of tag names and values.

## Arguments

### Tags

The structure tag names. Tag names may be specified either as scalar strings or a single string array. If scalar strings are specified, values alternate with the tag names. If a string array is provided, values must still be specified individually. Tag names must be enclosed in quotes. Tag names may not be IDL [Reserved Words](#), and must be unique within a given structure, although the same tag name can be used in more than one structure. Tag names follow the rules of IDL identifiers: they must begin with a letter; following characters can be letters, digits, or the underscore or dollar sign characters; and case is ignored.

### Note

---

If a tag name contains spaces, `CREATE_STRUCT` will replace the spaces with underscores. For example, if you specify a tag name of 'my tag', the tag will be created with the name 'my\_tag'.

---

### Values

The values for the structure fields. The number of *Values* arguments must match the number of *Tags* arguments (if tags are specified as scalar strings) or the number of elements of the *Tags* array (if tags are specified as a single array.)

## Structures

One or more existing structure variables whose tags and values will be inserted into the new structure. When concatenating structures in this manner, the following rules apply:

- All tag names, whether specified via the *Tags* argument or in an existing structure variable, must be unique.
- Names of named structures included via the *Structures* arguments are not used in the newly-created structure.
- *Structures* arguments can be interspersed with groups of *Tags* and *Values* arguments in the call to `CREATE_STRUCT`. Use caution, however, to ensure that the number of *Tags* and *Values* in each group are equal, to avoid inserting a structure variable as the value of a single tag when you mean to include the structure's data as individual tags and values.

## Keywords

### NAME

To create a named structure, set this keyword equal to a string specifying the structure name. If this keyword is not present, an anonymous structure is created. Structure names must begin with a letter; following characters can be letters, digits, or the underscore or dollar sign characters; and case is ignored.

If `NAME` is specified and no plain arguments (tags, values, or structures) are present, then `CREATE_STRUCT` will return a structure of known type, either from IDL's internal table of already known named structures or by locating the appropriate `__define.pro` file for that structure in the current IDL search path (`!PATH`) and executing it. Hence, the following IDL statements are equivalent:

```
Result = { mystruct }
Result = CREATE_STRUCT(NAME='mystruct')
```

The `CREATE_STRUCT` version can be convenient in situations where the name of the structure is computed at runtime, and the `EXECUTE` function is not available (e.g., code running in the free IDL Virtual Machine environment, in which `EXECUTE` is disallowed).

## Examples

To create the anonymous structure { A: 1, B: 'xxx' } in the variable *P*, enter:

```
p = CREATE_STRUCT('A', 1, 'B', 'xxx')
```

To add the fields “FIRST” and “LAST” to the structure, enter the following:

```
p = CREATE_STRUCT('FIRST', 0, p, 'LAST', 3)
```

The resulting structure contains { FIRST: 0, A: 1, B: 'xxx', LAST: 3}.

Finally, consider the following statements:

```
s1 = {Struct1, Tag1:'AAA', Tag2:'BBB'}
s2 = {Struct2, TagA:100, TagB:200}
s3 = CREATE_STRUCT(NAME='Struct3', ['A','B','C'], 1, 2, s1, s2)
```

Here, the variable `s3` contains the following named structure:

```
{Struct3, A: 1, B: 2, C:{Struct1, Tag1: 'AAA', Tag2: 'BBB'}, TagA: 100, TagB: 200}
```

Note that the value of `s3.C` is itself a “Struct1” structure, since the structure variable `s1` was interpreted as a *Values* argument, whereas the structure variable `s2` was interpreted as a *Structures* argument, thus including the tags from the “Struct2” structure directly in the new structure.

# CREATE\_VIEW

The `CREATE_VIEW` procedure sets the various system variables required to define a coordinate system and a 3-D view. This procedure builds the system viewing matrix (!P.T) in such a way that the correct aspect ratio of the data is maintained even if the display window is not square. `CREATE_VIEW` also sets the “Data” to “Normal” coordinate conversion factors (!X.S, !Y.S, and !Z.S) so that center of the unit cube will be located at the center of the display window.

`CREATE_VIEW` sets the following IDL system variables:

!P.T	!X.S	!Y.S	!Z.S
!P.T3D	!X.Style	!Y.Style	!Z.Style
!P.Position	!X.Range	!Y.Range	!Z.Range
!P.Clip	!X.Margin	!Y.Margin	!Z.Margin
!P.Region			

This routine is written in the IDL language. Its source code can be found in the file `create_view.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
CREATE_VIEW [, AX=value] [, AY=value] [, AZ=value] [, PERSP=value]
  [, /RADIANS] [, WINX=pixels] [, WINY=pixels] [, XMAX=scalar]
  [, XMIN=scalar] [, YMAX=scalar] [, YMIN=scalar] [, ZFAC=value]
  [, ZMAX=scalar] [, ZMIN=scalar] [, ZOOM=scalar or 3-element vector]
```

## Arguments

This procedure has no required arguments.

## Keywords

### AX

A floating-point value specifying the orientation (X rotation) of the view. The default is 0.0.

**AY**

A floating-point value specifying the orientation (Y rotation) of the view. The default is 0.0.

**AZ**

A floating-point value specifying the orientation (Z rotation) of the view. The default is 0.0.

**PERSP**

A floating-point value specifying the perspective projection distance. A value of 0.0 indicates an isometric projection (NO perspective). The default is 0.0.

**RADIANS**

Set this keyword if AX, AY, and AZ are specified in radians. The default is degrees.

**WINX**

A long integer specifying the X size, in pixels, of the window that the view is being set up for. The default is 640.

**WINY**

A long integer specifying the Y size, in pixels, of the window that the view is being set up for. The default is 512.

**XMAX**

A scalar specifying the maximum data value on the X axis. The default is 1.0.

**XMIN**

A scalar specifying the minimum data value on the X axis. The default is 0.0.

**YMAX**

A scalar specifying the maximum data value on the Y axis. The default is 1.0.

**YMIN**

A scalar specifying the minimum data value on the Y axis. The default is 0.0.

## ZFAC

Set this keyword to a floating-point value to expand or contract the view in the Z dimension. The default is 1.0.

## ZMAX

A scalar specifying the maximum data value on the Z axis. The default is 1.0.

## ZMIN

A scalar specifying the minimum data value on the Z axis. The default is 0.0.

## ZOOM

A floating-point number or 3-element vector specifying the view zoom factor. If zoom is a single value then the view will be zoomed equally in all 3 dimensions. If zoom is a 3-element vector then the view will be scaled zoom[0] in X, zoom[1] in Y, and zoom[2] in Z. The default is 1.0.

## Examples

Set up a view to display an iso-surface from volumetric data. First, create some data:

```
vol = FLTARR(40, 50, 30)
vol(3:36, 3:46, 3:26) = RANDOMU(S, 34, 44, 24)
FOR I = 0, 10 DO vol = SMOOTH(vol, 3)
```

Generate the iso-surface.

```
SHADE_VOLUME, vol, 0.2, polygon_list, vertex_list, /LOW
```

Set up the view. Note that the subscripts into the Vol array range from 0 to 39 in X, 0 to 49 in Y, and 0 to 29 in Z. As such, the 3-D coordinates of the iso-surface (vertex\_list) may have the same range. Set XMIN, YMIN, and ZMIN to zero (the default), and set XMAX=39, YMAX=49, and ZMAX=29.

```
WINDOW, XSIZE = 600, YSIZE = 400
CREATE_VIEW, XMAX = 39, YMAX = 49, ZMAX = 29, $
  AX = (-60.0), AZ = (30.0), WINX = 600, WINY = 400, $
  ZOOM = (0.7), PERSP = (1.0)
```

Display the iso-surface in the specified view.

```
img = POLYSHADE(polygon_list, vertex_list, /DATA, /T3D)
TVSCL, img
```

# CRVLENGTH

The CRVLENGTH function computes the length of a curve with a tabular representation,  $Y[i] = F(X[i])$ .

## Warning

---

Data that is highly oscillatory requires a sufficient number of samples for an accurate curve length computation.

---

This routine is written in the IDL language. Its source code can be found in the file `crvlength.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = CRVLENGTH( *X*, *Y* [, /DOUBLE] )

## Return Value

Returns the curve length.

## Arguments

### X

An  $n$ -element single- or double-precision floating-point vector.  $X$  must contain at least three elements, and values must be specified in ascending order. Duplicate  $X$  values will result in a warning message.

### Y

An  $n$ -element single- or double-precision floating-point vector.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Example

```

;Define a 21-element vector of X-values:
x = [-2.00, -1.50, -1.00, -0.50, 0.00, 0.50, 1.00, 1.50, 2.00, $
2.50, 3.00, 3.50, 4.00, 4.50, 5.00, 5.50, 6.00, 6.50, $
7.00, 7.50, 8.00]

;Define a 21-element vector of Y-values:
y = [-2.99, -2.37, -1.64, -0.84, 0.00, 0.84, 1.64, 2.37, 2.99, $
3.48, 3.86, 4.14, 4.33, 4.49, 4.65, 4.85, 5.13, 5.51, $
6.02, 6.64, 7.37]

;Compute the length of the curve:
result = CRVLENGTH(x, y)

```

```
Print, result
```

IDL prints:

```
14.8115
```

# CT\_LUMINANCE

The CT\_LUMINANCE function calculates the luminance of colors.

This routine is written in the IDL language. Its source code can be found in the file `ct_luminance.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CT_LUMINANCE( [R, G, B] [, BRIGHT=variable] [, DARK=variable]  
[, /READ_TABLES] )
```

## Return Value

The function returns an array containing the luminance values of the specified colors. If the *R*, *G*, and *B* parameters are not specified, or if *R* is of integer, byte or long type, the result is a longword array with the same number of elements as the input arguments. Otherwise, the result is a floating-point array with the same number of elements as the input arguments.

## Arguments

### R

An array representing the red color table. If omitted, the color values from either the `COLORS` common block, or the current color table are used.

### G

An array representing the green color table. This parameter is optional.

### B

An array representing the blue color table. This parameter is optional.

## Keywords

### BRIGHT

Set this keyword to a named variable in which the array index of the brightest color is returned.

## DARK

Set this keyword to a named variable in which the array index of the darkest color is returned.

## READ\_TABLES

Set this keyword, and don't specify the *R*, *G*, and *B* arguments, to read colors directly from the current colortable (using TVLCT, /GET) instead of using the COLORS common block.

## Version History

Pre 4.0	Introduced

# CTI\_TEST

The CTI\_TEST function constructs a “contingency table” from an array of observed frequencies and tests the hypothesis that the rows and columns are independent using an extension of the chi-square goodness-of-fit test.

This routine is written in the IDL language. Its source code can be found in the file `cti_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CTI_TEST( Obfreq [, COEFF=variable] [, /CORRECTED]
                  [, CRAMV=variable] [, DF=variable] [, EXFREQ=variable]
                  [, RESIDUAL=variable] )
```

## Return Value

Returns a two-element vector containing the chi-square test statistic  $\chi^2$  and the one-tailed probability of obtaining a value of  $\chi^2$  or greater.

## Arguments

### Obfreq

An  $m \times n$  array containing observed frequencies. *Obfreq* can contain either integer, single-precision, double-precision floating-point values.

## Keywords

### COEFF

Set this keyword to a named variable that will contain the coefficient of contingency. The coefficient of contingency is a non-negative scalar, in the interval [0.0, 1.0], which measures the degree of dependence within a contingency table. The larger the value of COEFF, the greater the degree of dependence.

### CORRECTED

Set this keyword to use the Yate’s correction for continuity” when computing the chi-squared test statistic,  $\chi^2$ . The Yate’s correction always decreases the magnitude of  $\chi^2$ . In general, this keyword should be set for small sample sizes.

## CRAMV

Set this keyword to a named variable that will contain Cramer's V. Cramer's V is a non-negative scalar, in the interval [0.0, 1.0], which measures the degree of dependence within a contingency table.

## DF

Set this keyword to a named variable that will contain the number of degrees of freedom used to compute the probability of obtaining the value of the chi-squared test statistic or greater.  $DF = (n - 1) * (m - 1)$  where  $m$  and  $n$  are the number of columns and rows of the contingency table, respectively.

## EXFREQ

Set this keyword to a named variable that will contain an array of  $m$ -columns and  $n$ -rows containing expected frequencies. The elements of this array are often referred to as the "cells" of the expected frequencies. The expected frequency of each cell is computed as the product of row and column marginal frequencies divided by the overall total of observed frequencies.

## RESIDUAL

Set this keyword to a named variable that will contain an array of  $m$ -columns and  $n$ -rows containing signed differences between corresponding cells of observed frequencies and expected frequencies.

## Examples

Define a 5-column and 4-row array of observed frequencies.

```
obfreq = [[748, 821, 786, 720, 672], $
          [ 74,  60,  51,  66,  50], $
          [ 31,  25,  22,  16,  15], $
          [  9,  10,   6,   5,   7]]
```

Test the hypothesis that the rows and columns of "obfreq" contain independent data at the 0.05 significance level.

```
result = CTI_TEST(obfreq, COEFF = coeff)
```

The result should be the two-element vector [14.3953, 0.276181].

The computed value of 0.276181 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level. The coefficient of contingency returned in the parameter "coeff" (coeff = 0.0584860) also indicates the lack of

dependence between the rows and columns of the observed frequencies. Setting the `CORRECTED` keyword returns the two-element vector `[12.0032, 0.445420]` and (`coeff = 0.0534213`) resulting in the same conclusion of independence.

# CURSOR

The CURSOR procedure is used to read the position of the interactive graphics cursor from the current graphics device. Note that not all graphics devices have interactive cursors. CURSOR enables the graphic cursor on the device and optionally waits for the operator to position it. On devices that have a mouse, CURSOR normally waits until a mouse button is pressed (or already down). If no mouse buttons are present, CURSOR waits for a key on the keyboard to be pressed. The *X* and *Y* arguments are named variables that receive the cursor position. Normally, the position is reported in data coordinates, but the `DATA`, `DEVICE`, and `NORMAL` keywords can be used to explicitly specify the coordinate system.

When CURSOR returns, the `button` field of the system variable `!MOUSE` is set to the button status. Each mouse button is assigned a bit in the `button` field. Bit 0 is the leftmost button (value = 1), bit 1 is the middle button (value = 2), and bit 3 is the rightmost button (value = 4) for the typical three-button mouse. See “[!MOUSE](#)” on page 4809 for details.

## Avoid Using CURSOR with Draw Widgets

Note that the CURSOR procedure is only for use with IDL direct graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, set the `BUTTON_EVENTS` and `MOTION_EVENTS` keywords to `WIDGET_DRAW`, and examine the `X`, `Y`, `PRESS`, and `RELEASE` fields in the structures returned by the draw widget in response to cursor events. See [WIDGET\\_DRAW](#) for more information.

## Using CURSOR with the TEK Device

Note that for the CURSOR procedure to work properly with Tektronix terminals, you may need to execute the command, `DEVICE, GIN_CHARS=6`.

## Syntax

```
CURSOR, X, Y [, Wait / [, /CHANGE | , /DOWN | , /NOWAIT | , /UP | , /WAIT]]
      [, /DATA | , /DEVICE, | , /NORMAL]
```

## Arguments

### X

A named variable to receive the cursor's current column position.

**Y**

A named variable to receive the cursor's current row position.

**Wait**

An integer that specifies the conditions under which `CURSOR` returns. This parameter can be used interchangeably with the keyword parameters listed below that specify the type of wait. The default value is 1. The table below describes each type of wait.

Note that not all modes of waiting work with all display devices.

Wait Value	Corresponding Keyword	Action
0	NOWAIT	Return immediately.
1	WAIT	Return if a button is down.
2	CHANGE	Return if a button is pressed, released, or the pointer is moved.
3	DOWN	Return when a button down transition is detected.
4	UP	Return when a button up transition is detected.

*Table 3-11: Values for CURSOR Wait Parameter*

**Keywords****CHANGE**

Set this keyword to wait for pointer movement or button transition within the currently selected window.

**DATA**

Set this keyword to return *X* and *Y* in data coordinates.

**DOWN**

Set this keyword to wait for a button down transition within the currently selected window.

## DEVICE

Set this keyword to return  $X$  and  $Y$  in device coordinates.

## NORMAL

Set this keyword to return  $X$  and  $Y$  in normalized coordinates.

## NOWAIT

Set this keyword to read the pointer position and button status and return immediately. If the pointer is not within the currently selected window, the device coordinates -1, -1 are returned.

## UP

Set this keyword to wait for a button up transition within the current window.

## WAIT

Set this keyword to wait for a button to be depressed within the currently selected window. If a button is already pressed, return immediately.

## Examples

Activate the graphics cursor, select a point in the graphics window, and return the position of the cursor in device coordinates. Enter:

```
CURSOR, X, Y, /DEVICE
```

Move the cursor over the graphics window and press the mouse button. The position of the cursor in device coordinates is stored in the variables  $X$  and  $Y$ . To label the location, enter:

```
XYOUTS, X, Y, 'X marks the spot.', /DEVICE
```

The following two programs demonstrate simple applications of the interactive graphics cursor and the `CURSOR` procedure.

The first routine is a simple drawing program. Straight lines are connected to positions marked with the left or middle mouse buttons until the right button is pressed.

```
PRO DRAW
; Start with a blank screen:
ERASE
; Get the initial point in normalized coordinates:
CURSOR, X, Y, /NORMAL, /DOWN
```

```

; Repeat until right button is pressed. Get the second point.
; Draw the line. Make the current second point be the new first.
WHILE (!MOUSE.button NE 4) DO BEGIN
    CURSOR, X1, Y1, /NORM, /DOWN
    PLOTS, [X,X1], [Y,Y1], /NORMAL
    X = X1 & Y = Y1
ENDWHILE
END

```

The second simple procedure can be used to label plots using the cursor to position the text:

```

; Text is the string to be written on the screen:
PRO LABEL, TEXT
; Ask the user to mark the position:
PRINT, 'Use the mouse to mark the text position:'
; Get the cursor position after pressing any button:
CURSOR, X, Y, /NORMAL, /DOWN
; Write the text at the specified position.
; The NOCLIP keyword is used to ensure that
; the text will appear even if it is outside
; the plotting region.
XYOUTS, X, Y, TEXT, /NORMAL, /NOCLIP
END

```

At the command line, set TEXT equal to the string of text you want to appear in the window. For example, enter,

```
Text = 'My Sample Text'
```

Compile and run the program by entering the following at the command line, passing your text string to the procedure:

```
LABEL, TEXT
```

Next, move the pointer device to the desired spot in the window and click the locator button. Consider how you might augment the LABEL procedure to allow you to specify the size and font of the annotation text.

---

### Note

Also see “[Cropping Images](#)” in Chapter 2 of the *Image Processing in IDL* manual for an example that uses the CURSOR function to extract a rectangular region of interest from an image.

# CURVEFIT

The CURVEFIT function uses a gradient-expansion algorithm to compute a non-linear least squares fit to a user-supplied function with an arbitrary number of parameters. The user-supplied function may be any non-linear function where the partial derivatives are known or can be approximated. Iterations are performed until the chi square changes by a specified amount, or until a maximum number of iterations have been performed.

This routine is written in the IDL language. Its source code can be found in the file `curvefit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CURVEFIT( X, Y, Weights, A [, Sigma] [, CHISQ=variable] [, /DOUBLE]
  [, FITA=vector] [, FUNCTION_NAME=string] [, ITER=variable]
  [, ITMAX=value] [, /NODERIVATIVE] [, STATUS={0 | 1 | 2}] [, TOL=value]
  [, YERROR=variable] )
```

## Return Value

Returns a vector of values for the dependent variables, as fitted by the function fit. If *A* is double-precision or if the `DOUBLE` keyword is set, calculations are performed in double-precision arithmetic, otherwise they are performed in single-precision arithmetic.

## Arguments

### X

An *n*-element vector of independent variables.

### Y

A vector of dependent variables. *Y* must have the same number of elements as *F* returned by the user-defined function.

### Weights

For instrumental (Gaussian) weighting, set  $Weights_i = 1.0/\text{standard\_deviation}(Y_i)^2$ . For statistical (Poisson) weighting,  $Weights_i = 1.0/Y_i$ . For no weighting, set

$Weights_i = 1.0$ . If *Weights* is set to an undefined variable then no weighting will be used.

## A

A vector with as many elements as the number of terms in the user-supplied function, containing the initial estimate for each parameter. On return, the vector *A* contains the fitted model parameters.

## Sigma

A named variable that will contain a vector of standard deviations for the elements of the output vector *A*.

### Note

---

If *Weights* is omitted, then you are assuming that your supplied model is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned for the *Sigma* argument are multiplied by  $\text{SQRT}(\text{CHISQ}/(N * M))$ , where *N* is the number of points in *X*, and *M* is the number of coefficients. See Section 15.2 of *Numerical Recipes in C (Second Edition)* for details.

---

## Keywords

### CHISQ

Set this keyword to a named variable that will contain the value of the reduced chi-square goodness-of-fit statistic.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### FITA

Set this keyword to a vector, with as many elements as *A*, which contains a zero for each fixed parameter, and a non-zero value for elements of *A* to fit. If not supplied, all parameters are taken to be non-fixed.

### FUNCTION\_NAME

Use this keyword to specify the name of the function to fit. If this keyword is omitted, CURVEFIT assumes that the IDL procedure `FUNCT` is to be used. If `FUNCT` is not already compiled, IDL compiles the function from the file `funct.pro`, located in the

lib subdirectory of the IDL distribution. `FUNCT` evaluates the sum of a Gaussian and a second-order polynomial.

The function to be fit must be written as an IDL procedure and compiled prior to calling `CURVEFIT`. The procedure must accept values of  $X$  (the independent variable), and  $A$  (the fitted function's initial parameter values). It must return values for  $F$  (the function's value at  $X$ ), and optionally  $PDER$  (a 2D array of partial derivatives).

The return value for  $F$  must have the same number of elements as  $Y$ . The return value for  $PDER$  (if supplied) must be a 2D array with dimensions `[N_ELEMENTS(Y), N_ELEMENTS(A)]`.

See the *Example* section below for an example function.

## ITER

Set this keyword equal to a named variable that will contain the actual number of iterations performed.

## ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 20.

## NODERIVATIVE

If this keyword is set, the routine specified by the `FUNCTION_NAME` keyword will not be requested to provide partial derivatives. The partial derivatives will be estimated by `CURVEFIT` using forward differences. If analytical derivatives are available they should always be used.

## STATUS

Set this keyword to a named variable that will contain an integer indicating the status of the computation. Possible return values are:

0	The computation was successful.
1	The computation failed. Chi-square was increasing without bounds.
2	The computation failed to converge in <code>ITMAX</code> iterations.

## TOL

Use this keyword to specify the desired convergence tolerance. The routine returns when the relative decrease in chi-squared is less than TOL in one iteration. The default value is  $1.0 \times 10^{-3}$ .

## YERROR

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

## Examples

Fit a function of the form  $F(x) = a * \exp(b*x) + c$  to sample pairs contained in arrays *X* and *Y*. The partial derivatives are easily computed symbolically:

```
df/da = EXP(b*x)
df/db = a * x * EXP(b*x)
df/dc = 1.0
```

First, define a procedure to return  $F(x)$  and the partial derivatives, given *X*. Note that *A* is an array containing the values *a*, *b*, and *c*.

```
PRO gfunct, X, A, F, pder
  bx = EXP(A[1] * X)
  F = A[0] * bx + A[2]

  ;If the procedure is called with four parameters, calculate the
  ;partial derivatives.
  IF N_PARAMS() GE 4 THEN $
    pder = [[bx], [A[0] * X * bx], [replicate(1.0, N_ELEMENTS(X))]]
  END
```

Compute the fit to the function we have just defined. First, define the independent and dependent variables:

```
X = FLOAT(INDGEN(10))
Y = [12.0, 11.0, 10.2, 9.4, 8.7, 8.1, 7.5, 6.9, 6.5, 6.1]

;Define a vector of weights.
weights = 1.0/Y

;Provide an initial guess of the function's parameters.
A = [10.0, -0.1, 2.0]

;Compute the parameters.
yfit = CURVEFIT(X, Y, weights, A, SIGMA, FUNCTION_NAME='gfunct')
```

```

;Print the parameters returned in A.
PRINT, 'Function parameters: ', A

```

IDL prints:

```

Function parameters:      9.91120      -0.100883      2.07773

```

Thus, the function that best fits the data is:

$$f(x) = 9.91120(e^{-0.100883x}) + 2.07773$$

## Version History

Pre 4.0	Introduced
5.6	Added YERROR keyword
6.0	Added FITA and STATUS keywords

# CV\_COORD

The CV\_COORD function converts 2D and 3D coordinates between the rectangular, polar, cylindrical, and spherical coordinate systems.

This routine is written in the IDL language. Its source code can be found in the file `cv_coord.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CV_COORD( [, /DEGREES] [, /DOUBLE] [, FROM_CYLIN=cyl_coords |
, FROM_POLAR=pol_coords | , FROM_RECT=rect_coords |
, FROM_SPHERE=sph_coords] [, /TO_CYLIN | , /TO_POLAR | , /TO_RECT |
, /TO_SPHERE] )
```

## Return Value

If the value specified in the “FROM\_” keyword is double precision, or if the DOUBLE keyword is set, then all calculations are performed in double precision and the returned value is double precision. Otherwise, single precision is used. If none of the “FROM\_” keyword are specified, 0 is returned. If none of the “TO\_” keywords are specified, the input coordinates are returned.

## Arguments

This function has no required arguments. All data is passed in via keywords.

## Keywords

### DEGREES

If set, then the input and output coordinates are in degrees (where applicable). Otherwise, the angles are in radians.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### FROM\_CYLIN

A vector of the form  $[angle, radius, z]$ , or a  $(3, n)$  array of cylindrical coordinates to convert.

## FROM\_POLAR

A vector of the form [*angle*, *radius*], or a (2, *n*) array of polar coordinates to convert.

## FROM\_RECT

A vector of the form [*x*, *y*] or [*x*, *y*, *z*], or a (2, *n*) or (3, *n*) array containing rectangular coordinates to convert.

## FROM\_SPHERE

A vector of the form [*longitude*, *latitude*, *radius*], or a (3, *n*) array of spherical coordinates to convert.

## TO\_CYLIN

If set, cylindrical coordinates are returned in a vector of the form [*angle*, *radius*, *z*], or a (3, *n*) array.

## TO\_POLAR

If set, polar coordinates are returned in a vector of the form [*angle*, *radius*], or a (2, *n*) array.

## TO\_RECT

If set, rectangular coordinates are returned in a vector of the form [*x*, *y*] or [*x*, *y*, *z*], or a (2, *n*) or (3, *n*) array.

## TO\_SPHERE

If set, spherical coordinates are returned in a vector of the form [*longitude*, *latitude*, *radius*], or a (3, *n*) array.

## Examples

Convert from spherical to cylindrical coordinates:

```
sph_coord = [[45.0, -60.0, 10.0], [0.0, 0.0, 0.0]]
rect_coord = CV_COORD(FROM_SPHERE=sph_coord, /TO_CYLIN, /DEGREES)
```

Convert from rectangular to polar coordinates:

```
rect_coord = [10.0, 10.0]
polar_coord = CV_COORD(FROM_RECT=rect_coord, /TO_POLAR)
```

# CVTTOBM

The CVTTOBM function converts a byte array in which each byte represents one pixel into a “bitmap byte array” in which each bit represents one pixel. This is useful when creating bitmap labels for buttons created with the WIDGET\_BUTTON function.

Most of IDL’s image file format reading functions (READ\_BMP, READ\_PICT, etc.) return a byte array which must be converted before use as a button label. Note that there is one exception to this rule; the READ\_X11\_BITMAP routine returns a bitmap byte array that needs no conversion before use.

This routine is written in the IDL language. Its source code can be found in the file `cvttobm.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

IDL supports color bitmaps for button labels. The IDL GUIBuilder has a Bitmap Editor that allows you to create color bitmaps for button labels. The BITMAP keyword to WIDGET\_BUTTON specifies that the button label is a color bitmap.

---

## Syntax

*Result* = CVTTOBM( *Array* [, THRESHOLD=*value*{0 to 255}] )

## Return Value

Returns a bitmap byte array. Bitmap byte arrays are monochrome; by default, CVTTOBM converts pixels that are darker than the median value to black and pixels that are lighter than the median value to white. You can supply a different threshold value via the THRESHOLD keyword.

## Arguments

### Array

A 2-dimensional pixel array, one byte per pixel.

## Keywords

### THRESHOLD

A byte value (or an integer value between 0 and 255) to be used as a threshold value when determining if a particular pixel is black or white. If `THRESHOLD` is not specified, the threshold is calculated to be the average of the input array.

## Examples

The following example creates a bitmap button label from a byte array:

```

; Create a byte array:
image = BYTSCALE(DIST(100))
; Create a widget base:
base = WIDGET_BASE(/COLUMN)

; Use CVTTOBM to create a bitmap byte array for a button label:
button = WIDGET_BUTTON(base, VALUE = CVTTOBM(image))

; Realize the widget:
WIDGET_CONTROL, base, /REALIZE

```

## Version History

[WIDGET\\_BUTTON](#), [XBM\\_EDIT](#), “Using the Bitmap Editor” in Chapter 29 of the *Building IDL Applications* manual.

## CW\_ANIMATE

The `CW_ANIMATE` function creates a compound widget that— along with its associated routines — displays an animated sequence of images using off-screen windows known as *pixmap*s. The speed and direction of the display can be adjusted using the widget interface.

`CW_ANIMATE` provides the graphical interface used by the `XINTERANIMATE` procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of `XINTERANIMATE` when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

### Using CW\_ANIMATE

Unlike `XINTERANIMATE`, using the `CW_ANIMATE` widget requires calls to two separate procedures, `CW_ANIMATE_LOAD` and `CW_ANIMATE_RUN`, to load the images to be animated and to run the animation. Alternatively, you can supply a vector of pre-existing pixmap window IDs, eliminating the need to use `CW_ANIMATE_LOAD`. The vector of pixmaps is commonly obtained from a call to `CW_ANIMATE_GETP` applied to a previous animation widget. Once the images are loaded, they are displayed by copying the images from the pixmap or buffer to the visible draw widget.

See the documentation for `CW_ANIMATE_LOAD`, `CW_ANIMATE_RUN`, and `CW_ANIMATE_GETP` for more information.

The only event returned by `CW_ANIMATE` indicates that the user has clicked on the “End Animation” button. The parent application should use this as a signal to kill the animation widget via `WIDGET_CONTROL`. When the widget is destroyed, the pixmaps used in the animation are destroyed as well, unless they were saved by a call to `CW_ANIMATE_GETP`.

See the animation widget’s help file (available by clicking the “Help” button on the widget) for more information about the widget’s controls.

**Note**

---

Three routines associated with the CW\_ANIMATE compound widget — CW\_ANIMATE\_GETP, CW\_ANIMATE\_LOAD, and CW\_ANIMATE\_RUN — do not create compound widgets themselves, but act on an existing CW\_ANIMATE widget.

---

**Syntax**

```
Result = CW_ANIMATE( Parent, Sizex, Sizey, Nframes [, /NO_KILL]
  [, OPEN_FUNC=string] [, PIXMAPS=vector] [, TAB_MODE=value]
  [, /TRACK] [, UNAME=string] [, UVALUE=value] )
```

**Return Value**

This function returns the widget ID of the newly-created animation widget.

**Arguments****Parent**

The widget ID of the parent widget.

**Sizex**

The width of the displayed image, in pixels.

**Sizey**

The height of the displayed image, in pixels

**Nframes**

The number of frames in the animation sequence.

**Keywords****NO\_KILL**

Set this keyword to omit the “End Animation” button from the animation widget.

## OPEN\_FUNC

Set this keyword equal to a scalar string specifying the name of a user-written function that loads animation data. If a function is specified, an “Open ...” button is added to the animation widget.

## PIXMAPS

Use this keyword to provide the animation widget with a vector of pre-existing pixmap (off screen window) IDs. This vector is usually obtained from a call to `CW_ANIMATE_GETP` applied to a previous animation widget.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-12: `TAB_MODE` Keyword Options

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

**TRACK**

Set this keyword to cause the frame slider to track the frame number of the currently-displayed frame.

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

**UVALUE**

The “user value” to be assigned to the widget.

**Keywords to `WIDGET_CONTROL` and `WIDGET_INFO`**

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

See “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

**Widget Events Returned by the `CW_ANIMATE`**

## Widget

The only event returned by this widget indicates that the user has pressed the DONE button. The parent application should use this as a signal to kill the animation widget via WIDGET\_CONTROL.

## Examples

Assume the following event handler procedure exists:

```
PRO EHANDLER, EV
WIDGET_CONTROL, /DESTROY, EV.TOP
end
```

### Tip

---

If you wish to create this event handler starting from the IDL command prompt, remember to begin with the `.RUN` command.

---

Enter the following commands to open the file `ABNORM.DAT` (a series of images of a human heart) and load the images it contains into an array `H`.

```
OPENR, 1, FILEPATH('abnorm.dat', SUBDIR = ['examples','data'])
H = BYTARR(64, 64, 16)
READU, 1, H
CLOSE, 1
H = REBIN(H, 128, 128, 16)
```

Create an instance of the animation widget and load the frames. Note that because the animation widget is realized before the call to `CW_ANIMATE_LOAD`, the frames are displayed as they are loaded. This provides the user with an indication of how things are progressing.

```
base = WIDGET_BASE(TITLE = 'Animation Widget')
animate = CW_ANIMATE(base, 128, 128, 16)
WIDGET_CONTROL, /REALIZE, base
FOR I=0,15 DO CW_ANIMATE_LOAD, animate, FRAME=I, IMAGE=H[*,* ,I]
```

Save the pixmap window IDs for future use:

```
CW_ANIMATE_GETP, animate, pixmap_vect
```

Start the animation:

```
CW_ANIMATE_RUN, animate
XMANAGER, 'CW_ANIMATE Demo', base, EVENT_HANDLER = 'EHANDLER'
```

Pressing the “End Animation” button kills the application.

# CW\_ANIMATE\_GETP

The `CW_ANIMATE_GETP` procedure gets a copy of the vector of pixmap window IDs being used by a `CW_ANIMATE` animation widget. If this routine is called, `CW_ANIMATE` does not destroy the pixmaps when it is destroyed. You can then provide the pixmaps to a later instance of `CW_ANIMATE` to re-use them, skipping the pixmap creation and rendering step (`CW_ANIMATE_LOAD`).

`CW_ANIMATE` provides the graphical interface used by the `XINTERANIMATE` procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of `XINTERANIMATE` when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
CW_ANIMATE_GETP, Widget, Pixmaps [, /KILL_ANYWAY]
```

## Arguments

### Widget

The widget ID of the animation widget (created with `CW_ANIMATE`) that contains the pixmaps.

### Pixmaps

A named variable that will contain a vector of the window IDs of the pixmap windows.

## Keywords

### KILL\_ANYWAY

Set this keyword to ensure that the pixmaps are destroyed anyway when `CW_ANIMATE` exits, despite the fact that `CW_ANIMATE_GETP` has been called.

## Example

See [“CW\\_ANIMATE”](#) on page 419.

[XINTERANIMATE](#)

# CW\_ANIMATE\_LOAD

The CW\_ANIMATE\_LOAD procedure creates an array of pixmaps which are loaded into a CW\_ANIMATE compound widget.

CW\_ANIMATE provides the graphical interface used by the XINTERANIMATE procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of XINTERANIMATE when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
CW_ANIMATE_LOAD, Widget [, /CYCLE] [, FRAME=value{0 to NFRAMES}]  
  [, IMAGE=value] [, /ORDER] [, WINDOW=[window_num [, XO, YO, Sx, Sy]]]  
  [, XOFFSET=pixels] [, YOFFSET=pixels]
```

## Arguments

### Widget

The widget ID of the animation widget (created with CW\_ANIMATE) into which the image should be loaded.

## Keywords

### CYCLE

Set this keyword to cause the animation to cycle. Normally, frames are displayed going either forward or backward. If CYCLE is set, the animation reverses direction after the last frame in either direction is displayed.

### FRAME

The frame number to be loaded. This is a value between 0 and NFRAMES. If not supplied, frame 0 is loaded.

## IMAGE

The image to be loaded. IMAGE can either be a 2D or a 3D (24-bit) image.

## ORDER

Set this keyword to display images from the top down instead of the default bottom up. This keyword is only used when loading images with the IMAGE keyword.

## WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap. Under some windowing systems, this technique is much faster than reading from the display and then loading with the IMAGE keyword.

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

## XOFFSET

The horizontal offset, in pixels from the left of the frame, of the image in the destination window.

## YOFFSET

The vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

## Example

See the documentation for CW\_ANIMATE for an example using this procedure. Note that if the widget is realized before calls to CW\_ANIMATE\_LOAD, the frames are displayed as they are loaded.

## Version History

[CW\\_ANIMATE](#), [CW\\_ANIMATE\\_GETP](#), [CW\\_ANIMATE\\_RUN](#),  
[XINTERANIMATE](#)

# CW\_ANIMATE\_RUN

The CW\_ANIMATE\_RUN procedure displays a series of images that have been loaded into a CW\_ANIMATE compound widget by a call to CW\_ANIMATE\_LOAD.

CW\_ANIMATE provides the graphical interface used by the XINTERANIMATE procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of XINTERANIMATE when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
CW_ANIMATE_RUN, Widget [, Rate{0 to 100}] [, NFRAMES=value] [, /STOP]
```

## Arguments

### Widget

The widget ID of the animation widget (created with CW\_ANIMATE) that will display the animation.

### Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation has a value of 100 and the slowest has a value of 0. The default animation rate is 100.

The animation rate can also be adjusted after the animation has begun by changing the value of the “Animation Speed” slider.

## Keywords

### NFRAMES

Set this keyword equal to the number of frames to animate. This number must be less than or equal to the *Nframes* argument to CW\_ANIMATE.

## STOP

If this keyword is set, the animation is stopped.

## Example

See “[CW\\_ANIMATE](#)” on page 419.

[XINTERANIMATE](#)

# CW\_ARCBALL

The `CW_ARCBALL` function creates a compound widget for intuitively specifying three-dimensional orientations.

The user drags a simulated track-ball with the mouse to interactively obtain arbitrary rotations. Sequences of rotations may be cascaded. The rotations may be unconstrained (about any axis), constrained to the view X, Y, or Z axes, or constrained to the object's X, Y, or Z axis.

This widget is based on "ARCBALL: A User Interface for Specifying Three-Dimensional Orientation Using a Mouse," by Ken Shoemake, Computer Graphics Laboratory, University of Pennsylvania, Philadelphia, PA 19104.

This widget can generate any rotation about any axis. Note, however, that not all rotations are compatible with the IDL `SURFACE` procedure, which is restricted to rotations that project the object Z axis parallel to the view Y axis.

This routine is written in the IDL language. Its source code can be found in the file `cw_arcball.pro` in the `lib` subdirectory of the IDL distribution.

## Using CW\_ARCBALL

Use the command:

```
WIDGET_CONTROL, id, GET_VALUE = matrix
```

to return the current 3x3 rotation matrix in the variable `matrix`.

You can set the arcball to new rotation matrix using the command:

```
WIDGET_CONTROL, id, SET_VALUE = matrix
```

after the widget is initially realized.

## Syntax

```
Result = CW_ARCBALL( Parent [, COLORS=array] [, /FRAME]
  [, LABEL=string] [, RETAIN={0 | 1 | 2}] [, SIZE=pixels] [, TAB_MODE=value]
  [, /UPDATE] [, UNAME=string] [, UVALUE=value] [, VALUE=array] )
```

## Return Value

This function returns the widget ID of the newly-created ARCBALL widget.

# Arguments

## Parent

The widget ID of the parent widget.

# Keywords

## COLORS

A 6-element array containing the color indices to be used.

- Colors[0] = view axis color,
- Colors[1] = object axis color,
- Colors[2] = XZ plane +Y side (body top) color,
- Colors[3] = YZ plane (fin) color,
- Colors[4] = XZ plane -Y side (body bottom),
- Colors[5] = background color.

For devices that are using indexed color (i.e., DECOMPOSED=0), the default value for COLORS is [1, 7, 2, 3, 7, 0], which yields good colors with the TEK\_COLOR table: (white, yellow, red, green, yellow, black). For devices that are using decomposed color (i.e., DECOMPOSED=1), the default value is an array of corresponding decomposed (rather than indexed) colors: (white, yellow, red, green, yellow, black).

For more information on decomposed color, refer to the [DECOMPOSED](#) keyword to the DEVICE routine.

## FRAME

Set this keyword to draw a frame around the widget.

## LABEL

Set this keyword to a string containing the widget's label.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, "Using Language Catalogs"](#) in the *Building IDL Applications* manual.

---

## RETAIN

Set this keyword to zero, one, or two to specify how backing store should be handled for the draw widget. `RETAIN=0` specifies no backing store. `RETAIN=1` requests that the server or window system provide backing store. `RETAIN=2` specifies that IDL provide backing store directly. See “[Backing Store](#)” on page 4728 for details.

## SIZE

The size of the square drawable area containing the arcball, in pixels. The default is 192.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-13: `TAB_MODE` Keyword Options

**Note**

---

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

**UPDATE**

Set this keyword to cause the widget will send an event each time the mouse button is released after a drag operation. By default, events are only sent when the “Update” button is pressed.

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

**UVALUE**

The “user value” to be assigned to the widget.

**VALUE**

Set this keyword to a 3 x 3 array that will be the initial value for the rotation matrix. `VALUE` must be a valid rotation matrix (no translation or perspective) where  $\text{TRANPOSE}(\text{VALUE}) = \text{INVERSE}(\text{VALUE})$ . This can be the upper-left corner of !P.T after executing the command

```
T3D, /RESET, ROTATE = [x,y,z].
```

The default is the identity matrix.

**Keywords to WIDGET\_CONTROL and WIDGET\_INFO**

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the

WIDGET\_CONTROL and WIDGET\_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the `GET_VALUE` and `SET_VALUE` keywords to WIDGET\_CONTROL to obtain or set the 3 x 3 rotation matrix in the arcball widget.

See “Creating a Compound Widget” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET\_CONTROL and WIDGET\_INFO.

## Widget Events Returned by the CW\_ARCBALL Widget

Arcball widgets generate event structures with the following definition:

```
event = {ID:0L, TOP:0L, HANDLER:0L, VALUE:fltarr(3,3) }
```

The VALUE field contains the 3 x 3 array representing the new rotation matrix.

## Examples

See the procedure `ARCBALL_TEST`, contained in the `cw_arcball.pro` file. To test CW\_ARCBALL, enter the following commands:

```
.RUN cw_arcball
ARCBALL_TEST
```

This results in the following:

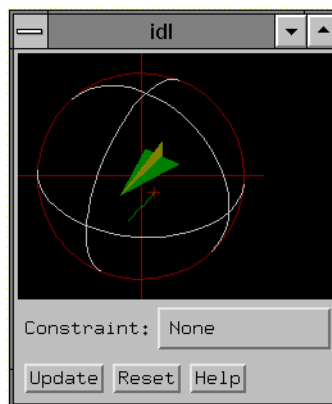

Figure 3-29: The CW\_ARCBALL widget.

## Version History

Pre 4.0	Introduced

# CW\_BGROU

The CW\_BGROU function creates a widget base of buttons. It simplifies creation of a cluster of buttons, and handles the details of creating the proper base (standard, exclusive, or non-exclusive) and filling in the desired buttons. Button groups can be simple menus in which each button acts independently, *exclusive* groups (also known as “radio buttons”), or *non-exclusive* groups (often called “checkboxes”). Events for the individual buttons are handled transparently, and a CW\_BGROU event returned. This event can return any one of the following:

- the index of the button within the base,
- the widget ID of the button,
- the name of the button,
- an arbitrary value taken from an array of user values.

Only buttons with textual names are handled by this widget. Bitmaps are not understood.

This routine is written in the IDL language. Its source code can be found in the file `cw_bgroup.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_BGROU( Parent, Names [, BUTTON_UVALUE=array]
  [, COLUMN=value] [, EVENT_FUNC=string] [{, /EXCLUSIVE | ,
  /NONEXCLUSIVE} | [, SPACE=pixels] [, XPAD=pixels] [, YPAD=pixels]]
  [, FONT=font] [, FRAME=width] [, IDS=variable]
  [, LABEL_LEFT=string | , LABEL_TOP=string] [, /MAP] [, /NO_RELEASE]
  [, /RETURN_ID | , /RETURN_INDEX | , /RETURN_NAME] [, ROW=value]
  [, /SCROLL] [, SET_VALUE=value] [SPACE=value] [, TAB_MODE=value]
  [, X_SCROLL_SIZE=width] [, Y_SCROLL_SIZE=height]
  [, SET_VALUE=value] [, UNAME=string] [, UVALUE=value]
  [, XOFFSET=value] [, XSIZE=width] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

This function returns the widget ID of the newly-created button group widget.

## Arguments

### Parent

The widget ID of the parent widget.

### Names

A string array, one string per button, giving the name of each button.

## Keywords

### BUTTON\_UVALUE

An array of user values to be associated with each button and returned in the event structure. If this keyword is set, the user values are always returned, even if the any of the RETURN\_ID, RETURN\_INDEX, or RETURN\_NAME keywords are set.

### COLUMN

Buttons will be arranged in the number of columns specified by this keyword.

### EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget. This function is called with the return value structure whenever a button is pressed, and follows the conventions for user-written event functions.

### EXCLUSIVE

Set this keyword to cause buttons to be placed in an exclusive base, in which only one button can be selected at a time.

### FONT

The name of the font to be used for the button titles. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

### FRAME

Specifies the width of the frame to be drawn around the base.

## IDS

A named variable in which the button IDs will be stored, as a longword vector.

## LABEL\_LEFT

Set this keyword to a string creating a text label to the left of the buttons.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## LABEL\_TOP

Set this keyword to a string creating a text label above the buttons.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## MAP

Set this keyword to cause the base to be mapped when the widget is realized (the default).

## NONEXCLUSIVE

Set this keyword to cause buttons to be placed in a non-exclusive base, in which any number of buttons can be selected at once.

## NO\_RELEASE

If set, button release events will not be returned.

## RETURN\_ID

Set this keyword to return the widget ID of the button in the VALUE field of returned events. This keyword is ignored if the BUTTON\_UVALUE keyword is set.

## RETURN\_INDEX

Set this keyword to return the zero-based index of the button within the base in the VALUE field of returned events. This keyword is ignored if the BUTTON\_UVALUE keyword is set. THIS IS THE DEFAULT.

## RETURN\_NAME

Set this keyword to return the name of the button within the base in the VALUE field of returned events. This keyword is ignored if the BUTTON\_UVALUE keyword is set.

## ROW

Buttons will be arranged in the number of rows specified by this keyword.

## SCROLL

If set, the base will include scroll bars to allow viewing a large base through a smaller viewport.

## SET\_VALUE

Allows changing the current state of toggle buttons (i.e., exclusive and nonexclusive groups of buttons). The behavior of SET\_VALUE differs between EXCLUSIVE and NONEXCLUSIVE CW\_BGROU widgets. With EXCLUSIVE CW\_BGROU widgets, the argument to SET\_VALUE is the id of the widget to be turned on. With NONEXCLUSIVE CW\_BGROU widgets the argument to SET\_VALUE should be an array of on/off flags for the array of buttons.

## SPACE

The space, in pixels, to be left around the edges of a row or column major base.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

---

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-14: *TAB\_MODE* Keyword Options

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The “user value” to be assigned to the widget.

## XOFFSET

The X offset of the widget relative to its parent.

**XPAD**

The horizontal space, in pixels, between children of a row or column major base.

**XSIZE**

The width of the base.

**X\_SCROLL\_SIZE**

The width of the viewport if SCROLL is specified.

**YOFFSET**

The Y offset of the widget relative to its parent.

**YPAD**

The vertical space, in pixels, between children of a row or column major base.

**YSIZE**

The height of the base.

**Y\_SCROLL\_SIZE**

The height of the viewport if SCROLL is specified.

**Keywords to WIDGET\_CONTROL and WIDGET\_INFO**

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET\_CONTROL and WIDGET\_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET\\_VALUE](#) and [SET\\_VALUE](#) keywords to WIDGET\_CONTROL to obtain or set the value of the button group. The values for different types of CW\_BGROUP widgets is shown in the table below:

Type	Value
normal	None
exclusive	Index of currently set button

*Table 3-15: Button Group Values*

Type	Value
non-exclusive	Vector indicating the position of each button (1-set, 0-unset)

Table 3-15: Button Group Values (Continued)

See “[Writing Compound Widgets](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET\_CONTROL and WIDGET\_INFO.

## Widget Events Returned by the CW\_BGROUП Widget

CW\_BGROUП generates an event that specifies which button or buttons were selected. The widgets generate event structures with the following definition:

```
event = { ID:0L, TOP:0L, HANDLER:0L, SELECT:0, VALUE:0 }
```

The SELECT field is passed through from the button event. VALUE is either the INDEX, ID, NAME, or BUTTON\_UVALUE of the button, depending on how the widget was created.

## Examples

See “[Creating Menus](#)” in Chapter 30 of the *Building IDL Applications* manual for example CW\_BGROUП code.

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

# CW\_CLR\_INDEX

The CW\_CLR\_INDEX function creates a compound widget that displays a horizontal color bar and allows the user to select a color index. Clicking on the bar sets the color index.

This routine is written in the IDL language. Its source code can be found in the file `cw_clr_index.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_CLR_INDEX( Parent [, COLOR_VALUES=vector |
    [, NCOLORS=value] [, START_COLOR=value]]
    [, EVENT_FUNC='function_name'] [, /FRAME] [, LABEL=string]
    [, NCOLORS=value] [, START_COLOR=value] [, TAB_MODE=value]
    [, UNAME=string] [, UVALUE=value] [, VALUE=value] [, XSIZE=pixels]
    [, YSIZE=pixels] )
```

## Return Value

This function returns the widget ID of the newly-created color index widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### COLOR\_VALUES

A vector of color indices containing the colors to be displayed in the color bar. If omitted, NCOLORS and START\_COLOR specify the range of color indices.

### EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget. This function is called with the return value structure whenever a button is pressed, and follows the conventions for user-written event functions.

## FRAME

If set, a frame will be drawn around the widget.

## LABEL

A text label that appears to the left of the color bar.

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

## NCOLORS

The number of colors to place in the color bar. The default is !D.N\_COLORS.

## START\_COLOR

Set this keyword to the starting color index, placed at the left of the bar.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.

Table 3-16: TAB\_MODE Keyword Options

Value	Description
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-16: *TAB\_MODE* Keyword Options (Continued)

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The “user value” to be assigned to the widget.

## VALUE

Set this keyword to the index of the color that is to be initially selected. The default is the `START_COLOR`.

## XSIZE

The width of the color bar in pixels. The default is 192.

## YSIZE

The height of the color bar in pixels. The default is 12.

## Keywords to WIDGET\_CONTROL and WIDGET\_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET\_CONTROL and WIDGET\_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET\\_VALUE](#) and [SET\\_VALUE](#) keywords to WIDGET\_CONTROL to obtain or set the value of the color selection widget. The value of a CW\_CLR\_INDEX widget is the index of the color selected.

See “[Writing Compound Widgets](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET\_CONTROL and WIDGET\_INFO.

## Widget Events Returned by the CW\_CLR\_INDEX Widget

This widget generates event structures with the following definition:

```
Event = {CW_COLOR_INDEX, ID: base, TOP: ev.top, HANDLER: 0L,
        VALUE:c}
```

The VALUE field is the color index selected.

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

## See Also

[CW\\_COLORSEL](#), [XLOADCT](#), [XPALETTE](#)

# CW\_COLORSEL

The `CW_COLORSEL` function creates a compound widget that displays all the colors in the current colormap in a 16 x 16 (320 x 320 pixels) grid. To select a color index, the user moves the mouse pointer over the desired color square and presses any mouse button. Alternatively, the color index can be selected by moving one of the three sliders provided around the grid.

This routine is written in the IDL language. Its source code can be found in the file `cw_colorsel.pro` in the `lib` subdirectory of the IDL distribution.

## Using CW\_COLORSEL

The command:

```
WIDGET_CONTROL, widgetID, SET_VALUE = -1
```

informs the widget to initialize itself and redraw. It should be called when any of the following happen:

- the widget is realized,
- the widget needs redrawing,
- the brightest or darkest color has changed.

To set the current color index, use the command:

```
WIDGET_CONTROL, widgetID, SET_VALUE = index
```

To retrieve the current color index and store it in the variable `var`, use the command:

```
WIDGET_CONTROL, widgetID, GET_VALUE = var
```

## Syntax

```
Result = CW_COLORSEL( Parent [, /FRAME]
  [, TAB_MODE=value][, UNAME=string] [, UVALUE=value]
  [, XOFFSET=value] [, YOFFSET=value] )
```

## Return Value

This function returns the widget ID of the newly-created color index widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### FRAME

If set, a frame is drawn around the widget.

### TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

#### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-17: TAB\_MODE Keyword Options

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `FIND_BY_UNAME` keyword to the `WIDGET_INFO` function. The `UNAME` should be unique to the widget hierarchy; `FIND_BY_UNAME` returns the ID of the first widget with the specified name.

**UVALUE**

The “user value” to be assigned to the widget.

**XOFFSET**

The X offset position

**YOFFSET**

The Y offset position

## Widget Events Returned by the `CW_COLORSEL` Widget

This widget generates event structures with the following definition:

```
Event = {COLORSEL_EVENT, ID: base, TOP: ev.top, HANDLER: 0L,  
VALUE:c}
```

The `VALUE` field is the color index selected.

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

## See Also

[CW\\_CLR\\_INDEX](#), [XLOADCT](#), [XPALETTE](#)

# CW\_DEFROI

The CW\_DEFROI function creates a compound widget that allows the user to define a region of interest within a widget draw window.

## Warning

---

This is a *modal* widget. No other widget applications will be responsive while this widget is in use. Also, since CW\_DEFROI has its own event-handling loop, it should not be created as a child of a modal base.

---

This routine is written in the IDL language. Its source code can be found in the file `cw_defroi.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_DEFROI( Draw [, IMAGE_SIZE=vector] [, OFFSET=vector]  
[, /ORDER] [, /RESTORE] [, TAB_MODE=value] [, ZOOM=vector] )
```

## Return Value

The is function returns an array of subscripts defining the region. If no region is defined, the scalar -1 is returned.

## Arguments

### Draw

The widget ID of draw window in which to draw the region. Note that the draw window must have both `BUTTON` and `MOTION` events enabled (see [WIDGET\\_DRAW](#) for more information).

## Keywords

### IMAGE\_SIZE

The size of the underlying array, expressed as a two element vector: [*columns*, *rows*]. Default is the size of the draw window divided by the value of `ZOOM`.

### OFFSET

The offset of lower left corner of image within the draw window. Default = [0,0].

## ORDER

Set this keyword to return inverted subscripts, as if the array were output from top to bottom.

## RESTORE

Set this keyword to restore the draw window to its previous appearance on exit. Otherwise, the regions remain on the drawable.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

---

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

---

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-18: TAB\_MODE Keyword Options*

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

**ZOOM**

If the image array was expanded (using `REBIN`, for example) specify this two element vector containing the expansion factor in X and Y. Default = [1,1]. Both elements of `ZOOM` must be integers.

**Widget Events Returned by the `CW_DEFROI` Widget**

Region definition widgets do not return an event structure.

**Examples**

The following two procedures create a region-of-interest widget and its event handler. Create a file containing the program code using a text editor and compile using the `.RUN` command, or type `.RUN` at the IDL prompt and enter the lines interactively. First, create the event handler:

```

PRO test_event, ev

; The common block holds variables that are shared between the
; routine and its event handler:
COMMON T, draw, dbutt, done, image

; Define what happens when you click the "Draw ROI" button:
IF ev.id EQ dbutt THEN BEGIN
  ; The ROI definition will be stored in the variable Q:
  Q = CW_DEFROI(draw)
  IF (Q[0] NE -1) THEN BEGIN
    ; Show the size of the ROI definition array:
    HELP, Q
    ; Duplicate the original image.
    image2 = image

    ; Set the points in the ROI array Q equal to a single
    ; color value:
    image2(Q) = !P.COLOR-1
  
```

```

; Get the window ID of the draw widget:
WIDGET_CONTROL, draw, GET_VALUE=W

; Set the draw widget as the current graphics window:
WSET, W

; Load the image plus the ROI into the draw widget:
TV, image2
ENDIF
ENDIF

; Define what happens when you click the "Done" button:
IF ev.id EQ done THEN WIDGET_CONTROL, ev.top, /DESTROY

END

```

Next, create a draw widget that can call CW\_DEFROI. Note that you *must* specify both button events and motion events when creating the draw widget, if it is to be used with CW\_DEFROI.

```

PRO test
COMMON T, draw, dbutt, done, image

; Create a base to hold the draw widget and buttons:
base = WIDGET_BASE(/COLUMN)

; Create a draw widget that will return both button and
; motion events:
draw = WIDGET_DRAW(base, XSIZE=256, YSIZE=256, /BUTTON, /MOTION)
dbutt = WIDGET_BUTTON(base, VALUE='Draw ROI')
done = WIDGET_BUTTON(base, VALUE='Done')
WIDGET_CONTROL, base, /REALIZE

; Get the widget ID of the draw widget:
WIDGET_CONTROL, draw, GET_VALUE=W

; Set the draw widget as the current graphics window:
WSET, W

; Create an original image:
image = BYTSCL(SIN(DIST(256)))

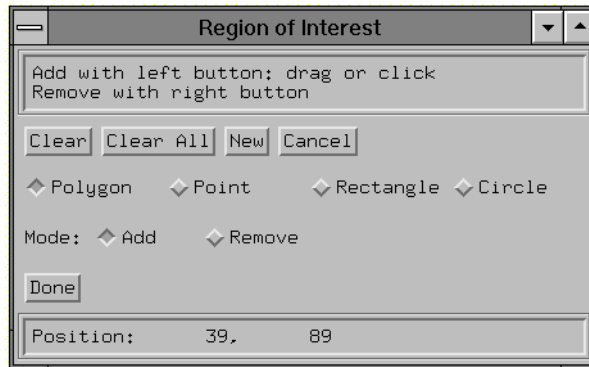

; Display the image in the draw widget:
TV, image

; Start XMANAGER:
XMANAGER, "test", base

END

```

This results in the following:

[DEFROI](#)

# CW\_FIELD

The CW\_FIELD function creates a widget data entry field. The field consists of a label and a text widget. CW\_FIELD can create string, integer, or floating-point fields. The default is an editable string field.

This routine is written in the IDL language. Its source code can be found in the file `cw_field.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_FIELD( Parent [, /ALL_EVENTS] [, /COLUMN]
  [, /FIELDFONT=font] [, /FLOATING | , /INTEGER | , /LONG | , /STRING]
  [, /FONT=string] [, /FRAME=pixels] [, /NOEDIT] [, /RETURN_EVENTS]
  [, /ROW] [, /STRING=string] [, /TAB_MODE=value] [, /TEXT_FRAME=pixels]
  [, /TITLE=string] [, /UNAME=string] [, /UVALUE=value] [, /VALUE=value]
  [, /XSIZE=characters] [, /YSIZE=lines] )
```

## Return Value

This function returns the widget ID of the newly created field widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### ALL\_EVENTS

Like RETURN\_EVENTS, but return an event whenever the contents of a text field have changed.

### COLUMN

Set this keyword to center the label above the text field. The default is to position the label to the left of the text field.

## FIELDFONT

Set this keyword to a string containing the name of the font to use for the TEXT part of the field.

## FLOATING

Set this keyword to have the field accept only floating-point values. Any number or string entered is converted to its floating-point equivalent.

## FONT

Set this keyword to a string containing the name of the font to use for the TITLE of the field. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

## FRAME

Set this keyword to the width, in pixels, of a frame to be drawn around the entire field cluster. The default is no frame.

## INTEGER

Set this keyword to have the field accept only integer values. Any number or string entered is converted to its integer equivalent (using FIX). For example, if 12.5 is entered in this type of field, it is converted to 12.

## LONG

Set this keyword to have the field accept only long integer values. Any number or string entered is converted to its long integer equivalent (using LONG).

## NOEDIT

Normally, the value in the text field can be edited. Set this keyword to make the field non-editable.

## RETURN\_EVENTS

Set this keyword to make CW\_FIELD return an event when a carriage return is pressed in a text field. The default is not to return events. Note that the value of the text field is always returned when the following command is used:

```
WIDGET_CONTROL, field, GET_VALUE = X
```

## ROW

Set this keyword to position the label to the left of the text field. This is the default.

## STRING

Set this keyword to have the field accept only string values. Numbers entered in the field are converted to their string equivalents. This is the default.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-19: TAB\_MODE Keyword Options

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## TEXT\_FRAME

Set this keyword to the width in pixels of a frame to be drawn around the text field. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets always have a frame of width 1 pixel.

## TITLE

A string containing the text to be used as the label for the field. The default is “Input Field”.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The “user value” to be assigned to the widget.

## VALUE

The initial value in the text widget. This value is automatically converted to the type defined by the `STRING`, `INTEGER`, `LONG`, and `FLOATING` keywords.

## XSIZE

An explicit horizontal size (in characters) for the text input area. The default is to let the window manager size the widget. Using the `XSIZE` keyword is not recommended.

## YSIZE

An explicit vertical size (in lines) for the text input area. The default is 1.

## Keywords to WIDGET\_CONTROL and WIDGET\_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET\_CONTROL and WIDGET\_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET\\_VALUE](#) and [SET\\_VALUE](#) keywords to WIDGET\_CONTROL to obtain or set the value of the field. If one of the FLOATING, INTEGER, LONG, or STRING keywords to CW\_FIELD is set, values set with the SET\_VALUE keyword to WIDGET\_CONTROL will be forced to the appropriate type. Values returned by the GET\_VALUE keyword to WIDGET\_CONTROL will be of the type specified when the field widget is created. Note that if the field contains string information, returned values will be contained in a string *array* even if the field contains only a single string.

See “[Writing Compound Widgets](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET\_CONTROL and WIDGET\_INFO.

## Widget Events Returned by the CW\_FIELD Widget

This widget generates event structures with the following definition:

```
event = { ID:0L, TOP:0L, HANDLER: 0L, VALUE:'', TYPE:0 , UPDATE:0 }
```

The VALUE field is the value of the field. TYPE specifies the type of data contained in the field and can be any of the following: 0=string, 1=floating-point, 2=integer, 3=long integer (the value of TYPE is determined by setting one of the STRING, FLOAT, INTEGER, or LONG keywords). UPDATE contains a zero if the field has not been altered or a one if it has.

## Examples

The code below creates a main base with a field cluster attached to it. The cluster accepts string input, has the title “Name”, and has a frame around it:

```
base = WIDGET_BASE()
field = CW_FIELD(base, TITLE = "Name", /FRAME)
WIDGET_CONTROL, base, /REALIZE
```

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

# CW\_FILESEL

The CW\_FILESEL function is a compound widget for file selection.

This routine is written in the IDL language. Its source code can be found in the file `cw_filesel.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_FILESEL ( Parent [, /FILENAME] [, FILTER=string array]
    [, /FIX_FILTER] [, /FRAME] [, /IMAGE_FILTER] [, /MULTIPLE | , /SAVE]
    [, /PATH=string] [, /TAB_MODE=value] [, /UNAME=string] [, /UVALUE=value]
    [, /WARN_EXIST] )
```

## Return Value

This function returns the widget ID of the newly-created file selection widget.

## Arguments

### Parent

The widget ID of the parent.

## Keywords

### FILENAME

Set this keyword to have the initial filename filled in the filename text area.

### FILTER

Set this keyword to an array of strings determining the filter types. If not set, the default is "All Files". All files containing the chosen filter string will be displayed as possible selections. "All Files" is a special filter which returns all files in the current directory.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, "Using Language Catalogs"](#) in the *Building IDL Applications* manual.

---

Example:

```
FILTER=["All Files", ".txt"]
```

Multiple filter types may be used per filter entry, using a comma as the separator.

Example:

```
FILTER=[".jpg, .jpeg", ".txt, .text"]
```

## **FIX\_FILTER**

If set, the user can not change the file filter.

## **FRAME**

If set, a frame is drawn around the widget.

## **IMAGE\_FILTER**

If set, the filter “Image Files” will be added to the end of the list of filters. If set, and `FILTER` is not set, “Image Files” will be the only filter displayed. Valid image files are determined from `QUERY_IMAGE`.

## **MULTIPLE**

If set, the file selection list will allow multiple filenames to be selected. The filename text area will not be editable in this case. It is illegal to specify both `/SAVE` and `/MULTIPLE`.

## **PATH**

Set this keyword to the initial path the widget is to start in. The default is the current directory.

## **SAVE**

Set this keyword to create a widget with a “Save” button instead of an “Open” button. It is illegal to specify both `/SAVE` and `/MULTIPLE`.

## **TAB\_MODE**

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-20: TAB\_MODE Keyword Options*

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET\_INFO function with the FIND\_BY\_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND\_BY\_UNAME keyword returns the ID of the first widget with the specified name.

**UVALUE**

The “user value” to be assigned to the widget.

## WARN\_EXIST

Set this keyword to produce a question dialog if the user selects a file that already exists. This keyword is useful when creating a “write” dialog. The default is to allow any filename to be quietly accepted, whether it exists or not.

## Keywords to WIDGET\_CONTROL

You can use the `GET_UVALUE` and `SET_UVALUE` keywords to `WIDGET_CONTROL` to obtain or set the user value of this widget. Use the command to read the currently selected filename (or filenames if `MULTIPLE` is set) including the full path:

```
WIDGET_CONTROL, id, GET_VALUE=filenames
```

To set the value of the filename, use the following command:

```
WIDGET_CONTROL, id, SET_VALUE=value
```

where *value* is a scalar string (or string array) containing the filenames, including the full path.

See “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

## Widget Events Returned by CW\_FILESEL

`CW_FILESEL` generates an event that specifies the name of the selected file, whether the user completed the file selection operation, and the filename filter used. This widget generates event structures with the following definition:

```
Event = { FILESEL_EVENT, ID:0L, TOP:0L, HANDLER:0L, VALUE:'',  
         DONE:0L, FILTER:'' }
```

The `ID` field is the widget ID of the `CW_FILESEL` widget. The `TOP` field contains the widget ID of the top-level widget. The `HANDLER` field is always set to zero. The `VALUE` field is a string containing the most recent filename selected, if any.

---

### Note

Even if `MULTIPLE` is set, `VALUE` will only contain the most recently selected filename. To retrieve all of the currently selected filenames, use the `GET_VALUE` keyword to `WIDGET_CONTROL`.

---

The DONE field can be any of the following:

- 0 = User selected a file but didn't double-click, or the user changed filters (in this case the VALUE field will be an empty string.)
- 1 = User pressed "Open"/"Save" or double-clicked on a file.
- 2 = User pressed "Cancel".

The FILTER field is a string containing the current filter.

## Examples

This example creates a CW\_FILESEL widget that is used to select image files for display. Note how the DONE tag of the event structure returned by CW\_FILESEL is used to determine which button was pressed, and how the VALUE tag is used to obtain the file that was selected:

```

PRO image_opener_event, event

    WIDGET_CONTROL, event.top, GET_UVALUE=state, /NO_COPY

    CASE event.DONE OF
        0: BEGIN
            state.file = event.VALUE
            WIDGET_CONTROL, event.top, SET_UVALUE=state, /NO_COPY
        END
        1: BEGIN
            IF (state.file NE '') THEN BEGIN
                img = READ_IMAGE(state.file)
                TV, img
            ENDIF
            WIDGET_CONTROL, event.top, SET_UVALUE=state, /NO_COPY
        END
        2: WIDGET_CONTROL, event.top, /DESTROY
    ENDCASE

END

PRO image_opener

    DEVICE, DECOMPOSED=0, RETAIN=2

    base = WIDGET_BASE(TITLE = 'Open Image', /COLUMN)
    filesel = CW_FILESEL(base, /IMAGE_FILTER, FILTER='All Files')
    file=''
    state = {file:file}

    WIDGET_CONTROL, base, /REALIZE

```

```

WIDGET_CONTROL, base, SET_UVALUE=state, /NO_COPY
XMANAGER, 'image_opener', base

```

END

This code opens the following dialog:

Figure 3-31: CW\_FILESEL

# CW\_FORM

The `CW_FORM` function is a compound widget that simplifies creating small forms which contain text, numeric fields, buttons, lists, and droplists. Event handling is also simplified.

This routine is written in the IDL language. Its source code can be found in the file `cw_form.pro` in the `lib` subdirectory of the IDL distribution.

## Using CW\_FORM

The form has a value that is a structure with a tag/value pair for each field in the form. Use the command

```
WIDGET_CONTROL, id, GET_VALUE=v
```

to read the current value of the form. To set the value of one or more tags, use the command

```
WIDGET_CONTROL, id, SET_VALUE={ Tag:value, ..., Tag:value }
```

## Syntax

```
Result = CW_FORM( [Parent,] Desc [, /COLUMN] [, IDS=variable]
  [, TAB_MODE=value] [, TITLE=string] [, UNAME=string]
  [, UVALUE=value] )
```

## Return Value

If the argument *Parent* is present, the returned value of this function is the widget ID of the newly-created form widget. If *Parent* is omitted, the form realizes itself as a modal, top-level widget and `CW_FORM` returns a structure containing the value of each field in the form when the user finishes.

## Arguments

### Parent

The widget ID of the parent widget. Omit this argument to create a modal, top-level widget.

## Desc

A string array describing the form. Each element of the string array contains two or more comma-delimited fields. Each string has the following format:

*'Depth, Item, Initial value, Settings'*

Use the backslash character (“\”) to escape commas that appear within fields. To include the backslash character, escape it with another backslash.

The fields are defined as follows:

- **Depth**

A digit defining the level at which the element will be placed on the form. Nesting is used primarily for layout, with row or column bases.

This field must contain the digit 0, 1, or 2, with the following effects:

- 0 = continue the current nesting level.
- 1 = begin a new level under the current level.
- 2 = last element at the current level.

- **Item**

A label defining the type of element to be placed in the form. *Item* must be one of the following: BASE, BUTTON, DROPLIST, FLOAT, INTEGER, LABEL, LIST, or TEXT.

BASEs and LABELs do not return a value in the widget value structure. The other items return the following value types:

Item	Description
BUTTON	An integer or integer array. For single buttons, the value is 1 if the button is set, or 0 if it is not set. For exclusive button groups, the value is the index of the currently set button. For non-exclusive button groups, the value is an array containing an element for each button. Array elements are set to 1 if the corresponding button is set, or 0 if it is not set.
DROPLIST	An integer. The value set in the widget value structure is the zero-based index of the item is selected.

*Table 3-21: Values for the Item field*

Item	Description
FLOAT	A floating-point value. The value set in the widget value structure is the floating-point value of the field.
INTEGER	An integer. The value set in the widget value structure is the integer value of the field.
LIST	An integer. The value set in the widget value structure is the zero-based index of the item is selected.
TEXT	A string. The value set in the widget value structure is the string value of the field.

Table 3-21: Values for the *Item* field (Continued)

- **Initial value**

The initial value of the field. The *Initial value* field is left empty for BASEs.

For BUTTON, DROPLIST, and LIST items, the value field contains one or more item names, separated by the | character. Strings do not need to be enclosed in quotes. For example, the following line defines an exclusive button group with buttons labeled “one,” “two,” and “three.”

```
'0, BUTTON, one|two|three, EXCLUSIVE'
```

For FLOAT, INTEGER, LABEL, and TEXT items, the value field contains the initial value of the field.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

- **Settings**

The *Settings* field contains one of the following keywords or keyword=*value* pairs. Keywords are used to specify optional attributes or options. Any number of keywords may be included in the description string.

Note that preceding keywords with a “/” character has no effect. Simply including a keyword in the *Settings* field enables that option.

Keyword	Description
CENTER	Specifies alignment of LABEL items.
COLUMN	If present, specifies column layout in BASES or for BUTTON groups.
EXCLUSIVE	If present, makes an exclusive set of BUTTONs. The default is nonexclusive.
FONT= <i>font name</i>	If present, the font for the item is specified. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “ <a href="#">About Device Fonts</a> ” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.
EVENT= <i>function</i>	Specifies the name of a user-written event function that is called whenever the element is changed. The event function is called with the widget event structure as a parameter. It may return an event structure or zero to indicate that no further event processing is desired.
FRAME	If present, a frame is drawn around the item. Valid only for BASEs.
LABEL_LEFT= <i>label</i>	Place a label to the left of the item. This keyword is valid with BUTTON, DROPLIST, FLOAT, INTEGER and TEXT items.
LABEL_TOP= <i>label</i>	Place a label above the item. This keyword is valid with BUTTON, DROPLIST, FLOAT, INTEGER and TEXT items.
LEFT	Specifies alignment of LABEL items.

Table 3-22: Values for the Settings Field

Keyword	Description
NO_RELEASE	If present, exclusive and non-exclusive buttons generate only select events. This keyword has no effect on regular buttons.
QUIT	If the form widget is created as a top-level, modal widget, when the user activates an item defined with this keyword, the form is destroyed and its widget value returned in the widget value structure of CW_FORM. For non-modal form widgets, events generated by changing this item have their QUIT field set to 1.
RIGHT	Specifies alignment of LABEL items.
ROW	If present, specifies row layout in BASES or for BUTTON groups.
SET_VALUE= <i>value</i>	Sets the initial value of BUTTON groups or DROPLISTS. For droplists and exclusive button groups, <i>value</i> should be the zero-based index of the item selected.
TAG= <i>name</i>	The tag name of this element in the widget's value structure. If not specified, the tag name is TAG <i>nnn</i> , where <i>nnn</i> is the zero-based index of the item in the <i>Desc</i> array.
WIDTH= <i>n</i>	Specifies the width, in characters, of a TEXT, INTEGER, or FLOAT item.

Table 3-22: Values for the Settings Field (Continued)

## Keywords

### COLUMN

Set this keyword to make the orientation of the form vertical. If COLUMN is not set, the form is laid out in a horizontal row.

### IDS

Set this keyword equal to a named variable into which the widget id of each widget corresponding to an element in the *Desc* array is stored.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-23: TAB\_MODE Keyword Options

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## TITLE

Set this keyword equal to a scalar string containing the title of the top level base. TITLE is not used if the form widget has a parent widget.

**Note**

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

**UVALUE**

Set this keyword equal to the user value associated with the form widget.

**Keywords to WIDGET\_CONTROL and WIDGET\_INFO**

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET\\_VALUE](#) and [SET\\_VALUE](#) keywords to `WIDGET_CONTROL` to obtain or set the value of the form. The form has a value that is a structure with a tag/value pair for each field in the form. Use the command

```
WIDGET_CONTROL, id, GET_VALUE=v
```

to read the current value of the form. To set the value of one or more tags, use the command

```
WIDGET_CONTROL, id, SET_VALUE={ Tag:value, ..., Tag:value}
```

See [“Creating a Compound Widget”](#) in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

## Widget Events Returned by the CW\_FORM Widget

CW\_FORM generates an event that specifies the which field within the form changed and the new value. This widget generates event structures each time the value of the form is changed. The event structure has the following definition:

```
Event = { ID:0L, TOP:0L, HANDLER:0L, TAG:'', VALUE:0, QUIT:0}
```

The ID field is the widget ID of the CW\_FORM widget. The TOP field is the widget ID of the top-level widget. The TAG field contains the tag name of the field that changed. The VALUE field contains the new value of the changed field. The QUIT field contains a zero if the quit flag is not set, or one if it is set.

## Examples

Define a form with a label, two groups of vertical buttons (one non-exclusive and the other exclusive), a text field, an integer field, and “OK” and “Done” buttons. If either the “OK” or “Done” buttons are pressed, the form exits.

Begin by defining a string array describing the form:

```
desc = [ $
    '0, LABEL, Centered Label, CENTER', $
    '1, BASE,, ROW, FRAME', $
    '0, BUTTON, B1|B2|B3, LABEL_TOP=Nonexclusive:', $
    + 'COLUMN, TAG=bg1', $
    '2, BUTTON, E1|E2|E2, EXCLUSIVE,LABEL_TOP=Exclusive:', $
    + 'COLUMN,TAG=bg2', $
    '0, TEXT, , LABEL_LEFT=Enter File name:, WIDTH=12,' $
    + 'TAG=fname', $
    '0, INTEGER, 0, LABEL_LEFT=File size:, WIDTH=6, TAG=fsize', $
    '1, BASE,, ROW', $
    '0, BUTTON, OK, QUIT,' $
    + 'TAG=OK', $
    '2, BUTTON, Cancel, QUIT']
```

To use the form as a modal widget:

```
a = CW_FORM(desc, /COLUMN)
```

When the form is exited, (when the user presses the OK or Cancel buttons), a structure is returned as the function’s value. We can examine the structure by entering:

```
HELP, /STRUCTURE, a
```

IDL Output			Meaning
BG1	INT	Array [3]	Set buttons = 1, unset = 0.
BG2	INT	1	Second button of exclusive button group was set.
FNAME	STRING	'test.dat'	Value of the text field
FSIZE	LONG	120	Value of the integer field
OK	LONG	1	This button was pressed
TAG8	LONG	0	This button wasn't pressed

*Table 3-24: Output from HELP, /STRUCTURE*

### Note

If the “Cancel” button is pressed, the “OK” field is set to 0.

To use CW\_FORM inside another widget:

```
a = WIDGET_BASE(TITLE='Testing')
b = CW_FORM(a, desc, /COLUMN)
WIDGET_CONTROL, a, /REALIZE
XMANAGER, 'Test', a
```

The event handling procedure (in this example, called TEST\_EVENT), may use the TAG field of the event structure to determine which field changed and perform any data validation or special actions required. It can also get and set the value of the widget by calling WIDGET\_CONTROL.

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

# CW\_FSLIDER

The CW\_FSLIDER function creates a slider that selects floating-point values.

This routine is written in the IDL language. Its source code can be found in the file `cw_fslider.pro` in the `lib` subdirectory of the IDL distribution.

## Using CW\_FSLIDER

To get or set the value of a CW\_FSLIDER widget, use the GET\_VALUE and SET\_VALUE keywords to WIDGET\_CONTROL.

### Note

The CW\_FSLIDER widget is based on the WIDGET\_SLIDER routine, which accepts only integer values. Because conversion between integers and floating-point numbers necessarily involves round-off errors, the slider value returned by CW\_FSLIDER may not exactly match the input value, even when a floating-point number is entered in the slider's text field as an ASCII value. For more information on floating-point issues, see [“Accuracy and Floating Point Operations”](#) in Chapter 13 of the *Building IDL Applications* manual.

## Syntax

```
Result = CW_FSLIDER( Parent [, /DOUBLE] [, /DRAG] [, /EDIT]
  [, /FORMAT=string] [, /FRAME] [, /MAXIMUM=value] [, /MINIMUM=value]
  [, /SCROLL=units] [, /SUPPRESS_VALUE] [, /TAB_MODE=value]
  [, /TITLE=string] [, /UNAME=string] [, /UVALUE=value]
  [, /VALUE=initial_value] [, /XSIZE=length | {, /VERTICAL [, /YSIZE=height}}] )
```

## Return Value

This function returns the widget ID of the newly-created slider widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### DOUBLE

Set this keyword to return double-precision values in the VALUE field of widget events generated by CW\_FSLIDER. Explicitly set DOUBLE=0 to ensure that values returned in the VALUE field are single-precision. By default, CW\_FSLIDER will return double-precision values if any of the values specified by the MINIMUM, MAXIMUM, or VALUE keywords is double-precision, or single-precision otherwise.

---

**Note**

The value returned by the GET\_VALUE keyword to WIDGET\_CONTROL is the value contained in the VALUE field of the widget event structure.

---

### DRAG

Set this keyword to cause events to be generated continuously when the slider is adjusted. The default is DRAG=0, in which case events are generated only when the mouse is released. Note that on slow systems, /DRAG performance can be inadequate.

### EDIT

Set this keyword to make the slider label editable. The default is EDIT=0. If EDIT is set, the GET\_VALUE keyword to WIDGET\_CONTROL will return the value of the slider label if it has been changed.

---

**Note**

If the user edits the slider label but does not press Enter, the slider position will not be updated to the new value. In this case, the widget programmer is responsible for using GET\_VALUE to retrieve the new value of the slider label, followed by SET\_VALUE to set the new value and update the slider position.

---

### FORMAT

Provides the format in which the slider value is displayed. This should be a format as accepted by the STRING procedure. The default FORMAT is ' (G13.6) '

### FRAME

Set this keyword to have a frame drawn around the widget. The default is FRAME=0.

## MAXIMUM

The maximum value of the slider. The default is `MAXIMUM=100`.

## MINIMUM

The minimum value of the slider. The default is `MINIMUM=0`.

## SCROLL

Set the `SCROLL` keyword to a floating-point value specifying the number of floating-point units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The default on both platforms is  $0.01 \times (\text{MAXIMUM} - \text{MINIMUM})$ , which is 1% of the slider range.

## SUPPRESS\_VALUE

If this keyword is set, the current slider value is not displayed.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.

Table 3-25: `TAB_MODE` Keyword Options

Value	Description
3	Navigate only off of the widget.

Table 3-25: *TAB\_MODE* Keyword Options (Continued)

---

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

## TITLE

Set this keyword to a string defining the title of the slider.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The “user value” to be assigned to the widget.

## VALUE

The initial floating-point numeric value of the slider.

## VERTICAL

If set, the slider will be oriented vertically. The default is horizontal.

## XSIZE

The length of horizontal sliders.

## YSIZE

The height of vertical sliders.

## Keywords to WIDGET\_CONTROL and WIDGET\_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET\_CONTROL and WIDGET\_INFO routines that affect or return information on base widgets can be used with compound widgets.

You can use the [GET\\_VALUE](#) and [SET\\_VALUE](#) keywords to WIDGET\_CONTROL to obtain or set the value of the slider. In addition, you can use the SET\_VALUE keyword to change the minimum and maximum values of the slider by setting the keyword equal to a three-element vector [*value*, *min*, *max*].

### Note

---

The SET\_SLIDER\_MAX and SET\_SLIDER\_MIN keywords to WIDGET\_CONTROL and the SLIDER\_MIN\_MAX keyword to WIDGET\_INFO *do not* work with floating point sliders created with CW\_FSLIDER.

---

See “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET\_CONTROL and WIDGET\_INFO.

## Widget Events Returned by the CW\_FSLIDER Widget

CW\_FSLIDER generates an event that specifies the current value of the slider and a flag specifying whether events are generated as the slider is dragged. This widget generates event structures with the following definition:

```
Event = { ID:0L, TOP:0L, HANDLER:0L, VALUE:0.0, DRAG:0 }
```

The VALUE field is the floating-point value selected by the slider. The DRAG field reports on whether events are generated continuously (when the DRAG keyword is set) or only when the mouse button is released (the default).

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

## See Also

[WIDGET\\_SLIDER](#)

# CW\_LIGHT\_EDITOR

The CW\_LIGHT\_EDITOR function creates a compound widget to edit properties of existing IDLgrLight objects in a view. Lights cannot be added or removed from a view using this widget. However, lights can be “turned off or on” by hiding or showing them (i.e., HIDE property).

---

## Note

Two routines associated with the CW\_LIGHT\_EDITOR compound widget — CW\_LIGHT\_EDITOR\_GET and CW\_LIGHT\_EDITOR\_SET — do not create compound widgets themselves, but act on an existing CW\_LIGHT\_EDITOR widget.

---

## Syntax

```
Result = CW_LIGHT_EDITOR (Parent [, /DIRECTION_DISABLED]
    [, /DRAG_EVENTS] [, FRAME=width] [, /HIDE_DISABLED]
    [, LIGHT=objref(s)] [, /LOCATION_DISABLED] [, TAB_MODE=value]
    [, /TYPE_DISABLED] [, /UNAME=string] [, UVALUE=value]
    [, XSIZE=pixels] [, YSIZE=pixels] [, XRANGE=vector] [, YRANGE=vector]
    [, ZRANGE=vector] )
```

## Return Value

This function returns the widget ID of a newly-created light editor.

## Arguments

### Parent

The widget ID of the parent widget for the new light editor.

## Keywords

### DIRECTION\_DISABLED

Set this keyword to make the direction widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

## DRAG\_EVENTS

Set this keyword to cause events to be generated continuously while a slider in the compound widget is being dragged or when the mouse cursor is being dragged across the draw widget portion of the compound widget. By default, events are only generated when the mouse comes to rest at its final position and the mouse button is released.

When this keyword is set, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

### Note

---

Under Microsoft Windows, sliders do not generate these events, but behave just like regular sliders.

---

## FRAME

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a 'hint' to the toolkit, and may be ignored in some instances. The default is no frame.

## HIDE\_DISABLED

Set this keyword to make the hide widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

## LIGHT

Set this keyword to one or more object references to `IDLgrLight` to edit. This will replace the current set of lights being edited with the list of lights from this keyword.

## LOCATION\_DISABLED

Set this keyword to make the location widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is

inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

---

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-26: TAB\_MODE Keyword Options*

---

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

## TYPE\_DISABLED

Set this keyword to make the light type widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

## UNAME

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## **UVALUE**

The 'user value' to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created. If `UVALUE` is not present, the widget's initial user value is undefined.

## **XRANGE**

A two-element vector defining the data range in the x direction. This keyword is used to determine the valid range for the light's location and direction properties

## **XSIZE**

The width of the drawable area in pixels. The default width is 180.

## **YRANGE**

A two-element vector defining the data range in the y direction. This keyword is used to determine the valid range for the light's location and direction properties.

## **YSIZE**

The height of the drawable area in pixels. The default height is 180.

## **ZRANGE**

A two-element vector defining the data range in the z direction. This keyword is used to determine the valid range for the light's location and direction properties

## **WIDGET\_CONTROL Keywords**

The widget ID returned by this compound widget is actually the ID of the compound widget's base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with this compound widget (e.g., `UNAME`, `UVALUE`).

## GET\_VALUE

Set this keyword to a named variable to contain the current value of the widget. An IDLgrLight object reference of the currently selected light is returned. The value of a widget can be set with the SET\_VALUE keyword to this routine.

## SET\_VALUE

Sets the value of the specified light editor compound widget. This widget accepts an IDLgrLight object reference of the light in the list of lights to make as the current selection. The property values are retrieved from the light object and the light editor controls are updated to reflect those properties.

## Widget Events Returned by the CW\_LIGHT\_EDITOR Widget

There are variations of the light editor event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER). The different light editor event structures are described below.

### Light Selected

This is the type of structure returned when the light selected in the light list box is modified by a user.

```
{ CW_LIGHT_EDITOR_LS, ID:0L, TOP:0L, HANDLER:0L, LIGHT:OBJ_NEW() }
```

LIGHT specifies the object ID of the new light selection.

### Light Modified

This is the type of structure returned when the user has modified a light property. This event maybe generated continuously if the DRAG\_EVENTS keyword was set. See DRAG\_EVENTS above.

```
{ CW_LIGHT_EDITOR_LM, ID:0L, TOP:0L, HANDLER:0L }
```

The value of the light editor will need to be retrieved (i.e., CW\_LIGHT\_EDITOR\_GET) in order to determine the extent of the actual user modification.

## Version History

# CW\_LIGHT\_EDITOR\_GET

The CW\_LIGHT\_EDITOR\_GET procedure gets the CW\_LIGHT\_EDITOR properties.

## Syntax

```
CW_LIGHT_EDITOR_GET, WidgetID [, DIRECTION_DISABLED=variable]  
[, DRAG_EVENTS=variable] [, HIDE_DISABLED=variable]  
[, LIGHT=variable] [, LOCATION_DISABLED=variable]  
[, TYPE_DISABLED=variable] [, XSIZE=variable] [, YSIZE=variable]  
[, XRANGE=variable] [, YRANGE=variable] [, ZRANGE=variable]
```

## Arguments

### WidgetID

The widget ID of the CW\_LIGHT\_EDITOR compound widget.

## Keywords

### DIRECTION\_DISABLED

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the direction widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

### DRAG\_EVENTS

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to cause events to be generated continuously while a slider in the compound widget is being dragged or when the mouse cursor is being dragged across the draw widget portion of the compound widget.

When this keyword is set, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

**Note**

Under Microsoft Windows, sliders do not generate these events, but behave just like regular sliders.

**HIDE\_DISABLED**

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the hide widget portion of the compound widget unchangeable by the user.

**LIGHT**

Set this keyword to a named variable that will contain one or more object references to IDLgrLight.

**LOCATION\_DISABLED**

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the location widget portion of the compound widget unchangeable by the user.

**TYPE\_DISABLED**

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the light type widget portion of the compound widget unchangeable by the user.

**XRANGE**

Set this keyword to a named variable that will contain a two-element vector defining the data range in the x direction.

**XSIZE**

Set this keyword to a named variable that will contain the width of the drawable area in pixels.

**YRANGE**

Set this keyword to a named variable that will contain a two-element vector defining the data range in the y direction.

## YSIZE

Set this keyword to a named variable that will contain the height of the drawable area in pixels.

## ZRANGE

Set this keyword to a named variable that will contain a two-element vector defining the data range in the z direction.

  [, /LOCATION_DISABLED] [, /TYPE_DISABLED] [, XSIZE=pixels]
  [, YSIZE=pixels] [, XRANGE=vector] [, YRANGE=vector] [, ZRANGE=vector]
```

## Arguments

### WidgetID

The widget ID of the CW\_LIGHT\_EDITOR compound widget.

## Keywords

### DIRECTION\_DISABLED

Set this keyword to make the direction widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

### DRAG\_EVENTS

Set this keyword to cause events to be generated continuously while a slider in the compound widget is being dragged or when the mouse cursor is being dragged across the draw widget portion of the compound widget.

When this keyword is set, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

#### Note

---

Under Microsoft Windows, sliders do not generate these events, but behave just like regular sliders.

---

### HIDE\_DISABLED

Set this keyword to make the hide widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

## LIGHT

Set this keyword to one or more object references to IDLgrLight to edit. This will replace the current set of lights being edited with the list of lights from this keyword.

## LOCATION\_DISABLED

Set this keyword to make the location widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

## TYPE\_DISABLED

Set this keyword to make the light type widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

## XRANGE

A two-element vector defining the data range in the x direction. This keyword is used to determine the valid range for the light's location and direction properties.

## XSIZE

The width of the drawable area in pixels.

## YRANGE

A two-element vector defining the data range in the y direction. This keyword is used to determine the valid range for the light's location and direction properties.

## YSIZE

The height of the drawable area in pixels.

## ZRANGE

# CW\_ORIENT

The CW\_ORIENT function creates a compound widget lets you interactively adjust the three-dimensional drawing transformation and resets the !P.T system variable field to reflect the changed orientation.

This routine is written in the IDL language. Its source code can be found in the file `cw_orient.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_ORIENT( Parent [, AX=degrees] [, AZ=degrees] [, /FRAME]
  [, TAB_MODE=value] [, TITLE=string] [, UNAME=string] [, UVALUE=value]
  [, XSIZE=width] [, YSIZE=height] )
```

## Return Value

This function returns the widget ID of the newly-created orientation-adjustment widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### AX

The initial rotation in the X direction. The default is 30 degrees.

### AZ

The initial rotation in the Z direction. The default is 30 degrees.

### FRAME

Set this keyword to draw a frame around the widget.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-27: TAB\_MODE Keyword Options*

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## TITLE

The title of the widget.

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the [FIND\\_BY\\_UNAME](#) keyword. The UNAME should be unique to the widget hierarchy because the [FIND\\_BY\\_UNAME](#) keyword returns the ID of the first widget with the specified name.

**UVALUE**

The “user value” to be assigned to the widget.

**XSIZE**

Determines the width of the widget. The default is 100.

**YSIZE**

Determines the height of the widget. The default is 100.

**Keywords to WIDGET\_CONTROL and WIDGET\_INFO**

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the [WIDGET\\_CONTROL](#) and [WIDGET\\_INFO](#) routines that affect or return information on base widgets can be used with compound widgets.

See [“Creating a Compound Widget”](#) in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using [WIDGET\\_CONTROL](#) and [WIDGET\\_INFO](#).

**Widget Events Returned by the CW\_ORIENT Widget**

[CW\\_ORIENT](#) only returns events when the three dimensional drawing transformation has been altered. The `!P.T` system variable field is automatically updated to reflect the new orientation.

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

[CW\\_ARCBALL](#), [T3D](#)

# CW\_PALETTE\_EDITOR

The CW\_PALETTE\_EDITOR function creates a compound widget to display and edit color palettes. The palette editor is a base that contains a drawable area to display the color palette, a set of vectors that represent the palette and an optional histogram.

## Note

---

Two routines associated with the CW\_PALETTE\_EDITOR compound widget — CW\_PALETTE\_EDITOR\_GET and CW\_PALETTE\_EDITOR\_SET — do not create compound widgets themselves, but act on an existing CW\_PALETTE\_EDITOR widget.

---

See “Using the CW\_PALETTE\_EDITOR” on page 505 for information on the palette editor’s interface components and interactive capabilities.

## Syntax

```
Result = CW_PALETTE_EDITOR (Parent [, DATA=array] [, FRAME=width]
    [, HISTOGRAM=vector] [, /HORIZONTAL] [, SELECTION=[start, end]]
    [, TAB_MODE=value] [, UNAME=string] [, UVALUE=value] [, XSIZE=width]
    [, YSIZE=height])
```

## Return Value

This function returns the widget ID of the newly created palette editor.

## Arguments

### Parent

The widget ID of the parent widget for the new palette editor.

## Keywords

### DATA

A 3x256 byte array containing the initial color values for Red, Green and Blue channels. The value supplied can also be a 4x256 byte array containing the initial color values and the optional Alpha channel. The value supplied can also be an IDLgrPalette object reference. If an IDLgrPalette object reference is supplied it is used internally and is not destroyed on exit. If an object reference is supplied the

ALPHA keyword to the CW\_PALETTE\_EDITOR\_SET routine can be used to supply the data for the optional Alpha channel.

## FRAME

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances. The default is no frame.

## HISTOGRAM

A 256 element byte vector containing the values for the optional histogram curve.

## HORIZONTAL

Set this keyword for a horizontal layout for the compound widget. This consists of the controls to the right of the display area. The default is a vertical layout with the controls below the display area.

## SELECTION

The selection is a two element vector defining the starting and ending point of the selection region of color indexes. The default is [0,255].

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

---

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.

Table 3-28: TAB\_MODE Keyword Options

Value	Description
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-28: TAB\_MODE Keyword Options (Continued)*

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## UNAME

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The ‘user value’ to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created. If `UVALUE` is not present, the widget's initial user value is undefined.

## XSIZE

The width of the drawable area in pixels. The default width is 256.

## YSIZE

The height of the drawable area in pixels. The default height is 256.

## WIDGET\_CONTROL Keywords for Palette Editor

The widget ID returned by this compound widget is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET\_CONTROL and WIDGET\_INFO routines that affect or return information on base widgets can be used with this compound widget (e.g., UNAME, UVALUE).

### GET\_VALUE

Set this keyword to a named variable to contain the current value of the widget. A 3xn (RGB) or 4xn (i.e., RGB and ALPHA) array containing the palette is returned.

The value of a widget can be set with the SET\_VALUE keyword to this routine.

### SET\_VALUE

Sets the value of the specified palette editor compound widget. This widget accepts a 3xn (RGB) or 4xn (i.e., RGB and ALPHA) array representing the value of the palette to be set. Another type of argument accepted is an IDLgrPalette object reference. If an IDLgrPalette object reference is supplied it is used internally and is not destroyed on exit.

## Widget Events Returned by the CW\_PALETTE\_EDITOR Widget

CW\_PALETTE\_EDITOR generates events when the selection region is changed and when the color palette has been modified. There are variations of the palette editor event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER). The different palette editor event structures are described below.

### Selection Moved

This is the type of structure returned when one of the vertical bars that define the selection region is moved by a user.

```
{ CW_PALETTE_EDITOR_SM, ID:0L, TOP:0L, HANDLER:0L,
  SELECTION: [0, 255] }
```

SELECTION indicates a two element vector defining the starting and ending point of the selection region of color indexes.

### Palette Edited

This is the type of structure returned when the user has modified the color palette.

```
{ CW_PALETTE_EDITOR_PM, ID:0L, TOP:0L, HANDLER:0L }
```

The value of the palette editor will need to be retrieved (i.e., `WIDGET_CONTROL`, `GET_VALUE`) in order to determine the extent of the actual user modification.

## Using the CW\_PALETTE\_EDITOR

### Graphics Area Components

#### Reference Color bar

A gray scale color bar is displayed at the top of the graphics area for reference purposes.

#### Palette Colorbar

A color bar containing a display of the current palette is displayed below the reference color bar.

#### Channel and Histogram Display

The palette channel vectors are displayed below the palette colorbar. The Red channel is displayed in red, the Green channel in green, the Blue channel in blue, and the optional Alpha channel in purple. The optional Histogram vector is displayed in Cyan.

An area with a white background represents the current selection, with gray background representing the area outside of the current selection. Yellow drag handles are an additional indicator of the selection endpoints. These selection endpoints represent the range for some editing operations. In addition, cursor X,Y values and channel pixel values at the cursor location are displayed in a status area below the graphics area.

### Interactive Capabilities

#### Color Space

A droplist allows selection of RGB, HSV or HLS color spaces. RGB is the default color space.

**Note**

Regardless of the color space in use, the color vectors retrieved with the GET\_VALUE keyword to widget control are always in the RGB color space.

**Editing Mode**

A droplist allows selection of the editing mode. Freehand is the default editing mode.

**Note**

Unless noted below, editing operations apply only to the channel vectors currently selected for editing and apply only to the portion of the vectors within the selection indicators.

Editing Mode	Description
Freehand	The user can click and drag in the graphics area to draw a new curve. Editable channel vectors will be modified to use the new curve for that part of the X range within the selection that was drawn in Freehand mode.
Line Segment	A click, drag and release operation defines the start point and end point of a line segment. Editable channel vectors will be modified to use the new curve for that part of the X range within the selection that was drawn in Line Segment mode.
Barrel Shift	Click and drag operations in the horizontal direction cause the editable curves to be shifted right or left, with the portion which is shifted off the end of selection area wrapping around to appear on the other side of the selection area. Only the horizontal component of drag movement is used.
Slide	Click and drag operations in the horizontal direction cause the editable curves to be shifted right or left. Unlike the Barrel Shift mode, the portion of the curves shifted off the end of the selection area does not wrap around. Only the horizontal component of drag movement is used.
Stretch	Click and drag operations in the horizontal direction cause the editable curves to be compressed or expanded. Only the horizontal component of drag movement is used.

Table 3-29: CW\_PALETTE\_EDITOR Editing Mode Options

The following table describes the buttons that provide editing operations but do not require cursor input:

Button	Operation
Ramp	Causes the selected part of the editable curves to be replaced with a linear ramp from 0 to 255.
Smooth	Causes the selected part of the editable curves to be smoothed.
Posterize	Causes the selected part of the editable curves to be replaced with a series of steps.
Reverse	Causes the selected part of the editable curves to be reversed in the horizontal direction.
Invert	Causes the selected part of the editable curves to be flipped in the vertical direction.
Duplicate	Causes the selected part of the editable curves to be compressed by 50% and duplicated to produce two contiguous copies of the channel vectors within the initial selection.
Load PreDefined	Leads to additional choices of pre-defined palettes. Loading a pre-defined palette replaces only the selected portion of the editable color channels, respecting of the settings of the selection endpoints and editable checkboxes. This allows loading only a single channel or only a portion of a pre-defined palette.

*Table 3-30: CW\_PALETTE\_EDITOR Button Operations*

### Channel Display and Edit

A row of checkboxes allows the user to indicate which channels of Red, Green, Blue and the optional Alpha channel should be displayed. A second row of checkboxes allows the user to indicate which channels should be edited by the current editing operation. The checkboxes for the Alpha channel will be sensitive only if an Alpha channel is loaded.

## Zoom

Four buttons allow the user to zoom the display of the palette:

Button	Description
	Zooms to show the current selection.
+	Zooms in 50%
-	Zooms out 100%
1:1	Returns the display to the full palette

*Table 3-31: Palette Zoom Options*

## Scrolling of the Palette Window

When the palette is zoomed to a scale greater than 1:1 the scroll bar at the bottom of the graphics area can be used to view a different part of the palette.

## Version History

# CW\_PALETTE\_EDITOR\_SET

The CW\_PALETTE\_EDITOR\_SET procedure sets the CW\_PALETTE\_EDITOR properties.

## Syntax

```
CW_PALETTE_EDITOR_SET, WidgetID [, ALPHA=byte_vector]
    [, HISTOGRAM=byte_vector]
```

## Arguments

### WidgetID

The widget ID of the CW\_PALETTE\_EDITOR compound widget.

## Keywords

### ALPHA

A 256 element byte vector that describes the alpha component of the color palette. The alpha value may also be set to the scalar value zero to remove the alpha curve from the display.

### HISTOGRAM

The histogram is an vector to be plotted below the color palette. This keyword can be used to display a distribution of color index values to facilitate editing the color palette. The histogram value may also be set to the scalar value zero to remove the histogram curve from the display.

# CW\_PDMENU

The CW\_PDMENU function creates widget pulldown menus, which can include sub-menus, from a set of buttons. It has a simpler interface than the XPDMENU procedure, which it replaces. Events for the individual buttons are handled transparently, and a CW\_PDMENU event returned. This event can return any one of the following:

- the Index of the button within the base
- the widget ID of the button
- the name of the button.
- the fully qualified name of the button. This allows different sub-menus to contain buttons with the same name in an unambiguous way.

Only buttons with textual names are handled by this widget. Bitmaps are not understood.

This routine is written in the IDL language. Its source code can be found in the file `cw_pdmenu.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_PDMENU( Parent, Desc [, /COLUMN] [, /CONTEXT_MENU]
  [, /DELIMITER=string] [, /FONT=value] [, /MBAR [, /HELP]] [, /IDS=variable]
  [, /RETURN_ID | , /RETURN_INDEX | , /RETURN_NAME | ,
  /RETURN_FULL_NAME] [, /TAB_MODE=value] [, /UNAME=string]
  [, /UVALUE=value] [, /XOFFSET=value] [, /YOFFSET=value] )
```

## Return Value

This function returns the widget ID of the newly-created pulldown menu widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Desc

An array of strings or structures. If *Desc* is an array of strings, each element contains the flag field, followed by a backslash character, followed by the name of the menu item, optionally followed by another backslash character and the name of an event-processing procedure for that element. A string element of the *Desc* array would look like:

```
'n\item_name'
```

or

```
'n\item_name\event_proc'
```

where *n* is the flag field and *item\_name* is the name of the menu item. The flag field is a bitmask that controls how the button is interpreted; appropriate values for the flag field are shown in the following table. If the *event\_proc* field is present, it is the name of an event-handling procedure for the menu element and all of its children.

If *Desc* is an array of structures, each structure must have the following definition:

```
{CW_PDMENU_S, flags:0, name:''}
```

The name tag is a string field with the following components:

```
'item_name'
```

or

```
'item_name\event_proc'
```

where *item\_name* is the name of the menu item. If the *event\_proc* field is present, it is the name of an event-handling procedure for the menu element and all of its children

The flags field is a bitmask that controls how the button is interpreted; appropriate values for the flag field are shown in the following table. Note that if *Desc* is an array of structures, you cannot specify individual event-handling procedures for each element.

Value	Meaning
0	This button is neither the beginning nor the end of a pulldown level.
1	This button is the root of a sub-pulldown menu. The sub-buttons start with the next button.

Table 3-32: Button Flag Bit Meanings

Value	Meaning
2	This button is the last button at the current pulldown level. The next button belongs to the same level as the current parent button. If the name field is not specified (or is an empty string), no button is created, and the next button is created one level up in the hierarchy.
3	This button is the root of a sub-pulldown menu, but it is also the last entry of the current level.

Table 3-32: Button Flag Bit Meanings (Continued)

## Keywords

### COLUMN

Set this keyword to create a vertical column of menu buttons. The default is to create a horizontal row of buttons.

### CONTEXT\_MENU

Set this keyword to create the pulldown menu within a context-sensitive menu. If `CONTEXT_MENU` is set, *Parent* must be the widget ID of a base widget, which also has the `CONTEXT_MENU` keyword set. The return value of `CW_PDMENU` is the *Parent's* widget ID. If `CONTEXT_MENU` is set, setting the `UNAME` or `UVALUE` on the same call to `CW_PDMENU` will override the `UNAME` or `UVALUE` values of the parent base.

For more on creating context menus, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual and the `CONTEXT_MENU` keyword to [WIDGET\\_BASE](#).

### DELIMITER

The character used to separate the parts of a fully qualified name in returned events. The default is to use the “.” character.

### FONT

The name of the font to be used for the button titles. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

## HELP

If the MBAR keyword is set, and one of the buttons on the menubar has the label “help” (case insensitive) then that button is created with the /HELP keyword to give it any special appearance it is supposed to have on a menubar. For example, Motif expects help buttons to be on the right.

## IDS

A named variable in which the button IDs will be stored as a longword vector.

## MBAR

Set this keyword to create a menubar pulldown. If MBAR is set, *Parent* must be the widget ID of a menubar belonging to a top-level base, and the return value of CW\_PDMENU is the *Parent* widget ID. For an example demonstrating the use of the MBAR keyword, see [Example 2](#) below. Also see the MBAR keyword to WIDGET\_BASE. If MBAR is set, setting the UNAME or UVALUE on the same call to CW\_PDMENU will override the UNAME or UVALUE values of the parent base.

## RETURN\_ID

If this keyword is set, the VALUE field of returned events will contain the widget ID of the button.

## RETURN\_INDEX

If this keyword is set, the VALUE field of returned events will contain the zero-based index of the button within the base. THIS IS THE DEFAULT.

## RETURN\_NAME

If this keyword is set, the VALUE field of returned events will be the name of the selected button.

## RETURN\_FULL\_NAME

Set this keyword and the VALUE field of returned events will be the fully qualified name of the selected button. This means that the names of all the buttons from the topmost button of the pulldown menu to the selected one are concatenated with the delimiter specified by the DELIMITER keyword. For example, if the top button was named COLORS, the second level button was named BLUE, and the selected button was named LIGHT, the returned value would be

```
COLORS . BLUE . LIGHT
```

This allows different submenus to have buttons with the same name (e.g., `COLORS.RED.LIGHT`).

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-33: `TAB_MODE` Keyword Options

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The “user value” to be assigned to the widget. If the `MBAR` keyword is set, the value specified for `UVALUE` is also assigned as the `UVALUE` of the parent menu (i.e., the widget specified by the *Parent* argument in the call to `CW_PDMENU`).

## XOFFSET

The X offset of the widget relative to its parent.

## YOFFSET

The Y offset of the widget relative to its parent.

## Keywords to `WIDGET_CONTROL` and `WIDGET_INFO`

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

See “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

## Widget Events Returned by the `CW_PDMENU` Widget

`CW_PDMENU` generates an event structure that specifies the index, widget ID, or name of the menu item selected with the following definition:

```
event = { ID:0L, TOP:0L, HANDLER:0L, VALUE:0 }
```

`VALUE` is either the `INDEX`, `ID`, `NAME`, or `FULL_NAME` of the button, depending on how the widget was created.

## Examples

### Example 1

The following is the description of a menu bar with two buttons: “Colors” and “Quit”. Colors is a pulldown containing the colors “Red”, “Green”, “Blue”, “Cyan”, and “Magenta”. Blue is a sub-pulldown containing “Light”, “Medium”, “Dark”, “Navy”, and “Royal.”

The following small program can be used with the above description to create the specified menu:

```

PRO PD_EXAMPLE
  desc = [ '1\Colors' , $
          '0\Red' , $
          '0\Green' , $
          '1\Blue' , $
          '0\Light' , $
          '0\Medium' , $
          '0\Dark' , $
          '0\Navy' , $
          '2\Royal' , $
          '0\Cyan' , $
          '2\Magenta' , $
          '2\Quit' ]

  ; Create the widget:
  base = WIDGET_BASE()
  menu = CW_PDMENU(base, desc, /RETURN_FULL_NAME)
  WIDGET_CONTROL, /REALIZE, base

  ;Provide a simple event handler:
  REPEAT BEGIN
    ev = WIDGET_EVENT(base)
    PRINT, ev.value
  END UNTIL ev.value EQ 'Quit'
  WIDGET_CONTROL, /DESTROY, base

END

```

The *Desc* array could also have been defined using a structure for each element. The following array of structures creates the same menu as the array of strings shown above. Note, however, that if the *Desc* array is composed of structures, you cannot specify individual event-handling routines.

First, make sure *CW\_PDMENU\_S* structure is defined:

```
junk = {CW_PDMENU_S, flags:0, name:'' }
```

Define the menu:

```
desc = [ { CW_PDMENU_S, 1, 'Colors' }, $
         { CW_PDMENU_S, 0, 'Red' }, $
         { CW_PDMENU_S, 0, 'Green' }, $
         { CW_PDMENU_S, 1, 'Blue' }, $
         { CW_PDMENU_S, 0, 'Light' }, $
         { CW_PDMENU_S, 0, 'Medium' }, $
         { CW_PDMENU_S, 0, 'Dark' }, $
         { CW_PDMENU_S, 0, 'Navy' }, $
         { CW_PDMENU_S, 2, 'Royal' }, $
         { CW_PDMENU_S, 0, 'Cyan' }, $
         { CW_PDMENU_S, 2, 'Magenta' }, $
         { CW_PDMENU_S, 2, 'Quit' } ]
```

## Example 2

This example demonstrates the use of the MBAR keyword to CW\_PDMENU to populate the “Colors” menu item on a menu bar created using WIDGET\_BASE.

```
PRO mbar_event, event

    WIDGET_CONTROL, event.id, GET_UVALUE=uval

    CASE uval OF
        'Quit': WIDGET_CONTROL, /DESTROY, event.top
    ELSE: PRINT, event.value
    ENDCASE

END

PRO mbar

; Create the base widget:
base = WIDGET_BASE(TITLE = 'Example', MBAR=bar, XSIZE=200, $
                  UVALUE='base')

file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
file_bbtn1=WIDGET_BUTTON(file_menu, VALUE='Quit', $
                          UVALUE='Quit')

colors_menu = WIDGET_BUTTON(bar, VALUE='Colors', /MENU)

; Define array for colors menu items:
desc = [ '0\Red' , $
         '0\Green' , $
         '1\Blue' , $
         '0\Light' , $
         '0\Medium' , $
```

```

        '0\Dark' , $
        '0\Navy' , $
        '2\Royal' , $
        '0\Cyan' , $
        '2\Magenta' ]

; Create colors menu items. Note that the Parent argument is
; set to the widget ID of the parent menu:
colors = CW_PDMENU(colors_menu, desc, /MBAR, $
    /RETURN_FULL_NAME, UVALUE='menu')

WIDGET_CONTROL, /REALIZE, base

XMANAGER, 'mbar', base, /NO_BLOCK

END

```

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

# CW\_RGBSLIDER

The CW\_RGBSLIDER function creates a compound widget that provides three sliders for adjusting color values. The RGB, CMY, HSV, and HLS color systems can all be used. No matter which color system is in use, the resulting color is always supplied in RGB, which is the base system for IDL.

This routine is written in the IDL language. Its source code can be found in the file `cw_rgbslider.pro` in the `lib` subdirectory of the IDL distribution.

## Using CW\_RGBSLIDER

The CW\_RGBSLIDER widget consists of a pulldown menu which allows the user to change between the supported color systems, and three color adjustment sliders, allowing the user to select a new color value.

## Syntax

```
Result = CW_RGBSLIDER( Parent [, /CMY | , /HSV | , /HLS | , /RGB]
    [, /COLOR_INDEX | , GRAPHICS_LEVEL={1 | 2}] [, /DRAG] [, /FRAME]
    [, LENGTH=value] [, /RGB] [, TAB_MODE=value] [, UNAME=string]
    [, UVALUE=value] [, VALUE=[r, g, b]] [, /VERTICAL] )
```

## Return Value

This function returns the widget ID of the newly-created color adjustment widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### CMY

If set, the initial color system used is CMY.

## **COLOR\_INDEX**

Set this keyword to display a small rectangle with the selected color. The color is updated as the values are changed. The color initially displayed in this rectangle corresponds to the value specified with the VALUE keyword. If using Object Graphics, it is recommended that you set the GRAPHICS\_LEVEL keyword to 2, in which case the COLOR\_INDEX keyword is ignored.

## **DRAG**

Set this keyword and events will be generated continuously when the sliders are adjusted. If not set, events will only be generated when the mouse button is released. Note: On slow systems, /DRAG performance can be inadequate. The default is DRAG = 0.

## **FRAME**

If set, a frame will be drawn around the widget. The default is FRAME = 0.

## **GRAPHICS\_LEVEL**

Set this keyword to 2 to use Object Graphics. Set to 1 for Direct Graphics (the default). If set to 2, a small rectangle is displayed with the selected color. The color is updated as the values are changed. The color initially displayed in this rectangle corresponds to the value specified with the VALUE keyword. If this keyword is set, the COLOR\_INDEX keyword is ignored.

## **HSV**

If set, the initial color system used is HSV.

## **HLS**

If set, the initial color system used is HLS.

## **LENGTH**

The length of the sliders. The default = 256.

## **RGB**

If set, the initial color system used is RGB. This is the default.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-34: TAB\_MODE Keyword Options*

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the FIND\_BY\_UNAME keyword. The UNAME should be unique to the widget

hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

The “user value” to be assigned to the widget.

## VALUE

Set this keyword to a 3-element  $[r, g, b]$  vector representing the initial RGB value for the `CW_RGBSLIDER` widget. If the `GRAPHICS_LEVEL` keyword is set to 2, the color swatch will also initially display this RGB value.

## VERTICAL

If set, the sliders will be oriented vertically. The default is `VERTICAL = 0`.

## Keywords to `WIDGET_CONTROL` and `WIDGET_INFO`

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

See “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

## Widget Events Returned by the `CW_RGBSLIDER` Widget

This widget generates event structures with the following definition:

```
event = { ID:0L, TOP:0L, HANDLER:0L, R:0B, G:0B, B:0B }
```

The ‘R’, ‘G’, and ‘B’ fields contain the Red, Green and Blue components of the selected color. Note that `CW_RGBSLIDER` reports back the Red, Green, and Blue values no matter which color system is selected.

## Version History

Pre 4.0	Introduced
6.1	Added TAB_MODE keyword

# CW\_TMPL

The CW\_TMPL procedure is a template for compound widgets that use the XMANAGER. Use this template instead of writing your compound widgets from “scratch”. This template can be found in the file `cw_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = CW_TMPL( Parent [, TAB_MODE=value] [, UNAME=string]
                [, UVALUE=value] )
```

## Arguments

### Parent

The widget ID of the parent widget of the new compound widget.

## Keywords

### TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

#### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.

Table 3-35: TAB\_MODE Keyword Options

Value	Description
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-35: TAB\_MODE Keyword Options (Continued)*

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UVALUE

A user-specified value for the compound widget.

## Version History

Pre 4.0	Introduced
6.1	Added <code>TAB_MODE</code> keyword

[XMNG\\_TMPL](#)

# CW\_ZOOM

The `CW_ZOOM` function creates a compound widget that displays two images: an original image in one window and a zoomed portion of the original image in another. The user can select the center of the zoom region, the zoom scale, the interpolation style, and the method of indicating the zoom center.

This routine is written in the IDL language. Its source code can be found in the file `cw_zoom.pro` in the `lib` subdirectory of the IDL distribution.

## Using CW\_ZOOM

The value of the `CW_ZOOM` widget is the original, un-zoomed image to be displayed (a two-dimensional array). To change the contents of the `CW_ZOOM` widget, use the command:

```
WIDGET_CONTROL, id, SET_VALUE = array
```

where `id` is the widget ID of the `CW_ZOOM` widget and `array` is the image array. The value of `CW_ZOOM` cannot be set until the widget has been realized. Note that the size of the original window, set with the `XSIZE` and `YSIZE` keywords to `CW_ZOOM`, must be the size of the input array.

To return the current zoomed image as displayed by `CW_ZOOM` in the variable `array`, use the command:

```
WIDGET_CONTROL, id, GET_VALUE = array
```

## Syntax

```
Result = CW_ZOOM( Parent [, /FRAME] [, MAX=scale] [, MIN=scale]
  [, RETAIN={0 | 1 | 2}] [, SAMPLE=value] [, SCALE=value]
  [, TAB_MODE=value] [, /TRACK] [, UNAME=string] [, UVALUE=value]
  [, XSIZE=width] [, X_SCROLL_SIZE=width] [, X_ZSIZE=zoom_width]
  [, YSIZE=height] [, Y_SCROLL_SIZE=height] [, Y_ZSIZE=zoom_height] )
```

## Return Value

This function returns the widget ID of the newly-created zoom widget.

## Arguments

### Parent

The widget ID of the parent widget.

## Keywords

### FRAME

If set, a frame will be drawn around the widget. The default is FRAME = 0.

### MAX

The maximum zoom scale, which must be greater than or equal to 1. The default is 20.

### MIN

The minimum zoom scale, which must be greater than or equal to 1. The default is 1.

### RETAIN

Set this keyword to zero, one, or two to specify how backing store should be handled for both windows. RETAIN=0 specifies no backing store. RETAIN=1 requests that the server or window system provide backing store. RETAIN=2 specifies that IDL provide backing store directly. See [“Backing Store”](#) on page 4728 for details.

### SAMPLE

Set to zero for bilinear interpolation, or to a non-zero value for nearest neighbor interpolation. Bilinear interpolation gives higher quality results, but requires more time. The default is 0.

### SCALE

The initial integer scale factor to use for the zoomed image. The default is SCALE = 4. The scale must be greater than or equal to 1.

### TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

*Table 3-36: TAB\_MODE Keyword Options*

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

**TRACK**

Set this keyword and events will be generated continuously as the cursor is moved across the original image. If not set, events will only be generated when the mouse button is released. Note: On slow systems, /TRACK performance can be inadequate. The default is 0.

**UNAME**

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the FIND\_BY\_UNAME keyword. The UNAME should be unique to the widget

hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## **UVALUE**

The “user value” to be assigned to the widget.

## **XSIZE**

The width of the window (in pixels) for the original image. The default is `XSIZE = 500`. Note that `XSIZE` *must* be set to the width of the original image array for the image to display properly.

## **X\_SCROLL\_SIZE**

The width of the visible part of the original image. This may be smaller than the actual width controlled by the `XSIZE` keyword. The default is 0, for no scroll bar.

## **X\_ZSIZE**

The width of the window for the zoomed image. The default is 250.

## **YSIZE**

The height of the window (in pixels) for the original image. The default is 500. Note that `YSIZE` *must* be set to the height of the original image array for the image to display properly.

## **Y\_SCROLL\_SIZE**

The height of the visible part of the original image. This may be smaller than the actual height controlled by the `YSIZE` keyword. The default is 0, for no scroll bar.

## **Y\_ZSIZE**

The height of the window for the zoomed image. The default is 250.

## **Keywords to WIDGET\_CONTROL and WIDGET\_INFO**

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the `GET_VALUE` and `SET_VALUE` keywords to `WIDGET_CONTROL` to obtain or set the value of the zoom widget. The value of the `CW_ZOOM` widget is the original, un-zoomed image to be displayed (a two-dimensional array). To change the contents of the `CW_ZOOM` widget, use the command:

```
WIDGET_CONTROL, id, SET_VALUE = array
```

where `id` is the widget ID of the `CW_ZOOM` widget and `array` is the image array. The value of `CW_ZOOM` cannot be set until the widget has been realized. Note that the size of the original window, set with the `XSIZE` and `YSIZE` keywords to `CW_ZOOM`, must be the size of the input array.

To return the current zoomed image as displayed by `CW_ZOOM` in the variable `array`, use the command:

```
WIDGET_CONTROL, id, GET_VALUE = array
```

See “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

## Widget Events Returned by the `CW_ZOOM` Widget

When the “Report Zoom to Parent” button is pressed, this widget generates event structures with the following definition:

```
event = { ZOOM_EVENT, ID:0L, TOP:0L, HANDLER:0L, $
          XSIZE:0L, YSIZE:0L, X0:0L, Y0:0L, X1:0L, Y1:0L }
```

This specifies the dimensions of the zoomed image and the corresponding coordinates within the original image. The `XSIZE` and `YSIZE` fields contain the dimensions of the zoomed image. The `X0` and `Y0` fields contain the coordinates of the lower left corner of the original image, and the `X1` and `Y1` fields contain the coordinates of the upper right corner of the original image.

## Examples

The following code samples illustrate a use of the `CW_ZOOM` widget.

First, create an event-handler. Note that clicking on the widget’s “Zoom” button displays IDL’s help output on the console.

```
PRO widzoom_event, event

WIDGET_CONTROL, event.id, GET_UVALUE=uvalue
```

```

CASE uvalue OF
  'ZOOM': HELP, /STRUCT, event
  'DONE': WIDGET_CONTROL, event.top, /DESTROY
ENDCASE

```

```
END
```

Next, create the widget program:

```
PRO widzoom
```

```

OPENR, lun, FILEPATH('people.dat', $
  SUBDIR = ['examples','data']), /GET_LUN
image=BYTARR(192,192)
READU, lun, image
FREE_LUN, lun
sz = SIZE(image)

base=WIDGET_BASE(/COLUMN)
zoom=CW_ZOOM(base, XSIZE=sz[1], YSIZE=sz[2], UVALUE='ZOOM')
done=WIDGET_BUTTON(base, VALUE='Done', UVALUE='DONE')
WIDGET_CONTROL, base, /REALIZE

WIDGET_CONTROL, zoom, SET_VALUE=image
XMANAGER, 'widzoom', base

```

```
END
```

Once you have entered these programs, type “widzoom” at the IDL command prompt to run the widget application.

## Version History

Pre 4.0	Introduced

# DataMiner Routines

The IDL DataMiner is an Open Database Connectivity (ODBC) interface that allows IDL users to access and manipulate information from a variety of database management systems.

For information, see the [Chapter 3, “IDL DataMiner API”](#) in the *DataMiner Guide* manual.

# DBLARR

The DBLARR function create a double-precision, floating-point vector or array of the specified dimensions.

## Syntax

*Result* = DBLARR(  $D_1$  [, ...,  $D_8$ ] [, /NOZERO] )

## Return Value

Returns a double-precision, floating-point vector or array.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

**NOZERO**

Normally, DBLARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and DBLARR executes faster.

## Examples

To create D, an 3-element by 3-element, double-precision, floating-point array with every element set to 0.0, enter:

```
D = DBLARR(3, 3)
```

# DCINDGEN

The DCINDGEN function creates a complex, double-precision, floating-point array with the specified dimensions. Each element of the array has its real part set to the value of its one-dimensional subscript. The imaginary part is set to zero.

## Syntax

$$Result = DCINDGEN( D_1 [, \dots, D_8 ] )$$

## Return Value

Returns a complex, double-precision, floating-point array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create DC, a 4-element vector of complex values with the real parts set to the value of their subscripts, enter:

```
DC = DCINDGEN(4)
```

## Version History

4.0	Introduced

# DCOMPLEX

The DCOMPLEX function returns double-precision complex scalars or arrays given one or two scalars or arrays. If only one parameter is supplied, the imaginary part of the result is zero, otherwise it is set to the value of the *Imaginary* parameter.

Parameters are first converted to double-precision floating-point. If either or both of the parameters are arrays, the result is an array, following the same rules as standard IDL operators. If three parameters are supplied, DCOMPLEX extracts fields of data from *Expression*.

## Syntax

$$Result = DCOMPLEX( Real [, Imaginary] )$$

or

$$Result = DCOMPLEX( Expression, Offset [, D_1 [, \dots, D_8]] )$$

## Return Value

Returns double-precision complex scalars or arrays given one or two scalars or arrays.

## Arguments

### Real

Scalar or array to be used as the real part of the complex result.

### Imaginary

Scalar or array to be used as the imaginary part of the complex result.

### Expression

The expression from which data is to be extracted.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as complex data. See the description in [Chapter 13, “Working with Data in IDL”](#) in the *Building IDL Applications* manual for details.

## $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON\_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Create a complex array from two integer arrays by entering the following commands:

```

; Create the first integer array:
A = [1,2,3]

; Create the second integer array:
B = [4,5,6]

; Make A the real parts and B the imaginary parts of the new
; complex array:
C = DCOMPLEX(A, B)

; See how the two arrays were combined:
PRINT, C

```

IDL prints:

```
( 1.0000000, 4.0000000) ( 2.0000000, 5.0000000)
( 3.0000000, 6.0000000)
```

The real and imaginary parts of the complex array can be extracted as follows:

```
; Print the real part of the complex array C:
PRINT, 'Real Part: ', REAL_PART(C)

; Print the imaginary part of the complex array C:
PRINT, 'Imaginary Part: ', IMAGINARY(C)
```

IDL prints:

```
Real Part:          1.0000000    2.0000000    3.0000000
Imaginary Part:    4.0000000    5.0000000    6.0000000
```

# DCOMPLEXARR

The DCOMPLEXARR function returns a complex, double-precision, floating-point vector or array.

## Syntax

$$Result = DCOMPLEXARR( D_1 [, \dots, D_8] [, /NOZERO] )$$

## Return Value

Returns a complex, double-precision, floating-point vector or array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, DCOMPLEXARR sets every element of the result to zero. If the NOZERO keyword is set, this zeroing is not performed, and DCOMPLEXARR executes faster.

## Examples

To create an empty, 5-element by 5-element, complex array DC, enter:

```
DC = DCOMPLEXARR(5, 5)
```

# DEFINE\_KEY

The `DEFINE_KEY` procedure programs the keyboard function *Key* with the string *Value*, or with one of the actions specified by the available keywords.

`DEFINE_KEY` is primarily intended for use with IDL's UNIX command line interface, but it has limited applications in the Microsoft Windows environment as well.

---

## Note

Key bindings for the UNIX graphical interface (IDLDE) can be created via X Window resources. See IDL's resource file, located in your IDL distribution and described in [Chapter 5, "Customizing IDL on Motif Systems"](#) in the *Using IDL* manual, for details on key bindings.

---

## Syntax

```
DEFINE_KEY, Key [, Value] [, /MATCH_PREVIOUS] [, /NOECHO]
[, /TERMINATE]
```

**UNIX-Only Keywords:** [ /BACK\_CHARACTER ] [ /BACK\_WORD ]  
 [ /CONTROL ] [ /ESCAPE ] [ /DELETE\_CHARACTER ] [ /DELETE\_CURRENT ]  
 [ /DELETE\_EOL ] [ /DELETE\_LINE ] [ /DELETE\_WORD ] [ /END\_OF\_FILE ]  
 [ /END\_OF\_LINE ] [ /ENTER\_LINE ] [ /FORWARD\_CHARACTER ]  
 [ /FORWARD\_WORD ] [ /INSERT\_OVERSTRIKE\_TOGGLE ] [ /NEXT\_LINE ]  
 [ /PREVIOUS\_LINE ] [ /RECALL ] [ /REDRAW ] [ /START\_OF\_LINE ]

## Arguments

### Key

A scalar string containing the name of a function key to be programmed. IDL maintains an internal list of function key names and the escape sequences they send. Different keys are available for mapping in the UNIX command-line interface and the Windows IDL Development Environment, as described below.

**UNIX** — Under UNIX, `DEFINE_KEY` allows you to set the values of two distinctly different types of keys:

- **Control characters:** Any of the 26 control characters (CTRL+A through CTRL+Z) can be associated with specific actions by specifying the `CONTROL` keyword. Control characters are the unprintable ASCII characters at the beginning of the ASCII character set. They are usually entered by holding down the Control key while the corresponding letter key is pressed.
- **Function keys:** Most terminals (and terminal emulators) send escape sequences when a function key is pressed. An escape sequence is a sequence of characters starting the ASCII Escape character. Escape sequences follow strict rules that allow applications such as IDL to determine when the sequence is complete. For instance, the left arrow key on most machines sends the sequence `<ESC>[D`. The available function keys and the escape sequences they send vary from keyboard to keyboard; IDL cannot be built to recognize all of the different keyboards in existence. The `ESCAPE` keyword allows you to program IDL with the escape sequences for your keyboard. When you press the function key, IDL will recognize the sequence and take the appropriate action.

If *Key* is not already on IDL's internal list, you must use the `ESCAPE` keyword to specify the escape sequence, otherwise, *Key* alone will suffice. The available function keys and the escape sequences they send vary from keyboard to keyboard; IDL's internal list already contains definitions for most keys. The following table describes the standard key definitions.

Editing Key	Function
Ctrl+A	Move cursor to start of line
Ctrl+B	Move cursor left one word
Ctrl+D	EOF if current line is empty, EOL otherwise
Ctrl+E	Move to end of line
Ctrl+F	Move cursor right one word
Ctrl+K	Erase from the cursor to the end of the line
Ctrl+N	Move back one line in the recall buffer
Ctrl+R	Retype current line

*Table 3-37: Standard Key Definitions for UNIX*

Editing Key	Function
Ctrl+U	Delete from current position to start of line
Ctrl+W	Delete previous word
Ctrl+X	Delete current character
Backspace, Delete	Delete previous character
ESC-I	Overstrike/insert toggle
ESC-Delete	Delete previous word
Up Arrow	Move back one line in the recall buffer
Down Arrow	Move forward one line in the recall buffer
Left Arrow	Move left one character
Right Arrow	Move right one character
R13	Move cursor left one word (Sun keyboards)
R15	Move cursor right one word (Sun keyboards)
<i>^text</i>	Recall the first line containing <i>text</i> . If <i>text</i> is blank, recall the previous line
<i>Other Characters</i>	Insert character at the current cursor position

Table 3-37: Standard Key Definitions for UNIX (Continued)

**Windows** — Under Windows, function keys F2, F4, and F12 can be customized.

In IDL for Windows, three special variables can be used to expand the current mouse selection, the current line, or the current filename into the output of defined keys.

Variable	Expansion
%f	filename of the currently-selected IDL Editor window
%l	number of the current line in an IDL Editor window
%s	Currently-selected text from an IDL Output Log or Editor window

Table 3-38: Variable expansions for defined keys

For example, to define F2 as a key that executes an IDL PRINT command with the current mouse selection as its argument, use the command:

```
DEFINE_KEY, 'F2', 'PRINT, "%S"'
```

Dragging the mouse over any text in an IDL Editor or Output Log window and pressing F2 causes the selected text to be given as the argument to the IDL PRINT procedure. The %1 and %f variables can be used in a similar fashion.

## Value

The scalar string that will be printed (as if it had been typed manually at the keyboard) when *Key* is pressed. If *Value* is not present, and no function is specified for the key with one of the keywords, the key is cleared so that nothing happens when it is pressed.

## Keywords

### BACK\_CHARACTER

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move the current cursor position left one character.

### BACK\_WORD

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move the current cursor position left one word.

### CONTROL

*This keyword is only available on UNIX platforms.*

Set this keyword to indicate that *Key* is the name of a control key. The default is for *Key* to define a function key escape sequence. To view the names used by IDL for the control keys, type the following at the Command Line:

```
HELP, /ALL_KEYS
```

### Warning

---

The CONTROL and ESCAPE keywords are mutually exclusive and cannot be specified together.

---

## **DELETE\_CHARACTER**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to delete the character to the left of the cursor.

## **DELETE\_CURRENT**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to delete the character directly underneath the cursor.

## **DELETE\_EOL**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to delete from the cursor position to the end of the line.

## **DELETE\_LINE**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to delete all characters to the left of the cursor.

## **DELETE\_WORD**

*This keyword is only available on UNIX platforms.*

Set this keyword to programs *Key* to delete the word to the left of the cursor.

## **END\_OF\_LINE**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move the cursor to the end of the line.

## **END\_OF\_FILE**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to exit IDL if the current line is empty, and to end the current input line if the current line is not empty.

## **ENTER\_LINE**

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to enter the current line (i.e., the action normally performed by the “Return” key).

## ESCAPE

*This keyword is only available on UNIX platforms.*

A scalar string that specifies the escape sequence that corresponds to *Key*. See “[Defining New Function Keys](#)” on page 551 for further details.

### Warning

---

The CONTROL and ESCAPE keywords are mutually exclusive and cannot be specified together.

---

## FORWARD\_CHARACTER

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move the current cursor position right one character.

## FORWARD\_WORD

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move the current cursor position right one word.

## INSERT\_OVERSTRIKE\_TOGGLE

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to toggle between “insert” and “overstrike” mode. When characters are typed into the middle of a line, insert mode causes the trailing characters to be moved to the right to make room for the new ones. Overstrike mode causes the new characters to overwrite the existing ones.

## MATCH\_PREVIOUS

Set this keyword to program *Key* to prompt the user for a string, and then search the saved command buffer for the most recently issued command that contains that string. If a match is found, the matching command becomes the current command, otherwise the last command entered is used. Under UNIX, the default match key is the up caret “^” key when pressed in column 1.

## NEXT\_LINE

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move forward one command in the saved command buffer and make that command the current one.

## NOECHO

Set this keyword to enter the Value assigned to *Key* when pressed, without echoing the string to the screen. This feature is useful for defining keys that perform such actions as erasing the screen. If NOECHO is set, TERMINATE is also assumed to be set.

## PREVIOUS\_LINE

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move back one command in the saved command buffer and make that command the current one.

## RECALL

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to prompt the user for a command number. The saved command corresponding to the entered number becomes the current command. In order to view the currently saved commands and the number currently associated with each, enter the IDL command:

```
HELP, /RECALL COMMANDS
```

### Example

The RECALL operation remembers the last command number entered, and if the user simply presses return, it recalls the command currently associated with that saved number. Since the number associated with a given command increases by one each time a new command is saved, this feature can be used to quickly replay a sequence of commands.

```
IDL> PRINT, 1
1
IDL> PRINT, 2
2
IDL> HELP, /RECALL_COMMANDS
Recall buffer length: 20
1          PRINT, 2
2          PRINT, 1
```

User presses key tied to RECALL.

```
IDL>
```

Line 2 is requested.

```
Recall Line #: 2
```

Saved command 2 is recalled.

```
IDL> PRINT, 1
1
```

User presses return.

```
Recall Line #:
```

Saved command 2 is recalled again.

```
IDL> PRINT, 2
2
```

## REDRAW

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to retype the current line.

## START\_OF\_LINE

*This keyword is only available on UNIX platforms.*

Set this keyword to program *Key* to move the cursor to the start of the line.

## TERMINATE

If this keyword is set, and *Value* is present, pressing *Key* terminates the current input operation after its assigned value is entered. Essentially, an implicit carriage return is added to the end of *Value*.

## Examples

### Defining New Function Keys

Under UNIX, IDL can handle arbitrary function keys. When adding a definition for a function key that is not built into IDL's default list of recognized keys, you must use the ESCAPE keyword to specify the escape sequence it sends. For example, to add a function key named "HELP" which sends the escape sequence <Escape>[28~, use the command:

```
DEFINE_KEY, 'HELP', ESCAPE = '\033[28~'
```

This command adds the HELP key to the list of keys understood by IDL. Since only the key name and escape sequence were specified, pressing the HELP key will do nothing. The Value argument, or one of the keywords provided to specify command line editing functions, could have been included in the above statement to program it with an action.

Once a key is defined using the ESCAPE keyword, it is contained in the internal list of function keys. It can then be subsequently redefined without specifying the escape sequence.

It is convenient to include commonly used key definitions in a startup file, so that they will always be available. See “[Startup Files](#)” in Chapter 1 of the *Using IDL* manual.

IDL is preloaded with definitions for most widely used function keys and their escape sequences, so it is generally not necessary to specify the ESCAPE keyword. For example, to program key “F2” to redraw the current line:

```
DEFINE_KEY, 'F2', /REDRAW
```

The CONTROL keyword alters the action that IDL takes when it sees the specified characters defining the control keys. IDL may not be able to alter the behavior of some control characters. For example, CTRL+S and CTRL+Q are usually reserved by the operating system for flow control. Similarly, CTRL+Z is usually the UNIX suspend character.

### Example

CTRL+D is the UNIX end-of-file character. It is a common UNIX convention (followed by IDL) for programs to quit upon encountering CTRL+D. However, CTRL+D is also used by some text editors to delete characters. To disable IDL default handling of CTRL+D, type the following:

```
DEFINE_KEY, /CONTROL, '^D'
```

To print a reminder of how to exit IDL properly, type the following:

```
DEFINE_KEY, /CONTROL, '^D', "print, 'Enter EXIT to quit IDL'", $
/NOECHO, /TERMINATE
```

To use CTRL+D to delete characters, type the following:

```
DEFINE_KEY, /CONTROL, '^D', /DELETE_CURRENT
```

## Version History

Original	Introduced
----------	------------

## See Also

[GET\\_KBRD](#)

# DEFINE\_MSGBLK

The `DEFINE_MSGBLK` procedure defines and loads a new message block into the currently running IDL session. Messages are issued from a message block using the `MESSAGE` procedure, which handles the details of IDL message display, including proper formatting, setting the values of the `!ERROR_STATE` system variable, and displaying traceback information if execution halts. See [MESSAGE](#) for details.

A message block is a collection of messages that are loaded into IDL as a single unit. Each block contains the messages required for a specific application. At startup, IDL contains a single internal message block named `IDL_MBLK_CORE`, which contains the standard messages required by the IDL system. Dynamically loadable modules (DLMs) usually define additional message blocks for their own needs when they are loaded. At the IDL programming level, the `DEFINE_MSGBLK` and `DEFINE_MSGBLK_FROM_FILE` procedures can be used to define and load message blocks. You can use the `HELP, /MESSAGES` command to see the currently defined message blocks.

## Syntax

```
DEFINE_MSGBLK, BlockName, ErrorNames, ErrorFormats  
[, /IGNORE_DUPLICATE] [, PREFIX = PrefixStr]
```

### Note

---

IDL will force the values of the message block name, the individual message names, and any message prefix string to upper case before installing the message block. Because IDL is generally case-insensitive, you do not need to use upper case when supplying these values to the `DEFINE_MSGBLK` or `MESSAGE` procedures. The values stored in the `!ERROR_STATE` system variable will, however, be upper-case strings. If you do string comparisons with values in `!ERROR_STATE`, you should take this case-folding into account.

---

## Arguments

### BlockName

A string giving the name of the message block to be defined. Block names must be unique within the IDL system. We recommend that you follow the advice given in [Chapter 6, “Library Authoring”](#) in the *Building IDL Applications* manual when selecting the message block name in order to avoid name conflicts. Use of the `PREFIX` keyword is also recommended to enforce a consistent naming convention.

## ErrorNames

An array of strings giving the names of the messages defined by the message block.

## ErrorFormats

An array of strings giving the formats for the messages defined by the message block. Note that the format string can include both static text (displayed every time the error is displayed) and dynamic text (specified when the error is generated by a call to the MESSAGE procedure). Each format is matched with the corresponding name in *ErrorNames*. For this reason, *ErrorFormats* should have the same number of elements as *ErrorNames*. We recommend the use of the PREFIX keyword to enforce a consistent naming scheme for your messages.

Error formats are simplified `printf`-style format strings. For more information on format strings, see “[C printf-Style Quoted String Format Code](#)” in Chapter 18 of the *Building IDL Applications* manual.

## Keywords

### IGNORE\_DUPLICATE

Attempts to define a given *BlockName* more than once in the same IDL session usually cause DEFINE\_MSGBLK to issue an error and stop execution of the IDL program. Specify IGNORE\_DUPLICATE to cause DEFINE\_MSGBLK to quietly ignore attempts to redefine a message block. In this case, no error is issued and execution continues. The original message block remains installed and available for use.

### PREFIX

It is a common and recommended practice to give each message name defined in *ErrorNames* a common unique prefix that identifies it as an error from a specific message block. However, specifying this prefix in each entry of *ErrorNames* is tedious and error prone. The PREFIX keyword can be used to specify a prefix string that will be added to each element of *ErrorNames*.

## Examples

This example defines a message block called ROADRUNNER that contains 2 messages:

```
name = ['BADPLAN', 'RRNOTCAUGHT']
fmt   = ['Bad plan detected: %s.', 'Road Runner not captured.']
DEFINE_MSGBLK, PREFIX = 'ACME_M_', 'ROADRUNNER', name, fmt
```

Once this message block is loaded, the ACME\_M\_BADPLAN message can be issued using the following statement:

```
MESSAGE, NAME = 'acme_m_badplan', BLOCK = 'roadrunner', $
    'Exploding bridge while standing underneath'
```

This MESSAGE statement produces the output similar to:

```
% Bad plan detected: Exploding bridge while standing underneath.
% Execution halted at: $MAIN$
```

The IDL command:

```
HELP, /STRUCTURES, !ERROR_STATE
```

can be used to examine the effect of this message on IDL's error state.

## See Also

[DEFINE\\_MSGBLK\\_FROM\\_FILE, MESSAGE](#)

# DEFINE\_MSGBLK\_FROM\_FILE

The `DEFINE_MSGBLK_FROM_FILE` procedure reads the definition of a message block from a file, and uses `DEFINE_MSGBLK` to load it into the currently running IDL session. Messages are issued from a message block using the `MESSAGE` procedure, which handles the details of IDL message display, including proper formatting, setting the values of the `!ERROR_STATE` system variable, and displaying traceback information if execution halts. See [MESSAGE](#) for details.

---

**Note**

For large message blocks, `DEFINE_MSGBLK_FROM_FILE` can be more convenient than `DEFINE_MSGBLK`.

---

## Format of Message Definition Files

A message definition file has a simple structure designed to ease the specification of message blocks. Any line starting with the character `@` specifies information about the message block. Any line not starting with an `@` character is ignored, and can be used for comments, documentation, notes, or other human readable information. All such text is ignored by `DEFINE_MSGBLK_FROM_FILE`.

There are three different types of lines starting with `@` allowed in a message definition file:

**@IDENT *name***

Specifies the name of the message block being defined. There should be exactly one such line in every message definition file. If the `BLOCK` keyword to `DEFINE_MSGBLK_FROM_FILE` is specified, the `@IDENT` line is ignored and can be omitted. RSI recommends always specifying an `@IDENT` line.

---

**Note**

IDL will force the string specified by the `@IDENT` line to upper case before installing the message block. You do not need to use upper case when supplying the `@IDENT name` string, but `!ERROR_STATE.BLOCK` will always contain an upper-case string.

---

**@PREFIX *PrefixStr***

If present, specifies a prefix string to be applied to the beginning of each message name in the message block. There should be at most one such line in every message definition file. If the `PREFIX` keyword to `DEFINE_MSGBLK_FROM_FILE` is

specified, the @PREFIX line is ignored and can be omitted. RSI recommends always specifying an @PREFIX line.

---

### Note

IDL will force the string specified by the @PREFIX line to upper case before installing the message block. You do not need to use upper case when supplying the @PREFIX *PrefixStr* string, but !ERROR\_STATE.BLOCK will always contain an upper-case string.

---

### @ *MessageName* "MessageFormat"

Specifies a single message name and format string pair. The format string should be delimited with double quotes. A message definition file should contain one such line for every message it defines.

This routine is written in the IDL language. Its source code can be found in the file `define_msgblk_from_file.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
DEFINE_MSGBLK_FROM_FILE, Filename [, BLOCK = BlockName]
    [, /IGNORE_DUPLICATE] [, PREFIX = PrefixStr] [, /VERBOSE]
```

---

### Note

IDL will force the values of the message block name, the individual message names, and any message prefix string to upper case before installing the message block. Because IDL is generally case-insensitive, you do not need to use upper case when supplying these values to the DEFINE\_MSGBLK\_FROM\_FILE or MESSAGE procedures. The values stored in the !ERROR\_STATE system variable will, however, be upper-case strings. If you do string comparisons with values in !ERROR\_STATE, you should take this case-folding into account.

---

## Arguments

### Filename

The name of the file containing the message block definition. The contents of this file must be formatted as described in the section “[Format of Message Definition Files](#)”.

## Keywords

### BLOCK

If present, this keyword specifies the name of the message block. Normally, this keyword is not specified, and an @IDENT line in the message file specifies the name of the block. We recommend that you follow the advice given in [Chapter 6, “Library Authoring”](#) in the *Building IDL Applications* manual when selecting this name in order to avoid name clashes. Use of a prefix is also recommended to enforce a consistent naming convention.

---

**Note**

IDL will force the string specified by the BLOCK keyword to upper case before installing the message block. You do not need to use upper case when supplying the BLOCK string to the DEFINE\_MSGBLK\_FROM\_FILE procedure, but !ERROR\_STATE.BLOCK will always contain an upper-case string.

---

### IGNORE\_DUPLICATE

Attempts to define a given *BlockName* more than once in the same IDL session usually cause DEFINE\_MSGBLK to issue an error and stop execution of the IDL program. Specify IGNORE\_DUPLICATE to cause DEFINE\_MSGBLK to quietly ignore attempts to redefine a message block. In this case, no error is issued and execution continues. The original message block remains installed and available for use.

### PREFIX

If present, this keyword specifies a prefix string to be applied to the beginning of each message name in the message block. Normally, this keyword is not specified, and an @PREFIX line in the message file specifies the prefix string. We recommend the use of a prefix to enforce a consistent naming scheme for your messages.

---

**Note**

IDL will force the string specified by the PREFIX keyword to upper case before installing the message block. You do not need to use upper case when supplying the PREFIX string to the DEFINE\_MSGBLK\_FROM\_FILE procedure, but !ERROR\_STATE.MSG\_PREFIX will always contain an upper-case string.

---

## VERBOSE

If set, causes `DEFINE_MSGBLK_FROM_FILE` to print informational messages describing the message block loaded.

## Examples

The following example uses the same message block as in the example given for “`DEFINE_MSGBLK`” on page 554, but uses a message definition file to create the message block. The first step is to create a message definition file called `roadrunner.msg` containing the following lines:

```
; Message definition file for ROADRUNNER message block
@IDENT roadrunner
@PREFIX ACME_M_
@      BADPLAN "Bad plan detected: %s."
@      RRNOTCAUGHT "Road Runner not captured."
```

Use the following statement to load in the message block:

```
DEFINE_MSGBLK_FROM_FILE, 'roadrunner.msg'
```

---

### Note

A message block can only be defined once during an IDL session. If you see a message that looks like this:

```
% Attempt to install an existing message block: ROADRUNNER.
% Execution halted at: $MAIN$
```

the `ROADRUNNER` message block has already been defined. You must either exit and restart IDL or issue the `.FULL_RESET_SESSION` executive command.

---

Once this message block is loaded, the `ACME_M_BADPLAN` message can be issued using the following statement:

```
MESSAGE, NAME = 'acme_m_badplan', BLOCK='roadrunner', $
      'Exploding bridge while standing underneath'
```

This `MESSAGE` statement produces the output similar to:

```
% Bad plan detected: Exploding bridge while standing underneath.
% Execution halted at: $MAIN$
```

The IDL command:

```
HELP, /STRUCTURES, !ERROR_STATE
```

can be used to examine the effect of this message on IDL’s error state.

[DEFINE\\_MSGBLK](#), [MESSAGE](#)

# DEFROI

The DEFROI function defines an irregular region of interest of an image using the image display system and the cursor and mouse. DEFROI only works for interactive, pixel oriented devices with a cursor and an exclusive or writing mode. Regions may have at most 1000 vertices.

## Warning

---

DEFROI does not function correctly when used with draw widgets. See [CW\\_DEFROI](#).

---

This routine is written in the IDL language. Its source code can be found in the file `defroi.pro` in the `lib` subdirectory of the IDL distribution.

## Using DEFROI

After calling DEFROI, click in the image with the left mouse button to mark points on the boundary of the region of interest. The points are connected in sequence. Alternatively, press and hold the left mouse button and drag to draw a curved region. Click the middle mouse button to erase points. The most recently-placed point is erased first. Click the right mouse button to close the region. The function returns after the region has been closed.

## Syntax

```
Result = DEFROI( Sx, Sy [, Xverts, Yverts] [, /NOREGION] [, /NOFILL]
               [, /RESTORE] [, X0=device_coord] [, Y0=device_coord] [, ZOOM=factor] )
```

## Return Value

Returns a vector of subscripts of the pixels inside the region. The lowest bit in which the write mask is enabled is changed.

## Arguments

### Sx, Sy

Integers specifying the horizontal and vertical size of image, in pixels.

### Xverts, Yverts

Named vectors that will contain the vertices of the enclosed region.

## Keywords

### NOREGION

Set this keyword to inhibit the return of the pixel subscripts.

### NOFILL

Set this keyword to inhibit filling of the defined region on completion.

### RESTORE

Set this keyword to restore the display to its original state upon completion.

### X0

Set this keyword equal to X coordinate of the lower left corner of the displayed image (in device coordinates). If omitted, the default value (0) is used.

### Y0

Set this keyword equal to Y coordinate of the lower left corner of the displayed image (in device coordinates). If omitted, the default value (0) is used.

### ZOOM

Set this keyword equal to the zoom factor. If not specified, a value of 1 is assumed.

## Example

```

; Create an image:
TVSCL, DIST(200,200)

; Call DEFROI. The cursor becomes active in the graphics window.
; Define a region and click the right mouse button:
X = DEFROI(200, 200)

; Print subscripts of points included in the defined region:
PRINT, X

```

[CW\\_DEFROI](#)

# DEFSYSV

The DEFSYSV procedure creates a new system variable called *Name* initialized to *Value*.

## Syntax

```
DEFSYSV, Name, Value [, Read_Only] [, EXISTS=variable]
```

## Arguments

### Name

A scalar string containing the name of the system variable to be created. All system variable names must begin with the character '!'.

### Value

An expression from which the type, structure, and initial value of the new system variable is taken. *Value* can be a scalar, array, or structure.

### Read\_Only

If the *Read\_Only* argument is present and nonzero, the value of the newly-created system variable cannot be changed (i.e., the system variable is read-only, like the !PI system variable). Otherwise, the value of the new system variable can be modified.

## Keywords

### EXISTS

Set this keyword to a named variable that returns 1 if the system variable specified by *Name* exists. If this keyword is specified, *Value* can be omitted. For example, the following commands could be used to check that the system variable XYZ exists:

```
DEFSYSV, '!XYZ', EXISTS = i
IF i EQ 1 THEN PRINT, '!XYZ exists' ELSE PRINT, $
    '!XYZ does not exist'
```

## Examples

To create a new, floating-point, scalar system variable called !NEWVAR with an initial value of 2.0, enter:

```
DEFSYSV, '!NEWVAR', 2.0
```

You can both define and use a system variable within a single procedure:

```
PRO foo
  DEFSYSV, '!foo', $
  'Rocky, watch me pull a squirrel out of my hat!'

  ; Print !foo after defining it:
  PRINT, !foo
END
```

[Appendix D, “System Variables”](#)

# DELVAR

The DELVAR procedure deletes variables from the main IDL program level. DELVAR frees any memory used by the variable and removes it from the main program's symbol table. The following restrictions apply:

- DELVAR can only be called from the main program level.
- If a main program is created with the .RUN or .RNEW command, then each time DELVAR is called, this main program is erased. Variables that are not deleted remain unchanged.

## Syntax

```
DELVAR,  $V_1$ , ...,  $V_n$ 
```

## Arguments

$V_i$

One or more named variables to be deleted.

## Examples

Suppose that the variable Q is defined at the main program level. Q can be deleted by entering:

```
DELVAR, Q
```

# DENDRO\_PLOT

Given a hierarchical tree cluster, usually created by the CLUSTER\_TREE function, the DENDRO\_PLOT procedure draws a two-dimensional dendrite plot on the current direct graphics device.

This routine is written in the IDL language. Its source code can be found in the file `dendro_plot.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
DENDRO_PLOT, Clusters, Linkdistance [, LABEL_CHARSIZE=value]
  [, LABEL_CHARTHICK=value] [, LABEL_COLOR=value]
  [, LABEL_NAMES=vector] [, LABEL_ORIENTATION=value]
  [, LINECOLOR=value] [, ORIENTATION={1|2|3|4}] [, /OVERPLOT]
```

**Graphics Keywords:** [, BACKGROUND=*color\_index*] [, CHARSIZE=*value*]  
 [, CHARTHICK=*integer*] [, CLIP=[*X<sub>0</sub>*, *Y<sub>0</sub>*, *X<sub>1</sub>*, *Y<sub>1</sub>*]] [, COLOR=*value*] [, /DATA |  
 /DEVICE | /NORMAL] [, FONT=*integer*] [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}]  
 [, /NOCLIP] [, /NODATA] [, /NOERASE] [, POSITION=[*X<sub>0</sub>*, *Y<sub>0</sub>*, *X<sub>1</sub>*, *Y<sub>1</sub>*]]  
 [, PSYM=*integer*{0 to 10}] [, SUBTITLE=*string*] [, SYMSIZE=*value*] [, /T3D]  
 [, THICK=*value*] [, TICKLEN=*value*] [, TITLE=*string*]  
 [, {X | Y | Z}CHARSIZE=*value*]  
 [, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}]  
 [, {X | Y | Z}MARGIN=[*left*, *right*]]  
 [, {X | Y | Z}MINOR=*integer*]  
 [, {X | Y | Z}RANGE=[*min*, *max*]]  
 [, {X | Y | Z}STYLE=*value*]  
 [, {X | Y | Z}THICK=*value*]  
 [, {X | Y | Z}TICK\_GET=*variable*]  
 [, {X | Y | Z}TICKFORMAT=*string*]  
 [, {X | Y | Z}TICKINTERVAL=*value*]  
 [, {X | Y | Z}TICKLAYOUT=*scalar*]  
 [, {X | Y | Z}TICKLEN=*value*]  
 [, {X | Y | Z}TICKNAME=*string\_array*]  
 [, {X | Y | Z}TICKS=*integer*]  
 [, {X | Y | Z}TICKUNITS=*string*]  
 [, {X | Y | Z}TICKV=*array*]  
 [, {X | Y | Z}TITLE=*string*]  
 [, ZVALUE=*value*{0 to 1}]

## Arguments

### Clusters

A 2-by- $(m-1)$  input array containing the cluster indices, where  $m$  is the number of items in the original dataset. This array is usually the result of the CLUSTER\_TREE function.

### Linkdistance

An  $(m-1)$ -element input vector containing the distances between cluster items, as returned by the Linkdistance argument to the CLUSTER\_TREE function.

## Keywords

### LABEL\_CHARSIZE

The overall character size for the leaf labels when Hershey or TrueType fonts are selected. This keyword does not apply when hardware fonts are selected. If this keyword is omitted, then the value of the CHARSIZE keyword is used.

### LABEL\_CHARTHICK

An integer value specifying the line thickness of the vector drawn font characters for the leaf labels. This keyword has no effect when used with the hardware drawn fonts. If this keyword is omitted, then the value of the CHARTHICK keyword is used.

### LABEL\_COLOR

The color index of the leaf labels. If this keyword is omitted, then the value of the COLOR keyword is used.

### LABEL\_NAMES

Set this keyword to an  $m$ -element string array containing the leaf labels. If this keyword is omitted then leaves are labelled using integers  $0 \dots m-1$ . If this keyword is set to a scalar value then the leaf labels are not drawn.

---

**Note**

The LABEL\_NAMES should be input in their original order, corresponding to the  $m$  items of the original dataset. DENDRO\_PLOT will automatically rearrange the labels to match the order of the leaf nodes in the dendrogram.

---

## LABEL\_ORIENTATION

Specifies the counterclockwise angle in degrees from horizontal of the text baseline for the leaf labels. If this keyword is omitted then labels are drawn horizontally, unless `ORIENTATION=0` or `2`, in which case the labels are drawn vertically if the largest label has more than two characters.

## LINECOLOR

The color index of the dendrite lines. If this keyword is omitted, then the value of the `COLOR` keyword is used.

## ORIENTATION

Set this keyword to an integer giving the orientation of the dendrite plot. Possible values are:

Value	Orientation
0	(Default): Bottom-to-top. Leaf nodes are drawn at the bottom.
1	Left-to-right. Leaf nodes are drawn at the left.
2	Top-to-bottom. Leaf nodes are drawn at the top.
3	Right-to-left. Leaf nodes are drawn at the right.

*Table 3-39: ORIENTATION Values*

## OVERPLOT

Set this keyword to avoid creating a new dendrite plot and axes. Instead, the dendrogram lines and leaf labels are drawn on the existing plot window.

### Note

If `OVERPLOT` is specified, then for `ORIENTATION = 0` or `2`, most keywords which affect the Y axis are ignored. Conversely, for `ORIENTATION = 1` or `3`, most keywords which affect the X axis are ignored.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, LINSTYLE, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, PSYM, SUBTITLE, SYMSIZE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK\_GET, [XYZ]TITLE, ZVALUE

---

**Note**

For ORIENTATION=0 or 2, the XRANGE, XTICKLEN, XTICKS, XTICKV, and XTICKNAME keywords are ignored. For ORIENTATION=1 or 3, the YRANGE, YTICKLEN, YTICKS, YTICKV, and YTICKNAME keywords are ignored.

---

**Note**

For the dendrite plot the default values for XSTYLE and YSTYLE are 1.

---

## Example

```
; Given a set of points in two-dimensional space.
m = 20
data = 7*RANDOMN(-1, 2, m)

; Compute the Euclidean distance between each point.
distance = DISTANCE_MEASURE(data)

; Compute the cluster analysis.
clusters = CLUSTER_TREE(distance, linkdistance, LINKAGE = 2)

DENDRO_PLOT, clusters, linkdistance, $
  POSITION = [0.08, 0.1, 0.48, 0.9], $
  XSTYLE = 9, YSTYLE = 9, $
  XTITLE = 'Leaf', YTITLE = 'Distance'

DENDRO_PLOT, clusters, linkdistance, $
  ORIENTATION = 1, /NOERASE, $
  POSITION=[0.56, 0.1, 0.96, 0.9], $
  XSTYLE = 9, YSTYLE = 9, $
  XTITLE = 'Distance', YTITLE = 'Leaf'
```

[CLUSTER\\_TREE](#), [DENDROGRAM](#), [DISTANCE\\_MEASURE](#)

# DENDROGRAM

Given a hierarchical tree cluster, usually created by the `CLUSTER_TREE` function, the `DENDROGRAM` procedure constructs a dendrogram and returns a set of vertices and connectivity that can be used to visualize the dendrite plot.

This routine is written in the IDL language. Its source code can be found in the file `dendro_plot.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
DENDROGRAM, Clusters, Linkdistance, Outverts, Outconn  
[, LEAFNODES=variable]
```

## Arguments

### Clusters

A 2-by- $(m-1)$  input array containing the cluster indices, where  $m$  is the number of items in the original dataset. This array is usually the result of the `CLUSTER_TREE` function.

### Linkdistance

An  $(m-1)$ -element input vector containing the distances between cluster items, as returned by the `Linkdistance` argument to the `CLUSTER_TREE` function.

### Outverts

Set this argument to a named variable that will contain a 2-dimensional array of floating-point vertices that make up the dendrogram.

### Outconn

Set this argument to a named variable that will contain an output array of connectivity values. The `Outverts` and `Outconn` arguments can be passed directly to `IDLgrPolyline` to construct the dendrite plot.

## Keywords

### LEAFNODES

Set this keyword to a named variable that will return a vector of integers giving the order of leaf nodes within the dendrogram. The LEAFNODES keyword is useful for labeling the nodes in a dendrite plot.

### Example

```

; Given a set of points in two-dimensional space.
m = 20
DATA = 7*RANDOMN(-1, 2, m)

; Compute the Euclidean distance between each point.
distance = DISTANCE_MEASURE(data)

; Compute the cluster analysis.
clusters = CLUSTER_TREE(distance, linkdistance, LINKAGE=2)

; Create the dendrogram.
DENDROGRAM, clusters, linkdistance, outverts, outconn, $
    LEAFNODES = LEAFNODES

PRINT, STRTRIM(LEAFNODES, 2)

OPOLY = OBJ_NEW('IDLgrPolyline', outverts, $
    POLYLINES = outconn)
LOC = FLTARR(2, m)
LOC[0, *] = FINDGEN(m)
OTEXT = OBJ_NEW('IDLgrText', STRTRIM(LEAFNODES,2), $
    ALIGNMENT = 1, VERTICAL_ALIGN = 0.5, $
    BASELINE = [0,1,0], UPDIR = [-1,0,0], $
    CHAR_DIM = [1,1], LOCATIONS = loc)
OAXIS = OBJ_NEW('IDLgrAxis', 1, /EXACT, $
    LOCATION = [-1,0,0], RANGE = [0, MAX(linkdistance)])
OAXIS -> SetProperty, TICKTEXT = oTick
OTICK -> SetProperty, CHAR_DIM = [1,1]
OMODEL = OBJ_NEW('IDLgrModel')
OMODEL -> Add, oPoly
OMODEL -> Add, oText
OMODEL -> Add, oAxis
XOBJVIEW, oModel

```

When this code is run, IDL prints:

```
4 15 1 2 11 6 9 14 17 0 3 10 16 7 12 8 18 19 5 13
```

# DERIV

The DERIV function performs numerical differentiation using 3-point, Lagrangian interpolation.

## Syntax

*Result* = DERIV([X,] Y)

## Return Value

Returns the derivative of the numerical differentiation.

## Arguments

### X

Differentiate with respect to this variable. If omitted, unit spacing for Y (i.e.,  $X_i = i$ ) is assumed.

### Y

The variable to be differentiated.

## Examples

```
X = [ 0.1, 0.3, 0.4, 0.7, 0.9]
Y = [ 1.2, 2.3, 3.2, 4.4, 6.6]
PRINT, DERIV(Y)
PRINT, DERIV(X, Y)
```

IDL prints:

```
1.20000  1.00000  1.05000  1.70000  2.70000
3.16666  7.83333  7.75000  8.20000  13.8000
```

[DERIVSIG](#)

# DERIVSIG

The DERIVSIG function computes the standard deviation of a derivative as found by the DERIV function, using the input variables of DERIV and the standard deviations of those input variables.

## Syntax

*Result* = DERIVSIG( [*X*, *Y*, *Sig<sub>x</sub>*] *Sig<sub>y</sub>* )

## Return Value

Returns the standard deviation of a derivative as found by the DERIV function.

## Arguments

### X

Differentiate with respect to this variable. If omitted, unit spacing for Y (i.e.,  $X_i = i$ ) is assumed.

### Y

The variable to be differentiated. Omit if X is omitted.

### Sigx

The standard deviation of X (either vector or constant). Use “0.0” if the abscissa is exact; omit if X is omitted.

### Sigy

The standard deviation of Y. *Sigy* must be a vector if the other arguments are omitted, but may be either a vector or a constant if X, Y, and *Sigx* are supplied.

## Keywords

None.

[DERIV](#)

# DETERM

The DETERM function computes the determinant of an  $n$  by  $n$  array. LU decomposition is used to represent the input array in triangular form. The determinant is then computed as the product of diagonal elements of the triangular form. Row interchanges are tracked during the LU decomposition to ensure the correct sign.

This routine is written in the IDL language. Its source code can be found in the file `determ.pro` in the `lib` subdirectory of the IDL distribution.

## Note

---

If you are working with complex inputs, use the `LA_DETERM` procedure instead.

---

## Syntax

*Result* = DETERM( *A* [, /CHECK] [, /DOUBLE] [, ZERO=*value*] )

## Return Value

Returns the determinant of an  $n$  by  $n$  array

## Arguments

### A

An  $n$  by  $n$  single- or double-precision floating-point array.

## Keywords

### CHECK

Set this keyword to check *A* for singularity. The determinant of a singular array is returned as zero if this keyword is set. Run-time errors may result if *A* is singular and this keyword is not set.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## ZERO

Use this keyword to set the absolute value of the floating-point zero. A floating-point zero on the main diagonal of a triangular array results in a zero determinant. For single-precision inputs, the default value is  $1.0 \times 10^{-6}$ . For double-precision inputs, the default value is  $1.0 \times 10^{-12}$ . Setting this keyword to a value less than the default may improve the precision of the result.

## Examples

```
; Define an array A:
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]

; Compute the determinant:
PRINT, DETERM(A)
```

IDL prints:

```
-16.0000
```

# DEVICE

The DEVICE procedure provides device-dependent control over the current graphics device (as set by the SET\_PLOT routine). The IDL graphics procedures and functions are device-independent. That is, IDL presents the user with a consistent interface to all devices. However, most devices have extra abilities that are not directly available through this interface. DEVICE is used to access and control such abilities. It is used by specifying various keywords that differ from device to device.

See [Appendix A, “IDL Direct Graphics Devices”](#) for a description of the keywords available for each graphics device.

## Syntax

### Note

Each keyword to DEVICE is followed by the device(s) to which it applies.

### DEVICE

```

## Examples

The following example retains the name of the current graphics device, sets plotting to the PostScript device, makes a PostScript file, then resets plotting to the original device:

```

; The NAME field of the !D system variable contains the name of the
; current plotting device.
mydevice = !D.NAME

; Set plotting to PostScript:
SET_PLOT, 'PS'

; Use DEVICE to set some PostScript device options:
DEVICE, FILENAME='myfile.ps', /LANDSCAPE

; Make a simple plot to the PostScript file:
PLOT, FINDGEN(10)

; Close the PostScript file:
DEVICE, /CLOSE

```

```
; Return plotting to the original device:  
SET_PLOT, mydevice
```

## Version History

Original	Introduced
6.1	Added CMYK keyword
Pre 6.1	Deprecated DEPTH and FONT keywords

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

# DFPMIN

The DFPMIN procedure minimizes a user-written function *Func* of two or more independent variables using the Broyden-Fletcher-Goldfarb-Shanno variant of the Davidon-Fletcher-Powell method, using its gradient as calculated by a user-written function *Dfunc*.

DFPMIN is based on the routine `dfuncmin` described in section 10.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
DFPMIN, X, Gtol, Fmin, Func, Dfunc [, /DOUBLE] [, EPS=value]  
    [, ITER=variable] [, ITMAX=value] [, STEPMAX=value] [, TOLX=value]
```

## Arguments

### X

On input, *X* is an *n*-element vector specifying the starting point. On output, it is replaced with the location of the minimum.

### Note

---

If DFPMIN is complex then only the real part is used for the computation.

---

### Gtol

An input value specifying the convergence requirement on zeroing the gradient.

### Fmin

On output, *Fmin* contains the value at the minimum-point *X* of the user-supplied function specified by *Func*.

### Func

A scalar string specifying the name of a user-supplied IDL function of two or more independent variables to be minimized. This function must accept a vector argument *X* and return a scalar result.

For example, suppose we wish to find the minimum value of the function

$$y = (x_0 - 3)^4 + (x_1 - 2)^2$$

To evaluate this expression, we define an IDL function named MINIMUM:

```
FUNCTION minimum, X
  RETURN, (X[0] - 3.0)^4 + (X[1] - 2.0)^2
END
```

## Dfunc

A scalar string specifying the name of a user-supplied IDL function that calculates the gradient of the function specified by *Func*. This function must accept a vector argument *X* and return a vector result.

For example, the gradient of the above function is defined by the partial derivatives:

$$\frac{\partial y}{\partial x_0} = 4(x_0 - 3)^3, \quad \frac{\partial y}{\partial x_1} = 2(x_1 - 2)$$

We can write a function GRAD to express these relationships in the IDL language:

```
FUNCTION grad, X
  RETURN, [4.0*(X[0] - 3.0)^3, 2.0*(X[1] - 2.0)]
END
```

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### EPS

Use this keyword to specify a number close to the machine precision. For single-precision calculations, the default value is  $3.0 \times 10^{-8}$ . For double-precision calculations, the default value is  $3.0 \times 10^{-16}$ .

## ITER

Use this keyword to specify a named variable which returns the number of iterations performed.

## ITMAX

Use this keyword to specify the maximum number of iterations allowed. The default value is 200.

## STEPMAX

Use this keyword to specify the scaled maximum step length allowed in line searches. The default value is 100.0

## TOLX

Use this keyword to specify the convergence criterion on  $X$  values. The default value is  $4 \times \text{EPS}$ .

## Examples

To minimize the function `MINIMUM`:

```

PRO example_dfpmn

    ; Make an initial guess (the algorithm's starting point):
    X = [1.0, 1.0]

    ; Set the convergence requirement on the gradient:
    Gtol = 1.0e-7

    ; Find the minimizing value:
    DFPMIN, X, Gtol, Fmin, 'minimum', 'grad'

    ; Print the minimizing value:
    PRINT, X

END

FUNCTION minimum, X
    RETURN, (X[0] - 3.0)^4 + (X[1] - 2.0)^2
END

FUNCTION grad, X
    RETURN, [4.0*(X[0] - 3.0)^3, 2.0*(X[1] - 2.0)]
END

```

IDL prints:

```
3.00175  2.00000
```

# DIAG\_MATRIX

The `DIAG_MATRIX` function constructs a diagonal matrix from an input vector, or if given a matrix, then `DIAG_MATRIX` will extract a diagonal vector.

## Syntax

*Result* = `DIAG_MATRIX(A [, Diag] )`

## Return Value

- If given an input vector with  $n$  values, the result is an  $n$ -by- $n$  array of the same type. The `DIAG_MATRIX` function may also be used to construct subdiagonal or superdiagonal arrays.
- If given an input  $n$ -by- $m$  array, the result is a vector with  $\text{MIN}(n,m)$  elements containing the diagonal elements. The `DIAG_MATRIX` function may also be used to extract subdiagonals or superdiagonals.

## Arguments

### A

Either an  $n$ -element input vector to convert to a diagonal matrix, or a  $n$ -by- $m$  input array to extract a diagonal.  $A$  may be any numeric type.

### Diag

An optional argument that specifies the subdiagonal ( $Diag < 0$ ) or superdiagonal ( $Diag > 0$ ) to fill or extract. The default is  $Diag=0$  which puts or extracts the values along the diagonal. If  $A$  is a vector with the  $m$  elements, then the result is an  $n$ -by- $n$  array, where  $n = m + \text{ABS}(Diag)$ . If  $A$  is an array, then the result is a vector whose length depends upon the number of elements remaining along the subdiagonal or superdiagonal.

**Tip**

The *Diag* argument may be used to easily construct tridiagonal arrays. For example, the expression,

```
DIAG_MATRIX(VL, -1) + DIAG_MATRIX(V) + DIAG_MATRIX(VU, 1)
```

will create an  $n$ -by- $n$  array, where  $VL$  is an  $(n - 1)$ -element vector containing the subdiagonal values,  $V$  is an  $n$ -element vector containing the diagonal values, and  $VU$  is an  $(n - 1)$ -element vector containing the superdiagonal values.

## Keywords

None.

## Examples

Create a tridiagonal matrix and extract the diagonal using the following program:

```
PRO ExDiagMatrix
; Convert three input vectors to a tridiagonal matrix:
diag = [1, -2, 3, -4]
sub = [5, 10, 15]
super = [3, 6, 9]
array = DIAG_MATRIX(diag) + $
DIAG_MATRIX(super, 1) + DIAG_MATRIX(sub, -1)
PRINT, 'DIAG_MATRIX array:'
PRINT, array

; Extract the diagonal:
PRINT, 'DIAG_MATRIX diagonal:'
PRINT, DIAG_MATRIX(array)
END
```

When this program is compiled and run, IDL prints:

```
DIAG_MATRIX array:
1      3      0      0
5     -2      6      0
0     10      3      9
0      0     15     -4
DIAG_MATRIX diagonal:
1     -2      3     -4
```

# DIALOG\_MESSAGE

The `DIALOG_MESSAGE` function creates a modal (blocking) dialog box that can be used to display information to the user. The dialog must be dismissed, by clicking on one of its option buttons, before execution of the widget program can continue.

This function differs from widgets in a number of ways. The `DIALOG_MESSAGE` dialog does not exist as part of a widget tree, has no children, does not exist in an unrealized state, and generates no events. Instead, the dialog is displayed whenever this function is called. While the `DIALOG_MESSAGE` dialog is displayed, widget activity is limited because the dialog is modal. The function does not return to its caller until the user selects one of the dialog's buttons. Once a button has been selected, the dialog disappears.

There are four basic dialogs that can be displayed. The default type is "Warning". Other types can be selected by setting one of the keywords described below. Each dialog type displays different buttons. Additionally any dialog can be made to show a "Cancel" button by setting the `CANCEL` keyword. The four types of dialogs are described in the table below:

Dialog Type	Default Buttons
Error	OK
Warning	OK
Question	Yes, No
Information	OK

Table 3-40: Types of `DIALOG_MESSAGE` Dialogs

## Syntax

```
Result = DIALOG_MESSAGE( Message_Text [, /CANCEL] [, /CENTER]
    [, /DEFAULT_CANCEL | , /DEFAULT_NO] [, DIALOG_PARENT=widget_id]
    [, DISPLAY_NAME=string] [, /ERROR | , /INFORMATION | , /QUESTION]
    [, RESOURCE_NAME=string] [, TITLE=string] )
```

## Return Value

`DIALOG_MESSAGE` returns a text string containing the text of the button selected by the user. Possible returned values are "Yes", "No", "OK", and "Cancel".

## Arguments

### Message\_Text

A scalar string or string array that contains the text of the message to be displayed. If this argument is set to an array of strings, each array element is displayed as a separate line of text.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## Keywords

### CANCEL

Set this keyword to add a “Cancel” button to the dialog.

### CENTER

Set this keyword to center the dialog on the screen.

---

**Note**

This keyword is ignored on Microsoft Windows platforms because the dialog is always automatically centered.

---

### DEFAULT\_CANCEL

Set this keyword to make the “Cancel” button the default selection for the dialog. The default selection is the button that is selected when the user presses the default keystroke (usually Space or Return depending on the platform). Setting DEFAULT\_CANCEL implies that the CANCEL keyword is also set.

### DEFAULT\_NO

Set this keyword to make the “No” button the default selection for “Question” dialogs. Normally, the default is “Yes”.

### DIALOG\_PARENT

Set this keyword to the widget ID of a widget over which the message dialog should be positioned. When displayed, the DIALOG\_MESSAGE dialog will be positioned

over the specified widget. Dialogs are often related to a non-dialog widget tree. The ID of the widget in that tree to which the dialog is most closely related should be specified.

## DISPLAY\_NAME

Set this keyword equal to a string indicating the name of the X Windows display on which the dialog is to appear. This keyword is ignored if the `DIALOG_PARENT` keyword is specified. This keyword is also ignored on Microsoft Windows platforms.

## ERROR

Set this keyword to create an “Error” dialog. The default dialog type is “Warning”.

## INFORMATION

Set this keyword to create an “Information” dialog. The default dialog type is “Warning”.

## QUESTION

Set this keyword to create a “Question” dialog. The default dialog type is “Warning”.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the dialog. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## TITLE

Set this keyword to a scalar string that contains the text of a title to be displayed in the dialog frame. If this keyword is not specified, the dialog has the dialog type as its title as shown in the table under [DIALOG\\_MESSAGE](#).

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## Version History

5.0	Introduced
6.2	Added CENTER keyword

[XDISPLAYFILE](#)

# DIALOG\_PICKFILE

The `DIALOG_PICKFILE` function allows you to interactively select a file, or multiple files, using the platform's own native graphical file selection dialog. You can also enter the name of a file that does not exist (see the description of the `WRITE` keyword). When the `DIRECTORY` keyword is set, you can select a directory (or create and select a directory on Windows) using the Browse for Folder dialog.

## Entering File Names Manually

Once the file selection dialog has been displayed, you can enter a file name manually by typing the name in the **File name** field (Windows) or **Selection** field (Motif).

### Windows

On Microsoft Windows systems, file names can be entered as they appear in the Windows Explorer, including spaces. If the `MULTIPLE_FILES` keyword is set, each file name should be surrounded by double quotes, and the file names should be separated by spaces. For example, to select two files named `First File.txt` and `Second File.txt`, you would enter the following in the **File name** field:

```
"First File.txt" "Second File.txt"
```

### Motif

To enter a file name that includes a space character on a Motif system, escape the space character with the `"\"` character. Similarly, if the file name includes the `"\"` character, escape the literal `"\"` with another `"\"` character. If the `MULTIPLE_FILES` keyword is set, file names should be separated by spaces. For example, to select two files named `First File.txt` and `Back\slash File.txt`, you would enter the following in the **Selection** field:

```
First\ File.txt Back\\slash\ File.txt
```

## Syntax

```
Result = DIALOG_PICKFILE( [, DEFAULT_EXTENSION=string]
  [, /DIRECTORY] [, DIALOG_PARENT=widget_id]
  [, DISPLAY_NAME=string] [, FILE=string] [, FILTER=string/string array]
  [, /FIX_FILTER] [, GET_PATH=variable] [, GROUP=widget_id]
  [, /MULTIPLE_FILES] [, /MUST_EXIST] [, /OVERWRITE_PROMPT]
  [, PATH=string] [, /READ | , /WRITE] [, RESOURCE_NAME=string]
  [, TITLE=string] )
```

## Return Value

When the `DIRECTORY` keyword is not specified, `DIALOG_PICKFILE` returns a string array that contains the full path name of the selected file or files. If no file is selected, `DIALOG_PICKFILE` returns a null string.

When the `DIRECTORY` keyword is specified, `DIALOG_PICKFILE` returns a string array that contains the full path of the selected directory.

## Keywords

### **DEFAULT\_EXTENSION**

Set this keyword to a scalar string representing the default extension to be appended onto the returned file name or names. If the returned file name already has an extension, then the value set for this keyword is not appended. The string value set for this keyword should not include a period (.).

---

**Note**

This keyword only applies to file names typed into the dialog. This keyword does not apply to files selected within the dialog.

---

### **DIALOG\_PARENT**

Set this keyword to the widget ID of a widget to be used as the parent of this dialog.

### **DIRECTORY**

Set this keyword to display only the existing directories in the directory specified by the `PATH` keyword. If a path is not specified, setting this keyword shows directories in the current directory. The Browse for Folder dialog is opened to the directory specified by the path definition. Individual files are not displayed. The return value contains the path of the directory selected, or directory created and selected by the user.

### **DISPLAY\_NAME**

Set this keyword equal to a string that specifies the name of the X Windows display on which the dialog should be displayed. This keyword is ignored on Microsoft Windows platforms.

## FILE

Set this keyword to a scalar string that contains the name of the initial file selection. This keyword is useful for specifying a default filename.

On Windows, this keyword also has the effect of filtering the file list if a wildcard is used, but this keyword should be used to specify a specific filename. To list only files of a certain type, use the `FILTER` keyword.

## FILTER

Set this keyword to a string value or an array of strings specifying the file types to be displayed in the file list. This keyword is used to reduce the number of files displayed in the file list. The user can modify the filter unless the `FIX_FILTER` keyword is set. If the value contains a vector of strings, multiple filters are used to filter the files. The filter `*.*` is automatically added to any filter you specify.

For example, to display only files of type `.jpg`, `.tif`, or `.png` in the file selection window, you could use the following code:

```
filters = ['*.jpg', '*.tif', '*.png']
file = DIALOG_PICKFILE(/READ, FILTER = filters)
```

The filter list shown above is displayed as five options in the dialog:

```
*.jpg, *.tif, *.png
*.jpg
*.tif
*.png
*.*
```

Multiple file types can be included in a single filter by providing a semicolon-separated list of types within the string. For example, to account for different extensions used for similar file types, you could use the following code:

```
filters = ['*.jpg;*.jpeg', '*.tif;*.tiff', '*.png']
file = DIALOG_PICKFILE(/READ, FILTER = filters)
```

The filter list shown above is displayed as five options in the dialog:

```
*.jpg, *.jpeg, *.tif, *.tiff, *.png
*.jpg, *.jpeg
*.tif, *.tiff
*.png
*.*
```

The `FILTER` keyword can optionally be set equal to an  $n \times 2$  array. In this case, the first vector contains the file types, and the second vector contains a list of

descriptions that are displayed in the dialog in place of the file type strings. For example:

```
filters = [['*.jpg;*.jpeg', '*.tif;*.tiff', '*.png', '*.*'], $
          ['JPEG', 'TIFF', 'Bitmap', 'All files']]
file = DIALOG_PICKFILE(/READ, FILTER = filters)
```

The filter list shown above is displayed as four options in the dialog:

```
JPEG
TIFF
Bitmap
All files
```

---

### Note

When an  $n \times 2$  array is provided, the `*.*` filter is not automatically added to the list. If you want this filter included in the list, you must include it explicitly.

---

Under Microsoft Windows, the user cannot modify the displayed filter. The user can enter a filter string in the Filename field to interactively update the list of files displayed. For example, entering `*.pro` in the Filename field causes only `.pro` files to be displayed.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## FIX\_FILTER

When this keyword is set, only files that satisfy the filter can be selected. The user has no ability to modify the filter and the filter is not shown.

Under Microsoft Windows, the filter string can never be modified, but the user can enter a filter string in the Filename field to interactively update the list of files displayed even if `FIX_FILTER` is set.

## GET\_PATH

Set this keyword to a named variable in which the path of the selection is returned.

## GROUP

*This keyword is obsolete and has been replaced by the `DIALOG_PARENT` keyword. Code that uses the `GROUP` keyword will continue to function as before, but we suggest that all new code use `DIALOG_PARENT`.*

## MULTIPLE\_FILES

Set this keyword to allow for multiple file selection in the file-selection dialog. When you set this keyword, the user can select multiple files using the platform-specific selection method. The currently selected files appear in the selection text field of the dialog. With this keyword set, `DIALOG_PICKFILE` can return a string array that contains the full path name of the selected file or files.

## MUST\_EXIST

Set this keyword to allow only files that already exist to be selected.

## OVERWRITE\_PROMPT

If this keyword is set along with the `WRITE` keyword and the user selects a file that already exists, then a dialog will be displayed asking if the user wants to replace the existing file or not. For multiple selections, the user is prompted separately for each file. If the user selects **No** the file selection dialog is displayed again; if the user selects **Yes** then the selection is allowed. This keyword has no effect unless the `WRITE` keyword is also set.

## PATH

Set this keyword to a string that contains the initial path from which to select files. Relative paths are appended to IDL's current working directory. If this keyword is not set, IDL's current working directory is used. (See "`CD`" on page 236 for a discussion of IDL's *default* current working directory.)

---

### Note

Under Microsoft Windows, if the path specified is not valid, `DIALOG_PICKFILE` will use the path to the last directory accessed by Windows. *This path may have been set by another application.* Under UNIX, `DIALOG_PICKFILE` will display the dialog using the specified path even if it does not exist.

---

---

### Tip

To specify a directory relative to IDL's installation directory, use statements similar to the following:

```
path = EXPAND_PATH('<IDL_DIR>')+PATH_SEP()+ 'examples/data'  
file = DIALOG_PICKFILE(PATH=path)
```

---

## READ

Set this keyword to make the title of the dialog “Select File to Read”.

## RESOURCE\_NAME

Set this keyword equal to a string containing an X Window System resource name to be applied to the dialog.

## TITLE

Set this keyword to a scalar string to be used for the dialog title. If it is not specified, the default title is “Please Select a File”.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## WRITE

Set this keyword to make the title of the dialog “Select File to Write”.

## Examples

Create a `DIALOG_PICKFILE` dialog that lets users select only files with the extension ‘pro’. Use the ‘Select File to Read’ title and store the name of the selected file in the variable `file`. Enter:

```
file = DIALOG_PICKFILE(/READ, FILTER = '*.pro')
```

Create a `DIALOG_PICKFILE` dialog that allows the user to select a DICOM file. The following code sets the initial path to the `data` directory contained in the `examples` directory of the IDL installation directory.

```
; Allow the user to select a DICOM file.  
sfile = DIALOG_PICKFILE(PATH='examples\data', $  
    TITLE='Select DICOM Patient File', FILTER='*.dcm')
```

When the `DIRECTORY` keyword is not set, as in the previous example, the user may select one or more files of the `FILTER` type from the directory specified by `PATH`.

The TITLE keyword defines the dialog title when DIRECTORY is not specified as shown in a subsection of the dialog in the following figure.

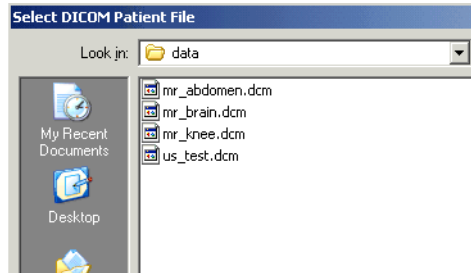

Figure 3-34: Filtered File Selection

Use the DIRECTORY keyword to DIALOG\_PICKFILE to open the “Browse for Folder” dialog. The PATH keyword specifies the initial directory selection and the TITLE keyword provides additional instruction to the user in the body of the dialog.

```
sFolder = DIALOG_PICKFILE(PATH='examples\data', /DIRECTORY, $
    TITLE="Choose directory containing DICOM patient data.")
```

The following figure shows the results of issuing this statement on the Windows platform.

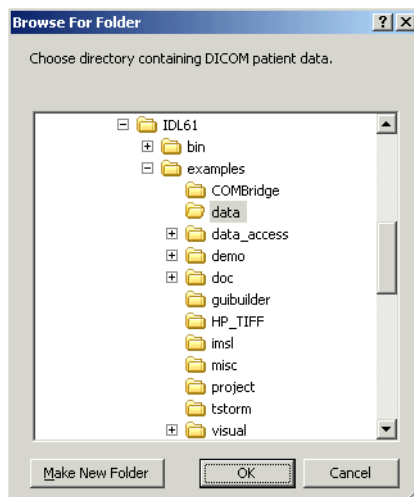

Figure 3-35: DIALOG\_PICKFILE with DIRECTORY Keyword Set

## Version History

5.0	Introduced
6.0	Added <code>DEFAULT_EXTENSION</code> and <code>OVERWRITE_PROMPT</code> keywords
6.1	Browse for Folder dialog updated to enable horizontal scrolling (when needed), and to allow for new folder creation on Windows
Pre 6.1	Deprecated <code>GROUP</code> keyword

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

# DIALOG\_PRINTERSETUP

The `DIALOG_PRINTERSETUP` function opens a native dialog for setting the applicable properties for a particular printer.

## Syntax

```
Result = DIALOG_PRINTERSETUP( [PrintDestination]  
    [, DIALOG_PARENT=widget_id] [, DISPLAY_NAME=string]  
    [, RESOURCE_NAME=string] [, TITLE=string] )
```

## Return Value

`DIALOG_PRINTERSETUP` returns a nonzero value if the user pressed the “OK” button in the dialog, or zero otherwise. You can programmatically begin printing based on the value returned by this function.

## Arguments

### PrintDestination

An instance of the `IDLgrPrinter` object for which setup properties are to be set. If no *PrintDestination* is specified, the printer used by the IDL Direct Graphics printer device is modified.

## Keywords

### DIALOG\_PARENT

Set this keyword to the widget ID of a widget to be used as the parent of this dialog.

### DISPLAY\_NAME

Set this keyword equal to a string indicating the name of the X Windows display on which the dialog is to appear. This keyword is ignored if the `DIALOG_PARENT` keyword is specified. This keyword is also ignored on Microsoft Windows platforms.

### RESOURCE\_NAME

Set this keyword equal to a string containing an X Window System resource name to be applied to the dialog.

## TITLE

Set this keyword equal to a string to be displayed on the dialog frame. This keyword is ignored on Microsoft Windows platforms.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

[DIALOG\\_PRINTJOB](#), “The Printer Device” on page 4743

# DIALOG\_PRINTJOB

The DIALOG\_PRINTJOB function opens a native dialog that allows you to set parameters for a printing job (number of copies to print, for example).

## Syntax

```
Result = DIALOG_PRINTJOB( [PrintDestination]  
    [, DIALOG_PARENT=widget_id] [, DISPLAY_NAME=string]  
    [, RESOURCE_NAME=string] [, TITLE=string] )
```

## Return Value

DIALOG\_PRINTJOB returns a nonzero value if the user pressed the “OK” button in the dialog, or zero otherwise. You can use the result of this function to programmatically begin printing.

## Arguments

### PrintDestination

An instance of the IDLgrPrinter object for which a printing job is to be initiated. If no *PrintDestination* is specified, the printer used by the IDL Direct Graphics printer device is modified.

## Keywords

### DIALOG\_PARENT

Set this keyword to the widget ID of a widget to be used as the parent of this dialog.

### DISPLAY\_NAME

Set this keyword to a string indicating the name of the X Windows display on which the dialog is to appear. This keyword is ignored if the DIALOG\_PARENT keyword is specified. This keyword is also ignored on Microsoft Windows platforms.

### RESOURCE\_NAME

Set this keyword to a string containing an X Window System resource name to be applied to the dialog.

## TITLE

Set this keyword to a string to be displayed on the dialog frame. This keyword is ignored on Microsoft Windows platforms.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

# DIALOG\_READ\_IMAGE

The `DIALOG_READ_IMAGE` function is a graphical interface allowing the user to select an image file and read it into an IDL variable. A preview of the selected image is provided. The interface is created as a modal dialog with an optional parent widget.

## Syntax

```
Result = DIALOG_READ_IMAGE ( [Filename] [, BLUE=variable]  
    [, DIALOG_PARENT=widget_id] [, FILE=variable] [, FILTER_TYPE=string]  
    [, /FIX_FILTER] [, GET_PATH=variable] [, GREEN=variable]  
    [, IMAGE=variable] [, PATH=string] [, QUERY=variable] [, RED=variable]  
    [, TITLE=string] )
```

## Return Value

This function returns 1 if the “Open” button was clicked, and 0 if the “Cancel” button was clicked.

## Arguments

### Filename

An optional scalar string containing the full pathname of the file to be highlighted.

## Keywords

### BLUE

Set this keyword to a named variable that will contain the blue channel vector (if any).

### DIALOG\_PARENT

The widget ID of a widget that calls `DIALOG_READ_IMAGE`. When this ID is specified, a death of the caller results in the death of the `DIALOG_READ_IMAGE` dialog. If `DIALOG_PARENT` is not specified, then the interface is created as a modal, top-level widget.

## FILE

Set this keyword to a named variable that will contain the selected filename with full path when the dialog is created.

## FILTER\_TYPE

Set this keyword to a scalar string containing the format type the dialog filter should begin with. The default is “Image Files”. The user cannot modify the filter if the `FIX_FILTER` keyword is set. Valid values are obtained from the list of supported image types returned from `QUERY_IMAGE`. In addition, there is also the “All Files” type. If set to “All Files”, queries will only happen on filename clicks, making the dialog much more efficient.

Example:

```
FILTER='.jpg, .tiff'
```

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## FIX\_FILTER

When this keyword is set, only files that satisfy the filter can be selected. The user has no ability to modify the filter.

## GET\_PATH

Set this keyword to a named variable in which the path of the selection is returned.

## GREEN

Set this keyword to a named variable that will contain the green channel vector (if any).

## IMAGE

Set this keyword to a named variable that will contain the image array read. If Cancel was clicked, no action is taken.

## PATH

Set this keyword to a string that contains the initial path from which to select files. If this keyword is not set, the current working directory is used.

## QUERY

Set this keyword to a named variable that will return the `QUERY_IMAGE` structure associated with the returned image. If the “Cancel” button was pressed, the variable set to this keyword is not changed. If an error occurred during the read, the `FILENAME` field of the structure will be a null string.

## RED

Set this keyword to a named variable that will contain the red channel vector (if any).

## TITLE

Set this keyword to a scalar string to be used for the dialog title. If it is not specified, the default title is “Select Image File”.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## Example

The following statement opens the dialog so that you can select among `.gif`, `.tiff`, `.dcm`, `.png` and `.jpg` files. When you select a file and click **Open**, the file path is stored in `selectedFile` variable and the image data is stored in the `Image` variable.

```
result = DIALOG_READ_IMAGE(FILE=selectedFile, IMAGE=image)
```

Enter the following line to display image data in an `iImage` display.

```
IF result EQ 1 THEN iImage, image
```

## Using the Select Image File Dialog Interface

When you open the **Select Image File** dialog using the `DIALOG_READ_IMAGE` function or the **Import Image** macro, a dialog similar to the following appears.

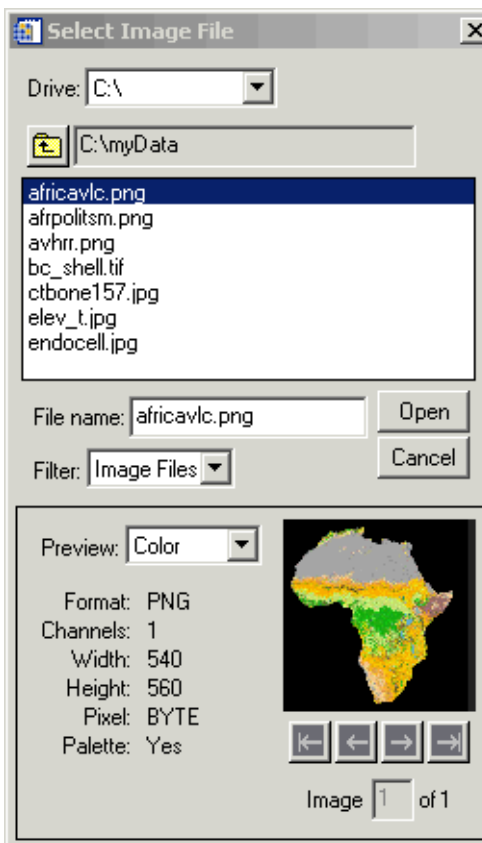

Figure 3-36: The `DIALOG_READ_IMAGE` Dialog

You can use the dialog fields as follows:

Drive	Select the main-level directory and then select the sub-directory or image file in the listbox.
Open	Opens the selected image file.

Cancel	Cancels the current image selection.
Preview	Selects the color mode of the preview or turns preview functionality off.
Arrow Keys	Scrolls through multiple images in the file. <b>Note</b> - You can only read in one image of a multi-image file. The image in the preview is the image that will be read.

## Version History

5.3	Introduced

[DIALOG\\_WRITE\\_IMAGE](#)

# DIALOG\_WRITE\_IMAGE

The `DIALOG_WRITE_IMAGE` function is a graphical user interface allowing you to save an IDL array variable as an image file, selecting a location and image file type. The interface is created as a modal dialog with an optional parent widget.

## Syntax

```
Result = DIALOG_WRITE_IMAGE ( Image [, R, G, B]  
    [, DIALOG_PARENT=widget_id] [, FILE=string] [, /FIX_TYPE]  
    [, /NOWRITE] [, OPTIONS=variable] [, PATH=string] [, TITLE=string]  
    [, TYPE=variable] [, /WARN_EXIST] )
```

## Return Value

This routine returns 1 if the “Save” button was clicked, and 0 if the “Cancel” button was clicked.

## Arguments

### Image

The array to be written to the image file.

### R, G, B

These are optional arguments defining the Red, Green, and Blue color tables to be associated with the image array.

## Keywords

### DIALOG\_PARENT

The widget ID of a widget that calls `DIALOG_WRITE_IMAGE`. When this ID is specified, a death of the caller results in the death of the `DIALOG_WRITE_IMAGE` dialog. If `DIALOG_PARENT` is not specified, then the interface is created as a modal, top-level widget.

### FILE

Set this keyword to a scalar string that contains the name of the initial file selection. This keyword is useful for specifying a default filename.

## FIX\_TYPE

When this keyword is set, only files that satisfy the type can be selected. The user has no ability to modify the type.

## NOWRITE

Set this keyword to prevent the dialog from writing the file when “Save” is clicked. No data conversions will take place when the save type is chosen.

## OPTIONS

Set this keyword to a named variable to contain a structure of the chosen options by the user, including the filename and image type chosen.

## PATH

Set this keyword to a string that contains the initial path from which to select files. If this keyword is not set, the current working directory is used.

## TITLE

Set this keyword to a scalar string to be used for the dialog title. If it is not specified, the default title is “Save Image File”.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## TYPE

Set this keyword to a scalar string containing the format type the “Save as type” field should begin with. The default is “TIFF”. The user can modify the type unless the `FIX_TYPE` keyword is set. Valid values are obtained from the list of supported image types returned from `QUERY_IMAGE`. The “Save as type” field will reflect the type of the selected file (if one is selected).

## WARN\_EXIST

Set this keyword to produce a question dialog if the user selects a file that already exists. The default is to quietly overwrite the file.

## Examples

The following statements create and write a simple image to a .tif file name `myimage.tif`:

```
myimage = DIST(100)
result = DIALOG_WRITE_IMAGE(myimage, FILENAME='myimage.tif')
```

### Using the Save Image File Dialog

When you issue the previous statements, the **Save Image File** dialog opens.

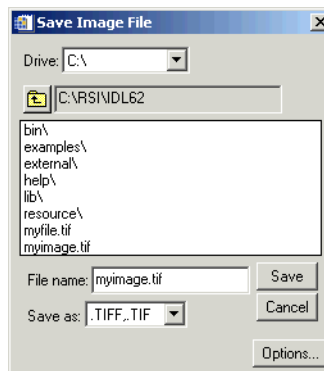

Figure 3-37: Save Image File Dialog

Use the following fields to configure how the image is saved.

Drive	Select the directory in which to save the image file
File name	Enter the file name
Save as	Select the image file format
Save	Save the image file
Cancel	Cancels the save function
Options	Brings up a dialog box of image format save options, which varies depending on image format

# DIGITAL\_FILTER

The `DIGITAL_FILTER` function returns the coefficients of a non-recursive, digital filter for evenly spaced data points. Frequencies are expressed in terms of the Nyquist frequency,  $1/2T$ , where  $T$  is the time between data samples. Highpass, lowpass, bandpass and bandstop filters may be constructed with this function.

This routine is written in the IDL language. Its source code can be found in the file `digital_filter.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = DIGITAL_FILTER( Flow, Fhigh, A, Nterms [, /DOUBLE] )
```

## Return Value

This function returns a vector of coefficients with  $(2 \times Nterms + 1)$  elements.

## Arguments

### Flow

The lower frequency of the filter as a fraction of the Nyquist frequency

### Fhigh

The upper frequency of the filter as a fraction of the Nyquist frequency. The following conditions are necessary for various types of filters:

- No Filtering:  $Flow = 0, Fhigh = 1$
- Low Pass:  $Flow = 0, 0 < Fhigh < 1$
- High Pass:  $0 < Flow < 1, Fhigh = 1$
- Band Pass:  $0 < Flow < Fhigh < 1$
- Band Stop:  $0 < Fhigh < Flow < 1$

### A

The filter power relative to the Gibbs phenomenon wiggles in decibels. 50 is a good choice.

## Nterms

The number of terms used to construct the filter.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. The default is `/DOUBLE` if the *Flow* input is double precision, otherwise the default is `DOUBLE=0`.

## Examples

```
; Get coefficients:
Coeff = DIGITAL_FILTER(Flow, Fhigh, A, Nterms)
; Apply the filter:
Yout = CONVOL(Yin, Coeff)
```

## Version History

Original	Introduced
5.6	Added DOUBLE keyword

# DILATE

The DILATE function implements the morphologic dilation operator on both binary and grayscale images. For details on using DILATE, see [“Using DILATE”](#) on page 621.

## Using DILATE

Mathematical morphology is a method of processing digital images on the basis of shape. A discussion of this topic is beyond the scope of this manual. A suggested reference is: Haralick, Sternberg, and Zhuang, “Image Analysis Using Mathematical Morphology,” *IEEE Transactions on Pattern Analysis and Machine Intelligence*, Vol. PAMI-9, No. 4, July, 1987, pp. 532-550. Much of this discussion is taken from that article.

Briefly, the DILATE function returns the dilation of *Image* by the structuring element *Structure*. This operator is commonly known as “fill”, “expand”, or “grow.” It can be used to fill “holes” of a size equal to or smaller than the structuring element.

Used with binary images, where each pixel is either 1 or 0, dilation is similar to convolution. Over each pixel of the image, the origin of the structuring element is overlaid. If the image pixel is nonzero, each pixel of the structuring element is added to the result using the “or” operator.

Letting  $A \oplus B$  represent the dilation of an image  $A$  by structuring element  $B$ , dilation can be defined as:

$$C = A \oplus B = \bigcup_{b \in B} (A)_b$$

where  $(A)_b$  represents the translation of  $A$  by  $b$ . Intuitively, for each nonzero element  $b_{i,j}$  of  $B$ ,  $A$  is translated by  $i,j$  and summed into  $C$  using the “or” operator. For example:

$$\begin{array}{r} 0100 \\ 0100 \\ 0110 \oplus 11 = 0111 \\ 1000 \\ 0000 \end{array} \quad \begin{array}{r} 0110 \\ 0110 \\ 0111 \\ 1100 \\ 0000 \end{array}$$

In this example, the origin of the structuring element is at (0,0).

Used with grayscale images, which are always converted to byte type, the DILATE function is accomplished by taking the maximum of a set of sums. It can be used to conveniently implement the neighborhood maximum operator with the shape of the neighborhood given by the structuring element.

### Openings and Closings

The *opening* of image  $B$  by structuring element  $K$  is defined as  $(B \otimes K) \oplus K$ . The *closing* of image  $B$  by  $K$  is defined as  $(B \oplus K) \otimes K$  where the  $\otimes$  symbol represents the erosion operator implemented by the IDL ERODE function.

As stated by Haralick *et al*, the result of iteratively applied dilations and erosions is an elimination of specific image detail smaller than the structuring element without the global geometric distortion of unsuppressed features. For example, opening an image with a disk structuring element smooths the contour, breaks narrow isthmuses, and eliminates small islands and sharp peaks or capes.

Closing an image with a disk structuring element smooths the contours, fuses narrow breaks and long thin gulfs, eliminates small holes, and fills gaps on the contours.

#### Note

---

MORPH\_OPEN and MORPH\_CLOSE can also be used to perform these tasks.

---

## Syntax

```
Result = DILATE( Image, Structure [, X0 [, Y0 [, Z0]]] [, /CONSTRAINED
  [, /BACKGROUND=value]] [, /GRAY [, /PRESERVE_TYPE | , /UINT |
  , /ULONG]] [, /VALUES=array] )
```

## Return Value

The DILATE function returns the dilation of *Image* by the structuring element *Structure*.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the dilation is to be performed. If the parameter is not of byte type, a temporary byte copy is obtained. If neither of

the keywords `GRAY` or `VALUES` is present, the image is treated as a binary image with all nonzero pixels considered as 1.

## Structure

A one-, two-, or three-dimensional array that represents the structuring element. Elements are interpreted as binary: values are either zero or nonzero. This argument must have the same number of dimensions as *Image*.

## $X_0, Y_0, Z_0$

Optional parameters specifying the one-, two-, or three-dimensional coordinate of the structuring element's origin. If omitted, the origin is set to the center,  $([N_x/2], [N_y/2], [N_z/2])$ , where  $N_x$ ,  $N_y$ , and  $N_z$  are the dimensions of the structuring element array. The origin need not be within the structuring element.

## Keywords

### BACKGROUND

Set this keyword to the pixel value that is to be considered the background when dilation is being performed in constrained mode. The default value is 0.

### CONSTRAINED

If this keyword is set and grayscale dilation has been selected, the dilation algorithm will operate in constrained mode. In this mode, a pixel is set to the value determined by normal grayscale dilation rules in the output image only if the current value destination pixel value matches the `BACKGROUND` pixel value. Once a pixel in the output image has been set to a value other than the `BACKGROUND` value, it cannot change.

### GRAY

Set this keyword to perform grayscale, rather than binary, dilation. The nonzero elements of the *Structure* parameter determine the shape of the structuring element (neighborhood). If `VALUES` is not present, all elements of the structuring element are 0, yielding the neighborhood maximum operator.

### PRESERVE\_TYPE

Set this keyword to return the same type as the input array. This keyword only applies if the `GRAY` keyword is set.

## UINT

Set this keyword to return an unsigned integer array. This keyword only applies if the GRAY keyword is set.

## ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies if the GRAY keyword is set.

## VALUES

An array with the same dimensions as *Structure* providing the values of the structuring element. The presence of this parameter implies grayscale dilation. Each pixel of the result is the maximum of the sum of the corresponding elements of VALUE and the *Image* pixel value. If the resulting sum is greater than 255, the return value is 255.

## Examples

### Note

---

Also see “[Eroding and Dilating Image Objects](#)” in Chapter 9 of the *Image Processing in IDL* manual.

---

### Example 1

This example thresholds a gray scale image at the value of 100, producing a binary image. The result is then “opened” with a 3 pixel by 3 pixel square shape operator, using the DILATE and ERODE operators. The effect is to remove holes, islands, and peninsula smaller than the shape operator:

```

; Threshold and make binary image:
B = A GE 100

; Create the shape operator:
S = REPLICATE(1, 3, 3)

; "Opening" operator:
C = DILATE(ERODE(B, S), S)

; Show the result:
TVSCL, C

```

## Example 2

For grayscale images, DILATE takes the neighborhood maximum, where the shape of the neighborhood is given by the structuring element. Elements for which the structuring element extends off the array are indeterminate. For example, assume you have the following image and structuring element:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1]
```

If the origin of the structuring element is not specified in the call to DILATE, the origin defaults to one half the width of the structuring element, which is 1 in this case. Therefore, for the first element in the image array, the structuring element is aligned with the image as depicted below:

```
  [2,1,3,3,3,3,1,2]
   ↑
  [1,1]
```

This will cause an indeterminate value for the first element in the DILATE result. If edge values are important, you must pad the image with as many zeros as there are elements in the structuring element that extend off the array, in all dimensions. In this case, you would need to pad the image with a single leading zero. If the structuring element were  $s = [1, 1, 1, 1]$ , and you specified an origin of 2, the structuring element would align with the image as follows:

```
    [2,1,3,3,3,3,1,2]
     ↑           ↑
  [1,1,1,1]    [1,1,1,1]
```

Therefore, you would need to pad the image with at least two leading zeros and at least one trailing zero. You would then perform the dilation operation on the padded image, and remove the padding from the result.

The following code illustrates this method:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1] ; Structuring element
PRINT, 'Image: '
PRINT, image

PRINT, 'Dilation using no padding: '
PRINT, DILATE(image, s, /GRAY)

result = DILATE([0, image], s, /GRAY)
PRINT, 'Dilation using padding: '
PRINT, result[1:N_ELEMENTS(image)]
```

IDL prints:

```

Image:
  2  1  3  3  3  3  1  2
Dilation using no padding:
  1  3  3  3  3  3  2  2
Dilation using padding:
  2  3  3  3  3  3  2  2

```

# DINDGEN

The DINDGEN function creates a double-precision, floating-point array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$Result = DINDGEN(D_1 [, \dots, D_8])$$

## Return Value

Returns a double-precision, floating-point array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create D, a 100-element, double-precision, floating-point array with each element set to the value of its subscript, enter:

```
D = DINDGEN(100)
```

# DISSOLVE

The DISSOLVE procedure provides a digital “dissolve” effect for images. The routine copies pixels from the image (arranged into square tiles) to the display in pseudo-random order. This routine is written in the IDL language. Its source code can be found in the file `dissolve.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
DISSOLVE, Image [, DELAY=seconds] [, /ORDER] [, SIZ=pixels] [, X0=pixels]  
[, Y0=pixels]
```

## Arguments

### Image

The image to be displayed. It is assumed that the image is already scaled. Byte-valued images display most rapidly.

## Keywords

### DELAY

The wait between displaying tiles. The default is 0.01 second.

### ORDER

The Image display order: 0 = bottom up (the default), 1 = top-down.

### SIZ

Size of square tile. The default is 32 x 32 pixels.

### X0

The X offset of the lower-left corner of the image on screen, in pixels.

### Y0

The Y offset of the lower-left corner of the image on screen, in pixels.

## Examples

Display an image using 16 x 16 pixel tiles:

```
DISSOLVE, DIST(200), SIZ=16
```

## Version History

Pre 4.0	Introduced

[ERASE, TV](#)

# DIST

The DIST function creates an array in which each array element value is proportional to its frequency. This array may be used for a variety of purposes, including frequency-domain filtering.

This routine is written in the IDL language. Its source code can be found in the file `dist.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$$Result = DIST(N [, M])$$

## Return Value

Returns a rectangular array in which the value of each element is proportional to its frequency.

## Arguments

### N

The number of columns in the resulting array.

### M

The number of rows in the resulting array. If *M* is omitted, the resulting array will be *N* by *N*.

## Keywords

None.

## Examples

```
; Display the results of DIST as an image:  
TVSCL, DIST(100)

# DISTANCE\_MEASURE

The `DISTANCE_MEASURE` function computes the pairwise distance between a set of items or observations. The `DISTANCE_MEASURE` function is designed to be used with the `CLUSTER_TREE` function.

This routine is written in the IDL language. Its source code can be found in the file `distance_measure.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = DISTANCE_MEASURE( Array [, /DOUBLE] [, /MATRIX]  
    [, MEASURE=value] [, POWER_MEASURE=value] )
```

## Return Value

The *Result* is a vector of  $m*(m-1)/2$  elements containing the distance matrix in compact form. Given a distance between two items,  $D_{i,j}$ , the distances within *Result* are returned in the order:  $[D_{0,1}, D_{0,2}, \dots, D_{0,m-1}, D_{1,2}, \dots, D_{m-2,m-1}]$ .

If `MATRIX` is set, then the *Result* is an  $m$ -by- $m$  symmetric array containing the full distance matrix, with zeroes down the diagonal.

## Arguments

### Array

An  $n$ -by- $m$  array representing the coordinates (in an  $n$ -dimensional space) of  $m$  items. For example, a set of  $m$  points in a two-dimensional Cartesian space would be passed in as a 2-by- $m$  array.

## Keywords

### DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result. Set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE=0`.

## MATRIX

Set this keyword to return the distance matrix as an  $m$ -by- $m$  symmetric array. If this keyword is not set then the distance matrix is returned in compact vector form.

## MEASURE

Set this keyword to an integer giving the distance measure (the metric) to use. Possible values are:

Value	Distance
0	(Default): Euclidean distance. The Euclidean distance is defined as: $\sqrt{\sum  x_i - y_i ^2}$
1	CityBlock (Manhattan) distance. The CityBlock distance is defined as: $\sum  x_i - y_i $
2	Chebyshev distance. The Chebyshev distance is defined as: $\text{Max}( x_i - y_i )$
3	Correlative distance. The correlative distance, where $r$ is the correlation coefficient between two items, is defined as: $\sqrt{(1 - r)/2}$
4	Percent disagreement. This distance is useful for categorical data and is defined as: $(\text{Number of } x_i \neq y_i)/n$

Table 3-41: MEASURE Values

### Note

This keyword is ignored if POWER\_MEASURE is set.

## POWER\_MEASURE

Set this keyword to a scalar or a two-element vector giving the parameters  $p$  and  $r$  to be used in the power distance, defined as:

$$(\sum |x_i - y_i|^p)^{1/r}$$

If POWER\_MEASURE is a scalar then the same value is used for both  $p$  and  $r$  (this is also known as the Minkowski distance).

---

### Note

POWER\_MEASURE=1 is the same as the CityBlock distance, while POWER\_MEASURE=2 is the same as Euclidean distance.

---

## Example

```

; Given a set of points in two-dimensional space.

DATA = [ $
[1, 1], $
[1, 3], $
[2, 2.2], $
[4, 1.75], $
[4, 4], $
[5, 1], $
[5.5, 3]]

; Compute the Euclidean distance between each point.
DISTANCE = DISTANCE_MEASURE(data)

i1 = [0,0,0,0,0,0, 1,1,1,1,1, 2,2,2,2, 3,3,3, 4,4, 5]
i2 = [1,2,3,4,5,6, 2,3,4,5,6, 3,4,5,6, 4,5,6, 5,6, 6]
PRINT, 'Item# Item# Distance'
PRINT, TRANSPOSE([[i1],[i2],[distance]]), $
    FORMAT = '(I3, I7, F10.2)'

PLOT, data[0,*], data[1,*], PSYM = 6, SYMSIZE = 2, $
    XRANGE = [0,6], YRANGE = [0,5], $
    TITLE='Distance between each point'

FOR i = 0,N_ELEMENTS(distance)-1 DO $
    PLOTS, data[*], [i1[i], i2[i]], linestyle = 1

; Midpoint of each pair.

AVG = 0.5*(data[*], i1] + data[*], i2])

```

```
XYOUTS, avg[0,*], avg[1,*], ALIGN = 0.5, $  
STRTRIM(STRING(distance, format = '(F7.2)'), 2)
```

When this code is run, IDL prints:

Item#	Item#	Distance
0	1	2.00
0	2	1.56
0	3	3.09
0	4	4.24
0	5	4.00
0	6	4.92
1	2	1.28
1	3	3.25
1	4	3.16
1	5	4.47
1	6	4.50
2	3	2.05
2	4	2.69
2	5	3.23
2	6	3.59
3	4	2.25
3	5	1.25
3	6	1.95
4	5	3.16
4	6	1.80
5	6	2.06

# DLM\_LOAD

Normally, IDL system routines that reside in dynamically loadable modules (DLMs) are automatically loaded on demand when a routine from a DLM is called. The `DLM_LOAD` procedure can be used to explicitly cause a DLM to be loaded.

## Syntax

```
DLM_LOAD, DLMNameStr1 [, DLMNameStr2, ..., DLMNameStrn]
```

## Arguments

### *DLMNameStr*<sub>*n*</sub>

A string giving the name of the DLM to be loaded. `DLM_LOAD` causes each named DLM to be immediately loaded.

## Keywords

None

## Example

Force the JPEG DLM to be loaded:

```
DLM_LOAD, 'jpeg'
```

IDL prints:

```
% Loaded DLM: JPEG.
```

## Version History

5.1	Introduced
-----	------------

# DLM\_REGISTER

The DLM\_REGISTER procedure registers a Dynamically Loadable Module (DLM) in IDL that was not registered when starting IDL. This allows you to create DLMS using the MAKE\_DLL procedure and register them in your current session without having to exit and restart IDL.

## Warning

---

DLM\_REGISTER intended as a convenience to be used when testing and debugging DLMS or when running demonstration code included in the IDL distribution. It is *not* the recommended way to make Dynamically Loadable Modules known to your IDL session. By design, DLMS are registered when IDL starts; among other things, this allows programs written in the IDL language that call the routines in a DLM to be compiled before the DLM itself is loaded into IDL. The mechanism involved is described in “[Dynamically Loadable Modules](#)” in Chapter 21 of the *External Development Guide* manual; you should read and understand this section before deciding to use DLM\_REGISTER.

---

## Syntax

DLM\_REGISTER, *DLMDefFilePath*<sub>1</sub> [, *DLMDefFilePath*<sub>2</sub>, ..., *DLMDefFilePath*<sub>*n*</sub>]

## Arguments

### *DLMDefFilePath*<sub>*n*</sub>

The name of the DLM module definition file to read.

## Keywords

None.

## Version History

Introduced: 5.4

## See Also

“[Dynamically Loadable Modules](#)” in Chapter 21 of the *External Development Guide* manual

# DOC\_LIBRARY

The `DOC_LIBRARY` procedure extracts documentation headers from one or more IDL programs (procedures or functions). This command provides a standard interface to the operating-system specific `DL_DOS` and `DL_UNIX` procedures.

The documentation header of the `.pro` file in question must have the following format:

- The first line of the documentation block contains only the characters  `; +`, starting in column 1.
- The last line of the documentation block contains only the characters  `; -`, starting in column 1.
- All other lines in the documentation block contain a  `;` in column 1.

## Example Code

---

The file `template.pro` in the `general` subdirectory of the `examples` subdirectory of the IDL distribution contains a template for creating your own documentation headers.

---

This routine is supplied for users to view online documentation from their own IDL programs. Though it could be used to view documentation headers from the `lib` subdirectory of the IDL distribution, we do not recommend doing so. The documentation headers on the files in the `lib` directory are used for historical purposes—most do not contain the most current or accurate documentation for those routines. The most current documentation for IDL's built-in and library routines is found in IDL's online help system (enter `?` at the IDL prompt).

This routine is written in the IDL language. Its source code can be found in the file `doc_library.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

`DOC_LIBRARY` [, *Name*] [, `/PRINT`]

**UNIX-Only keywords:** [, `DIRECTORY=string`] [, `/MULTI`]

## Arguments

### Name

A string containing the name of the IDL routine in question. Under Windows or UNIX, *Name* can be “\*” to get information on all routines.

## Keywords

### DIRECTORY

*This keyword is only available on UNIX platforms.*

A string containing the name of the directory to search. If omitted, the current directory and !PATH are used.

### MULTI

*This keyword is only available on UNIX platforms.*

Set this keyword to allow printing of more than one file if the requested module exists in more than one directory.

### PRINT

Set this keyword to send the output of DOC\_LIBRARY to the default printer. Under UNIX, if PRINT is a string, it is interpreted as a shell command used for output with the documentation from DOC\_LIBRARY providing standard input (i.e., PRINT="cat > junk").

## Examples

To view the documentation header for the library function DIST, enter:

```
DOC_LIBRARY, 'DIST'
```

## Version History

Original	Introduced
Pre 6.1	Deprecated the FILE, PATH, and OUTPUTS keywords

For information on deprecated keywords, see [Appendix J, “Obsolete Features”](#).

[MK\\_HTML\\_HELP](#)

# DOUBLE

The DOUBLE function converts *Expression* into a double-precision floating-point value.

## Syntax

$$Result = \text{DOUBLE}(Expression[, Offset [, D_1 [, \dots, D_8]])$$

## Return Value

Returns a double-precision floating-point value or array of the specified dimensions. If *Expression* is a complex number, DOUBLE returns the real part.

## Arguments

### Expression

The expression to be converted to double-precision, floating-point.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as double-precision, floating-point data. See the description in [Chapter 13, “Working with Data in IDL”](#) in the *Building IDL Applications* manual for details.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON\_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Suppose that A contains the integer value 45. A double-precision, floating-point version of A can be stored in B by entering:

```
B = DOUBLE(A)
PRINT, B
```

IDL prints:

```
45.000000
```

# DRAW\_ROI

The DRAW\_ROI procedure draws a region or group of regions to the current Direct Graphics device. The primitives used to draw each ROI are based on the TYPE property of the given IDLanROI object. The TYPE property selects between points, polylines, and filled polygons.

## Syntax

```
DRAW_ROI, oROI [, /LINE_FILL] [, SPACING=value]
```

**Graphics Keywords:** [, CLIP=[*X<sub>0</sub>*, *Y<sub>0</sub>*, *X<sub>1</sub>*, *Y<sub>1</sub>*]] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, LINestyle={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, ORIENTATION=*ccw\_degrees\_from\_horiz*] [, PSYM=*integer*{0 to 10}] [, SYMSIZE=*value*] [, /T3D] [, THICK=*value*]

## Arguments

### oROI

A reference to an IDLanROI object to be drawn.

## Keywords

### LINE\_FILL

Set this keyword to indicate that polygonal regions are to be filled with parallel lines, rather than using the default solid fill. When using a line fill, the thickness, linestyle, orientation, and spacing of the lines may be specified by keywords.

### SPACING

The spacing, in centimeters, between the parallel lines used to fill polygons.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

**CLIP, COLOR, DATA, DEVICE, LINSTYLE, NOCLIP, NORMAL, ORIENTATION, PSYM, SYMSIZE, T3D, THICK**

## Examples

The following example displays an image and collects data for a region of interest. The resulting ROI is displayed as a filled polygon.

```

PRO roi_ex
; Load and display an image.
img=READ_DICOM(FILEPATH('mr_knee.dcm', SUBDIR=['examples', 'data']))
TV, img

; Create a polygon region object.
oROI = OBJ_NEW('IDLanROI', TYPE=2)

; Print instructions.
PRINT, 'To create a region:'
PRINT, ' Left mouse: select points for the region.'
PRINT, ' Right mouse: finish the region.'

; Collect first vertex for the region.
CURSOR, xOrig, yOrig, /UP, /DEVICE
oROI->AppendData, xOrig, yOrig
PLOTS, xOrig, yOrig, PSYM=1, /DEVICE

; Continue to collect vertices for region until right mouse button.
x1 = xOrig
y1 = yOrig
while !MOUSE.BUTTONON ne 4 do begin
    x0 = x1
    y0 = y1
    CURSOR, x1, y1, /UP, /DEVICE
    PLOTS, [x0,x1], [y0,y1], /DEVICE
    oROI->AppendData, x1, y1
endwhile
PLOTS, [x1,xOrig], [y1,yOrig], /DEVICE

; Draw the the region with a line fill.
DRAW_ROI, oROI, /LINE_FILL, SPACING=0.2, ORIENTATION=45, /DEVICE
END

```

---

# EFONT

The EFONT procedure provides a simple widget-based vector font editor and display. Use this procedure to read and/or modify a local copy of the file `hershl.chr`, located in the `resource/fonts` subdirectory of the main IDL directory, which contains the vector fonts used by IDL in plotting. This is a very rudimentary editor. Click the “Help” button on the EFONT main menu for more information.

This routine is written in the IDL language. Its source code can be found in the file `efont.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
EFONT [, Init_Font] [, /BLOCK] [, GROUP=widget_id]
```

## Arguments

### Init\_Font

The initial font index, from 3 to 29. The default is 3.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have EFONT block, any earlier calls to XMANAGER must have been called with the [NO\\_BLOCK](#) keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

## GROUP

The widget ID of the widget that calls EFONT. If GROUP is set, the death of the caller results in the death of EFONT.

## Version History

Pre 4.0	Introduced

# EIGENQL

The EIGENQL function computes the eigenvalues and eigenvectors of an  $n$ -by- $n$  real, symmetric array using Householder reductions and the QL method with implicit shifts.

This routine is written in the IDL language. Its source code can be found in the file `eigenql.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

If you are working with complex inputs, use the `LA_EIGENQL` function instead.

---

## Syntax

```
Result = EIGENQL( A [, /ABSOLUTE] [, /ASCENDING] [, /DOUBLE]  
[, EIGENVECTORS=variable] [, /OVERWRITE | , RESIDUAL=variable] )
```

## Return Value

This function returns an  $n$ -element vector containing the eigenvalues.

## Arguments

### A

An  $n$ -by- $n$  symmetric single- or double-precision floating-point array.

## Keywords

### ABSOLUTE

Set this keyword to sort the eigenvalues by their absolute value (their magnitude) rather than by their signed value.

### ASCENDING

Set this keyword to return eigenvalues in ascending order (smallest to largest). If not set or set to zero, eigenvalues are returned in descending order (largest to smallest). The eigenvectors are correspondingly reordered.

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## EIGENVECTORS

Set this keyword equal to a named variable that will contain the computed eigenvectors in an  $n$ -by- $n$  array. The  $i^{\text{th}}$  row of the returned array contains the  $i^{\text{th}}$  eigenvalue. If no variable is supplied, the array will not be computed.

## OVERWRITE

Set this keyword to use the input array for internal storage and to overwrite its previous contents.

## RESIDUAL

Use this keyword to specify a named variable that will contain the residuals for each eigenvalue/eigenvector ( $\lambda/x$ ) pair. The residual is based on the definition  $Ax - (\lambda)x = 0$  and is an array of the same size as  $A$  and the same type as *Result*. The rows of this array correspond to the residuals for each eigenvalue/eigenvector pair.

### Note

---

If the OVERWRITE keyword is set, the RESIDUAL keyword has no effect.

---

## Examples

```
; Define an n-by-n real, symmetric array:
A = [[ 5.0,  4.0,  0.0, -3.0], $
     [ 4.0,  5.0,  0.0, -3.0], $
     [ 0.0,  0.0,  5.0, -3.0], $
     [-3.0, -3.0, -3.0,  5.0]]

; Compute the eigenvalues and eigenvectors:
eigenvalues = EIGENQL(A, EIGENVECTORS = evecs, $
                    RESIDUAL = residual)

;Print the eigenvalues and eigenvectors:
PRINT, 'Eigenvalues: '
PRINT, eigenvalues
PRINT, 'Eigenvectors: '
PRINT, evecs
```

IDL prints:

```
Eigenvalues:
12.0915      6.18662      1.00000      0.721870

Eigenvectors:
-0.554531    -0.554531    -0.241745     0.571446
-0.342981    -0.342981     0.813186    -0.321646
 0.707107    -0.707107    -6.13503e-008 -6.46503e-008
 0.273605     0.273605     0.529422     0.754979
```

The accuracy of each eigenvalue/eigenvector ( $\lambda/x$ ) pair may be checked by printing the residual array:

```
PRINT, residual
```

The RESIDUAL array has the same dimensions as the input array and the same type as the result. The residuals are contained in the rows of the RESIDUAL array. All residual values should be floating-point zeros.

## Version History

5.0	Introduced
-----	------------

## See Also

[EIGENVEC](#), [LA\\_EIGENQL](#), [TRIQL](#)

# EIGENVEC

The EIGENVEC function computes the eigenvectors of an  $n$ -by- $n$  real, non-symmetric array using Inverse Subspace Iteration. Use ELMHES and HQR to find the eigenvalues of an  $n$ -by- $n$  real, nonsymmetric array.

This routine is written in the IDL language. Its source code can be found in the file `eigenvec.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

If you are working with complex inputs, use the LA\_EIGENVEC function instead.

---

## Syntax

```
Result = EIGENVEC( A, Eval [, /DOUBLE] [, ITMAX=value]
                 [, RESIDUAL=variable] )
```

## Return Value

This function returns a complex array with a column dimension equal to  $n$  and a row dimension equal to the number of eigenvalues.

## Arguments

### A

An  $n$ -by- $n$  nonsymmetric, single- or double-precision floating-point array.

### EVAL

An  $n$ -element complex vector of eigenvalues.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ITMAX

The maximum number of iterations allowed in the computation of each eigenvector. The default value is 4.

## RESIDUAL

Use this keyword to specify a named variable that will contain the residuals for each eigenvalue/eigenvector ( $\lambda/x$ ) pair. The residual is based on the definition  $Ax - \lambda x = 0$  and is an array of the same size and type as that returned by the function. The rows of this array correspond to the residuals for each eigenvalue/eigenvector pair.

## Examples

```

; Define an n-by-n real, nonsymmetric array:
A = [[1.0, -2.0, -4.0, 1.0], $
      [0.0, -2.0, 3.0, 4.0], $
      [2.0, -6.0, -1.0, 4.0], $
      [3.0, -3.0, 1.0, -2.0]]

; Compute the eigenvalues of A using double-precision
; complex arithmetic and print the result:
eval = HQR(ELMHES(A), /DOUBLE)
PRINT, 'Eigenvalues: '
PRINT, eval

evec = EIGENVEC(A, eval, RESIDUAL = residual)

; Eigenvectors are not generally unique.
; Multiply each eigenvector by a complex scaling
; factor to force the initial term to be real.
; This normalization ensures a unique solution.
FOR i=0,3 DO evec[* ,i] *= ABS(evec[0,i])/evec[0,i]

PRINT, 'Eigenvectors:'
PRINT, evec, FORMAT='(4("(",f8.5,"",f8.5,"") ) )'

PRINT, 'Residuals:'
FOR i=0,3 DO print, A ## evec[* ,i] - eval[i]*evec[* ,i], $
      FORMAT = '(4("(",g9.2,"",g9.2,"") ) )'

```

IDL prints:

```

Eigenvalues:
(0.26366252,-6.1925900) (0.26366252,6.1925900)

[ELMHES](#), [HQR](#), [LA\\_EIGENVEC](#), [TRIQL](#), [TRIRED](#)

# ELMHES

The ELMHES function reduces a real, nonsymmetric  $n$  by  $n$  array  $A$  to upper Hessenberg form. ELMHES is based on the routine `elmhes` described in section 11.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the `LA_ELMHES` function instead.

---

## Syntax

*Result* = ELMHES(  $A$  [, /COLUMN] [, /DOUBLE] [, /NO\_BALANCE] )

## Return Value

The result is an upper Hessenberg array with eigenvalues that are identical to those of the original array  $A$ . The Hessenberg array is stored in the upper triangle and the first subdiagonal. Elements below the subdiagonal should be ignored but are not automatically set to zero.

## Arguments

### A

An  $n$  by  $n$  real, nonsymmetric array.

## Keywords

### COLUMN

Set this keyword if the input array  $A$  is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## NO\_BALANCE

Set this keyword to disable balancing. By default, a balancing algorithm is applied to  $A$ . Balancing a nonsymmetric array is recommended to reduce the sensitivity of eigenvalues to rounding errors.

## Examples

See the description of the [HQR](#) for an example using this function.

## Version History

# EMPTY

The EMPTY procedure causes all buffered output for the current graphics device to be written. IDL uses buffered output on many display devices for reasons of efficiency. This buffering leads to rare occasions where a program needs to be certain that data are not waiting in a buffer, but have actually been output. EMPTY is a low-level graphics routine. IDL graphics routines generally handle flushing of buffered data transparently to the user, so the need for EMPTY is very rare.

## Syntax

EMPTY

## Arguments

None.

## Keywords

None.

## Version History

Original	Introduced

[FLUSH](#)

# ENABLE\_SYSRTN

The `ENABLE_SYSRTN` procedure enables/disables IDL system routines. This procedure is intended for use by runtime and callable IDL applications, and is not generally useful for interactive use.

## Special Cases

The following is a list of cases in which `ENABLE_SYSRTN` is unable to enable or disable a requested routine. All such attempts are simply ignored without issuing an error, allowing the application to run without error in different IDL environments:

- Attempts to enable/disable non-existent system routines.
- Attempts to enable a system routine disabled due to the mode in which IDL is licensed, as opposed to being disabled via `ENABLE_SYSRTN`, are quietly ignored (e.g. demo mode).
- The routines `CALL_FUNCTION`, `CALL_METHOD`, `CALL_PROCEDURE`, and `EXECUTE` cannot be disabled via `ENABLE_SYSRTN`. However, anything that can be called from them *can* be disabled, so this is not a significant drawback.

## Syntax

```
ENABLE_SYSRTN [, Routines ] [, /DISABLE ] [, /EXCLUSIVE ] [, /FUNCTIONS ]
```

## Arguments

### Routines

A string scalar or array giving the names of routines to be enabled or disabled. By default, these are procedures, but this can be changed by setting the `FUNCTIONS` keyword.

## Keywords

### DISABLE

By default, the Routines are enabled. Setting this keyword causes them to be disabled instead.

## EXCLUSIVE

By default, `ENABLE_SYSRTN` does not alter routines not listed in `Routines`. If `EXCLUSIVE` is set, the specified routines are taken to be the only routines that should be enabled or disabled, and all other routines have the opposite action applied.

Therefore, setting `EXCLUSIVE` and not `DISABLE` means that the routines in the `Routines` argument are enabled and all other system routines of the same type (function or procedure) are disabled. Setting `EXCLUSIVE` and `DISABLE` means that all listed routines are disabled and all others are enabled.

## FUNCTIONS

Normally, the `Routines` argument specifies the names of procedures. Set the `FUNCTIONS` keyword to manipulate functions instead.

## Examples

To disable the `PRINT` procedure:

```
ENABLE_SYSRTN, /DISABLE, 'PRINT'
```

To enable the `PRINT` procedure and disable all other procedures:

```
ENABLE_SYSRTN, /EXCLUSIVE, 'PRINT'
```

To ensure all possible functions are enabled:

```
ENABLE_SYSRTN, /DISABLE, /EXCLUSIVE, /FUNCTIONS
```

In the last example, all named functions should be disabled and all other functions should be enabled. Since no *Routines* argument is provided, this means that all routines become enabled.

## Version History

5.2.1	Introduced
-------	------------

# EOF

The EOF function tests the specified file unit for the end-of-file condition.

**Note**

The EOF function cannot be used with files opened with the RAWIO keyword to the OPEN routines. Many of the devices commonly used with RAWIO signal their end-of-file by returning a zero transfer count to the I/O operation that encounters the end-of-file.

## Syntax

*Result* = EOF(*Unit*)

## Return Value

If the file pointer is positioned at the end of the file, EOF returns true (1), otherwise false (0) is returned.

## Arguments

### Unit

The file unit to test for end-of-file.

## Keywords

None.

## Examples

If file unit number 1 is open, the end-of-file condition can be checked by examining the value of the expression EOF(1). For example, the following IDL code reads and prints a text file:

```
; Open the file test.lis:
OPENR, 1, 'test.lis'
; Define a string variable:
A = ''
; Loop until EOF is found:
WHILE ~ EOF(1) DO BEGIN
```

```
    ; Read a line of text:  
    READF, 1, A  
    ; Print the line:  
    PRINT,  
ENDWHILE  
; Close the file:  
CLOSE, 1
```

# ERASE

The ERASE procedure erases the screen of the currently selected graphics device (or starts a new page if the device is a printer). The device is reset to alphanumeric mode if it has such a mode (e.g., Tektronix terminals).

## Syntax

```
ERASE [, Background_Color] [, CHANNEL=value] [, COLOR=value]
```

## Arguments

### Background\_Color

The color index for the screen to be erased to. If this argument is omitted, ERASE resets the screen to the default background color (normally 0) stored in the system variable !P.BACKGROUND. Providing a value for *Background\_Color* overrides the default.

### Warning

---

Not all devices support this feature.

---

## Keywords

### CHANNEL

The channel or channel mask for the erase operation. This parameter has meaning only when used with devices that support TrueColor or multiple-display channels. The default value is !P.CHANNEL.

### COLOR

Specifies the background color. Using this keyword is analogous to using the *Background\_Color* argument.

## Examples

```
; Display a simple image in the current window:  
TV, DIST(255)  
  
; Erase the image from the window:  
ERASE
```

# ERF

The ERF function returns the value of the error function:

$$\text{erf}(z) = \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2} dt$$

For real input, the error function is computed using rational functions, as described in “Rational Chebyshev approximations for the error function,” W. J. Cody, *Math. Comp.*, 1969, pp. 631-638. For complex input, the error function is computed as  $\text{Sign} \times \text{IGAMMA}(0.5, Z^2)$ , where *Sign* is taken from the real part of  $Z$ .

## Syntax

*Result* = ERF(*Z*)

## Return Value

The result is double-precision if the argument is double-precision, otherwise the result is floating-point. The result always has the same structure as  $Z$ . The ERF function also accepts complex arguments.

## Arguments

**Z**

The expression for which the error function is to be evaluated.  $Z$  may be complex.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

To find the error function of 0.4 and print the result, enter:

```
PRINT, ERF(0.4D)
```

IDL prints:

```
0.42839236
```

# ERFC

The ERFC function returns the value of the complementary error function:

$$\operatorname{erfc}(z) = 1 - \operatorname{erf}(z) = \frac{2}{\sqrt{\pi}} \int_z^{\infty} e^{-t^2} dt$$

For real input, ERFC is computed using rational functions, as described in “Rational Chebyshev approximations for the error function,” W. J. Cody, *Math. Comp.*, 1969, pp. 631-638. For complex input, ERFC is computed as  $1 - \operatorname{ERF}(Z)$ .

## Syntax

*Result* = ERFC(*Z*)

## Return Value

The result is double-precision if the argument is double-precision, otherwise the result is floating-point. The result always has the same structure as *Z*. The ERFC function also accepts complex arguments.

## Arguments

### Z

The expression for which the complementary error function is to be evaluated. *Z* may be complex.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. # ERFCX

The ERFCX function returns the value of the scaled complementary error function:

$$\text{erfcx}(z) = e^{z^2} \text{erfc}(z)$$

For real input, ERFCX is computed using rational functions, as described in “Rational Chebyshev approximations for the error function,” W. J. Cody, *Math. Comp.*, 1969, pp. 631-638. For complex input, ERFCX is computed as  $\text{EXP}(Z^2)\text{ERFC}(Z)$ .

## Syntax

*Result* = ERFCX(*Z*)

## Return Value

The result is double-precision if the argument is double-precision, otherwise the result is floating-point. The result always has the same structure as *Z*. The ERFCX function also accepts complex arguments.

## Arguments

### Z

The expression for which the scaled complementary error function is to be evaluated. *Z* may be complex.

## Keywords

### Thread Pool Keywords

# ERODE

The ERODE function implements the erosion operator on binary and grayscale images and vectors. This operator is commonly known as “shrink” or “reduce”.

## Using ERODE

See the description of the [DILATE](#) function for background on morphological operators. Erosion is the dual of dilation. It does to the background what dilation does to the foreground. Briefly, given an *Image* and a structuring element, *Structure*, the ERODE function can be used to remove islands smaller than the structuring element.

Over each pixel of the image, the origin of the structuring element is overlaid. If each nonzero element of the structuring element is contained in the image, the output pixel is set to one. Letting  $A \otimes B$  represent the erosion of an image  $A$  by structuring element  $B$ , erosion can be defined as:

$$C = A \otimes B = \bigcap_{b \in B} (A)_{-b}$$

where  $(A)_{-b}$  represents the translation of  $A$  by  $b$ . The structuring element  $B$  can be visualized as a probe that slides across image  $A$ , testing the spatial nature of  $A$  at each point. If  $B$  translated by  $i,j$  can be contained in  $A$  (by placing the origin of  $B$  at  $i,j$ ), then  $i,j$  belongs to the erosion of  $A$  by  $B$ . For example:

$$\begin{array}{cc} 0100 & 0000 \\ 0100 & 0000 \\ 1110 \otimes 11 & = 1100 \\ 1000 & 0000 \\ 0000 & 0000 \end{array}$$

In this example, the origin of the structuring element is at (0, 0).

Used with grayscale images, which are always converted to byte type, the ERODE function is accomplished by taking the minimum of a set of differences. It can be used to conveniently implement the neighborhood minimum operator with the shape of the neighborhood given by the structuring element.

## Syntax

```
Result = ERODE( Image, Structure [, X0 [, Y0 [, Z0]]] [, /GRAY
[, /PRESERVE_TYPE | , /UINT | , /ULONG]] [, VALUES=array] )
```

## Return Value

The ERODE function returns the erosion of *Image* by the structuring element *Structure*.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the erosion is to be performed. If this parameter is not of byte type, a temporary byte copy is obtained. If neither of the keywords GRAY or VALUES is present, the image is treated as a binary image with all nonzero pixels considered as 1.

### Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values—either zero or nonzero. The structuring element must have the same number of dimensions as *Image*.

### X<sub>0</sub>, Y<sub>0</sub>, Z<sub>0</sub>

Optional parameters specifying the one-, two-, or three-dimensional coordinate of the structuring element's origin. If omitted, the origin is set to the center, ( $[N_x/2]$ ,  $[N_y/2]$ ,  $[N_z/2]$ ), where  $N_x$ ,  $N_y$ , and  $N_z$  are the dimensions of the structuring element array. The origin need not be within the structuring element.

## Keywords

### GRAY

Set this keyword to perform grayscale, rather than binary, erosion. Nonzero elements of the *Structure* parameter determine the shape of the structuring element (neighborhood). If VALUES is not present, all elements of the structuring element are 0, yielding the neighborhood minimum operator.

## PRESERVE\_TYPE

Set this keyword to return the same type as the input array. This keyword only applies if the GRAY keyword is set.

## UINT

Set this keyword to return an unsigned integer array. This keyword only applies if the GRAY keyword is set.

## ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies if the GRAY keyword is set.

## VALUES

An array of the same dimensions as *Structure* providing the values of the structuring element. The presence of this keyword implies grayscale erosion. Each pixel of the result is the minimum of Image less the corresponding elements of VALUE. If the resulting difference is less than zero, the return value will be zero.

## Examples

### Note

---

Also see [“Eroding and Dilating Image Objects”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

### Example 1

This example thresholds a grayscale image at the value of 100, producing a binary image. The result is then “opened” with a 3 pixel by 3 pixel square shape operator, using the ERODE and DILATE operators. The effect is to remove holes, islands, and peninsula smaller than the shape operator:

```

; Threshold and make binary image:
B = A GE 100

; Create the shape operator:
S = REPLICATE(1, 3, 3)

; "Opening" operator:
C = DILATE(ERODE(B, S), S)

; Show the result:

```

TVSCL, C

## Example 2

For grayscale images, ERODE takes the neighborhood minimum, where the shape of the neighborhood is given by the structuring element. Elements for which the structuring element extends off the array are indeterminate. For example, assume you have the following image and structuring element:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1]
```

If the origin of the structuring element is not specified in the call to ERODE, the origin defaults to one half the width of the structuring element, which is 1 in this case. Therefore, for the first element in the image array, the structuring element is aligned with the image as depicted below:

```
  [2,1,3,3,3,3,1,2]
   ↑
  [1,1]
```

This will cause an indeterminate value for the first element in the ERODE result. If edge values are important, you must pad the image with as many elements as there are elements in the structuring element that extend off the array, in all dimensions. The value of the padding elements must be the maximum value in the image, since ERODE calculates a neighborhood minimum. In this case, you would need to pad the image with a single leading 3. If the structuring element were  $s = [1, 1, 1, 1]$ , and you specified an origin of 2, the structuring element would align with the image as follows:

```
  [2,1,3,3,3,3,1,2]
   ↑           ↑
 [1,1,1,1]     [1,1,1,1]
```

Therefore, you would need to pad the image with at least two leading 3s and at least one trailing 3. You would then perform the erosion operation on the padded image, and remove the padding from the result.

The following code illustrates this method:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1] ; Structuring element
PRINT, 'Image: '
PRINT, image

PRINT, 'Erosion using no padding: '
PRINT, ERODE(image, s, /GRAY)
```

```

result = ERODE([MAX(image), image], s, /GRAY)
PRINT, 'Erosion using padding: '
PRINT, result[1:N_ELEMENTS(image)]

```

IDL prints:

```

Image:
  2  1  3  3  3  3  1  2
Erosion using no padding:
  0  1  1  3  3  3  1  1
Erosion using padding:
  2  1  1  3  3  3  1  1

```

# ERRPLOT

The ERRPLOT procedure plots error bars over a previously drawn plot.

This routine is written in the IDL language. Its source code can be found in the file `errplot.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
ERRPLOT, [ X, ] Low, High [, WIDTH=value]
```

## Arguments

### X

A vector containing the abscissa values at which the error bars are to be plotted. X only needs to be provided if the abscissa values are not the same as the index numbers of the plotted points.

### Low

A vector of lower estimates, equal to data - error.

### High

A vector of upper estimates, equal to data + error.

## Keywords

### WIDTH

The width of the error bars. The default is 1% of plot width.

## Examples

To plot symmetrical error bars where Y is a vector of data values and ERR is a symmetrical error estimate, enter:

```
; Plot data:  
PLOT, Y  
  
; Overplot error bars:  
ERRPLOT, Y-ERR, Y+ERR
```

If error estimates are non-symmetrical, provide actual error estimates in the *upper* and *lower* arguments.

```
; Plot data:  
PLOT, Y  
  
; Provide custom lower and upper bounds:  
ERRPLOT, lower, upper
```

To plot Y versus a vector of abscissas:

```
; Plot data (X versus Y):  
PLOT, X, Y  
  
; Overplot error estimates:  
ERRPLOT, X, Y-ERR, Y+ERR
```

# EXECUTE

The EXECUTE function compiles and executes one or more IDL statements contained in a string at run-time. EXECUTE is limited by two factors:

- The need to compile the string at runtime makes EXECUTE inefficient in terms of speed.
- The EXECUTE function cannot be used in code that runs in the IDL Virtual Machine.

## Warning

---

Use of the EXECUTE function is not permitted when IDL is in Virtual Machine mode. The [CALL\\_FUNCTION](#), [CALL\\_METHOD](#), and [CALL\\_PROCEDURE](#) routines do not share this limitation; in many cases, uses of EXECUTE can be replaced with calls to these routines.

---

Like the [CALL\\_PROCEDURE](#) and [CALL\\_FUNCTION](#) routines, calls to EXECUTE can be nested. However, compiling the string at run-time is inefficient. [CALL\\_FUNCTION](#) and [CALL\\_PROCEDURE](#) provide much of the functionality of EXECUTE without imposing this limitation, and should be used instead of EXECUTE whenever possible.

## Syntax

*Result* = EXECUTE(*String* [, *QuietCompile*] [, *QuietExecution*])

## Return Value

EXECUTE returns *true* (1) if the string was successfully compiled and executed. If an error occurs during either phase, the result is *false* (0).

## Arguments

### String

A string containing the command(s) to be compiled and executed. Multiple statements in the string should be separated with the “&” character. GOTO statements and labels are not allowed.

## QuietCompile

If this argument is set to a non-zero value, EXECUTE will not print compiler generated error messages (such as syntax errors) to the console or IDL Output Log. If *QuietCompile* is omitted or set to 0, EXECUTE will output such errors.

## QuietExecution

If this argument is set to a non-zero value, EXECUTE will not print error messages generated during execution to the console or IDL Output Log. If *QuietExecution* is omitted or set to 0, EXECUTE will output such errors.

## Keywords

None.

## Examples

Create a string that holds a valid IDL command and execute the command by entering:

```
com = 'PLOT, [0,1] '
void = EXECUTE(com)
```

Execute the contents of the string by entering:

```
R = EXECUTE(com)
```

A plot should appear. You can confirm that the string was successfully compiled and executed by checking that the value of R is 1.

# EXIT

The EXIT procedure quits IDL and exits back to the operating system. All buffers are flushed and open files are closed. The values of all variables that were not saved are lost.

## Syntax

```
EXIT [, /NO_CONFIRM] [, STATUS=code]
```

## Arguments

None.

## Keywords

### NO\_CONFIRM

Set this keyword to suppress any confirmation dialog that would otherwise be displayed in a GUI version of IDL such as the IDL Development Environment.

### STATUS

Set this keyword equal to an exit status code that will be returned when IDL exits. For example, on a UNIX system using the Bourne shell:

Start IDL:

```
$ idl
```

Exit IDL specifying exit status 45:

```
IDL> exit, status=45
```

Display last exit status code:

```
$ echo $?
```

The following displays:

```
45
```

# EXP

The EXP function returns the natural exponential function of *Expression*.

## Syntax

*Result* = EXP(*Expression*)

## Return Value

Returns the natural exponential function of the given *Expression*.

## Arguments

### Expression

The expression to be evaluated. If *Expression* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. The definition of the exponential function for complex arguments is:

$$\text{EXP}(x) = \text{COMPLEX}(e^R \cos I, e^R \sin I)$$

where:

$R$  = real part of  $x$ , and  $I$  = imaginary part of  $x$ . If *Expression* is an array, the result has the same structure, with each element containing the result for the corresponding element of *Expression*.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Plot a Gaussian with a  $1/e$  width of 10 and a center of 50 by entering:

```
PLOT, EXP(-(FINDGEN(100)/10. - 5.0)^2)
```

# EXPAND

The EXPAND procedure shrinks or expands a two-dimensional array, using bilinear interpolation. It is similar to the CONGRID and REBIN routines.

This routine is written in the IDL language. Its source code can be found in the file `expand.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
EXPAND, A, Nx, Ny, Result [, FILLVAL=value] [, MAXVAL=value]
```

## Arguments

### A

A two-dimensional array to be magnified.

### Nx

Desired size of the X dimension, in pixels.

### Ny

Desired size of the Y dimension, in pixels.

### Result

A named variable that will contain the magnified array.

## Keywords

### FILLVAL

Set this keyword equal to the value to use when elements larger than MAXVAL are encountered. The default is -1.

### MAXVAL

Set this keyword equal to the largest desired value. Elements greater than this value are set equal to the value of the FILLVAL keyword.

## Version History

# EXPAND\_PATH

The `EXPAND_PATH` function is used to expand a simple path-definition string into a full path listing. The returned path can be useful for setting the `!PATH`, and `!HELP_PATH` system variables, for example.

- `!PATH` is a list of locations where IDL searches for currently undefined procedures and functions.
- `!HELP_PATH` is a list of locations where IDL searches for online help files when the online help facility is used.

---

**Note**

The mechanism used by `EXPAND_PATH` to expand the path-definition string is the same as that is used to expand the contents of the `IDL_PATH`, `IDL_DLM_PATH`, and `IDL_HELP_PATH` preferences at startup. See [“The Path Definition String”](#) below for more information.

---

## The Path Definition String

`EXPAND_PATH` accepts a single argument, a scalar string that contains a simple path-definition string. `EXPAND_PATH` expands the path-definition string into a list of directories that can be assigned to the `!PATH`, `!DLM_PATH`, or `!HELP_PATH` system variables.

---

**Note**

The syntax of the path definition string describe here can also be used when setting the `IDL_PATH`, `IDL_DLM_PATH`, and `IDL_HELP_PATH` preferences. When IDL starts, it will treat the value of the preference in the same way `EXPAND_PATH` treats the path definition string.

---

IDL supports the following special notations within the path definition string:

- **Using “+”** — When IDL encounters a “+” in front of a directory name, it searches the directory and all of its subdirectories for files of the appropriate type for the given path:
  - IDL program files (`.pro` or `.sav`) if neither the `DLM` nor the `HELP` keywords to `EXPAND_PATH` are present.
  - Dynamically Loadable Module files (`.dlm`) if the `DLM` keyword to `EXPAND_PATH` is present.

- Files that can be used by IDL's online help system, if the HELP keyword to EXPAND\_PATH is present. On UNIX platforms, help files are Adobe Portable Document Format (.pdf) files, HTML format (.html or .htm) files, or have the file extension .help. On Windows systems, help files can be either HTML Help (.chm), WinHelp (.hlp), PDF (.pdf), or HTML (.html or .htm) files.

Any directory containing one or more of the appropriate type of file is added to the path.

If the "+" is *not* present, the specified directory is added to the path regardless of its contents.

### Order of Expanded Directories

When expanding a path segment starting with "+", IDL ensures that all directories containing the appropriate type files are placed in the path string. The order in which the directories in such an expanded path segment appear is completely unspecified, and does not necessarily correspond to any specific order (such as top-down alphabetized). This allows IDL to construct the path in the fastest possible way and speeds the process of loading paths at startup. This is only a problem if two subdirectories in such a hierarchy contain a file with the same name.

If the order in which "+" expands directories is a problem for your application, you should add the directories to the path explicitly and not use "+". Only the order of the files within a given "+" entry are determined by IDL. It never reorders !PATH (or !DLM\_PATH or !HELP\_PATH) in any other way. You can therefore obtain any search order you desire by writing the path explicitly.

- Using "<IDL\_DEFAULT>"** — IDL replaces any occurrence of the token <IDL\_DEFAULT> in a path definition string with the default value IDL would have used if no environment variable or preference were set. The actual value of this placeholder depends on where IDL has been installed. Hence, to view IDL's default path:

```
PRINT, EXPAND_PATH(' <IDL_DEFAULT>')
```

To append your own directory after IDL's default DLM path using the IDL\_DLM\_PATH environment variable (under UNIX):

```
% setenv IDL_DLM_PATH "<IDL_DEFAULT>:/your/path/here"
```

(Setting the Windows environment variable IDL\_DLM\_PATH to a similar string would produce the same result on a Windows system.) This substitution allows you to set up your paths without having to hard-code IDL's defaults into your startup scripts or environment variables.

Note that the actual path that the token `<IDL_DEFAULT>` expands to depends on the context in which it is used. The default path for `.pro` and `.sav` files is different from the default path for `.dlm` files or help files. To see this, enter the following statements into IDL:

```
PRINT, EXPAND_PATH('<IDL_DEFAULT>')
PRINT, EXPAND_PATH('<IDL_DEFAULT>', /DLM)
PRINT, EXPAND_PATH('<IDL_DEFAULT>', /HELP)
```

Three variations of the `<IDL_DEFAULT>` token eliminate this dependence on context:

- `<IDL_DEFAULT_PATH>` defines the default path to `.pro` and `.sav` files.
- `<IDL_DEFAULT_DLM>` defines the default path to `.dlm` files.
- `<IDL_DEFAULT_HELP>` defines the default path to help (`.pdf`, `.html`, and `.chm`) files.
- **Using “`<IDL_BIN_DIRNAME>`”** — IDL replaces any occurrence of the token `<IDL_BIN_DIRNAME>` in a path definition string with the name of the subdirectory within the installed IDL distribution where binaries for the current system are kept. This feature is useful for distributing packages of DLMs (Dynamically Loadable Modules) with support for multiple operating system and hardware combinations.
- **Using “`<IDL_VERSION_DIRNAME>`”** — IDL replaces any occurrence of the token `<IDL_VERSION_DIRNAME>` in a path definition string with a unique name for the IDL version that is currently running. This feature can be combined with `<IDL_BIN_DIRNAME>` to easily distribute packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms.

---

### Note

See “[!DLM\\_PATH](#)” on page 4814 for examples using the `<IDL_BIN_DIRNAME>` and `<IDL_VERSION_DIRNAME>` tokens.

---

## Syntax

```
Result = EXPAND_PATH( String [, /ALL_DIRS] [, /ARRAY] [, COUNT=variable]
[, /DLM] [, /HELP] )
```

## Return Value

Returns a list of directories that can be assigned to the `!PATH`, `!DLM_PATH`, or `!HELP_PATH` system variables given a string path to be expanded.

## Arguments

### String

A scalar string containing the path-definition string to be expanded. See [“The Path Definition String”](#) for details.

## Keywords

### ALL\_DIRS

Set this keyword to return all directories without concern for their contents, otherwise, `EXPAND_PATH` only returns those directories that contain `.pro` or `.sav` files.

### ARRAY

Set this keyword to return the result as a string array with each element containing one path segment. In this case, there is no need for a separator character and none is supplied. Normally, the result is a string array with the path segments separated with the correct special delimiter character for the current operating system.

### COUNT

Set this keyword to a named variable which returns the number of path segments contained in the result.

### DLM

Set this keyword to return those directories that contain IDL Dynamically Loadable Module (`.dlm`) description files.

### HELP

Set this keyword to return directories that contain help files. On UNIX platforms, help files are in Adobe Portable Document Format (`.pdf`), HTML format (`.html` or `.htm`), or have the file extension `.help`. On Windows systems, help files can be

either HTML Help (.chm), WinHelp (.hlp), PDF (.pdf), or HTML (.html or .htm) files.

## Examples

### Example 1

Assume you have the following directory structure:

```
/home
  myfile.txt
  /programs
    /pro
      myfile.pro
```

Search the /home directory and all its subdirectories, and return the directories containing .pro and .sav files:

```
PRINT, EXPAND_PATH('+/home')
```

IDL prints:

```
/home/programs/pro
```

### Example 2

Search the same directory, but this time return all directories, not just those containing .pro and .sav files:

```
PRINT, EXPAND_PATH('+home', /ALL_DIRS)
```

IDL prints:

```
/home/programs/pro:/home/programs
```

### Example 3

Print the default value of the !DLM\_PATH system variable:

```
PRINT, EXPAND_PATH('<IDL_DEFAULT>', /DLM)
```

## Version History

Pre 4.0	Introduced
5.6	Modified to use the <IDL_*_PATH> syntax

## See Also

[“IDL Environment System Variables”](#) on page 4812.

# EXPINT

The EXPINT function returns the value of the exponential integral  $E_n(x)$ .

EXPINT is based on the routine `expint` described in section 6.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = EXPINT( N, X [, /DOUBLE] [, EPS=value] [, ITER=variable]
               [, ITMAX=value] )
```

## Return Value

Returns the exponential integral  $E_n(x)$ .

## Arguments

### N

An integer specifying the order of  $E_n(x)$ .  $N$  can be either a scalar or an array.

### Note

---

If EXPINT is complex then only the real part is used for the computation.

---

### X

The value at which  $E_n(x)$  is evaluated.  $X$  can be either a scalar or an array.

Note: If an array is specified for both  $N$  and  $X$ , then EXPINT evaluates  $E_n(x)$  for each  $N_i$  and  $X_i$ . If either  $N$  or  $X$  is a scalar and the other an array, the scalar is paired with each array element in turn.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.  
Set this keyword to zero to return a single-precision result.

**Note**

---

All internal computations are done using double-precision arithmetic.

---

**EPS**

Use this keyword to specify a number close to the desired relative error. The default value is  $3.0 \times 10^{-12}$ .

**ITER**

Set this keyword equal to a named variable that will contain the actual number of iterations performed.

**ITMAX**

An input integer specifying the maximum allowed number of iterations. The default value is 100000.

**Thread Pool Keywords**

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

**Examples**

To compute the value of the exponential integral at the following X values:

```

; Define the parametric X values:
X = [1.00, 1.05, 1.27, 1.34, 1.38, 1.50]

; Compute the exponential integral of order 1:
result = EXPINT(1, X)

; Print the result:
PRINT, result

```

IDL prints:

```
0.219384 0.201873 0.141911 0.127354 0.119803 0.100020
```

This is the exact solution vector to six-decimal accuracy.

## Version History

4.0	Introduced
5.6	Added ITER keyword

[ERF](#)

# EXTRAC

The EXTRAC function returns a defined portion of an array or vector. The main advantage to EXTRAC is that, when parts of the specified subsection lie outside the bounds of the array, zeros are returned for these outlying elements. It is usually more efficient to use the array subscript ranges (the “:” operator; see “[Subscript Ranges](#)” in Chapter 15 of the *Building IDL Applications* manual) to perform such operations.

EXTRAC was originally a built-in system procedure in the PDP-11 version of IDL, and was retained in that form in the original VAX/VMS IDL for compatibility. Most applications of the EXTRAC function are more concisely written using subscript ranges (e.g., X(10:15)). EXTRAC has been rewritten as a library function that provides the same interface as the previous versions.

---

**Note**

If you know that the subarray will never lie beyond the edges of the array, it is more efficient to use array subscript ranges (the “:” operator) to extract the data instead of EXTRAC.

---

This routine is written in the IDL language. Its source code can be found in the file `extrac.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$$Result = EXTRAC(Array, C_1, C_2, \dots, C_n, S_1, S_2, \dots, S_n)$$

## Return Value

Returns any rectangular sub-matrix or portion of the parameter array.

## Arguments

### Array

The array from which the subarray will be copied.

### $C_i$

The starting subscript in *Array* for the subarray. There should be one  $C_i$  for each dimension of *Array*. These arguments must be integers.

**$S_i$** 

The size of each dimension. The result will have dimensions of  $(S_1, S_2, \dots, S_n)$ . There should be one  $S_i$  for each dimension of *Array*. These arguments must be non-negative.

**Keywords**

None.

**Examples**

Extracting elements from a vector:

```
; Create a 1000 element floating-point vector with each element set
; to the value of its subscript:
A = FINDGEN(1000)
; Extract 300 points starting at A[200] and extending to A[499]:
B = EXTRAC(A, 200, 300)
```

In the next example, the first 50 elements extracted — B[0] to B[49] — lie outside the bounds of the vector and are set to 0. The value of B[50] is the same as the value of A[0], and the value of B[51] is equal to A[1] which is 1. Enter:

```
; Create a 1000 element vector:
A = FINDGEN(1000)
; Extract 50 elements, 49 of which lie outside the bounds of A:
B = EXTRAC(A, -50, 100)
```

The following commands illustrate the use of EXTRAC with multi-dimensional arrays:

```
; Make a 64 by 64 array:
A = INTARR(64,64)
; Extract a 32 by 32 portion starting at A(20,30):
B = EXTRAC(A, 20, 30, 32, 32)
```

As suggested in the discussion above, a better way to perform the same operation as the previous line is:

```
; Use the array subscript operator instead of EXTRAC:
B = A(20:51, 30:61)
```

Extract the 20th column and 32nd row of A:

```
; Extract 20th column of A:
B = EXTRAC(A, 19, 0, 1, 64)
; Extract 32nd row of A:
B = EXTRAC(A, 0, 31, 64, 1)
```

Take a 32 BY 32 matrix from A starting at A(40,50):

```
; Note that those points beyond the boundaries of A are set to 0:  
B = EXTRAC(A, 40, 50, 32, 32)
```

# EXTRACT\_SLICE

The `EXTRACT_SLICE` function extracts a specified planar slice of volumetric data. This function allows for a rotation or vector form of the slice equation. In the vector form, the slice plane is governed by the plane equation ( $ax+by+cz+d=0$ ) and a single vector which defines the x direction. This form is more common throughout the IDL polygon interface. In the rotation form, the slicing plane can be oriented at any angle and can pass through any desired location in the volume.

This function allows for a vertex grid to be generated without sampling the data. In this form, the vertices could be used to sample additional datasets or used to form polygonal meshes. It would also be useful to return the planar mesh connectivity in this case.

Support for anisotropic data volumes is included via an `ANISOTROPY` keyword. This is an important feature in the proper interpolation of common medical imaging data.

This routine is written in the IDL language. Its source code can be found in the file `extract_slice.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = EXTRACT_SLICE( Vol, Xsize, Ysize, Xcenter, Ycenter, Zcenter, Xrot, Yrot,
    Zrot [, ANISOTROPY=[xspacing, yspacing, zspacing]] [, OUT_VAL=value]
    [, /RADIANS] [, /SAMPLE] [, VERTICES=variable] )
```

or

```
Result = EXTRACT_SLICE( Vol, Xsize, Ysize, Xcenter, Ycenter, Zcenter,
    PlaneNormal, Xvec [, ANISOTROPY=[xspacing, yspacing, zspacing]]
    [, OUT_VAL=value] [, /SAMPLE] [, VERTICES=variable] )
```

## Return Value

Returns a two-dimensional planar slice extracted from 3-D volumetric data or returns a vertex grid in the form of a `[3,n]` array of vertices.

## Arguments

### PlaneNormal

Set this input argument to a 3 element array. The values are interpreted as the normal of the slice plane.

### Xvec

Set this input argument to a 3 element array. The three values are interpreted as the 0 dimension directional vector. This should be a unit vector.

### Vol

The volume of data to slice. This argument is a three-dimensional array of any type except string or structure. The planar slice returned by `EXTRACT_SLICE` has the same data type as *Vol*.

### Xsize

The desired X size (dimension 0) of the returned slice. To preserve the correct aspect ratio of the data, Xsize should equal Ysize. For optimal results, set Xsize and Ysize to be greater than or equal to the largest of the three dimensions of *Vol*.

### Ysize

The desired Ysize (dimension 1) of the returned slice. To preserve the correct aspect ratio of the data, Ysize should equal Xsize. For optimal results, set Xsize and Ysize to be greater than or equal to the largest of the three dimensions of *Vol*.

### Xcenter

The X coordinate (index) of the point within the volume that the slicing plane passes through. The center of the slicing plane passes through *Vol* at the coordinate (*Xcenter*, *Ycenter*, *Zcenter*).

### Ycenter

The Y coordinate (index) of the point within the volume that the slicing plane passes through. The center of the slicing plane passes through *Vol* at the coordinate (*Xcenter*, *Ycenter*, *Zcenter*).

## Zcenter

The Z coordinate (index) of the point within the volume that the slicing plane passes through. The center of the slicing plane passes through *Vol* at the coordinate (*Xcenter*, *Ycenter*, *Zcenter*).

## Xrot

The X-axis rotation of the slicing plane, in degrees. Before transformation, the slicing plane is parallel to the X-Y plane. The slicing plane transformations are performed in the following order:

- Rotate *Z\_rot* degrees about the Z axis.
- Rotate *Y\_rot* degrees about the Y axis.
- Rotate *X\_rot* degrees about the X axis.
- Translate the center of the plane to *Xcenter*, *Ycenter*, *Zcenter*.

## Yrot

The Y-axis rotation of the slicing plane, in degrees.

## Zrot

The orientation Z-axis rotation of the slicing plane, in degrees.

## Keywords

### ANISOTROPY

Set this keyword to a three-element array. This array specifies the spacing between the planes of the input volume in grid units of the (isotropic) output image.

### OUT\_VAL

Set this keyword to a value that will be assigned to elements of the returned slice that lie outside of the original volume.

### RADIANS

Set this keyword to indicate that *Xrot*, *Yrot*, and *Zrot* are in radians. The default is degrees.

## SAMPLE

Set this keyword to perform nearest neighbor sampling when computing the returned slice. The default is to use bilinear interpolation. A small reduction in execution time results when SAMPLE is set and the OUT\_VAL keyword is *not* used.

## VERTICES

Set this output keyword to a named variable in which to return a [3,Xsize,Ysize] floating point array. This is an array of the x, y, z sample locations for each pixel in the normal output.

## Examples

Display an oblique slice through volumetric data:

```

; Create some data:
vol = RANDOMU(s, 40, 40, 40)

; Smooth the data:
FOR i=0, 10 DO vol = SMOOTH(vol, 3)

; Scale the smoothed part into the range of bytes:
vol = BYTSCAL(vol(3:37, 3:37, 3:37))

; Extract a slice:
slice = EXTRACT_SLICE(vol, 40, 40, 17, 17, 17, 30.0, 30.0, 0.0, $
    OUT_VAL=0B)

; Display the 2D slice as a magnified image:
TVSCALE, REBIN(slice, 400, 400)

```

### Note

Also see [“Planar Slicing of Volumetric Data”](#) in Chapter 2 of the *Image Processing in IDL* manual for a more extensive example.

## F\_CVF

The `F_CVF` function computes the cutoff value  $V$  in an F distribution with degrees of freedom in the numerator and degrees of freedom in the denominator such that the probability that a random variable  $X$  is greater than  $V$  is equal to a user-supplied probability  $P$ .

This routine is written in the IDL language. Its source code can be found in the file `f_cvf.pro` in the `lib` subdirectory of the IDL distribution.

### Syntax

$$Result = F\_CVF(P, Dfn, Dfd)$$

### Return Value

Returns the cutoff value  $V$ , given a distribution  $F$ , with specified degrees of freedom in the numerator and denominator.

### Arguments

#### P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

#### Dfn

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the F distribution numerator.

#### Dfd

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the F distribution denominator.

### Keywords

None.

## Examples

Use the following command to compute the cutoff value in an F distribution with ten degrees of freedom in the numerator and six degrees of freedom in the denominator such that the probability that a random variable  $X$  is greater than the cutoff value is 0.01. The result should be 7.87413:

```
PRINT, F_CVF(0.01, 10, 6)
```

## Version History

4.0	Introduced

[CHISQR\\_CVF](#), [F\\_PDF](#), [GAUSS\\_CVF](#), [T\\_CVF](#)

# F\_PDF

The `F_PDF` function computes the probability  $P$  that, in an F distribution with defined degrees of freedom in the numerator and denominator, a random variable  $X$  is less than or equal to a user-specified cutoff value  $V$ .

This routine is written in the IDL language. Its source code can be found in the file `f_pdf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$$Result = F\_PDF(V, Dfn, Dfd)$$

## Return Value

If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of  $V$ ,  $Dfn$ , and  $Dfd$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments are arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

## Arguments

### **V**

A scalar or array that specifies the cutoff value(s).

### **Dfn**

A positive scalar or array that specifies the number of degrees of freedom of the F distribution numerator.

### **Dfd**

A positive scalar or array that specifies the number of degrees of freedom of the F distribution denominator.

## Keywords

None.

## Examples

Use the following command to compute the probability that a random variable  $X$ , from the F distribution with five degrees of freedom in the numerator and 24 degrees of freedom in the denominator, is less than or equal to 3.90. The result should be 0.990059:

```
PRINT, F_PDF(3.90, 5, 24)
```

## Version History

4.0	Introduced

# FACTORIAL

The FACTORIAL function computes the factorial  $N!$  For integers, the factorial is computed as  $(N) \cdot (N - 1) \cdot (N - 2) \cdot \dots \cdot 3 \cdot 2 \cdot 1$ . For non-integers the factorial is computed using  $\text{GAMMA}(N+1)$ .

This routine is written in the IDL language. Its source code can be found in the file `factorial.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = FACTORIAL( *N* [, /STIRLING] [, /UL64] )

## Return Value

Returns the product of the non-negative scalar value or array of values.

## Arguments

### N

A non-negative scalar or array of values.

### Note

---

Large values of  $N$  will cause floating-point overflow errors. The maximum size of  $N$  varies with machine architecture. On machines that support the IEEE standard for floating-point arithmetic, the maximum value of  $N$  is 170. See [MACHAR](#) for a discussion of machine-specific parameters affecting floating-point arithmetic.

---

## Keywords

### STIRLING

Set this keyword to use Stirling's asymptotic formula to approximate  $N!$ :

$$N! = \sqrt{2\pi N} \left[ \frac{N}{e} \right]^N$$

where  $e$  is the base of the natural logarithm.

## UL64

Set this keyword to return the results as unsigned 64-bit integers. This keyword is ignored if `STIRLING` is set.

**Note**

Unsigned 64-bit integers will overflow for values of  $N$  greater than 20.

## Examples

Compute 20!:

```
PRINT, FACTORIAL(20)
```

IDL prints:

```
2.4329020e+18
```

## Version History

Pre 4.0	Introduced

[BINOMIAL](#), [TOTAL](#)

# FFT

The FFT function returns a result equal to the complex, discrete Fourier transform of *Array*. The result of this function is a single- or double-precision complex array.

The discrete Fourier transform,  $F(u)$ , of an  $N$ -element, one-dimensional function,  $f(x)$ , is defined as:

$$F(u) = \frac{1}{N} \sum_{x=0}^{N-1} f(x) \exp[-j2\pi ux/N]$$

And the inverse transform, (*Direction* > 0), is defined as:

$$f(x) = \sum_{u=0}^{N-1} F(u) \exp[j2\pi ux/N]$$

If the keyword **OVERWRITE** is set, the transform is performed in-place, and the result overwrites the original contents of the array.

## Running Time

For a one-dimensional FFT, running time is roughly proportional to the total number of points in *Array* times the sum of its prime factors. Let  $N$  be the total number of elements in *Array*, and decompose  $N$  into its prime factors:

$$N = 2^{K_2} \cdot 3^{K_3} \cdot 5^{K_5} \dots$$

Running time is proportional to:

$$T_0 + N(T_1 + 2K_2T_2 + T_3(3K_3 + 5K_5 + \dots))$$

where  $T_3 \sim 4T_2$ . For example, the running time of a 263 point FFT is approximately 10 times longer than that of a 264 point FFT, even though there are fewer points. The sum of the prime factors of 263 is 264 (1 + 263), while the sum of the prime factors of 264 is 20 (2 + 2 + 2 + 3 + 11).

## Syntax

```
Result = FFT( Array [, Direction] [, DIMENSION=vector] [, /DOUBLE]
             [, /INVERSE] [, /OVERWRITE] )
```

## Return Value

FFT returns a complex array that has the same dimensions as the input array. The output array is ordered in the same manner as almost all discrete Fourier transforms. Element 0 contains the zero frequency component,  $F_0$ . The array element  $F_1$  contains the smallest, nonzero positive frequency, which is equal to  $1/(N_i T_i)$ , where  $N_i$  is the number of elements and  $T_i$  is the sampling interval of the  $i^{\text{th}}$  dimension.  $F_2$  corresponds to a frequency of  $2/(N_i T_i)$ . Negative frequencies are stored in the reverse order of positive frequencies, ranging from the highest to lowest negative frequencies.

### Note

The FFT function can be performed on functions of up to eight (8) dimensions. If a function has  $n$  dimensions, IDL performs a transform in each dimension separately, starting with the first dimension and progressing sequentially to dimension  $n$ . For example, if the function has two dimensions, IDL first does the FFT row by row, and then column by column.

For an even number of points in the  $i^{\text{th}}$  dimension, the frequencies corresponding to the returned complex values are:

$$0, 1/(N_i T_i), 2/(N_i T_i), \dots, (N_i/2-1)/(N_i T_i), 1/(2T_i), -(N_i/2-1)/(N_i T_i), \dots, -1/(N_i T_i)$$

where  $1/(2T_i)$  is the Nyquist critical frequency.

For an odd number of points in the  $i^{\text{th}}$  dimension, the frequencies corresponding to the returned complex values are:

$$0, 1/(N_i T_i), 2/(N_i T_i), \dots, (N_i/2-0.5)/(N_i T_i), -(N_i/2-0.5)/(N_i T_i), \dots, -1/(N_i T_i)$$

## Arguments

### Array

The array to which the Fast Fourier Transform should be applied. If *Array* is not of complex type, it is converted to complex type. The dimensions of the result are identical to those of *Array*. The size of each dimension may be any integer value and does not necessarily have to be an integer power of 2, although powers of 2 are certainly the most efficient.

## Direction

*Direction* is a scalar indicating the direction of the transform, which is negative by convention for the forward transform, and positive for the inverse transform. If *Direction* is not specified, the forward transform is performed.

A normalization factor of  $1/N$ , where  $N$  is the number of points, is applied during the forward transform.

---

### Note

When transforming from a real vector to complex and back, it is slightly faster to set *Direction* to 1 in the real to complex FFT.

---

Note also that the value of *Direction* is ignored if the INVERSE keyword is set.

## Keywords

### DIMENSION

Set this keyword to the dimension across which to calculate the FFT. If this keyword is not present or is zero, then the FFT is computed across all dimensions of the input array. If this keyword is present, then the FFT is only calculated only across a single dimension. For example, if the dimensions of *Array* are N1, N2, N3, and DIMENSION is 2, the FFT is calculated only across the second dimension.

### DOUBLE

Set this keyword to a value other than zero to force the computation to be done in double-precision arithmetic, and to give a result of double-precision complex type. If DOUBLE is set equal to zero, computation is done in single-precision arithmetic and the result is single-precision complex. If DOUBLE is not specified, the data type of the result will match the data type of *Array*.

### INVERSE

Set this keyword to perform an inverse transform. Setting this keyword is equivalent to setting the *Direction* argument to a positive value. Note, however, that setting INVERSE results in an inverse transform even if *Direction* is specified as negative.

### OVERWRITE

If this keyword is set, and the *Array* parameter is a variable of complex type, the transform is done “in-place”. The result overwrites the previous contents of the variable.

For example, to perform a forward, in-place FFT on the variable a:

```
a = FFT(a, -1, /OVERWRITE)
```

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

### Note

Specifically, FFT will use the thread pool to overlap the inner loops of the computation when used on data with dimensions which have factors of 2, 3, 4, or 5. The prime-number DFT does not use the thread pool, as doing so would yield a relatively small benefit for the complexity it would introduce. Our experience shows that the improvement in performance from using the thread pool for FFT is highly dependent upon many factors (data length and dimensions, single vs. double precision, operating system, and hardware) and can vary between platforms.

## Examples

### Note

Also see ["Transforming Between Domains with FFT"](#) in Chapter 7 of the *Image Processing in IDL* manual.

Display the log of the power spectrum of a 100-element index array by entering:

```
PLOT, /YLOG, ABS(FFT(FINDGEN(100), -1))
```

As a more complex example, display the power spectrum of a 100-element vector sampled at a rate of 0.1 seconds per point. Show the 0 frequency component at the center of the plot and label the abscissa with frequency:

```
; Define the number of points and the interval:
N = 100
T = 0.1

; Midpoint+1 is the most negative frequency subscript:
N21 = N/2 + 1
; The array of subscripts:
F = INDGEN(N)
```

```

; Insert negative frequencies in elements F(N/2 +1), ..., F(N-1):
F[N21] = N21 -N + FINDGEN(N21-2)

; Compute T0 frequency:
F = F/(N*T)

; Shift so that the most negative frequency is plotted first:
PLOT, /YLOG, SHIFT(F, -N21), SHIFT(ABS(FFT(F, -1)), -N21)

```

Compute the FFT of a two-dimensional image by entering:

```

; Create a cosine wave damped by an exponential.
n = 256
x = FINDGEN(n)
y = COS(x*!PI/6)*EXP(-((x - n/2)/30)^2/2)

; Construct a two-dimensional image of the wave.
z = REBIN(y, n, n)
; Add two different rotations to simulate a crystal structure.
z = ROT(z, 10) + ROT(z, -45)
WINDOW, XSIZE=540, YSIZE=540
LOADCT, 39
TVSCL, z, 10, 270

; Compute the two-dimensional FFT.
f = FFT(z)
logpower = ALOG10(ABS(f)^2) ; log of Fourier power spectrum.
TVSCL, logpower, 270, 270

; Compute the FFT only along the first dimension.
f = FFT(z, DIMENSION=1)
logpower = ALOG10(ABS(f)^2) ; log of Fourier power spectrum.
TVSCL, logpower, 10, 10

; Compute the FFT only along the second dimension.
f = FFT(z, DIMENSION=2)
logpower = ALOG10(ABS(f)^2) ; log of Fourier power spectrum.
TVSCL, logpower, 270, 10

```

# FILE\_BASENAME

The FILE\_BASENAME function returns the *basename* of a *file path*. A file path is a string containing one or more segments consisting of names separated by directory delimiter characters (slash (/) under UNIX, or backslash (\) under Microsoft Windows). The basename is the final rightmost segment of the file path; it is usually a file, but can also be a directory name. See “Rules used by FILE\_BASENAME” on page 716 for additional information.

---

**Note**

FILE\_BASENAME operates on strings based strictly on their syntax. The *Path* argument need not refer to actual or existing files.

---

FILE\_BASENAME is based on the standard UNIX `basename (1)` utility.

---

**Note**

To retrieve the leftmost portion of the file path (the *dirname*), use the FILE\_DIRNAME function.

---

## Syntax

*Result* = FILE\_BASENAME(*Path* [, *RemoveSuffix*] [, /FOLD\_CASE])

## Return Value

A scalar string or string array containing the basename for each element of the *Path* argument.

## Arguments

### Path

A scalar string or string array containing paths for which the basename is desired.

---

**Note**

Under Microsoft Windows, the backslash (\) character is used to separate directories within a path. For compatibility with UNIX, and general convenience, the forward slash (/) character is also accepted as a directory separator in the *Path* argument.

---

## RemoveSuffix

An optional scalar string or 1-element string array specifying a filename suffix to be removed from the end of the basename, if present.

---

**Note**

If the entire basename string matches the suffix, the suffix is *not* removed.

---

## Keywords

### FOLD\_CASE

By default, FILE\_BASENAME follows the case sensitivity policy of the underlying operating system when attempting to match a string specified by the *RemoveSuffix* argument. By default, matches are case sensitive on UNIX platforms, and case insensitive on Microsoft Windows platforms. The FOLD\_CASE keyword is used to change this behavior. Set it to a non-zero value to cause FILE\_BASENAME to do all string matching case insensitively. Explicitly set FOLD\_CASE equal to zero to cause all string matching to be case sensitive.

---

**Note**

The value of the FOLD\_CASE keyword is ignored if the *RemoveSuffix* argument is not present.

---

## Rules used by FILE\_BASENAME

FILE\_BASENAME makes a copy of the input file path string, then modifies the copy according to the following rules:

- If *Path* is a NULL string, then FILE\_BASENAME returns a NULL string.
- If *Path* consists entirely of directory delimiter characters, the result of FILE\_BASENAME is a single directory delimiter character.
- If there are any trailing directory delimiter characters, they are removed.
- Under Microsoft Windows, remove any of the following, if present:
  - The drive letter and colon (for file paths of the form `c:\directory\file`).
  - The initial double-backslash and host name (for UNC file paths of the form `\\host\share\directory\file`).

- If any directory delimiter characters remain, all characters up to and including the last directory delimiter are removed.
- If the *RemoveSuffix* argument is present, is not identical to the characters remaining, and matches the *suffix* of the characters remaining, the suffix is removed. Otherwise, the *Result* is not modified by this step. The case sensitivity of the string comparison used in this step is controlled by the `FOLD_CASE` keyword.

## Examples

The following command prints the basename of an IDL `.pro` file, removing the `.pro` suffix:

```
PRINT, FILE_BASENAME('/usr/local/rsi/idl/lib/dist.pro', '.pro')
```

IDL prints:

```
dist
```

Similarly, the following command prints the basenames of all `.pro` files in the `lib` subdirectory of the IDL distribution that begin with the letter “I,” performing a case insensitive match for the suffix:

```
PRINT, FILE_BASENAME(FILE_SEARCH(FILEPATH('lib')+'i*.pro'),  
                      '.pro', /FOLD_CASE)
```

# FILE\_CHMOD

The FILE\_CHMOD procedure allows you to change the current access permissions (sometimes known as modes on UNIX platforms) associated with a file or directory. File modes are specified using the standard Posix convention of three protection classes (user, group, other), each containing three attributes (read, write, execute). These permissions can be specified as an octal bitmask in which desired permissions have their associated bit set and unwanted ones have their bits cleared. This is the same format familiar to users of the UNIX `chmod(1)` command).

Keywords are available to specify permissions without the requirement to specify a bitmask, providing a simpler way to handle many situations. All of the keywords share a similar behavior: Setting them to a non-zero value adds the specified permission to the *Mode* argument. Setting the keyword to 0 removes that permission.

To find the current protection settings for a given file, you can use the GET\_MODE keyword to the FILE\_TEST function.

## Syntax

```
FILE_CHMOD, File [, Mode] [, /A_EXECUTE | /A_READ | /A_WRITE]
  [, /G_EXECUTE | /G_READ | /G_WRITE] [, /NOEXPAND_PATH]
  [, /O_EXECUTE | /O_READ | /O_WRITE]
  [, /U_EXECUTE | /U_READ | /U_WRITE]
```

**UNIX-Only Keywords:** [, /SETGID] [, /SETUID] [, /STICKY\_BIT]

## Arguments

### File

A scalar or array of file or directory names for which protection modes will be changed.

### Mode

An optional bit mask specifying the absolute protection settings to be applied to the files. If *Mode* is not supplied, FILE\_CHMOD looks up the current modes for the file and uses it instead. Any additional modes specified via keywords are applied relative to the value in *Mode*. Setting a keyword adds the necessary mode bits to *Mode*, and clearing it by explicitly setting a keyword to 0 removes those bits from *Mode*.

The values of the bits in these masks correspond to those used by the UNIX `chmod(2)` system call and `chmod(1)` user command, and are given in the following table. Since these bits are usually manipulated in groups of three, octal notation is commonly used when referring to them. When constructing a mode, the following platform specific considerations should be kept in mind:

- The `setuid`, `setgid`, and sticky bits are specific to the UNIX operating system, and have no meaning elsewhere. `FILE_CHMOD` ignores them on non-UNIX systems. The UNIX kernel may quietly refuse to set the sticky bit if you are not the root user. Consult the `chmod(2)` man page for details.
- The Microsoft Windows operating system does not have 3 permission classes like UNIX does. Therefore, setting for all three classes are combined into a single request.
- The Microsoft Windows operating system always allows read access to any files visible to a program. `FILE_CHMOD` therefore ignores any requests to remove read access.
- The Microsoft Windows operating system does not maintain an execute bit for files, but instead uses the file suffix to decide if a file is executable. `FILE_CHMOD` cannot change the execution status of a file in the Windows environment; such requests are quietly ignored.

Bit	Octal Mask	Meaning
12	'4000'o	Setuid: Set user ID on execution.
11	'2000'o	Setgid: Set group ID on execution.
10	'1000'o	Turn on sticky bit. See the UNIX documentation on <code>chmod(2)</code> for details.
9	'0400'o	Allow read by owner.
8	'0200'o	Allow write by owner.
7	'0100'o	Allow execute by owner.
6	'0040'o	Allow read by group.
5	'0020'o	Allow write by group.
4	'0010'o	Allow execute by group.
3	'0004'o	Allow read by others.

Table 3-42: UNIX `chmod(2)` mode bits

Bit	Octal Mask	Meaning
2	'0002 'o	Allow write by others.
1	'0001 'o	Allow execute by others.

Table 3-42: UNIX `chmod(2)` mode bits (Continued)

## Keywords

### **A\_EXECUTE**

Execute access for all three (user, group, other) categories.

### **A\_READ**

Read access for all three (user, group, other) categories.

### **A\_WRITE**

Write access for all three (user, group, other) categories.

### **G\_EXECUTE**

Execute access for the group category.

### **G\_READ**

Read access for the group category.

### **G\_WRITE**

Write access for the group category.

### **NOEXPAND\_PATH**

Set this keyword to cause `FILE_CHMOD` to use the *File* argument exactly as specified, without applying the usual file path expansion.

### **O\_EXECUTE**

Execute access for the other category.

### **O\_READ**

Read access for the other category.

## **O\_WRITE**

Write access for the other category.

## **SETGID**

*This keyword is only available on UNIX platforms.*

The Set Group ID bit.

## **SETUID**

*This keyword is only available on UNIX platforms.*

The Set User ID bit.

## **STICKY\_BIT**

*This keyword is only available on UNIX platforms.*

Sets the sticky bit.

## **U\_EXECUTE**

Execute access for the user category.

## **U\_READ**

Read access for the user category.

## **U\_WRITE**

Write access for the user category.

## **Examples**

In the first example, we make the file `moose.dat` read only to everyone except the owner of the file, but not change any other settings:

```
FILE_CHMOD, 'moose.dat', /U_WRITE, G_WRITE=0, O_WRITE=0
```

In the next example, we make the file readable and writable to the owner and group, but read-only to anyone else, and remove any other modes:

```
FILE_CHMOD, 'moose.dat', '664'o
```

**Note**

To find the current protection settings for a given file, you can use the GET\_MODE keyword to the [FILE\\_TEST](#) function.

## Version History

5.4	Introduced
-----	------------

# FILE\_COPY

The FILE\_COPY procedure copies files, or directories of files, to a new location. The copies retain the permission settings of the original files, and belong to the user that performed the copy. See “Rules Used By FILE\_COPY” on page 725 for additional information.

FILE\_COPY copies files based on their names. To copy data between open files, see the COPY\_LUN procedure.

## Syntax

```
FILE_COPY, SourcePath, DestPath [, /ALLOW_SAME] [, /NOEXPAND_PATH]
      [, /OVERWRITE] [, /RECURSIVE] [, /REQUIRE_DIRECTORY]
      [, /VERBOSE]
```

```
UNIX-Only Keywords: [, /COPY_NAMED_PIPE] [, /COPY_SYMLINK]
      [, /FORCE]
```

## Arguments

### SourcePath

A scalar string or string array containing the names of the files or directories to be copied.

#### Note

---

If *SourcePath* contains a directory, the RECURSIVE keyword must be set.

---

### DestPath

A scalar string or string array containing the names of the destinations to which the files and directories specified by *SourcePath* are to be copied. If more than one file is to be copied to a given destination, that destination must exist and be a directory.

## Keywords

### ALLOW\_SAME

Attempting to copy a file on top of itself by specifying the same file for *SourcePath* and *DestPath* is usually considered to be an error. If the ALLOW\_SAME keyword is set, no copying is done and the operation is considered successful.

## COPY\_NAMED\_PIPE

*This keyword is only available on UNIX platforms.*

When `FILE_COPY` encounters a UNIX *named pipe* (also called a *fifo*) in *SourcePath*, it usually opens it as a regular file and attempts to copy data from it to the destination file. If `COPY_NAMED_PIPE` is set, `FILE_COPY` will instead replicate the pipe, creating a new named pipe at the destination using the system `mkfifo()` function.

## COPY\_SYMLINK

*This keyword is only available on UNIX platforms.*

When `FILE_COPY` encounters a UNIX *symbolic link* in *SourcePath*, it attempts to copy the file or directory pointed to by the link. If `COPY_SYMLINK` is set, `FILE_COPY` will instead create a symbolic link at the destination with the same name as the source symbolic link, and pointing to the same path as the source.

## FORCE

*This keyword is only available on UNIX platforms.*

Even if the `OVERWRITE` keyword is set, `FILE_COPY` does not overwrite files that have their file permissions set to prevent it. If the `FORCE` keyword is set, such files are quietly removed to make way for the overwrite operation to succeed.

### Note

---

`FORCE` does not imply `OVERWRITE`; both must be specified to overwrite a protected file.

---

## NOEXPAND\_PATH

Set this keyword to cause `FILE_COPY` to use *SourcePath* and *DestPath* exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE\\_SEARCH](#) for details on path expansion.

## OVERWRITE

Set this keyword to allow `FILE_COPY` to overwrite an existing file.

## RECURSIVE

Set this keyword to cause directories specified by *SourcePath* to be copied to *DestPath* recursively, preserving the hierarchy and names of the files from the

source. If *SourcePath* includes one or more directories, the RECURSIVE keyword *must* be set.

---

**Note**

On a UNIX system, when performing a recursive copy on a directory hierarchy that includes files that are links to other files, the destination files will be copies, not links. Setting the COPY\_SYMLINK keyword will cause files that are *symbolic* links to be copied as symbolic links, but FILE\_COPY does not include a similar facility for copying *hard* links. See the description of the [FILE\\_LINK](#) for more information on UNIX file links.

---

## REQUIRE\_DIRECTORY

Set this keyword to cause FILE\_COPY to require that *DestPath* exist and be a directory.

## VERBOSE

Set this keyword to cause FILE\_COPY to issue an informative message for every file copy operation it carries out.

## Rules Used By FILE\_COPY

The following rules govern how FILE\_COPY operates:

- The arguments to FILE\_COPY can be scalar or array. If both arguments are arrays, the arrays must contain the same number of elements; in this case, the files are copied pairwise, with each file from *SourcePath* being copied to the corresponding file in the *DestPath*. If *SourcePath* is an array and *DestPath* is a scalar, all files in *SourcePath* are copied to the single location given by *DestPath*, which must exist and be a directory.
- Elements of *SourcePath* may use wildcard characters (as accepted by the [FILE\\_SEARCH](#) function) to specify multiple files. All the files matched for a given element of *SourcePath* are copied to the location specified by the corresponding element of *DestPath*. If multiple files are copied to a single element of *DestPath*, that element must exist and be a directory.
- If a file specified in *DestPath* does not exist, the corresponding file from *SourcePath* is copied using the name specified by *DestPath*. Any parent directories to the file specified by *DestPath* must already exist.
- If *DestPath* names an existing regular file, FILE\_COPY will not overwrite it, unless the OVERWRITE keyword is specified.

- If *DestPath* names an existing directory and *SourcePath* names a regular (non-directory) file, then `FILE_COPY` creates a file with the same name as the file given by *SourcePath* within the *DestPath* directory.
- If *DestPath* specifies an existing directory and *SourcePath* also names a directory, and the `RECURSIVE` keyword is set, `FILE_COPY` checks for the existence of a subdirectory of *DestPath* with the same name as the source directory. If this subdirectory does not exist, it is created using the same permissions as the directory being copied. Then, all the files and directories underneath the source directory are copied to this subdirectory. `FILE_COPY` will refuse to overwrite existing files within the destination subdirectory unless the `OVERWRITE` keyword is in effect.

## Examples

Make a backup copy of a file named `myroutine.pro` in the current working directory:

```
FILE_COPY, 'myroutine.pro', 'myroutine.pro.backup'
```

Create a subdirectory named `BACKUP` in the current working directory and copy all `.pro` files, `makefile`, and `mydata.dat` into it:

```
FILE_MKDIR, 'BACKUP'
FILE_COPY, ['*.pro', 'makefile', 'mydata.dat'], 'BACKUP'
```

## Version History

5.6	Introduced
-----	------------

## See Also

[COPY\\_LUN](#), [FILE\\_LINK](#), [FILE\\_MOVE](#)

# FILE\_DELETE

The FILE\_DELETE procedure deletes a file or empty directory, if the process has the necessary permissions to remove the file as defined by the current operating system. FILE\_CHMOD can be used to change file protection settings.

## Note

On UNIX, if a file to be deleted is a symbolic link, FILE\_DELETE deletes the link itself, and not the file that the link points to.

## Syntax

```
FILE_DELETE, File1 [... Filen] [, /ALLOW_NONEXISTENT]  
[, /NOEXPAND_PATH] [, /QUIET] [, /RECURSIVE] [, /VERBOSE]
```

## Arguments

### *File*<sub>*j*</sub>

A scalar or array of file or directory names to be deleted, one name per string element. Directories must be specified in the native syntax for the current operating system.

## Keywords

### ALLOW\_NONEXISTENT

If set, FILE\_DELETE will quietly ignore attempts to delete a non-existent file. Other errors will still be reported. The QUIET keyword can be used instead to suppress all errors.

### NOEXPAND\_PATH

Set this keyword to cause FILE\_DELETE to use the *File* argument exactly as specified, without applying the usual file path expansion.

### QUIET

FILE\_DELETE will normally issue an error if it is unable to remove a requested file or directory. If QUIET is set, no error is issued and FILE\_DELETE simply moves on to the next requested item.

## RECURSIVE

By default, `FILE_DELETE` will refuse to delete directories that are not empty. If `RECURSIVE` is set, `FILE_DELETE` will instead quietly delete all files contained within that directory and any subdirectories below it, and then remove the directory itself.

### Warning

---

Recursive delete is a very powerful and useful operation. However, it is a relatively dangerous command with the ability to rapidly destroy a great deal of data. Once deleted, files cannot be recovered unless you have a separate backup, so a mistaken recursive delete can be very damaging. Be very careful to specify correct arguments to `FILE_DELETE` when using the `RECURSIVE` keyword.

---

## VERBOSE

The `VERBOSE` keyword causes `FILE_DELETE` to issue an informative message for every file it deletes.

## Examples

In this example, we remove an empty directory named `moose`:

```
FILE_DELETE, 'moose'
```

## Version History

5.4	Introduced
5.6	Added <code>ALLOW_NONEXISTANT</code> and <code>VERBOSE</code> keywords

# FILE\_DIRNAME

The FILE\_DIRNAME function returns the *dirname* of a *file path*. A file path is a string containing one or more segments consisting of names separated by directory delimiter characters (slash (/) under UNIX, or backslash (\) under Microsoft Windows). The dirname is all of the file path except for the final rightmost segment, which is usually a file name, but can also be a directory name. See “Rules used by FILE\_DIRNAME” on page 730 for additional information.

---

**Note**

FILE\_DIRNAME operates on strings based strictly on their syntax. The *Path* argument need not refer to actual or existing files.

---

FILE\_DIRNAME is based on the standard Unix `dirname(1)` utility.

---

**Note**

To retrieve the rightmost portion of the file path (the *basename*), use the FILE\_BASENAME function.

---

## Syntax

*Result* = FILE\_DIRNAME(*Path* [, /MARK\_DIRECTORY])

## Return Value

A scalar string or string array containing the dirname for each element of the *Path* argument.

---

**Note**

By default, the dirname does not include a final directory separator character; this behavior can be changed using the MARK\_DIRECTORY keyword.

---

---

**Note**

On Windows platforms, the string returned by FILE\_DIRNAME always uses the backslash (\) as the directory separator character, even if the slash (/) was used in the *Path* argument.

---

# Arguments

## Path

A scalar string or string array containing paths for which the `dirname` is desired.

---

### Note

Under Microsoft Windows, the backslash (\) character is used to separate directories within a path. For compatibility with UNIX, and general convenience, the forward slash (/) character is also accepted as a directory separator in the *Path* argument. However, all *results* produced by `FILE_DIRNAME` on Windows platforms use the standard backslash for this purpose, regardless of the separator character used in the input *Path* argument.

---

## Keywords

### MARK\_DIRECTORY

Set this keyword to include a directory separator character at the end of the returned directory name string. Including the directory character allows you to concatenate a file name to the end of the directory name string without having to supply the separator character manually. This is convenient for cross platform programming, as the separator characters differ between operating systems.

## Rules used by FILE\_DIRNAME

`FILE_DIRNAME` makes a copy of the input path string, and then modifies the copy according to the following rules:

- If *Path* is a NULL string, then `FILE_DIRNAME` returns a single dot (.) character, representing the current working directory of the IDL process.
- Under Microsoft Windows, a file path can start with either of the following:
  - A drive letter and a colon (for file paths of the form `c:\directory\file`).
  - An initial double-backslash and a host name (for UNC file paths of the form `\\host\share\directory\file`).

If either of these are present in *Path*, they are considered to be part of the `dirname`, and are copied to the result *without interpretation by the remaining steps below*.

- If *Path* consists entirely of directory delimiter characters, the result of `FILE_DIRNAME` is a single directory delimiter character (prefixed by a Windows drive letter and colon or a UNC prefix, if necessary).
- All characters to the right of the rightmost directory delimiter character are removed.
- All trailing directory delimiter characters are removed.
- If the `MARK_DIRECTORY` keyword is set, a single directory delimiter character is appended to the end.

## Examples

The following statements print the directory in which IDL locates the file `dist.pro` when it needs a definition for the `DIST` function. (`DIST` is part of the standard IDL user library, included with IDL):

```
temp = DIST(4) ; Ensure that DIST is compiled
PRINT, FILE_DIRNAME((ROUTINE_INFO('DIST', $
    /FUNCTION, /SOURCE)).path)
```

Depending on the platform and location where IDL is installed, IDL prints something like:

```
/usr/local/rsi/idl/lib
```

[FILE\\_BASENAME](#), [PATH\\_SEP](#), [STREGEX](#), [STRMID](#), [STRPOS](#), [STRSPLIT](#)

# FILE\_EXPAND\_PATH

The FILE\_EXPAND\_PATH function expands a given file or partial directory name to its fully qualified name and returns it regardless of the current working directory.

## Note

---

This routine should be used only to make sure that file paths are fully qualified, but not to expand wildcard characters (e.g. \*). The behavior of FILE\_EXPAND\_PATH when it encounters a wildcard is platform dependent, and should not be depended on. These differences are due to the underlying operating system, and are beyond the control of IDL. To expand wildcards and obtain fully qualified paths, use the FILE\_SEARCH function with the FULLY\_QUALIFY\_PATH keyword:

```
A = FILE_SEARCH('*.pro', /FULLY_QUALIFY_PATH)
```

Alternatively, you can use the FULLY\_QUALIFY\_PATH keyword to FILE\_SEARCH:

```
A = FILE_SEARCH('*.pro', /FULLY_QUALIFY_PATH)
```

---

## Syntax

*Result* = FILE\_EXPAND\_PATH (*Path*)

## Return Value

FILE\_EXPAND\_PATH returns a fully qualified file path that completely specifies the location of *Path* without the need to consider the user's current working directory. If *Path* is a NULL string, FILE\_EXPAND\_PATH returns the fully qualified path to the current working directory.

## Arguments

### Path

A scalar or array of file or directory names to be fully qualified.

## Keywords

None.

## Examples

In this example, we change directories to the IDL lib directory and expand the file path for the DIST function:

```
cd, FILEPATH('', SUBDIRECTORY=['lib'])
print, FILE_EXPAND_PATH('dist.pro')
```

This results in the following if run on a UNIX system:

```
/usr/local/rsi/idl_6.2/lib/dist.pro
```

## Version History

[FILE\\_SEARCH](#)

# FILE\_INFO

The FILE\_INFO function returns status information about a specified file.

## Syntax

*Result* = FILE\_INFO(*Path* [, /NOEXPAND\_PATH])

## Return Value

The FILE\_INFO function returns a structure expression of type FILE\_INFO containing status information about the specified file or files. The result will contain one structure for each element in the *Path* argument.

## Fields of the FILE\_INFO Structure

The FILE\_INFO structure consists of the following fields:

Field Name	Meaning
NAME	The name of the file.
EXISTS	True (1) if the file exists. False (0) if it does not exist.
READ	True (1) if the file is exists and is readable by the user. False (0) if it is not readable.
WRITE	True (1) if the file exists and is writable by the user. False (0) if it is not writable.
EXECUTE	True (1) if the file exists and is executable by the user. False (0) if it is not executable. The source of this information differs between operating systems: <b>UNIX:</b> IDL checks the execute bit maintained by the operating system. <b>Microsoft Windows:</b> The determination is made on the basis of the file name extension (e.g. .exe).

Table 3-43: Fields of the FILE\_INFO Structure

Field Name	Meaning
REGULAR	True (1) if the file exists and is a regular disk file and not a directory, pipe, socket, or other special file type. False (0) if it is not a regular disk file (it maybe a directory, pipe, socket, or other special file type).
DIRECTORY	True (1) if the file exists and is a directory. False (0) if it is not a directory.
BLOCK_SPECIAL	True (1) if the file exists and is a UNIX block special device. On non-UNIX operating systems, this field will always be False (0).
CHARACTER_SPECIAL	True (1) if the file exists and is a UNIX character special device. On non-UNIX operating systems, this field will always be False (0).
NAMED_PIPE	True (1) if the file exists and is a UNIX named pipe (fifo) device. On non-UNIX operating systems, this field will always be False (0).
SETGID	True (1) if the file exists and has its Set-Group-ID bit set. On non-UNIX operating systems, this field will always be False (0).
SETUID	True (1) if the file exists and has its Set-User-ID bit set. On non-UNIX operating systems, this field will always be False (0).
SOCKET	True (1) if the file exists and is a UNIX domain socket. On non-UNIX operating systems, this field will always be False (0).
STICKY_BIT	True (1) if the file exists and has its sticky bit set. On non-UNIX operating systems, this field will always be False (0).
SYMLINK	True (1) if the file exists and is a UNIX symbolic link. On non-UNIX operating systems, this field will always be False (0).

*Table 3-43: Fields of the FILE\_INFO Structure (Continued)*

Field Name	Meaning
DANGLING_SYMLINK	True (1) if the file exists and is a UNIX symbolic link that points at a non-existent file. On non-UNIX operating systems, this field will always be False (0).
ATIME, CTIME, MTIME	The date of last access, date of creation, and date of last modification given in seconds since 1 January 1970 UTC. Use the SYSTIME function to convert these dates into a textual representation.  Note that some file systems do not maintain all of these dates (e.g. MS DOS FAT file systems), and may return 0. On some non-UNIX operating systems, access time is not maintained, and ATIME and MTIME will always return the same date.
SIZE	The current length of the file in bytes. If <i>Path</i> is not to a regular file (possibly to a directory, pipe, socket, or other special file type), the value of SIZE will not contain any useful information.

Table 3-43: Fields of the FILE\_INFO Structure (Continued)

## Arguments

### Path

A string or string array containing the path or paths to the file or files about which information is required.

## Keywords

### NOEXPAND\_PATH

If specified, FILE\_INFO uses *Path* exactly as specified, without applying the usual file path expansion.

## Examples

To get information on the file `dist.pro` within the IDL User Library:

```
HELP,/STRUCTURE, FILE_INFO(FILEPATH('dist.pro', $
SUBDIRECTORY = 'lib'))
```

Executing the above command will produce output similar to:

```
** Structure FILE_INFO, 21 tags, length=72:
NAME                STRING      '/usr/local/rsi/idl/lib/dist.pro'
EXISTS              BYTE        1
READ                BYTE        1
WRITE              BYTE        0
EXECUTE            BYTE        0
REGULAR            BYTE        1
DIRECTORY          BYTE        0
BLOCK_SPECIAL      BYTE        0
CHARACTER_SPECIAL  BYTE        0
NAMED_PIPE         BYTE        0
SETGID             BYTE        0
SETUID             BYTE        0
SOCKET            BYTE        0
STICKY_BIT        BYTE        0
SYMLINK           BYTE        0
DANGLING_SYMLINK  BYTE        0
MODE              LONG        420
ATIME             LONG64     970241431
CTIME            LONG64     970241595
MTIME           LONG64     969980845
SIZE             LONG64     1717
```

## FILE\_LINES

The `FILE_LINES` function reports the number of lines of text contained within the specified file or files.

Text files containing data are very common. To read such a file usually requires knowing how many lines of text it contains. Under UNIX and Windows, there is no special text file type, and it is not possible to tell how many lines are contained in a file from basic file attributes. Rather, lines are encoded using a special character or characters at the end of each line:

- UNIX operating systems use an ASCII linefeed (LF) character at the end of each line.
- Older Macintosh systems (prior to the UNIX-based Mac OS X) use a carriage return (CR).
- Microsoft Windows uses a two character CR/LF sequence.

The only way to determine the number of lines of text contained within a file is to open it and count lines while reading and skipping over them until the end of the file is encountered. Since files are often copied from one type of system to another without going through the proper line termination conversion, portable software needs to be able to recognize any of these terminations, regardless of the system being used. `FILE_LINES` performs this operation in an efficient and portable manner, handling all three of the line termination conventions listed above.

This routine works by opening the file and reading the data contained within. It is therefore only suitable for regular disk files, and only when access to that file is fast enough to justify reading it more than once. For other types of files, other approaches are necessary, such as:

- Reading the file once, using an adaptive (expandable) data structure, counting the number of lines as they are input, and growing the data structure as necessary.
- Building a header into your file format that includes the necessary information, or somehow embedding the number of lines into the file data.
- Maintaining file information in a separate file associated with each file.
- Using a self describing data format that avoids these issues.

This routine assumes that the specified file or files contain only lines of text. It is unable to correctly count lines in files that contain binary data, or which do not use the standard line termination characters. Results are undefined for such files.

Note that `FILE_LINES` is equivalent to the following IDL code:

```
FUNCTION file_lines, filename
  OPENR, unit, filename, /GET_LUN
  str = ''
  count = 0
  WHILE ~ EOF(unit) DO BEGIN
    READF, unit, str
    count = count + 1
  ENDWHILE
  FREE_LUN, unit
  RETURN, count
END
```

The primary advantage of `FILE_LINES` over the IDL version shown here is efficiency. `FILE_LINES` is able to avoid the overhead of the `WHILE` loop as well as not having to create an IDL string for each line of the file.

## Syntax

*Result* = `FILE_LINES(Path [, /COMPRESS] [, /NOEXPAND_PATH] )`

## Return Value

Returns the number of lines of text contained within the specified file or files. If an array of file names is specified via the *Path* parameter, the return value is an array with the same number of elements as *Path*, with each element containing the number of lines in the corresponding file.

## Arguments

### Path

A scalar string or string array containing the names of the text files for which the number of lines is desired.

## Keywords

### COMPRESS

If this keyword is set, `FILE_LINES` assumes that the files specified in *Path* contain data compressed in the standard GZIP format, and decompresses the data in order to count the number of lines. See the description of the `COMPRESS` keyword to the [OPENR/OPENU/OPENW](#) procedure for additional information.

## NOEXPAND\_PATH

If this keyword is set, `FILE_LINES` uses *Path* exactly as specified, without expanding any wildcard characters or environment variable names included in the path. See [FILE\\_SEARCH](#) for details on path expansion.

## Examples

Read the contents of the text file `mydata.dat` into a string array.

```
nlines = FILE_LINES('mydata.dat')
sarr = STRARR(nlines)
OPENR, unit, 'mydata.dat', /GET_LUN
READF, unit, sarr
FREE_LUN, unit
```

## Version History

5.6	Introduced
6.0	Added COMPRESS keyword

# FILE\_LINK

The `FILE_LINK` procedure creates UNIX file links, both regular (hard) and symbolic. `FILE_LINK` is available only under UNIX.

A hard link is a directory entry that references a file. UNIX allows multiple such links to exist simultaneously, meaning that a given file can be referenced by multiple names. All such links are fully equivalent references to the same file (there are no concepts of primary and secondary names). All files carry a reference count that contains the number of hard links that point to them; deleting a link to a file does not remove the actual file from the filesystem until the last hard link to the file is removed. The following limitations on hard links are enforced by the operating system:

- Hard links may not span filesystems, as hard linking is only possible within a single filesystem.
- Hard links may not be created between directories, as doing so has the potential to create infinite circular loops within the hierarchical UNIX filesystem. Such loops will confuse many system utilities, and can even cause filesystem damage.

A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span filesystems and may refer to directories.

Many users find symbolic links easier to understand and use. Due to their generality and lack of restriction, RSI recommends their use over hard links for most purposes. `FILE_LINK` creates symbolic links by default.

See “[Rules Used by FILE\\_LINK](#)” on page 742 for information on how `FILE_LINK` interprets its arguments.

## Syntax

```
FILE_LINK, SourcePath, DestPath [, /ALLOW_SAME] [, /HARDLINK]  
[, /NOEXPAND_PATH] [, /VERBOSE]
```

## Arguments

### SourcePath

A scalar string or string array containing the names of the files or directories to be linked.

## DestPath

A scalar string or string array containing the names of the destinations to which the files and directories given by *SourcePath* are to be linked. If more than one file is to be linked to a given destination, that destination must exist and be a directory.

## Keywords

### ALLOW\_SAME

Attempting to link a file to itself by specifying the same file for *SourcePath* and *DestPath* is usually considered to be an error. If the ALLOW\_SAME keyword is set, no link is created and the operation is considered to be successful.

### HARDLINK

Set this keyword to create hard links. By default, FILE\_LINK creates symbolic links.

### NOEXPAND\_PATH

Set this keyword to cause FILE\_LINK to use *SourcePath* and *DestPath* exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE\\_SEARCH](#) for details on path expansion.

### VERBOSE

Set this keyword to cause FILE\_LINK to issue an informative message for every file link operation it carries out.

## Rules Used by FILE\_LINK

The following rules govern how FILE\_LINK operates:

- The arguments to FILE\_LINK can be scalar or array. If both arguments are arrays, they must contain the same number of elements, and the files are paired, with each file from *SourcePath* being linked to the corresponding file in the *DestPath*. If *SourcePath* is an array and *DestPath* is a scalar, all links are created in the single location given by *DestPath*, which must exist and be a directory.

- Elements of *SourcePath* may use wildcard characters (as accepted by the [FILE\\_SEARCH](#) function) to specify multiple files. All the files matched for a given element of *SourcePath* are linked to the corresponding element of *DestPath*. If multiple files are linked to a single element of *DestPath*, that element must exist and be a directory.
- If a file specified in *DestPath* does not exist, the corresponding file from *SourcePath* is linked using the name specified by *DestPath*. Any parent directories to the filename specified by *DestPath* must already exist.
- If *DestPath* names an existing regular file, `FILE_LINK` will not overwrite it.
- If *DestPath* names an existing directory, a link with the same name as the source file is created in the directory. This is primarily of interest with hard links.

## Examples

Create a symbolic link named `current.dat` in the current working directory, pointing to the file `/master/data/saturn7.dat`:

```
FILE_LINK, '/master/data/saturn7.dat', 'current.dat'
```

# FILE\_MKDIR

The FILE\_MKDIR procedure creates a new directory, or directories, with the default access permissions for the current process.

## Note

---

Use the FILE\_CHMOD procedure to alter access permissions.

---

If a specified directory has non-existent parent directories, FILE\_MKDIR automatically creates all the intermediate directories as well.

## Syntax

```
FILE_MKDIR, File1 [... FileN] [, /NOEXPAND_PATH]
```

## Arguments

### FileN

A scalar or array of directory names to be created, one name per string element. Directories must be specified in the native syntax for the current operating system.

## Keywords

### NOEXPAND\_PATH

Set this keyword to cause FILE\_MKDIR to use the *File* argument exactly as specified, without applying the usual file path expansion.

## Examples

To create a subdirectory named `moose` in the current working directory:

```
FILE_MKDIR, 'moose'
```

## Version History

5.4	Introduced
-----	------------

# FILE\_MOVE

The FILE\_MOVE procedure renames files and directories, effectively moving them to a new location. The moved files retain their permission and ownership attributes. Within a given filesystem or volume, FILE\_MOVE does not copy file data. Rather, it simply changes the file names by updating the directory structure of the filesystem. This operation is fast and safe, but is only possible within a single filesystem. Attempts to move a regular file from one filesystem to another are carried out by copying the file using FILE\_COPY, and then deleting the original file. It is an error to attempt to use FILE\_MOVE to move a directory from one filesystem to another.

See “[Rules Used by FILE\\_MOVE](#)” on page 746 for information on how FILE\_MOVE interprets its arguments.

## Syntax

```
FILE_MOVE, SourcePath, DestPath [, /ALLOW_SAME] [, /NOEXPAND_PATH]  
[, /OVERWRITE] [, /REQUIRE_DIRECTORY] [, /VERBOSE]
```

## Arguments

### SourcePath

A scalar string or string array containing the names of the files or directories to be moved.

### DestPath

A scalar string or string array containing the names of the destinations to which the files and directories specified by *SourcePath* are to be moved. If more than one file is to be moved to a given destination, that destination must exist and be a directory.

## Keywords

### ALLOW\_SAME

Attempting to move a file on top of itself by specifying the same file for *SourcePath* and *DestPath* is usually considered to be an error. If the ALLOW\_SAME keyword is set, no renaming is done and the operation is considered to be successful.

## NOEXPAND\_PATH

Set this keyword to cause `FILE_MOVE` to use *SourcePath* and *DestPath* exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE\\_SEARCH](#) for details on path expansion.

## OVERWRITE

Set this keyword to allow `FILE_MOVE` to overwrite an existing file.

## REQUIRE\_DIRECTORY

Set this keyword to cause `FILE_MOVE` to require that *DestPath* exist and be a directory.

## VERBOSE

Set this keyword to cause `FILE_MOVE` to issue an informative message for every file move operation it carries out.

## Rules Used by FILE\_MOVE

The following rules govern how `FILE_MOVE` operates:

- The arguments to `FILE_MOVE` can be scalar or array. If both arguments are arrays, they must contain the same number of elements, and the files are moved in pairs, with each file from *SourcePath* being renamed to the corresponding file in the *DestPath*. If *SourcePath* is an array and *DestPath* is a scalar, all files in *SourcePath* are renamed to the single location given by *DestPath*, which must exist and be a directory.
- Elements of *SourcePath* may use wildcard characters (as accepted by the [FILE\\_SEARCH](#) function) to specify multiple files. All the files matched for that element of *SourcePath* are renamed to the location specified by the corresponding element of *DestPath*. If multiple files are renamed to a single element of *DestPath*, that element must exist and be a directory.
- If a file specified in *DestPath* does not exist, the corresponding file from *SourcePath* is moved using the name specified by *DestPath*. Any parent directories to the filename specified by *DestPath* must already exist.
- If *DestPath* names an existing regular file, `FILE_MOVE` will not overwrite it, unless the `OVERWRITE` keyword is specified.
- If *DestPath* names an existing directory and *SourcePath* names a regular (non-directory) file, the source file is moved into the specified directory.

- If *DestPath* specifies an existing directory and *SourcePath* also names a directory, `FILE_MOVE` checks for the existence of a subdirectory of *DestPath* with the same name as the source directory. If this subdirectory does not exist, the source directory is moved to the specified location. If the subdirectory does exist, an error is issued, and the rename operation is not carried out.

## Examples

Rename the file `backup.dat` to `primary.dat` in the current working directory:

```
FILE_MOVE, 'backup.dat', 'primary.dat'
```

Create a subdirectory named `BACKUP` in the current working directory and move all `.pro` files, `makefile`, and `mydata.dat` into it:

```
FILE_MKDIR, 'BACKUP'  
FILE_MOVE, ['*.pro', 'makefile', 'mydata.dat'], 'BACKUP'
```

[COPY\\_LUN](#), [FILE\\_COPY](#), [FILE\\_LINK](#)

# FILE\_POLL\_INPUT

Given a list of file logical units (LUNs), the `FILE_POLL_INPUT` function will *block* (not return) until it detects that a read operation for a byte of data from at least one of the specified files will succeed. On return, `FILE_POLL_INPUT` reports True (1) for each file for which a read operation will succeed, or False (0) for those that will not succeed.

This operation is of particular interest when using internet socket files opened with the `SOCKET` procedure. If a program opens multiple sockets and reads from any one of them, the read operation will block until data becomes available from the server on the other end of the connection. While blocked in an input operation, the program is unable to respond to data that might become available on any of the other sockets. This can be a serious problem, since latencies on internet connections can be large, and response times inconsistent. The solution to this problem is to block in `FILE_POLL_INPUT`, giving it the file LUNs of all the open socket files. `FILE_POLL_INPUT` will wait until one or more of the specified files has data available, and then return the blocking status of each file.

If `FILE_POLL_INPUT` returns False for a given file, your program can safely assume that a read operation on that file will block for an arbitrary amount of time until data becomes available. If it returns True, the current situation is one of the following:

- There is at least one byte of data immediately available
- An input operation on that file will immediately generate an error. For example, a file that is at EOF (end of file) will be reported as True

In other words, a True value from `FILE_POLL_INPUT` ensures that an input operation will not block, not that it will necessarily succeed.

In the case where a True value from `FILE_POLL_INPUT` means that there is data available, the guarantee only applies to a single byte of data. If your program is expecting to read more than a single byte, the possibility exists that your program will still block while waiting for data beyond the first byte. In cases where this is a critical concern, you may need to use repeated calls to `FILE_POLL_INPUT`, reading your data one byte at a time. In the vast majority of cases this is unnecessary — the presence of the first byte of data is a strong indication that the rest of the data is either present or will be present in the very near future. For example, if you are reading a 4-byte integer, the presence of the 1st byte is a fairly safe indication that the following 3 bytes are also available.

FILE\_POLL\_INPUT will return immediately if used with any of the following types of files:

- A regular disk file (even if it physically resides on network based storage)
- The standard input LUN, if IDL is running with the IDLDE graphical user interface

Since these file types always return True, there is no reason to ever pass one to FILE\_POLL\_INPUT. FILE\_POLL\_INPUT is therefore of primary interest when used with sockets. Under UNIX operating systems, it can also be used with ttys, pipes, and other device special files.

## Syntax

```
Result = FILE_POLL_INPUT(Units [, COUNT=variable] [, TIMEOUT=value] )
```

## Return Value

The result is an array of byte values with the same structure as *Units*. Each element of the returned array is set to True (1) or False (0), reflecting whether an input operation on the corresponding LUN in *Units* will succeed or not.

## Arguments

### Units

A scalar or array of IDL logical file units (LUNs) to be tested. All specified files must be open for input.

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of True results. If none of the specified files returns True, the variable will contain zero (0).

### TIMEOUT

By default, FILE\_POLL\_INPUT does not return until at least one of the specified files will yield a True value. To change this behavior, set the TIMEOUT keyword equal to a double-precision floating-point value specifying the number of seconds to

wait (at most) before the function will return. If TIMEOUT is specified, its value is interpreted as follows:

< 0	Do not return until at least one file yields True (the default behavior).
0	Test the files and return immediately.
> 0	Wait until at least one file yields True <i>or</i> until the specified timeout period expires. In this form, the TIMEOUT keyword places a worst-case bound on the amount of time that will elapse before FILE_POLL_INPUT returns.

[SOCKET](#)

# FILE\_READLINK

The FILE\_READLINK function returns the path pointed to by UNIX symbolic links.

## Syntax

```
Result = FILE_READLINK(Path [, /ALLOW_NONEXISTENT]  
[, /ALLOW_NONSYMLINK] [, /NOEXPAND_PATH] )
```

## Return Value

Returns the path associated with a symbolic link.

## Arguments

### Path

A scalar string or string array containing the names of the symbolic links to be translated.

## Keywords

### ALLOW\_NONEXISTENT

Set this keyword to return a NULL string rather than throwing an error if *Path* contains a non-existent file.

### ALLOW\_NONSYMLINK

Set this keyword to return a NULL string rather than throwing an error if *Path* contains a path to a file that is not a symbolic link.

### NOEXPAND\_PATH

Set this keyword to cause FILE\_READLINK to use *Path* exactly as specified, without expanding any wildcard characters or environment variable names included in the path. See [FILE\\_SEARCH](#) for details on path expansion.

## Examples

Under Mac OS X, the `/etc` directory is actually a symbolic link. The following statement reads it and returns the location to which the link points:

```
path = FILE_READLINK('/etc')
```

It is possible to have chains of symbolic links, each pointing to another. The following function uses `FILE_READLINK` to iteratively translate such links until it finds the actual file:

```
FUNCTION RESOLVE_SYMLINK, path

  savepath = path      ; Remember last successful translation
  WHILE (path NE '') DO BEGIN
    path = FILE_READLINK(path, /ALLOW_NONEXISTENT, $
      /ALLOW_NONSYMLINK)
    IF (path NE '') THEN BEGIN
      ; If returned path is not absolute, use it to replace the
      ; last path segment of the previous path.
      IF (STRMID(path, 0, 1) NE '/') THEN BEGIN
        last = STRPOS(savepath, '/', /REVERSE_SEARCH)
        IF (last NE -1) THEN path = STRMID(savepath, 0, last) $
          + '/' + path
      ENDIF
      savepath = path
    ENDIF
  ENDWHILE

  ; FILE_EXPAND_PATH removes redundant things like ./ from
  ; the result.
  RETURN, FILE_EXPAND_PATH(savepath)

END
```

## Version History

5.6	Introduced

[FILE\\_LINK](#)

## FILE\_SAME

It is common for a given file to be accessible via more than one name. For example, a relative path and a fully-qualified path to the same file are considered different names, since the strings that make up the paths are not lexically identical. In addition, under UNIX, the widespread use of links (hard and symbolic) makes multiple names for the same file very common.

The `FILE_SAME` function is used to determine if two different file names refer to the same underlying file.

The mechanism used to determine whether two names refer to the same file depends on the operating system in use:

**UNIX:** Under UNIX, all files are uniquely identified by two integer values: the filesystem that contains the file and the *inode number*, which identifies the file within the filesystem. If the input arguments are lexically identical, `FILE_SAME` will return True, regardless of whether the file specified actually exists. Otherwise, `FILE_SAME` compares the device and inode numbers of the two files, and returns True if they are identical, or False otherwise.

**Windows:** Unlike UNIX, Microsoft Windows identifies files solely by their names. `FILE_SAME` therefore expands the two supplied paths to their fully qualified forms, converts any “8.3 short names” to their real names, and then performs a simple case insensitive string comparison to determine if the paths are identical. (See “[Microsoft Windows “8.3 Short Names”](#)” on page 769 for more information on this subject). This is reliable for local disk files, but can produce incorrect results under some circumstances:

- UNC network paths can expand to different, but equivalent, paths. For example, a network server may be referred to by either a name or an IP address.
- Network attached storage can have mechanisms for giving multiple names to the same file, but to the Windows client system the names will appear to refer to different files. For example, a UNIX server using Samba software to serve files to machines on a Windows network can use symbolic links to produce two names for the same file, but these will appear as two distinct files to a Windows machine.

For these reasons, `FILE_SAME` is primarily of interest on UNIX systems. Under Windows, RSI recommends its use only on local files.

## Syntax

Result = FILE\_SAME(*Path1*, *Path2* [, /NOEXPAND\_PATH] )

## Return Value

FILE\_SAME returns True (1) if two filenames refer to the same underlying file, or False (0) otherwise. If either or both of the input arguments are arrays of file names, the result is an array, following the same rules as standard IDL operators.

## Arguments

### Path1, Path2

Scalar or array string values containing the two file paths to be compared.

## Keywords

### NOEXPAND\_PATH

Set this keyword to cause FILE\_SAME to use the *Path* arguments exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE\\_SEARCH](#) for details on path expansion. The utility of doing this depends on the operating system in use:

**UNIX:** Under UNIX, path expansion is not necessary unless the *Path* arguments use shell meta characters or environment variables.

**Windows:** By default, FILE\_SAME expands the supplied paths to their fully qualified forms in order to be able to compare them. Preventing this path expansion cripples its ability to make a useful comparison, and is not recommended.

## Examples

UNIX command shells often provide the HOME environment variable to point at the user's home directory. Many shells also expand the '~' character to point at the home directory. The following IDL statement determines if these two mechanisms refer to the same directory:

```
PRINT, FILE_SAME('~', '$HOME')
```

On a UNIX system, the following statement determines if the current working directory is the same as your home directory:

```
PRINT, FILE_SAME('.', '$HOME')
```

On some BSD-derived UNIX systems, the three commands `/bin/cp`, `/bin/ln`, and `/bin/mv` are actually three hard links to the same binary file. The following statement will print the number 1 if this is true on your system:

```
PRINT, TOTAL(FILE_SAME('/bin/cp', ['/bin/ln', '/bin/mv'])) EQ 2
```

Under Mac OS X, the `/etc` directory is actually a symbolic link to `/private/etc`. As a result, the following lines of code provide a simple test to determine whether Mac OS X is the current platform:

```
IF FILE_SAME('/etc', '/private/etc') THEN $
PRINT, 'Running Mac OS X' ELSE $
PRINT, 'Not Running Mac OS X'
```

---

### Note

The above lines are shown simply as an example; checking the value of `!VERSION.OS_FAMILY` is a more reliable method of determining which operating system is in use.

[FILE\\_EXPAND\\_PATH](#), [FILE\\_INFO](#), [FILE\\_SEARCH](#), [FILE\\_TEST](#)

# FILE\_SEARCH

The `FILE_SEARCH` function returns a string array containing the names of all files matching the input path specification. Input path specifications may contain wildcard characters, enabling them to match multiple files. `FILE_SEARCH`'s interpretation of wildcard characters in the path specification is described in [“Supported Wildcards and Expansions”](#) on page 765.

A *relative path* is a path specification that can only be unambiguously interpreted by basing it relative to some other known location. Usually, this location is the current working directory for the process. A *fully qualified path* is a complete and unambiguous path that can be interpreted directly. For example, `bin/idl` is a relative path, while `/usr/local/rsi/idl/bin/idl` is a fully qualified path. By default, `FILE_SEARCH` follows the format of the input to decide whether to return relative or fully-qualified paths.

---

## Note

In most cases, the operation of `FILE_SEARCH` is straightforward. There are, however, numerous options available; while these options make the routine more powerful, they may also make its behavior less intuitive. Read the keyword descriptions for additional details.

In addition, there are platform-specific behaviors of which you should be aware, especially if you work in a multiplatform environment. See [“Platform-Specific Filename Matching Issues”](#) on page 767 for details.

---

## Syntax

*Result* = `FILE_SEARCH(Path_Specification)`

or for recursive searching,

*Result* = `FILE_SEARCH(Dir_Specification, Recur_Pattern)`

**Keywords:** `[, COUNT=variable ]` `[, /EXPAND_ENVIRONMENT ]`  
`[, /EXPAND_TILDE ]` `[, /FOLD_CASE ]` `[, /FULLY_QUALIFY_PATH ]`  
`[, /ISSUE_ACCESS_ERROR ]` `[, /MARK_DIRECTORY ]`  
`[, /MATCH_ALL_INITIAL_DOT | /MATCH_INITIAL_DOT ]` `[, /NOSORT ]`  
`[, /QUOTE ]` `[, /TEST_DIRECTORY ]` `[, /TEST_EXECUTABLE ]`  
`[, /TEST_READ ]` `[, /TEST_REGULAR ]` `[, /TEST_WRITE ]`  
`[, /TEST_ZERO_LENGTH ]` `[, /WINDOWS_SHORT_NAMES ]`

**UNIX-Only Keywords:** [, /TEST\_BLOCK\_SPECIAL ]  
 [, /TEST\_CHARACTER\_SPECIAL ] [, /TEST\_DANGLING\_SYMLINK ]  
 [, /TEST\_GROUP ] [, /TEST\_NAMED\_PIPE ] [, /TEST\_SETGID ]  
 [, /TEST\_SETUID ] [, /TEST\_SOCKET ] [, /TEST\_STICKY\_BIT ]  
 [, /TEST\_SYMLINK ] [, /TEST\_USER ]

## Return Value

Returns all matched filenames in a string array, one file name per array element. If no files exist with names matching the input arguments, a null scalar string is returned instead of a string array.

If the input path is relative, the results will be relative. If the input is fully qualified, the results will also be fully qualified. If you specify the FULLY\_QUALIFY\_PATH keyword, the results will be fully qualified no matter which form of input is used. FILE\_SEARCH returns results based on standard and recursive searches:

- **Standard:** When called with a single *Path\_Specification* argument, FILE\_SEARCH returns all files that match that specification. This is the same operation, sometimes referred to as *file globbing*, performed by most operating system command interpreters when wildcard characters are used in file specifications.
- **Recursive:** When called with two arguments, FILE\_SEARCH performs recursive searching of directory hierarchies. In a recursive search, FILE\_SEARCH looks recursively for any and all subdirectories in the file hierarchy rooted at the *Dir\_Specification* argument. Within each of these subdirectories, it returns the names of all files that match the pattern in the *Recur\_Pattern* argument. This operation is similar to that performed by the UNIX `find(1)` command.

---

### Note

To avoid going into an infinite loop, the FILE\_SEARCH routine does not follow symbolic links.

---

## Arguments

Any of the arguments described in this section can contain wildcard characters, as described in [“Supported Wildcards and Expansions”](#) on page 765.

## Path\_Specification

A scalar or array variable of string type, containing file paths to match. If *Path\_Specification* is not supplied, or if it is supplied as a null string, FILE\_SEARCH uses a default pattern of ' \* ', which matches all files in the current directory.

## Dir\_Specification

A scalar or array variable of string type, containing directory paths within which FILE\_SEARCH will perform recursive searching for files matching the *Recur\_Pattern* argument. FILE\_SEARCH examines *Dir\_Specification*, and any directory found below it, and returns the paths of any files in those directories that match *Recur\_Pattern*. If *Dir\_Specification* is supplied as a null string, FILE\_SEARCH searches the current directory.

## Recur\_Pattern

A scalar string containing a pattern for files to match in any of the directories specified by the *Dir\_Specification* argument. If *Recur\_Pattern* is supplied as a null string, FILE\_SEARCH uses a default pattern of ' \* ', which matches all files in the specified directories.

## Keywords

### COUNT

A named variable into which the number of files found is placed. If no files are found, a value of 0 (zero) is returned.

### EXPAND\_ENVIRONMENT

By default, FILE\_SEARCH follows the conventions of the underlying operating system to determine whether it should expand environment variable references in input file specification patterns. The default is to do such expansions under UNIX, and not to do them under Microsoft Windows. The EXPAND\_ENVIRONMENT keyword is used to change this behavior. Set it to a non-zero value to cause FILE\_SEARCH to perform environment variable expansion on all platforms. Set it to zero to disable such expansion.

The syntax for expanding environment variables in an input file pattern is based on that supported by the standard UNIX shell (`/bin/sh`), as described in [“Supported Wildcards and Expansions”](#) on page 765.

## EXPAND\_TILDE

Users of the UNIX C-shell (`/bin/csh`), and other tools influenced by it, are familiar with the use of a tilde (`~`) character at the beginning of a path to denote a home directory. A tilde by itself at the beginning of the path (e.g. `~/directory/file`) is equivalent to the home directory of the user executing the command, while a tilde followed by the name of a user (e.g. `~user/directory/file`) is expanded to the home directory of the named user.

By default, `FILE_SEARCH` follows the conventions of the underlying operating system in deciding whether to expand a leading tilde or to treat it as a literal character. Hence, the default is to expand the leading tilde under UNIX, and not under Microsoft Windows. The `EXPAND_TILDE` keyword is used to change this behavior.

Set `EXPAND_TILDE` to 0 (zero) to disable tilde expansion on all platforms. Set it to a non-zero value to enable tilde expansion.

---

### Note

Under Microsoft Windows, only the plain form of tilde is recognized. Attempts to use the `~user` form will cause IDL to issue an error. IDL uses the `HOME` and `HOMEPATH` environment variables to obtain a home directory for the current Windows user.

---

## FOLD\_CASE

By default, `FILE_SEARCH` follows the case sensitivity policy of the underlying operating system. By default, matches are case sensitive on UNIX platforms, and case insensitive on Microsoft Windows platforms. The `FOLD_CASE` keyword is used to change this behavior. Set it to a non-zero value to cause `FILE_SEARCH` to do all file matching case insensitively. Explicitly set `FOLD_CASE` equal to zero to cause all file matching to be case sensitive.

RSI does not recommend changing the default value of `FOLD_CASE`, for the following reasons:

- Under UNIX, case-insensitive file searching (that is, setting `FOLD_CASE=1`) can lead to confusing behavior, since files with the same name in different combinations of upper- and lower-case letters are actually distinct files that can exist simultaneously in the same directory. However, case insensitivity can be useful under UNIX when combined with wildcards in order to find all instances of a given file type without regard to case.

For example, the following will find all files in the current directory that end with a `.dat` extension without regard to the case of the extension:

```
datafiles = FILE_SEARCH('*.*dat', /FOLD_CASE)
```

- Under Windows, case-sensitive file searching (that is, setting `FOLD_CASE=0`) is rarely useful, since files with the same name in different combinations of upper- and lower-case letters cannot exist simultaneously in the same directory, and a case-insensitive search will return any version.

## FULLY\_QUALIFY\_PATH

If set, `FILE_SEARCH` expands all returned file paths so that they are complete. Under UNIX, this means that all files are specified relative to the root of the file system. On Windows platforms, it means that all files are specified relative to the drive on which they are located. By default, `FILE_SEARCH` returns fully qualified paths when the input specification is fully qualified, and returns relative paths otherwise. For example:

```
CD, '/usr/local/rsi/idl/bin'
PRINT, FILE_SEARCH('idl')
idl
PRINT, FILE_SEARCH('idl',/FULLY_QUALIFY_PATH)
/usr/local/rsi/idl/bin/idl
```

Under Microsoft Windows, any use of a drive letter colon (`:`) character implies full qualification, even if the path following the colon does not start with a slash character.

## ISSUE\_ACCESS\_ERROR

If the IDL process lacks the necessary permission to access a directory included in the input specification, `FILE_SEARCH` will normally skip over it quietly and not include it in the generated results. Set `ISSUE_ACCESS_ERROR` to cause an error to be issued instead.

## MARK\_DIRECTORY

If set, all directory paths are returned with a path separator character appended to the end. This allows the caller to concatenate a file name directly to the end without having to supply a separator character first. This is convenient for cross-platform programming, as the separator characters differ between operating systems:

```
PRINT, FILE_SEARCH(!DIR)
/usr/local/rsi/idl
PRINT, FILE_SEARCH(!DIR, /MARK_DIRECTORY)
/usr/local/rsi/idl/
```

## MATCH\_ALL\_INITIAL\_DOT

By default, wildcards do not match leading dot (.) characters, and `FILE_SEARCH` does not return the names of files that start with the dot (.) character unless the leading dot is actually contained within the search string. Set `MATCH_ALL_INITIAL_DOT` to change this policy so that wildcards will match all files starting with a dot, including the special “.” (current directory) and “..” (parent directory) entries. RSI recommends the use of the `MATCH_INITIAL_DOT` keyword instead of `MATCH_ALL_INITIAL_DOT` for most purposes.

## MATCH\_INITIAL\_DOT

`MATCH_INITIAL_DOT` serves the same function as `MATCH_ALL_INITIAL_DOT`, except that the special “.” (current directory) and “..” (parent directory) directories are not included.

## NOSORT

Normally, `FILE_SEARCH` sorts the list of files returned by the operating system in a case-sensitive manner. If the `NOSORT` keyword is set, `FILE_SEARCH` will not perform the sort, instead returning exactly what is returned by the underlying operating system calls. On some operating systems, this can make `FILE_SEARCH` execute faster. The order of the results returned when `NOSORT` is set depends on the implementation of the operating system, and should not be relied upon.

## QUOTE

`FILE_SEARCH` usually treats all wildcards found in the input specification as having the special meanings described in [“Supported Wildcards and Expansions”](#) on page 765. This means that such characters cannot normally be used as plain literal characters in file names. For example, it is not possible to match a file that contains a literal asterisk character in its name because asterisk is interpreted as the “match zero or more characters” wildcard.

If the `QUOTE` keyword is set, the backslash character can be used to escape any character so that it is treated as a plain character with no special meaning. In this mode, `FILE_SEARCH` replaces any two-character sequence starting with a backslash with the second character of the pair. In the process, any special wildcard meaning that character might have had disappears, and the character is treated as a literal.

If `QUOTE` is set, any literal backslash characters in your path must themselves be escaped with a backslash character. This is especially important for Microsoft Windows users, because the directory separator character for that platform is the

backslash. Windows IDL also accepts UNIX-style forward slashes for directory separators, so Windows users have two choices in handling this issue:

```
Result = FILE_SEARCH('C:\\home\\bob\\*.dat', /QUOTE)
Result = FILE_SEARCH('C:/home/bob/*.dat', /QUOTE)
```

On a Windows system, either of these options gives the path to a file named \*.dat.

## TEST\_BLOCK\_SPECIAL

*This keyword is only available on UNIX platforms.*

Only include a matching file if it is a block special device.

## TEST\_CHARACTER\_SPECIAL

*This keyword is only available on UNIX platforms.*

Only include a matching file if it is a character special device.

## TEST\_DANGLING\_SYMLINK

*This keyword is only available on UNIX platforms.*

Only include a matching file if it is a symbolic link that points at a non-existent file.

## TEST\_DIRECTORY

Only include a matching file if it is a directory.

## TEST\_EXECUTABLE

Only include a matching file if it is executable. The source of this information differs between operating systems:

**UNIX:** IDL checks the per-file information (the execute bit) maintained by the operating system.

**Microsoft Windows:** The determination is made on the basis of the file name extension (e.g. .exe).

## TEST\_GROUP

*This keyword is only available on UNIX platforms.*

Only include a matching file if it belongs to the same effective group ID (GID) as the IDL process.

## TEST\_NAMED\_PIPE

*This keyword is only available on UNIX platforms.*

Only include a matching file if it is a named pipe (fifo) device.

## TEST\_READ

Only include a matching file if it is readable by the user.

### Note

---

This keyword does not support Access Control List (ACL) settings for files.

---

## TEST\_REGULAR

Only include a matching file if it is a regular disk file and not a directory, pipe, socket, or other special file type.

## TEST\_SETGID

*This keyword is only available on UNIX platforms.*

Only include a matching file if it has its Set-Group-ID bit set.

## TEST\_SETUID

*This keyword is only available on UNIX platforms.*

Only include a matching file if it has its Set-User-ID bit set.

## TEST\_SOCKET

*This keyword is only available on UNIX platforms.*

Only include a matching file if it is a UNIX domain socket.

## TEST\_STICKY\_BIT

*This keyword is only available on UNIX platforms.*

Only include a matching file if it has its sticky bit set.

## TEST\_SYMLINK

*This keyword is only available on UNIX platforms.*

Only include a matching file if it is a symbolic link that points at an existing file.

## TEST\_USER

*This keyword is only available on UNIX platforms.*

Only include a matching file if it belongs to the same effective user ID (UID) as the IDL process.

## TEST\_WRITE

Only include a matching file if it is writable by the user.

### Note

---

This keyword does not support Access Control List (ACL) settings for files.

---

## TEST\_ZERO\_LENGTH

Only include a matching file if it has zero length.

### Note

---

The length of a directory is highly system-dependent and does not necessarily correspond to the number of files it contains. In particular, it is possible for an empty directory to report a non-zero length. RSI does not recommend using the `TEST_ZERO_LENGTH` keyword on directories, as the information returned cannot be used in a meaningful way.

---

## TEST\_\* Keywords

The keywords with names that start with the `TEST_` prefix allow you to filter the list of resulting file paths based on various criteria. If you remove the `TEST_` prefix from these keywords, they correspond directly to the same keywords to the `FILE_TEST` function, and are internally implemented by the same test code. One could therefore use `FILE_TEST` instead of the `TEST_` keywords to `FILE_SEARCH`. For example, the following statement locates all subdirectories of the current directory:

```
Result = FILE_SEARCH(/TEST_DIRECTORY)
```

It is equivalent to the following statements, using `FILE_TEST`:

```
result = FILE_SEARCH()
idx = where(FILE_TEST(result, /DIRECTORY), count)
result = (count eq 0) ? '' : result[idx]
```

The `TEST_*` keywords are more succinct, and can be more efficient in the common case in which `FILE_SEARCH` generates a long list of results, only to have `FILE_TEST` discard most of them.

## WINDOWS\_SHORT\_NAMES

By default, FILE\_SEARCH ignores Microsoft Windows 8.3 short names when performing file matching and only considers the real file names. Set the WINDOWS\_SHORT\_NAMES keyword to change this policy. If this keyword is set, FILE\_SEARCH looks at both the real and 8.3 short names associated with each file as it checks for a match. See “Microsoft Windows “8.3 Short Names”” on page 769 for more information on this subject. This keyword is quietly ignored on non-Windows platforms.

You should be aware that turning on short name support can lead to confusing results. Such use should be considered carefully. For example, consider running the following IDL statement in a directory containing a single file named `file_search.html`:

```
PRINT, FILE_SEARCH('*.*htm')
```

Because this statement does not enable short name support, no files matching the specified pattern are found, and IDL does not print any filenames. This is the result most people would expect. If short name support is enabled, however:

```
PRINT, FILE_SEARCH('*.*htm', /WINDOWS_SHORT_NAMES)
```

IDL prints:

```
file_search.html
```

In this case, IDL checks the short names as well as the real names. The 8.3 short name for `file_search.html` will be similar to `FILE_S~1.HTM`, which matches the *Path Specification*. As such, FILE\_SEARCH reports the real name for the matched file. This is the correct answer, but probably not the expected result.

## Supported Wildcards and Expansions

The wildcards understood by FILE\_SEARCH are based on those used by the standard UNIX shell `/bin/sh` (the `?`, `*`, `[`, and `]` characters, and environment variables) with some enhancements commonly found in the C-shell `/bin/csh` (the `~`, `{`, and `}` characters). These wildcards are processed identically across all IDL supported platforms. The supported wildcards are shown in the following table:

Wildcard	Description
*	Matches any string, including the null string.

Table 3-44: Supported Wildcards and Expansions

Wildcard	Description
?	Matches any single character.
[...]	Matches any one of the enclosed characters. A pair of characters separated by “-” matches any character lexically between the pair, inclusive. If the first character following the opening bracket ( [ ) is a ! or ^, any character not enclosed is matched.
{ <i>str</i> , <i>str</i> , ...}	Expand to each string (or filename-matching pattern) in the comma-separated list.
~ ~ <i>user</i>	If used at start of input file specification, is replaced with the path to the appropriate home directory. See the description of the <a href="#">EXPAND_TILDE</a> keyword for details.
<i>\$var</i>	Replace with value of the named environment variable. See the description of the <a href="#">EXPAND_ENVIRONMENT</a> keyword for full details.
<i>\${var}</i>	Replace <i>\${var}</i> with the value of the <i>var</i> environment variable. If <i>var</i> is not found in the environment, <i>\${var}</i> is replaced with a null string. This format is useful when the environment variable reference sits directly next to unrelated text, as the use of the {} brackets make it possible for IDL to determine where the environment variable ends and the remaining text starts (e.g. <i>\${mydir}other_text</i> ).
<i>\${var:-alttext}</i>	If environment variable <i>var</i> is present in the environment and has a non-NULL value, then substitute that value. If <i>var</i> is not present, or has a NULL value, then substitute the alternative text ( <i>alttext</i> ) provided instead.
<i>\${var-alttext}</i>	If environment variable <i>var</i> is present in the environment (even if it has a NULL value) then substitute that value. If <i>var</i> is not present, then substitute the alternative text ( <i>alttext</i> ) provided instead.

*Table 3-44: Supported Wildcards and Expansions (Continued)*

These wildcards can appear anywhere in an input file specification, with the following exceptions:

## Tilde (~)

The tilde character is only considered to be a wildcard if it is the first character in the input file specification and the `EXPAND_TILDE` keyword is set. Otherwise, it is treated as a regular character.

## Initial Dot Character

The default is for wildcards not to match the dot (.) character if it occurs as the first character of a directory or file name. This follows the convention of UNIX shells, which treat such names as hidden files. In order to match such files, you can take any of the following actions:

- Explicitly include the dot character at the start of your pattern (e.g. `.*`).
- Specify the `MATCH_INITIAL_DOT` keyword, which changes the dot matching policy so that wildcards will match any names starting with dot (except for the special `.` and `..` directories).
- Specify the `MATCH_ALL_INITIAL_DOT` keyword, which changes the dot matching policy so that wildcards will match any names starting with dot (including the special `.` and `..` directories).

## Microsoft Windows UNC Paths

On a local area network, Microsoft Windows offers an alternative to the drive letter syntax for accessing files. The *Universal Naming Convention* (UNC) allows for specification of paths on other hosts using the syntax:

```
\\hostname\sharename\dir\dir\...\file
```

UNC paths are distinguished from normal paths by the use of two initial slashes in the path. `FILE_SEARCH` can process such paths, but wildcard characters are not allowed in the `hostname` or `sharename` segments. Wildcards are allowed for specifying directories and files. For performance reasons, RSI does not recommend using the recursive form of `FILE_SEARCH` with UNC paths on very large directory trees.

## Platform-Specific Filename Matching Issues

When using `FILE_SEARCH`, you should be aware of the following platform-specific issues.

## File Path Syntax

The syntax allowed for file paths differs between operating systems. `FILE_SEARCH` always processes file paths using the syntax rules for the platform on which the IDL session is running. As a convenience for Microsoft Windows users, Windows IDL accepts UNIX style forward slashes as well as the usual backslashes as path separators.

## Differing Defaults Between Platforms

The different operating systems supported by IDL have some conventions for processing file paths that are inherently incompatible. If `FILE_SEARCH` attempted to force an identical default policy for these features across all platforms, the resulting routine would be inconvenient to use on all platforms. `FILE_SEARCH` resolves this inherent tension between convenience and control in the following way:

- These features are controlled by keywords which are listed in the table below. If a keyword is not explicitly specified, `FILE_SEARCH` will determine an appropriate default for that feature based on the conventions of the underlying operating system. Hence, `FILE_SEARCH` will by default behave in a way that is reasonable on the platform on which it is used.
- If one of these keywords is explicitly specified, `FILE_SEARCH` will use its value to determine support for that feature. Hence, if the keyword is used, `FILE_SEARCH` will behave identically on all platforms. If maximum cross-platform control is desired, you can achieve it by specifying all the relevant keywords.

The keywords that have different defaults on different platforms are listed in the following table:

Wildcard	Keyword	Default UNIX	Default Win
<code>\$var</code> <code>\${var}</code> <code>\${var:-alttext}</code> <code>\${var-alttext}</code>	EXPAND_ENVIRONMENT	yes	no
~	EXPAND_TILDE	yes	no
	FOLD_CASE	no	yes

Table 3-45: `FILE_SEARCH` Defaults that Differ Between Platforms

## Microsoft Windows “8.3 Short Names”

Older versions of Microsoft operating systems limited files to very short names: up to eight characters were allowed for the file name, followed by a dot (.), followed by an extension of up to three characters. This scheme is often referred to as “8.3 short names” or just “8.3”. Newer releases of the Windows operating system have moved past the 8.3 limits, and allow much longer names. In order to allow old programs from older systems to run on newer systems without first being rebuilt, these newer versions of Windows actually maintain two separate and distinct file names for each file. Every file has, in addition to its real (potentially long) name, an automatically generated “8.3 short name”. If the real name fits within the 8.3 limits, the real and short names are the same. If the real name does not fit within the 8.3 limits, the operating system constructs an 8.3 short name for it by applying a set of heuristic rules (See Microsoft’s documentation for more detail on how these names are constructed). For example, the file `file_search.html` will be given a short name that looks something like `FILE_S~1.HTM`.

---

### Note

8.3 short names are strictly a Windows backwards compatibility feature, and are not generally useful in newer software.

---

8.3 short names are an issue for `FILE_SEARCH` if the *Path\_Specification* argument includes them. `FILE_SEARCH` handles this situation using the following rules:

1. Before starting the process of file name matching, `FILE_SEARCH` examines the portion of *Path\_Specification* between the first character and the first wildcard character (or the entire string if there are no wildcards) for non-wildcarded short names. Any such names are replaced by their real names.
2. By default, `FILE_SEARCH` only considers the real name during the process of matching *Path\_Specification* with files, ignoring the 8.3 short names. The `WINDOWS_SHORT_NAMES` keyword can be set to change this policy. If `WINDOWS_SHORT_NAMES` is set, `FILE_SEARCH` looks at *both* the real and 8.3 short names associated with each file as it checks for a match.
3. If `WINDOWS_SHORT_NAMES` is set and `FILE_SEARCH` matches the 8.3 short name for a file, the real file name is returned. For instance, in the above example if `FILE_SEARCH` matches `FILE_S~1.HTM`, it will return `file_search.html`.

**Warning**

---

Windows 8.3 short names can be very confusing to understand. RSI recommends not using them unless absolutely necessary. Most modern applications will not encounter a need to match 8.3 short names.

---

**Examples****Example 1**

Find all files in the current working directory:

```
Result = FILE_SEARCH()
```

**Example 2**

Find all IDL program (\*.pro) files in the current working directory:

```
Result = FILE_SEARCH('*.pro')
```

To determine the number of IDL procedure files that exist in the current directory, use the following statement:

```
PRINT, '# IDL pro files:', N_ELEMENTS(FILE_SEARCH('*.pro'))
```

**Example 3**

Under Microsoft Windows, find all files in the top level directories of all drives other than the floppy drives:

```
Result=FILE_SEARCH('[!ab]:*')
```

This example relies on the following:

- FILE\_SEARCH allows wildcards within the drive letter part of an input file specification.
- Drives A and B are always floppies, and are not used by Windows for any other type of drive.

**Example 4**

Find all files in the user's home directory that start with the letters A-D. Match both upper and lowercase letters:

```
Result = FILE_SEARCH('~/[a-d]*', /EXPAND_TILDE, /FOLD_CASE)
```

## Example 5

Find all directories in the user's home directory that start with the letters A-D. Match both upper and lowercase letters:

```
Result = FILE_SEARCH('~/[a-d]*', /EXPAND_TILDE, /FOLD_CASE, $
                  /TEST_DIRECTORY)
```

## Example 6

Recursively find all subdirectories found underneath the user's home directory that do not start with a dot character:

```
Result = FILE_SEARCH('$HOME', '*', /EXPAND_ENVIRONMENT, $
                  /TEST_DIRECTORY)
```

## Example 7

Recursively find all subdirectories found underneath the user's home directory, including those that start with a dot character, but excluding the special "." and ".." directories:

```
Result = FILE_SEARCH('$HOME', '*', /MATCH_INITIAL_DOT, $
                  /EXPAND_ENVIRONMENT, /TEST_DIRECTORY)
```

## Example 8

Find all .pro and .sav files in an IDL library search path, sorted by directory, in the order IDL searches for them:

```
Result = FILE_SEARCH(STRSPPLIT(!PATH, PATH_SEP(/SEARCH_PATH), $
                  /EXTRACT) + '/*.{pro,sav}')
```

Colon (:) is the UNIX path separator character, so the call to `STRSPPLIT` breaks the IDL search path into an array of directories. To each directory name, we concatenate the wildcards necessary to match any .pro or .sav files in that directory. When this array is passed to `FILE_SEARCH`, it locates all files that match these specifications. `FILE_SEARCH` sorts all of the files found by each input string. The files for each string are then placed into the output array in the order they were searched for.

## Example 9

Recursively find all directories in your IDL distribution:

```
Result = FILE_SEARCH(!DIR, '*', /TEST_DIRECTORY)
```

## Example 10

Under Microsoft Windows, `FILE_SEARCH` can be used to convert a path that uses 8.3 short names into an equivalent path that uses the real names. For example, Windows provides a directory for each user where applications are expected to create temporary files. Consider a user of Windows 2000 named Scott. The short name for Scott's temporary directory (which is usually available via the Windows "Temp" environment variable) will typically be something like

`C:\DOCUME~1\scott\LOCALS~1\Temp`. This can be converted to real names using a statement like the following:

```
PRINT, FILE_SEARCH(GETENV('Temp'))
```

IDL prints:

```
C:\Documents and Settings\scott\Local Settings\Temp
```

There are some noteworthy facts about this example:

1. Short names are relatively rare in modern Windows systems. Environment variables are one of the few ways in which they are still seen.
2. It was not necessary to specify the `WINDOWS_SHORT_NAMES` keyword in this example, although it would have been harmless to do so, because the path being converted contains no wildcard characters. `FILE_SEARCH` will always attempt to convert any non-wildcarded path components at the beginning of the path to their long names before it begins searching.
3. The `GETENV` function supports a special token (`IDL_TMPDIR`) that should be used to obtain the directory where temporary files go. This provides a portable cross platform way to find a good temporary directory. Under Windows, `GETENV` automatically converts the result of translating the `IDL_TMPDIR` preference to real names in a manner similar to that shown in this example.
4. People find the 8.3 short names confusing, and you may wish to translate them to real names for display purposes. However, most file handling functions and procedures in IDL will accept either without issue. There is little reason to translate them before using them in programs.

## Version History

5.5	Introduced
6.1	Added WINDOWS_SHORT_NAMES keyword

## See Also

[FILE\\_TEST](#), [FILEPATH](#), [GETENV](#)

# FILE\_TEST

The FILE\_TEST function checks files for existence and other attributes without having to first open the file.

## Syntax

```
Result = FILE_TEST( File [, /DIRECTORY | , /EXECUTABLE | , /READ | ,  
/REGULAR | , /WRITE | , /ZERO_LENGTH] [, GET_MODE=variable]  
[, /NOEXPAND_PATH] )
```

**UNIX-Only Keywords:** [ , /BLOCK\_SPECIAL | , /CHARACTER\_SPECIAL | ,  
/DANGLING\_SYMLINK | , /GROUP | , /NAMED\_PIPE | , /SETGID | ,  
/SETUID | , /SOCKET | , /STICKY\_BIT | , /SYMLINK | , /USER ]

## Return Value

FILE\_TEST returns 1 (true), if the specified file exists and all of the attributes specified by the keywords are also true. If no keywords are present, a simple test for existence is performed. If the file does not exist or one of the specified attributes is not true, then FILE\_TEST returns 0 (false).

## Arguments

### File

A scalar or array of file names to be tested. The result is of type integer with the same number of elements as *File*.

## Keywords

### BLOCK\_SPECIAL

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and is a block special device.

### CHARACTER\_SPECIAL

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and is a character special device.

## DANGLING\_SYMLINK

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* is a symbolic link that points at a non-existent file.

## DIRECTORY

Set this keyword to return 1 (true) if *File* exists and is a directory.

## EXECUTABLE

Set this keyword to return 1 (true) if *File* exists and is executable. The source of this information differs between operating systems:

- UNIX: IDL checks the per-file information (the execute bit) maintained by the operating system.
- Microsoft Windows: The determination is made on the basis of the file name extension (e.g. `.exe`).

## GET\_MODE

Set this keyword to a named variable to receive the UNIX style mode (permission) mask for the specified file. The bits in these masks correspond to those used by the UNIX `chmod(2)` system call, and are explained in detail in the description of the *Mode* argument to the [FILE\\_CHMOD](#) procedure. When interpreting the value returned by this keyword, the following platform specific details should be kept in mind:

- The `setuid`, `setgid`, and sticky bits are specific to the UNIX operating system, and will never be returned on any other platform. Consult the `chmod(2)` man page and/or other UNIX programming documentation for more details.
- The Microsoft Windows operating system does not have 3 permission classes like UNIX does. Therefore, IDL returns the same settings for all three classes.
- The Microsoft Windows operating system does not maintain an execute bit for files, but instead uses the file suffix to decide if a file is executable.

## GROUP

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and belongs to the same effective group ID (GID) as the IDL process.

## NAMED\_PIPE

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and is a named pipe (fifo) device.

## NOEXPAND\_PATH

Set this keyword to cause FILE\_TEST to use the *File* argument exactly as specified, without applying the usual file path expansion.

## READ

Set this keyword to return 1 (true) if *File* exists and is readable by the user.

## REGULAR

Set this keyword to return 1 (true) if *File* exists and is a regular disk file and not a directory, pipe, socket, or other special file type.

## SETGID

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and has its Set-Group-ID bit set.

## SETUID

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and has its Set-User-ID bit set.

## SOCKET

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and is a UNIX domain socket.

## STICKY\_BIT

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and has its sticky bit set.

## SYMLINK

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and is a symbolic link that points at an existing file.

## USER

*This keyword is only available on UNIX platforms.*

Set this keyword to return 1 (true) if *File* exists and belongs to the same effective user ID (UID) as the IDL process.

## WRITE

Set this keyword to return 1 (true) if *File* exists and is writable by the user.

## ZERO\_LENGTH

Set this keyword to return 1 (true) if *File* exists and has zero length.

### Note

---

The length of a directory is highly system dependent and does not necessarily correspond to the number of files it contains. In particular, it is possible for an empty directory to report a non-zero length. RSI does not recommend using the ZERO\_LENGTH keyword on directories, as the information returned cannot be used in a meaningful way.

---

## Examples

To determine whether your IDL distribution supports the SGI IRIX operating system:

```
result = FILE_TEST(!DIR + '/bin/bin.sgi', /DIRECTORY)
PRINT, 'IRIX IDL Installed: ', result ? 'yes' : 'no'
```

## Version History

5.4	Introduced

## See Also

[FILE\\_INFO](#), [FILE\\_SEARCH](#), [FSTAT](#)

# FILE\_WHICH

The FILE\_WHICH function separates a specified file path into its component directories, and searches each directory in turn for a specific file. This command is modeled after the UNIX `which(1)` command, but is written in the IDL language and is available on all platforms. Its source code can be found in the file `file_which.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = FILE_WHICH( [Path, ] File [, /INCLUDE_CURRENT_DIR] )
```

## Return Value

Returns the path for the first file for the given name found by searching the specified path. If FILE\_WHICH does not find the desired file, a NULL string is returned.

## Arguments

### Path

A search path to be searched. If *Path* is not present, the value of the IDL `!PATH` system variable is used.

### File

The file to look for in the directories given by *Path*.

## Keywords

### INCLUDE\_CURRENT\_DIR

If set, FILE\_WHICH looks in the current directory before starting to search *Path* for *File*. When IDL searches for a routine to compile, it looks in the current working directory before searching `!PATH`. The INCLUDE\_CURRENT\_DIR keyword allows FILE\_WHICH to mimic this behavior.

## Examples

To find the location of the `file_which.pro` file:

```
Result = FILE_WHICH('file_which.pro')
```

To find the location of the UNIX `ls` command:

```
Result = FILE_WHICH(getenv('PATH'), 'ls')
```

## Version History

5.4	Introduced
-----	------------

# FILEPATH

The FILEPATH function returns the fully-qualified path to a file contained in the IDL distribution. Operating system dependencies are taken into consideration. This routine is used by RSI to make the library routines portable. This routine is written in the IDL language. Its source code can be found in the file `filepath.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = FILEPATH( Filename [, ROOT_DIR=string]
                  [, SUBDIRECTORY=string/string_array] [, /TERMINAL] [, /TMP] )
```

## Return Value

Returns the fully-qualified path to a specified file.

## Arguments

### Filename

A string containing the name of the file to be found. The file should be specified in all lowercase characters. No device or directory information should be included.

## Keywords

### ROOT\_DIR

A string containing the name of the directory from which the resulting path should be based. If not present, the value of `!DIR` is used. This keyword is ignored if `TERMINAL` or `TMP` are specified.

### SUBDIRECTORY

The name of the subdirectory in which the file should be found. If this keyword is omitted, the main IDL directory is used. This variable can be either a scalar string or a string array with the name of each level of subdirectory depth represented as an element of the array.

For example, to get a path to the file `filepath.pro` in IDL's `lib` subdirectory, enter:

```
path = FILEPATH('filepath.pro', SUBDIR=['lib'])
```

## TERMINAL

Set this keyword to return the filename of the user's terminal.

## TMP

Set this keyword to indicate that the specified file is a scratch file. Returns a path to the proper place for temporary files under the current operating system.

Under Microsoft Windows, FILEPATH checks to see if the following environment variables are set—TMP, TEMP, WINDIR—and uses the value of the first one it finds. If none of these environment variables exists, \TMP is used as the temporary directory.

## Examples

Open the IDL distribution file `people.dat`:

```
OPENR, 1, FILEPATH('people.dat', SUBDIRECTORY=['examples','data'])
```

## Version History

# FINDGEN

The FINDGEN function creates a floating-point array of the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$Result = \text{FINDGEN}(D_1 [, \dots, D_8])$$

## Return Value

Returns a single-precision, floating-point array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create F, a 6-element vector of single-precision, floating-point values where each element is set to the value of its subscript, enter:

```
F = FINDGEN(6)
```

The value of F[0] is 0.0, F[1] is 1.0, and so on.

## Version History

Original	Introduced

# FINITE

The FINITE function identifies whether or not a given argument is finite.

## Syntax

```
Result = FINITE( X [, /INFINITY] [, /NAN] [, SIGN=value] )
```

## Return Value

Returns 1 (True) if its argument is finite. If the argument is infinite or not a defined number (*NaN*), the FINITE function returns 0 (False). The result is a byte expression of the same structure as the argument *X*.

### Note

---

See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.

---

## Arguments

### X

A floating-point, double-precision, or complex scalar or array expression. Strings are first converted to floating-point. This function is meaningless for byte, integer, or longword arguments.

## Keywords

### INFINITY

Set this keyword to cause FINITE to return True if the *X* argument is the IEEE special floating-point value *Infinity* (either positive or negative), or False otherwise.

### NAN

Set this keyword to cause FINITE to return True if the *X* argument is the IEEE special floating-point value “Not A Number” (*NaN*), or False otherwise.

## SIGN

If the INFINITY or NAN keyword is set, then set this keyword to one of the following values:

Value	Description
> 0	If the INFINITY keyword is set, return True (1) if $X$ is positive infinity, False (0) otherwise. If the NAN keyword is set, return True (1) if $X$ is +NaN (negative sign bit is not set), False (0) otherwise.
0 (the default)	The sign of $X$ (positive or negative) is ignored.
< 0	If the INFINITY is set, return True (1) if $X$ is negative infinity, False (0) otherwise. If the NAN keyword is set, return True (1) if $X$ is -NaN (negative sign bit is set), False (0) otherwise.

Table 3-46: SIGN Keyword Values

If neither the INFINITY nor NAN keyword is set, then this keyword is ignored.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

### Example 1

To find out if the logarithm of 5.0 is finite, enter:

```
PRINT, FINITE(ALOG(5.0))
```

IDL prints "1" because the argument is finite.

## Example 2

To determine which elements of an array are infinity or NaN (Not a Number) values:

```
A = FLTARR(10)

; Set some values to +/-NaN and positive or negative Infinity:
A[3] = !VALUES.F_NAN
A[4] = -!VALUES.F_NAN
A[6] = !VALUES.F_INFINITY
A[7] = -!VALUES.F_INFINITY
```

Find the location of values in A that are positive or negative

```
Infinity:
PRINT, WHERE(FINITE(A, /INFINITY))
```

IDL prints:

```
6          7
```

Find the location of values in A that are NaN:

```
PRINT, WHERE(FINITE(A, /NAN))
```

IDL prints:

```
3          4
```

Find the location of values in A that are negative Infinity:

```
PRINT, WHERE(FINITE(A, /INFINITY, SIGN=-1))
```

IDL prints:

```
7
```

Find the location of values in A that are +NaN:

```
PRINT, WHERE(FINITE(A, /NAN, SIGN=1))
```

IDL prints:

```
3
```

---

### Note

On some platforms, there is no distinction between +NaN and -NaN.

---

# FIX

The FIX function converts a given expression to an integer type. Optionally, the conversion type can be specified at runtime, allowing flexible runtime type-conversion to arbitrary types.

## Syntax

```
Result = FIX( Expression [, Offset [, D1 [, ..., D8]]] [, /PRINT]
             [, TYPE=type code{0 to 15}] )
```

## Return Value

Returns a result equal to *Expression* converted to integer type.

## Arguments

### Expression

The expression to be converted.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as integer data. See the description in [Chapter 13, “Working with Data in IDL”](#) in the *Building IDL Applications* manual for details.

The *Offset* and *Dim<sub>i</sub>* arguments are not allowed when converting to or from the string type.

### D<sub>i</sub>

When extracting fields of data, the *D<sub>i</sub>* arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The *D<sub>i</sub>* arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

The *Offset* and *D<sub>i</sub>* arguments are not allowed when converting to or from the string type.

## Keywords

### PRINT

Set this keyword to specify that any special-case processing when converting between string and byte data, or the reverse, should be suppressed. The PRINT keyword is ignored unless the TYPE keyword is used to convert to these types.

### TYPE

FIX normally converts *Expression* to the integer type. If TYPE is specified, it is the type code to set the type of the conversion. This feature allows dynamic type conversion, where the desired type is not known until runtime, to be carried out without the use of large CASE or IF...THEN logic. When TYPE is specified, FIX behaves as if the appropriate type conversion routine for the desired type had been called. See the “See Also” list below for the complete list of such routines.

When using the TYPE keyword to convert BYTE data to STRING or the reverse, you should be aware of the special-case processing that the BYTE and STRING functions do in this case. To prevent this, and get a simple type conversion in these cases, you must specify the PRINT keyword.

### Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Convert the floating-point array [2.2, 3.0, 4.5] to integer type and store the new array in the variable I by entering:

```
I = FIX([2.2, 3.0, 4.5])
```

# FLICK

The FLICK procedure causes the display to flicker between two output images at a given rate.

This routine is written in the IDL language. Its source code can be found in the file `flick.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
FLICK, A, B [, Rate]
```

## Arguments

### A

Byte image number 1, scaled from 0 to 255.

### B

Byte image number 2, scaled from 0 to 255.

### Rate

The flicker rate. The default is 1.0 sec/frame

## Keywords

None.

[CW\\_ANIMATE](#), [XINTERANIMATE](#)

# FLOAT

The `FLOAT` function converts a given *Expression* into a single-precision floating-point value.

## Syntax

$$Result = \text{FLOAT}( Expression [, Offset [, D_1 [, \dots, D_8]]])$$

## Return Value

Returns the conversion of the given expression into single-precision floating point values. If *Expression* is a complex number, `FLOAT` returns the real part.

## Arguments

### Expression

The expression to be converted to single-precision floating-point.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as single-precision floating point data.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The `ON_IOERROR` procedure can be used to establish a statement to be jumped to in case of such errors.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

If *A* contains the integer value 6, it can be converted to floating-point and stored in the variable *B* by entering:

```
B = FLOAT(A)
```

## Version History

Original	Introduced
----------	------------

# FLOOR

The FLOOR function returns the closest integer less than or equal to its argument.

## Syntax

*Result* = FLOOR(*X* [, /L64 ] )

## Return Value

If the input argument *X* is an integer type, *Result* has the same value and type as *X*. Otherwise, *Result* is a 32-bit longword integer with the same structure as *X*.

## Arguments

### X

The value for which the FLOOR function is to be evaluated. This value can be any numeric type (integer, floating, or complex).

## Keywords

### L64

If set, the result type is 64-bit integer regardless of the input type. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To print the floor function of 5.9, enter:

```
PRINT, FLOOR(5.9)
; IDL prints:
5
```

To print the floor function of 3000000000.1, the result of which is too large to represent in a 32-bit integer:

```
PRINT, FLOOR(3000000000.1D, /L64)
; IDL prints:
3000000000
```

# FLOW3

The FLOW3 procedure draws lines representing a 3D flow/velocity field. Note that the 3D scaling system must be in place before calling FLOW3. This procedure works best with Z buffer output device.

This routine is written in the IDL language. Its source code can be found in the file `flow3.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
FLOW3, Vx, Vy, Vz [, ARROWSIZE=value] [, /BLOB] [, LEN=value]
      [, NSTEPS=value] [, NVECS=value] [, SX, SY, SZ=vector]
```

## Arguments

### Vx, Vy, Vz

3D arrays containing X, Y, and Z components of the field.

## Keywords

### ARROWSIZE

Size of arrowheads (default = 0.05).

### BLOB

Set this keyword to draw a blob at the beginning of each flow line and suppress the arrows.

### LEN

Length of each step used to follow flow lines (default = 2.0). Expressed in units of largest field vector (i.e., the length of the longest step is set to len times the grid spacing).

### NSTEPS

Number of steps used to follow the flow lines (default = largest dimension of  $Vx / 5$ ).

## NVECS

Number of random flow lines to draw (default = 200). Only used if *Sx*, *Sy*, *Sz* are not present.

## SX

## SY

## SZ

Optional vectors containing the starting coordinates of the flow lines. If any of *SX*, *SY*, and *SZ* are specified, all three vectors must be specified. If omitted random starting points are chosen.

## Examples

```
; Create a set of random three-dimensional arrays to represent
; the field:
vx = RANDOMU(seed, 5, 5, 5)
vy = RANDOMU(seed, 5, 5, 5)
vz = RANDOMU(seed, 5, 5, 5)

; Set up the 3D scaling system:
SCALE3, xr=[0,4], yr=[0,4], zr = [0,4]

; Plot the vector field:
FLOW3, vx, vy, vz
```

# FLTARR

The FLTARR function creates a floating-point vector or array of the specified dimensions.

## Syntax

$$\text{Result} = \text{FLTARR}(D_1 [, \dots, D_8] [, \text{NOZERO}])$$

## Return Value

Returns a single-precision, floating-point vector or array.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, FLTARR sets every element of the result to zero. Set this keyword to inhibit zeroing of the array elements and cause FLTARR to execute faster.

## Examples

Create F, a 3-element by 3-element floating-point array with each element set to 0.0 by entering:

```
F = FLTARR(3, 3)
```

# FLUSH

The FLUSH procedure causes all buffered output on the specified file units to be written. IDL uses buffered output for reasons of efficiency. This buffering leads to rare occasions where a program needs to be certain that output data are not waiting in a buffer, but have actually been output.

## Syntax

FLUSH, *Unit*<sub>1</sub>, ..., *Unit*<sub>*n*</sub>

## Arguments

### *Unit*<sub>*j*</sub>

The file units (logical unit numbers) to flush.

## Version History

Original	Introduced
----------	------------

## See Also

[CLOSE](#), [EMPTY](#), [EXIT](#)

# FOR

The FOR statement executes one or more statements repeatedly, incrementing or decrementing a variable with each repetition, until a condition is met.

**Note**

For more information on using FOR and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

## Syntax

```
FOR variable = init, limit [, Increment] DO statement
```

or

```
FOR variable = init, limit [, Increment] DO BEGIN
```

```
  statements
```

```
ENDFOR
```

## Examples

The following example iterates over the elements of an array, printing the value of each element:

```
array = ['one', 'two', 'three']  
n = N_ELEMENTS(array)  
FOR i=0,n-1 DO BEGIN  
  PRINT, array[i]  
ENDFOR
```

## Version History

# FORMAT\_AXIS\_VALUES

The `FORMAT_AXIS_VALUES` function converts a vector of numeric values into a vector of string values. This routine uses the same rules for formatting as do the axis routines that label tick marks given a set of tick values.

## Syntax

*Result* = `FORMAT_AXIS_VALUES( Values )`

## Return Value

Returns a vector of formatted string values from an input vector of numeric values.

## Arguments

### Values

Set this argument to a vector of numeric values to be formatted.

## Keywords

None.

## Examples

Suppose we have a vector of axis values:

```
axis_values = [7.9, 12.1, 15.3, 19.0]
```

Convert these values into an array of strings:

```
new_values = FORMAT_AXIS_VALUES(axis_values)
HELP, new_values
PRINT, new_values
PRINT, axis_values
```

IDL prints:

```
NEW_VALUES      STRING      = Array[4]
7.9 12.1 15.3 19.0
7.90000      12.1000      15.3000      19.0000
```

## Version History

5.1	Introduced
-----	------------

# FORWARD\_FUNCTION

The `FORWARD_FUNCTION` statement causes argument(s) to be interpreted as functions rather than variables (versions of IDL prior to 5.0 used parentheses to declare arrays).

## Syntax

```
FORWARD_FUNCTION Name1, Name2, ..., Namen
```

## Example

Ambiguities can arise between function calls and array references when a function has not yet been compiled, or when there is no file with the same name as the function found in the IDL path.

For example, attempting to compile the IDL statement:

```
A = xyz(1, COLOR=1)
```

will cause an error if the user-written function `XYZ` has not been compiled and the filename `xyz.pro` is not found in the IDL path. IDL reports a syntax error, because `xyz` is interpreted as an array variable instead of a function name.

This problem can be eliminated by using the `FORWARD_FUNCTION` statement. This statement has the following syntax:

```
FORWARD_FUNCTION Name1, Name2, ..., NameN
```

where *Name* is the name of a function that has not yet been compiled. Any names declared as forward-defined functions will be interpreted as functions (instead of as variable names) for the duration of the IDL session.

For example, we can resolve the ambiguity in the previous example by adding a `FORWARD_FUNCTION` definition:

```
; Define XYZ as the name of a function that has not yet been
; compiled.
FORWARD_FUNCTION XYZ

; IDL now understands this statement to be a function call instead
; of a bad variable reference.
a = XYZ(1, COLOR=1)
```

**Note**

---

Declaring a function that will be merged into IDL via the [LINKIMAGE](#) command with the `FORWARD_FUNCTION` statement will not have the desired effect. Routines merged via `LINKIMAGE` are considered by IDL to be built-in routines, and thus need no compilation or declaration. They must, however, be merged with IDL before any routines that call them are compiled.

---

## Version History

---

Pre 4.0	Introduced

# FREE\_LUN

The `FREE_LUN` procedure deallocates previously-allocated file units. This routine is usually used with file units allocated with `GET_LUN`, but it will also close any other specified file unit. If the specified file units are open, they are closed prior to the deallocation.

## Syntax

```
FREE_LUN [, Unit1, ..., Unitn] [, EXIT_STATUS=variable] [, /FORCE]
```

## Arguments

### *Unit*<sub>*j*</sub>

The IDL file units (logical unit numbers) to deallocate.

## Keywords

### EXIT\_STATUS

Set this keyword to a named variable that will contain the exit status reported by a UNIX child process started via the `UNIT` keyword to `SPAWN`. This value is the exit value reported by the process by calling `EXIT`, and is analogous to the value returned by  `$?`  under most UNIX shells.

### FORCE

Set this keyword to override the IDL file output buffer and force the file to be closed no matter what errors occur in the process.

IDL buffers file output for performance reasons. If it is not possible to properly flush this data when a file close is requested, an error is normally issued and the file remains open. An example of this might be that your disk does not have room to write the remaining data. This default behavior prevents data from being lost. To override it and force the file to be closed no matter what errors occur in the process, specify `FORCE`.

## Examples

See the example for the `GET_LUN` procedure.

## Version History

Original	Introduced
----------	------------

## See Also

[CLOSE](#), [GET\\_LUN](#)

# FSTAT

The FSTAT function returns status information about a specified file unit.

## Syntax

*Result* = FSTAT(*Unit*)

## Return Value

The FSTAT function returns a structure expression of type FSTAT (or FSTAT64 in the case of files that are longer than  $2^{31}-1$  bytes in length) containing status information about a specified file unit. The contents of this structure are documented in [“Returning Information About a File Unit”](#) in Chapter 18 of the *Building IDL Applications* manual.

## Fields of the FSTAT Structure

The following descriptions are of *fields* in the structure returned by the FSTAT function. They are *not* keywords to FSTAT.

- **UNIT** — The IDL logical unit number (LUN).
- **NAME** — The name of the file.
- **OPEN** — Nonzero if the file unit is open. If OPEN is zero, the remaining fields in FSTAT will not contain useful information.
- **ISATTY** — Nonzero if the file is actually a terminal instead of a normal file. For example, if you are using an `xterm` window on a UNIX system and you invoke FSTAT on logical unit 0 (standard input), ISATTY will be set to 1.
- **ISAGUI** — Nonzero if the file is actually a Graphical User Interface (for example, a logical unit associated with the IDL Development Environment). Thus, if you are using the IDLDE and you invoke FSTAT on logical unit 0 (standard input), ISAGUI will be set to 1.
- **INTERACTIVE** — Nonzero if *either* ISATTY or ISAGUI is nonzero.
- **XDR** — Nonzero if the file was opened with the XDR keyword, and is therefore considered to contain data in the XDR format.
- **COMPRESS** — Nonzero if the file was opened with the COMPRESS keyword, and is therefore considered to contain compressed data in the GZIP format.

- **READ** — Nonzero if the file is open for read access.
- **WRITE** — Nonzero if the file is open for write access.
- **ATIME, CTIME, MTIME** — The date of last access, date of creation, and date of last modification given in seconds since 1 January 1970 UTC. Use the `SYSTIME` function to convert these dates into a textual representation.

---

**Note**

Some file systems do not maintain all of these dates (e.g. MS DOS FAT file systems), and may return 0. On some non-UNIX operating systems, access time is not maintained, and `ATIME` and `MTIME` will always return the same date.

---

- **TRANSFER\_COUNT** — The number of scalar IDL data items transferred in the last input/output operation on the unit. This is set by the following IDL routines: `READU`, `WRITEU`, `PRINT`, `PRINTF`, `READ`, and `READF`. `TRANSFER_COUNT` is useful when attempting to recover from input/output errors.
- **CUR\_PTR** — The current position of the file pointer, given in bytes from the start of the file. If the device is a terminal (`ISATTY` is nonzero), the value of `CUR_PTR` will not contain useful information. When reporting on file units opened with the `COMPRESS` keyword to `OPEN`, the position reported by `CUR_PTR` is the “logical” position—the position it would be at in the uncompressed version of the same file.
- **SIZE** — The current length of the file in bytes. If the device is a terminal (`ISATTY` is nonzero), the value of `SIZE` will not contain useful information. When reporting on file units opened with the `COMPRESS` keyword to `OPEN`, the size reported by `SIZE` is the compressed size of the actual file, and not the logical length of the uncompressed data contained within. This is inconsistent with the position reported by `CUR_PTR`. The reason for reporting the size in this way is that the logical length of the data cannot be known without reading the entire file from beginning to end and counting the uncompressed bytes, and this would be extremely inefficient.
- **REC\_LEN** — This field is obsolete and will always contain zero.

## Arguments

### Unit

The file unit about which information is required. This parameter can be an integer or an associated variable, in which case information about the variable's associated file is returned.

## Keywords

None.

## Examples

If file unit number 1 is open, the FSTAT information on that unit can be seen by entering:

```
PRINT, FSTAT(1)
```

Specific information can be obtained by referring to single fields within the structure returned by FSTAT. The following code prints the name and length of the file open on unit 1:

```
; Put FSTAT information in variable A:
A = FSTAT(1)

; Print the name and size fields:
PRINT, 'File: ', A.NAME, ' is ', A.SIZE, ' bytes long.'
```

# FULSTR

The `FULSTR` restores a row-indexed sparse array to full storage mode. If the sparse array was created with the `SPRSIN` function using the `THRESH` keyword, any values in the original array that were below the specified threshold are replaced with zeros.

## Syntax

*Result* = `FULSTR(A)`

## Return Value

Returns a given array to full storage mode.

## Arguments

### A

A row-indexed sparse array created by the `SPRSIN` function.

## Keywords

None.

## Examples

Suppose we have converted an array to sparse storage format with the following commands:

```
A = [[ 5.0, -0.2, 0.1], $
      [ 3.0, -2.0, 0.3], $
      [ 4.0, -1.0, 0.0]]
```

```
; Convert to sparse storage mode. All elements of the array A that
; have absolute values less than THRESH are set to zero:
sparse = SPRSIN(A, THRESH=0.5)
```

The variable `SPARSE` now contains a representation of the array `A` in structure form. To restore the array from the sparse-format structure:

```
; Restore the array:
result = FULSTR(sparse)
```

```
; Print the result:  
PRINT, result
```

IDL prints:

```
5.00000      0.00000      0.00000  
3.00000     -2.00000      0.00000  
4.00000     -1.00000      0.00000
```

Note that the elements with an absolute value less than the specified threshold have been set to zero.

# FUNCT

The FUNCT procedure evaluates the sum of a Gaussian and a 2nd-order polynomial and optionally returns the value of its partial derivatives. Normally, this function is used by CURVEFIT to fit the sum of a line and a varying background to actual data.

This routine is written in the IDL language. Its source code can be found in the file `funct.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
FUNCT, X, A, F [, Pder]
```

## Arguments

### X

A vector of values for the independent variable.

### A

A vector of coefficients for the equations:

$$F = A_0 e^{-Z^2/2} + A_3 + A_4 X + A_5 X^2$$

$$Z = (X - A_1) / A_2$$

### F

A named variable that will contain the value of the function at each  $X_i$ .

### Pder

A named variable that will contain an array of the size  $(N\_ELEMENTS(X), 6)$  that contains the partial derivatives.  $Pder(i, j)$  represents the derivative at the  $i^{th}$  point with respect to  $j^{th}$  parameter.

## FV\_TEST

The FV\_TEST function computes the F-statistic and the probability that two sample populations  $X$  and  $Y$  have significantly different variances.  $X$  and  $Y$  may be of different lengths. The F-statistic formula for sample populations  $x$  and  $y$  with means  $\bar{x}$  and  $\bar{y}$  is defined as:

$$F = \frac{\left( \frac{M-1}{N-1} \left[ \sum_{j=0}^{N-1} (x_j - \bar{x})^2 - \frac{1}{N} \left[ \sum_{j=0}^{N-1} (x_j - \bar{x}) \right]^2 \right] \right)}{\left[ \sum_{j=0}^{M-1} (y_j - \bar{y})^2 - \frac{1}{M} \left[ \sum_{j=0}^{M-1} (y_j - \bar{y}) \right]^2 \right]}$$

where  $x = (x_0, x_1, x_2, \dots, x_{N-1})$  and  $y = (y_0, y_1, y_2, \dots, y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `fv_test.pro` in the `lib` subdirectory of the IDL distribution.

### Syntax

*Result* = FV\_TEST(*X*, *Y*)

### Return Value

The result is a two-element vector containing the F-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that  $X$  and  $Y$  have significantly different variances. This type of test is often referred to as the F-variance test.

### Arguments

#### **X**

An  $n$ -element integer, single- or double-precision floating-point vector.

#### **Y**

An  $m$ -element integer, single- or double-precision floating-point vector.

## Keywords

None.

## Examples

```
; Define two n-element sample populations:
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201,  56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the F-statistic (of X and Y) and its significance:
PRINT, FV_TEST(X, Y)
```

IDL prints:

```
2.48578      0.0540116
```

The result indicates that X and Y have significantly different variances.

# FX\_ROOT

The `FX_ROOT` function computes a real or complex root of a univariate nonlinear function using an optimal Müller's method.

This routine is written in the IDL language. Its source code can be found in the file `fx_root.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = FX_ROOT(X, Func [, /DOUBLE] [, ITMAX=value] [, /STOP]
               [, TOL=value] )
```

## Return Value

The return value is the real or complex root of a univariate nonlinear function. Which root results depends on the initial guess provided for this routine.

## Arguments

### X

A 3-element real or complex initial guess vector. Real initial guesses may result in real or complex roots. Complex initial guesses will result in complex roots.

### Func

A scalar string specifying the name of a user-supplied IDL function that defines the univariate nonlinear function. This function must accept the vector argument `X`.

For example, suppose we wish to find a root of the following function:

$$y = e^{(\sin^2 x + \cos^2 x - 1)} - 1$$

We write a function `FUNC` to express the function in the IDL language:

```
FUNCTION func, X
  RETURN, EXP(SIN(X)^2 + COS(X)^2 - 1) - 1
END
```

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ITMAX

The maximum allowed number of iterations. The default is 100.

### STOP

Use this keyword to specify the stopping criterion used to judge the accuracy of a computed root  $r(k)$ . Setting `STOP = 0` (the default) checks whether the absolute value of the difference between two successively-computed roots,  $|r(k) - r(k+1)|$  is less than the stopping tolerance `TOL`. Setting `STOP = 1` checks whether the absolute value of the function `FUNC` at the current root,  $|FUNC(r(k))|$ , is less than `TOL`.

### TOL

Use this keyword to specify the stopping error tolerance. The default is  $1.0 \times 10^{-4}$ .

## Examples

This example finds the roots of the function `FUNC` defined above:

```
; First define a real 3-element initial guess vector:
x = [0.0, -!pi/2, !pi]

; Compute a root of the function using double-precision
; arithmetic:
root = FX_ROOT(X, 'FUNC', /DOUBLE)

; Check the accuracy of the computed root:
PRINT, EXP(SIN(ROOT)^2 + COS(ROOT)^2 - 1) - 1
```

IDL prints:

```
0.0000000
```

We can also define a complex 3-element initial guess vector:

```
x = [COMPLEX(-!PI/3, 0), COMPLEX(0, !PI), COMPLEX(0, -!PI/6)]

; Compute the root of the function:
root = FX_ROOT(x, 'FUNC')
```

```
; Check the accuracy of the computed complex root:  
PRINT, EXP(SIN(ROOT)^2 + COS(ROOT)^2 - 1) - 1
```

IDL prints:

```
(      0.00000,      0.00000)
```

# FZ\_ROOTS

The FZ\_ROOTS function is used to find the roots of an  $m$ -degree complex polynomial, using Laguerre's method.

FZ\_ROOTS is based on the routine `zroots` described in section 9.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = FZ_ROOTS(C [, /DOUBLE] [, EPS=value] [, /NO_POLISH] )
```

## Return Value

Returns an  $m$ -element complex vector containing the roots of an  $m$ -degree complex polynomial.

## Arguments

### C

A vector of length  $m+1$  containing the coefficients of the polynomial, in ascending order (see example). The type can be real or complex.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### EPS

The desired fractional accuracy. The default value is  $2.0 \times 10^{-6}$ .

### NO\_POLISH

Set this keyword to suppress the usual polishing of the roots by Laguerre's method.

## Examples

**Example 1:** Real coefficients yielding real roots.

Find the roots of the polynomial:

$$P(x) = 6x^3 - 7x^2 - 9x - 2$$

The exact roots are  $-1/2, -1/3, 2.0$ .

```
coeffs = [-2.0, -9.0, -7.0, 6.0]
roots = FZ_ROOTS(coeffs)
PRINT, roots
```

IDL prints:

```
( -0.500000, 0.000000) ( -0.333333, 0.000000) ( 2.000000, 0.000000)
```

**Example 2:** Real coefficients yielding complex roots.

Find the roots of the polynomial:

$$P(x) = x^4 + 3x^2 + 2$$

The exact roots are:

$$0.0 - i\sqrt{2.0}, 0.0 + i\sqrt{2.0}, 0.0 - i, 0.0 + i$$

```
coeffs = [2.0, 0.0, 3.0, 0.0, 1.0]
roots = FZ_ROOTS(coeffs)
PRINT, roots
```

IDL Prints:

```
(0.000000, -1.41421) (0.000000, 1.41421)
(0.000000, -1.00000) (0.000000, 1.00000)
```

**Example 3:** Real and complex coefficients yielding real and complex roots.

Find the roots of the polynomial:

$$P(x) = x^3 + (-4 - i4)x^2 + s(-3 + i4)x + (18 + i24)$$

The exact roots are  $-2.0, 3.0, (3.0 + i4.0)$

```
coeffs = [COMPLEX(18,24), COMPLEX(-3,4), COMPLEX(-4,-4), 1.0]
roots = FZ_ROOTS(coeffs)
PRINT, roots
```

IDL Prints:

```
( -2.000000, 0.000000) ( 3.000000, 0.000000) ( 3.000000, 4.000000)
```

# GAMMA

The GAMMA function returns the gamma function of  $Z$ .

The gamma function is defined as:

$$\Gamma(x) \equiv \int_0^{\infty} t^{x-1} e^{-t} dt$$

Use the LNGAMMA function to obtain the natural logarithm of the gamma function when there is a possibility of overflow.

## Syntax

*Result* = GAMMA( $Z$ )

## Return Value

If  $Z$  is double-precision, the result is double-precision (either double or double complex), otherwise the result is single-precision (either float or complex).

## Arguments

### $Z$

The expression for which the gamma function will be evaluated.  $Z$  may be complex.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Plot the gamma function over the range 0.01 to 1.0 with a step size of 0.01 by entering:

```
Z = FINDGEN(99)/100. + 0.01
PLOT, Z, GAMMA(Z)
```

## Version History

Original	Introduced
5.6	Z argument accepts complex input

# GAMMA\_CT

The GAMMA\_CT procedure applies gamma correction to a color table.

This routine is written in the IDL language. Its source code can be found in the file `gamma_ct.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
GAMMA_CT, Gamma [, /CURRENT] [, /INTENSITY]
```

## Arguments

### Gamma

The value of gamma correction. A value of 1.0 indicates a linear ramp (i.e., no gamma correction). Higher values of *Gamma* give more contrast. Values less than 1.0 yield lower contrast.

## Keywords

### CURRENT

Set this keyword to apply correction from the “current” color table (i.e., the values `R_CURR`, `G_CURR`, and `B_CURR` in the `COLORS` common block). Otherwise, correction is applied from the “original” color table (i.e., the values `R_ORIG`, `G_ORIG`, and `B_ORIG` in the `COLORS` common block). The gamma corrected color table is always saved in the “current” table (`R_CURR`, `G_CURR`, `B_CURR`) and the new table is loaded.

### INTENSITY

Set this keyword to correct the individual intensities of each color in the colortable. Otherwise, the colors are shifted according to the gamma function.

# GAUSS\_CVF

The GAUSS\_CVF function computes the cutoff value  $V$  in a standard Gaussian (normal) distribution with a mean of 0.0 and a variance of 1.0 such that the probability that a random variable  $X$  is greater than  $V$  is equal to a user-supplied probability  $P$ .

This routine is written in the IDL language. Its source code can be found in the file `gauss_cvf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = GAUSS\_CVF(*P*)

## Return Value

Returns the cutoff value  $V$  in a standard Gaussian (normal) distribution with a mean of 0.0 and a variance of 1.0.

## Arguments

### P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

## Keywords

None.

## Examples

Use the following command to compute the cutoff value in a Gaussian distribution such that the probability that a random variable  $X$  is greater than the cutoff value is 0.025:

```
PRINT, GAUSS_CVF(0.025)
```

IDL prints:

```
1.95997
```

## Version History

4.0	Introduced

# GAUSS\_PDF

The GAUSS\_PDF function computes the probability  $P$  that, in a standard Gaussian (normal) distribution with a mean of 0.0 and a variance of 1.0, a random variable  $X$  is less than or equal to a user-specified cutoff value  $V$ .

This routine is written in the IDL language. Its source code can be found in the file `gauss_pdf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = GAUSS\_PDF(*V*)

## Return Value

This function returns a scalar or array with the same dimensions as  $V$ . If  $V$  is double-precision, the result is double-precision, otherwise the result is single-precision.

## Arguments

### V

A scalar or array that specifies the cutoff value(s).

## Keywords

None.

## Examples

### Example 1

Compute the probability that a random variable  $X$ , from the standard Gaussian (normal) distribution, is less than or equal to 2.44:

```
PRINT, GAUSS_PDF(2.44)
```

IDL Prints:

```
0.992656
```

## Example 2

Compute the probability that a random variable X, from the standard Gaussian (normal) distribution, is less than or equal to 10.0 and greater than or equal to 2.0:

```
PRINT, GAUSS_PDF(10.0) - GAUSS_PDF(2.0)
```

IDL Prints:

```
0.0227501
```

## Example 3

Compute the probability that a random variable X, from the Gaussian (normal) distribution with a mean of 0.8 and a variance of 4.0, is less than or equal to 2.44:

```
PRINT, GAUSS_PDF( (2.44 - 0.80)/SQRT(4.0) )
```

IDL Prints:

```
0.793892
```

[BINOMIAL](#), [CHISQR\\_PDF](#), [F\\_PDF](#), [GAUSS\\_CVF](#), [T\\_PDF](#)

# GAUSS2DFIT

The GAUSS2DFIT function fits a two-dimensional, elliptical Gaussian equation to rectilinearly gridded data.

$$Z = F(x, y)$$

where:

$$F(x, y) = A_0 + A_1 e^{-U/2}$$

And the elliptical function is:

$$U = (x'/a)^2 + (y'/b)^2$$

The parameters of the ellipse  $U$  are:

- Axis lengths are  $2a$  and  $2b$ , in the unrotated X and Y axes, respectively.
- Center is at  $(h, k)$ .
- Rotation of  $T$  radians from the X axis, in the *clockwise* direction.

The rotated coordinate system is defined as:

$$x' = (x - h)\cos T - (y - k)\sin T$$

$$y' = (x - h)\sin T + (y - k)\cos T$$

The rotation is optional, and can be forced to 0, making the major and minor axes of the ellipse parallel to the X and Y axes.

Coefficients of the computed fit are returned in argument A.

## Procedure Used and Other Notes

The peak/valley is found by first smoothing  $Z$  and then finding the maximum or minimum, respectively. GAUSSFIT is then applied to the row and column running through the peak/valley to estimate the parameters of the Gaussian in X and Y. Finally, CURVEFIT is used to fit the 2D Gaussian to the data.

Be sure that the 2D array to be fit contains the entire peak/valley out to at least 5 to 8 half-widths, or the curve-fitter may not converge.

This is a computationally-intensive routine. The time required is roughly proportional to the number of elements in  $Z$ .

This routine is written in the IDL language. Its source code can be found in the file `gauss2dfit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = GAUSS2DFIT( Z, A [, X, Y] [, /NEGATIVE] [, /TILT] )
```

## Arguments

### Z

The dependent variable.  $Z$  should be a two-dimensional array with dimensions ( $N_x$ ,  $N_y$ ). Gridding in the array must be rectilinear.

### A

A named variable in which the coefficients of the fit are returned.  $A$  is returned as a seven element vector the coefficients of the fitted function. The meanings of the seven elements in relation to the discussion above is:

- $A[0] = A_0 =$  constant term
- $A[1] = A_1 =$  scale factor
- $A[2] = a =$  width of Gaussian in the X direction
- $A[3] = b =$  width of Gaussian in the Y direction
- $A[4] = h =$  center X location
- $A[5] = k =$  center Y location.
- $A[6] = T =$  *Theta*, the rotation of the ellipse from the X axis in radians, *counter-clockwise*.

### X

An optional vector with  $N_x$  elements that contains the X values of  $Z$  (i.e.,  $X_i$  is the X value for  $Z_{i,j}$ ). If this argument is omitted, a regular grid in X is assumed, and the X location of  $Z_{i,j} = i$ .

## Y

An optional vector with  $N_y$  elements that contains the Y values of Z (i.e.,  $Y_j$  is the Y value for  $Z_{i,j}$ ). If this argument is omitted, a regular grid in Y is assumed, and the Y location of  $Z_{i,j} = j$ .

## Keywords

### NEGATIVE

Set this keyword to indicate that the Gaussian to be fitted is a valley (such as an absorption line). By default, a peak is fit.

### TILT

Set this keyword to allow the orientation of the major and minor axes of the ellipse to be unrestricted. The default is that the axes of the ellipse must be parallel to the X and Y axes. Therefore, in the default case, A[6] is always returned as 0.

## Examples

This example creates a 2D gaussian, adds random noise and then applies GAUSS2DFIT.

```

; Define array dimensions:
nx = 128 & ny = 100
; Define input function parameters:
A = [ 5., 10., nx/6., ny/10., nx/2., .6*ny]
; Create X and Y arrays:
X = FINDGEN(nx) # REPLICATE(1.0, ny)
Y = REPLICATE(1.0, nx) # FINDGEN(ny)
; Create an ellipse:
U = ((X-A[4])/A[2])^2 + ((Y-A[5])/A[3])^2
; Create gaussian Z:
Z = A[0] + A[1] * EXP(-U/2)
; Add random noise, SD = 1:
Z = Z + RANDOMN(seed, nx, ny)
; Fit the function, no rotation:
yfit = GAUSS2DFIT(Z, B)
; Report results:
PRINT, 'Should be: ', STRING(A, FORMAT='(6f10.4)')
PRINT, 'Is: ', STRING(B(0:5), FORMAT='(6f10.4)')
```

## Version History

[COMFIT](#), [GAUSSFIT](#), [POLY\\_FIT](#), [REGRESS](#), [SFIT](#), [SVDFIT](#), “Curve and Surface Fitting” in Chapter 11 of the *Using IDL* manual

# GAUSSFIT

The GAUSSFIT function computes a non-linear least-squares fit to a function  $f(x)$  with from three to six unknown parameters.  $f(x)$  is a linear combination of a Gaussian and a quadratic; the number of terms is controlled by the keyword parameter NTERMS.

This routine is written in the IDL language. Its source code can be found in the file `gaussfit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = GAUSSFIT( X, Y [, A] [, CHISQ=variable] [, ESTIMATES=array]  
[, MEASURE_ERRORS=vector] [, NTERMS=integer{3 to 6}]  
[, SIGMA=variable] [, YERROR=variable])
```

## Return Value

Returns three to six values that are the non-linear least squares fit to a function  $f(x)$ .

## Arguments

### X

An  $n$ -element vector of independent variables.

### Y

A vector of dependent variables, the same length as X.

### A

A named variable that will contain the coefficients A of the fit.

## Keywords

### CHISQ

Set this keyword to a named variable that will contain the value of the reduced chi-square goodness-of-fit statistic.

## ESTIMATES

Set this keyword equal to an array of starting estimates for the parameters of the equation. If the NTERMS keyword is specified, the ESTIMATES array should have NTERMS elements. If NTERMS is not specified, the ESTIMATES array should have six elements. If the ESTIMATES array is not specified, estimates are calculated by first subtracting a constant (if NTERMS  $\geq$  4) or a linear term (if NTERMS  $\geq$  5), and then forming a simple estimate of the Gaussian coefficients.

---

**Note**

If ESTIMATES[2] (the Gaussian width) is zero, then GAUSSFIT will automatically compute a best guess for the starting value for this term.

---

## MEASURE\_ERRORS

Set this keyword to a vector containing standard measurement errors for each point  $Y[i]$ . This vector must be the same length as  $X$  and  $Y$ .

---

**Note**

For Gaussian errors (e.g., instrumental uncertainties), MEASURE\_ERRORS should be set to the standard deviations of each point in  $Y$ . For Poisson or statistical weighting, MEASURE\_ERRORS should be set to  $\text{SQRT}(Y)$ .

---

## NTERMS

Set this keyword to an integer value between three and six to specify the function to be used for the fit. The values correspond to the functions shown below. In all cases:

$$z = \frac{x - A_1}{A_2}$$

**NTERMS=6**

$$f(x) = A_0 e^{\frac{-z^2}{2}} + A_3 + A_4 x + A_5 x^2$$

**NTERMS=5**

$$f(x) = A_0 e^{\frac{-z^2}{2}} + A_3 + A_4 x$$

**NTERMS=4**

$$f(x) = A_0 e^{\frac{-z^2}{2}} + A_3$$

**NTERMS=3**

$$f(x) = A_0 e^{\frac{-z^2}{2}}$$

NTERMS=6 is the default setting. Here, A0 is the height of the Gaussian, A1 is the center of the Gaussian, A2 is the width (the standard deviation) of the Gaussian, A3 is the constant term, A4 is the linear term, and A5 is the quadratic term.

**Tip**

---

The full width at half maximum (FWHM) of the Gaussian may be computed as  $2 * \text{SQRT}(2 * \text{ALOG}(2)) * A2$ .

---

**SIGMA**

Set this keyword to a named variable that will contain the 1-sigma error estimates of the returned parameters.

**Note**

---

If MEASURE\_ERRORS is omitted, then you are assuming that a polynomial is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by  $\text{SQRT}(\text{CHISQ}/(N * M))$ , where  $N$  is the number of points in  $X$ , and  $M$  is the number of coefficients. See Section 15.2 of *Numerical Recipes in C (Second Edition)* for details.

---

## YERROR

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

## Examples

The following example shows how to use GAUSSFIT to fit to four different functions, with NTERMS=3,4,5,6. To simulate actual data, random noise has been added to each function.

```

pro ex_gaussfit

; Define the independent variable.
n = 101
x = (FINDGEN(n) - (n/2))/4

; Define the coefficients.
a = [4.0, 1.0, 2.0, 1.0, 0.25, 0.01]
print, 'Expected: ', a
z = (x - a[1])/a[2] ; Gaussian variable
!P.MULTI = [0,2,2] ; set up 2x2 plot window
seed = 123321 ; Pick a starting seed value

for nterms=3,6 do begin
; Define the dependent variables. Start with random noise.
y = 0.4*RANDOMN(seed, n)

; Use a switch statement so we fall through to each term.
switch nterms of
6: y = y + a[5]*x^2
5: y = y + a[4]*x
4: y = y + a[3]
3: y = y + a[0]*exp(-z^2/2)
endswitch

; Fit the data to the function, storing coefficients in
; coeff:
yfit = GAUSSFIT(x, y, coeff, NTERMS=nterms)
print, 'Result: ', coeff[0:nterms-1]
; Plot the original data and the fitted curve:
PLOT, x, y, TITLE='nterms='+STRTRIM(nterms,2)
OPLOT, x, yfit, THICK=2
endfor
end

```

When this program is compiled and executed, IDL prints the following results:

```
IDL> ex_gaussfit
Expected: 4.00000 1.00000 2.00000 1.00000 0.250000 0.0100000
Result: 3.95437 1.03176 2.07216
Result: 4.38669 0.948479 1.84426 0.909676
Result: 3.93348 0.839296 2.02112 1.05237 0.249002
Result: 3.80389 0.993375 2.07302 1.16684 0.249051 0.0484357
```

## Version History

# GAUSSINT

The GAUSSINT function evaluates the integral of the Gaussian probability function.

The Gaussian integral is defined as:

$$\text{Gaussint}(x) \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-t^2/2} dt$$

## Syntax

*Result* = GAUSSINT(*X*)

## Return Value

Returns the result of the Gaussian probability function integral evaluation. If *X* is double-precision, the result is double-precision, otherwise the argument is converted to floating-point and the result is floating-point. The result has the same structure as the input argument, *X*.

## Arguments

**X**

The expression for which the Gaussian integral is to be evaluated.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Plot the Gaussian probability function over the range -5 to 5 with a step size of 0.1 by entering:

```
X = FINDGEN(101)/10. - 5.  
PLOT, X, GAUSSINT(X)
```

# GET\_DRIVE\_LIST

The GET\_DRIVE\_LIST function returns valid drive or volume names for the file system. Under Microsoft Windows, keywords can be used to specify that only drives of certain types should be returned.

---

**Note**

The UNIX operating system presents all files within a single unified file hierarchy, and does not support the concept of drive letters or volume names. As such, GET\_DRIVE\_LIST always returns a scalar null string under UNIX.

---

## Syntax

*Result* = GET\_DRIVE\_LIST( [, COUNT=*variable*] )

**Windows-Only Keywords:** [, /CDROM] [, /FIXED] [, /REMOTE]  
[, /REMOVABLE]

## Return Value

Returns a string array of the names of valid drives / volumes for the file system. If GET\_DRIVE\_LIST has no drives to return, it returns a scalar null string.

## Arguments

None.

## Keywords

---

**Note**

If a Windows-only keyword is specified, only drives of the specified types are reported.

---

### CDROM

*This keyword is only available on Windows platforms.*

If set, compact disk drives are reported. Note that although CDROM devices are removable, they are treated as a special case, and the REMOVABLE keyword does not apply to them.

## COUNT

A named variable into which the number of drives/volumes found is placed. If no drives/volumes are found, a value of zero is returned. Under UNIX, the value returned by this keyword will always be zero.

## FIXED

*This keyword is only available on Windows platforms.*

If set, hard drives physically attached to the current system are reported.

## REMOTE

*This keyword is only available on Windows platforms.*

If set, remote (i.e. network) drives are reported.

## REMOVABLE

*This keyword is only available on Windows platforms.*

If set, removable media devices (e.g. floppy, zip drive) other than CDROMs are reported.

## Examples

Under Windows, the following will report all local hard drives:

```
drives = GET_DRIVE_LIST(/FIXED)
```

This statement obtains the names of all floppy drives, cdroms, and other removable media drives:

```
drives = GET_DRIVE_LIST(/CDROM, /REMOVABLE)
```

## Version History

5.3	Introduced
-----	------------

# GET\_KBRD

The `GET_KBRD` function returns the next character available from the standard input (IDL file unit 0). Depending on the value of the *Wait* argument, it will either return immediately or wait until a character is present in the terminal type-ahead buffer.

---

**Note**

RSI recommends the use of a GUI interface (e.g. `WIDGET_BUTTON`) instead of `GET_KBRD` where possible.

---

---

**Tip**

Under Microsoft Windows, the `GET_KBRD` function can be used to return Windows special characters (in addition to the standard keyboard characters). To get a special character, hold down the **Alt** key and type the character's ANSI equivalent on the numeric keypad while `GET_KBRD` is waiting. **Ctrl** + *key* combinations are not supported.

---

---

**Warning**

`GET_KBRD` is intended for use in IDL's UNIX command-line mode. While `GET_KBRD` will return values for some characters when run from the IDL Development Environment (either UNIX or Microsoft Windows), other characters are treated as special cases by the underlying windowing system, and may not be returned by `GET_KBRD`. In addition, the event-handling mechanism used by the IDL Development Environment may not respond to keyboard events in the way that you expect. Use caution when using `GET_KBRD` within a loop.

---

## Syntax

```
Result = GET_KBRD([Wait] [, /ESCAPE | , /KEY_NAME])
```

## Return Value

Returns a string containing the next available character that is input from the keyboard. If no keywords are specified, the result will always be a one-character string. If the `ESCAPE` or `KEY_NAME` keyword is specified, the result may contain multiple characters, as described below.

## Arguments

### Wait

If *Wait* is zero, GET\_KBRD returns the null string if there are no characters in the terminal type-ahead buffer. If the *Wait* argument is either not present or present and non-zero, the function waits for a character to be typed before returning.

## Keywords

### ESCAPE

This keyword is intended for use with IDL's UNIX command line interface; it controls how the GET\_KBRD function handles *escape sequences*. If ESCAPE is set and GET\_KBRD encounters an escape sequence, the return value will be a string containing the entire sequence. See “[Escape Sequences](#)” below for more information.

### KEY\_NAME

This keyword is intended for use with IDL's UNIX command line interface; it controls how the GET\_KBRD function handles *escape sequences*. If KEY\_NAME is set and GET\_KBRD encounters an escape sequence, it reads the complete sequence and compares it to IDL's table of known function keys. If the escape sequence corresponds to a known function key, the return value will be a string containing the *name* of the key, or a null string otherwise. See “[Escape Sequences](#)” below for more information.

## Escape Sequences

The UNIX command line version of IDL is usually used within the environment provided by a program called a *terminal emulator*. (The `xterm` program is the most common such emulator, but there are others.) When you press an alphanumeric key on the keyboard, the terminal emulator sends the ASCII code for that character to the running program (IDL, in this case). For example, if you press the lowercase **a** key, the terminal emulator sends IDL the ASCII code for “a” (ASCII 97).

Some keys, including the arrow keys and the function keys on the top row of the keyboard, do not correspond directly to a single ASCII character. Instead, they send an *escape sequence* that the program can interpret and map to a useful meaning. An escape sequence consists of the ASCII ESC (ASCII 27) character, followed by one or more characters, following a special syntax that lets the reading program determine when a complete sequence has been seen. For example, when you press the up-arrow

key, the vast majority of terminal emulators send the three-character sequence ESC [A.

By default, GET\_KBRD returns the next available single ASCII character entered at the command line. In this mode, it does not treat escape sequences as special characters. If you call GET\_KBRD and press the up-arrow key, GET\_KBRD will return the ASCII ESC character and ignore the characters following it. The ESCAPE and KEY\_NAME keywords can be used to alter this behavior.

If the ESCAPE keyword is set and GET\_KBRD sees an escape sequence, it will read and return the entire escape sequence. For example, if the up-arrow key is pressed, GET\_KBRD would (with most terminal emulators) return a string containing the three characters ESC [A (or, more specifically, the three characters defined by the ASCII codes 27 91 65 ).

---

**Note**

Escape sequences are not printable characters. This means that in order to see the characters that make up the escape sequence, you must view their byte values. For example, entering the following at the IDL command line, followed by the up-arrow key, may not produce visible output, depending on the terminal emulator in use:

```
PRINT, GET_KBRD (/ESCAPE)
```

If you enter the following at the IDL command line, followed by the up-arrow key:

```
PRINT, BYTE (GET_KBRD (/ESCAPE))
```

IDL will print

```
27 91 65
```

(or the values of the equivalent ASCII characters used by your terminal emulator).

---

If the KEY\_NAME keyword is set and GET\_KBRD sees an escape sequence, it will read the entire sequence. If the escape sequence is associated with a known function key, it will return the name of that key. If the sequence is not associated with a known function key, it will return a null string. In the case of the up-arrow key example, GET\_KBRD would return the string UP.

**Note**

The command `HELP`, `/KEYS`, `/FULL` can be used to see the full set of known keys and the escape sequences they are bound to. The `DEFINE_KEY` procedure can be used to add additional keys and/or escape sequences.

The `ESCAPE` and `KEY_NAME` keywords do not affect the way that `GET_KBRD` handles non-escape sequence characters. `GET_KBRD` always returns the single ASCII character seen in those situations.

The `ESCAPE` and `KEY_NAME` keywords are only applicable to the UNIX IDL command line interface. They are accepted, but ignored, when used with the IDLDE graphical interface.

## Examples

To store the next character typed at the IDL prompt in the variable `R`, enter:

```
R = GET_KBRD()
```

Press any key. To see the character that was typed, enter:

```
PRINT, R
```

The following code fragment reads one character at a time and echoes that character's numeric code (or codes, for keys that generate escape sequences). It quits when a "q" is entered:

```
REPEAT BEGIN
  A = GET_KBRD(/ESCAPE)
  PRINT, BYTE(A)
ENDREP UNTIL A EQ 'q'
```

The following code fragment reads one character at a time and echoes that character (or the key's name, for named keys). It quits when a "q" is entered:

```
REPEAT BEGIN
  A = GET_KBRD(/KEY_NAME)
  PRINT, A
ENDREP UNTIL A EQ 'q'
```

**Note**

The `GET_KBRD` function can be used to return Windows special characters (in addition to standard keyboard characters), created by holding down the Alt key and entering the character's ANSI equivalent. For example, to return the paragraph marker (¶), ANSI number 0182, enter:

```
C = GET_KBRD()
```

While `GET_KBRD` is waiting, press and hold the Alt key and type 0182 on the numeric keypad. When the IDL prompt returns, enter:

```
PRINT, C
```

IDL prints the paragraph marker, “¶”.

`GET_KBRD` *cannot* be used to return control characters or other editing keys (e.g., Delete, Backspace, etc.). These characters are used for keyboard shortcuts and command line editing only. `GET_KBRD` can be used to return the Enter key.

---

## Version History

# GET\_LUN

The GET\_LUN procedure allocates a file unit from a pool of free units. Instead of writing routines to assume the use of certain file units, IDL functions and procedures should use GET\_LUN to reserve unit numbers in order to avoid conflicts with other routines. Use FREE\_LUN to free the file units when finished.

## Syntax

```
GET_LUN, Unit
```

## Arguments

### Unit

The named variable into which GET\_LUN should place the file unit number. *Unit* is converted into a longword integer in the process. The file unit number obtained is in the range 100 to 128.

## Keywords

None.

## Examples

Instead of explicitly specifying a file unit number that may already be used, use GET\_LUN to obtain a free one and store the result in the variable U by entering:

```
GET_LUN, U
```

Now U can be used in opening a file:

```
OPENR, U, 'file.dat'
```

Once the data from “file.dat” has been read, the file can be closed and the file unit can be freed with the command:

```
FREE_LUN, U
```

Note also that OPENR has a GET\_LUN keyword that allows you to simultaneously obtain a free file unit and open a file. The following command performs the same tasks as the first two commands above:

```
OPENR, U, 'file.dat', /GET_LUN
```

# GET\_SCREEN\_SIZE

The `GET_SCREEN_SIZE` function returns size, measured in device units, of the screen.

## Syntax

*Result* = `GET_SCREEN_SIZE`( [*Display\_name*] [, **RESOLUTION**=*variable*] )

**Unix-Only Keywords:** [, **DISPLAY\_NAME**=*string*]

## Return Value

Returns a two-element vector of the form [*width*, *height*] that represents the dimensions, measured in device units, of the screen

## Arguments

### Display\_name

*This argument is only available on UNIX platforms.*

A string indicating the name of the X Windows display that should be used to determine the screen size.

## Keywords

### DISPLAY\_NAME

*This keyword is only available on UNIX platforms.*

Set this keyword equal to a string indicating the name of the X Windows display that should be used to determine the screen size. Setting this keyword is equivalent to setting the optional *Display\_name* argument.

### RESOLUTION

Set this keyword equal to a named variable that will contain a two-element vector, [*xres*, *yres*], specifying the screen resolution in cm/pixel.

## Examples

You can find the dimensions and screen resolution of your screen by entering the following:

```
dimensions = GET_SCREEN_SIZE(RESOLUTION=resolution)
PRINT, dimensions, resolution
```

For the screen on which this was tested, IDL prints:

```
1280.00      1024.00
0.0282031    0.0281250
```

## Version History

5.6	Introduced
-----	------------

# GETENV

The GETENV function returns the value of one or more specified environment variables from the environment of the IDL process.

## About the Process Environment

Every process has an *environment* consisting of environment variables, each of which has an associated string value. Some environment variables always exist, such as PATH, which tells the shell where to look for programs. Others can be added by the user, either interactively via a shell, via a UNIX startup file such as `.login`, or a via a Windows control panel.

When a process is created, it is given a copy of the environment from its parent process. IDL is no exception to this; when started, it inherits a copy of the environment of its parent process, which may be an interactive shell, the windowing system's desktop environment, or some other process. In turn, any child process created by IDL (such as those from the SPAWN procedure) inherits a copy of IDL's current environment.

## Note

---

It is important to realize that environment variables are not an IDL feature; they are part of every process. Although they can serve as a form of global memory, it is best to avoid using them in that way. Instead, IDL heap variables (pointers or object references), IDL system variables, or common blocks should be used in that role. Environment variables should be used for communicating with child processes. One example is setting the value of the SHELL environment variable prior to calling SPAWN to change the shell executed by SPAWN.

---

## Syntax

```
Result = GETENV( Name [, /ENVIRONMENT] )
```

## Return Value

Returns the value of the environment variable *Name* from the environment of the IDL process, or a null string if *Name* does not exist in the environment. If *Name* is an array, the result has the same structure, with each element containing the value for the corresponding element of *Name*.

# Arguments

## Name

A scalar string or string array variable containing the names of environment variables for which values are desired.

### Special Handling of the IDL\_TMPDIR Environment Variable

The normal action of GETENV is to look up the specified name in the environment without performing any special action, and to return a NULL string if it is not found. However, if you specify “IDL\_TMPDIR” as the value of *Name*, GETENV takes the following special actions:

- If the IDL\_TMPDIR preference has a non-NULL value, GETENV returns the value of that preference. For more information on this preference, see [“IDL\\_TMPDIR”](#) on page 4858. For general information, see [“IDL Preferences”](#) on page 4841.
- On UNIX systems, IDL uses the value of the standard TMPDIR environment variable. If TMPDIR is not defined, IDL chooses a reasonable temporary directory based on operating system and vendor conventions.
- On Windows systems, IDL uses the value provided by Windows, which is the first of the following that is defined: the value of the TMP environment variable, the value of the TEMP environment variable, or the default value for the current Windows version.

This special processing has the following benefits:

- IDL\_TMPDIR always yields a temporary directory path, so IDL code can use it immediately without additional work.
- The default behavior is to use the system defined location for temporary files, meaning that IDL applications automatically follow the standard conventions of the underlying platform.
- Sometimes, local site considerations require the use of a non-standard location. The IDL\_TMPDIR preference lets this requirement be managed in an easy and flexible manner.

## Keywords

### ENVIRONMENT

Set this keyword to return a string array containing all entries in the current process, one variable per entry, in the SETENV format (*Variable=Value*). If ENVIRONMENT is set, the *Name* argument should not be supplied.

## Examples

To print the name of the current UNIX shell, enter the command:

```
PRINT, 'The current shell is: ', GETENV('SHELL')
```

To store the path to the directory where IDL believes temporary files should be placed in the variable `mytemp`, use the following statement:

```
mytemp = GETENV('IDL_TMPDIR')
```

## See Also

[SETENV](#)

## Version History

Original	Introduced
6.1	ENVIRONMENT keyword modified to work on all platforms

# GOTO

The GOTO statement transfers program control to point specified by a label. The GOTO statement is generally considered to be a poor programming practice that leads to unwieldy programs. Its use should be avoided. However, for those cases in which the use of a GOTO is appropriate, IDL does provide the GOTO statement.

Note that using a GOTO to jump into the middle of a loop results in an error.

## Warning

---

You must be careful in programming with GOTO statements. It is not difficult to get into a loop that will never terminate, especially if there is not an escape (or test) within the statements spanned by the GOTO.

---

For information on using GOTO and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

## Syntax

GOTO, *label*

## Examples

In the following example, the statement at label JUMP1 is executed after the GOTO statement, skipping any intermediate statements:

```
GOTO, JUMP1
PRINT, 'Skip this' ; This statement is skipped
PRINT, 'Skip this' ; This statement is also skipped
JUMP1: PRINT, 'Do this'
```

The label can also occur before the GOTO statement that refers to the label, but you must be careful to avoid an endless loop. GOTO statements are frequently the subjects of IF statements, as in the following statement:

```
IF A NE G THEN GOTO, MISTAKE
```

## Version History

Original	Introduced

# GRID\_INPUT

The GRID\_INPUT procedure preprocesses and sorts two-dimensional scattered data points, and removes duplicate values. This procedure is also used for converting spherical coordinates to Cartesian coordinates.

## Note

---

GRID\_INPUT accepts complex input but only utilizes the real part of any complex number.

---

## Syntax

```
GRID_INPUT, X, Y, F, X1, Y1, F1 [, DUPPLICATES=string ] [, EPSILON=value ]
    [, EXCLUDE=vector ]
```

or

```
GRID_INPUT, Lon, Lat, F, Xyz, F1, /SPHERE [, /DEGREES]
    [, DUPPLICATES=string ] [, EPSILON=value ] [, EXCLUDE=vector ]
```

or

```
GRID_INPUT, R, Theta, F, X1, Y1, F1, /POLAR [, /DEGREES]
    [, DUPPLICATES=string ] [, EPSILON=value ] [, EXCLUDE=vector ]
```

## Arguments

### X, Y

These are input arguments for scattered data points, where X, and Y are location. All of these arguments are N point vectors.

### F

The function value at each location in the form of an N point vector.

### Lon, Lat

These are input arguments representing scattered data points on a sphere, specifying location (longitude and latitude). All are N point vectors. *Lon*, *Lat* are in degrees or radians (default).

## R, Theta

These are scattered data point input arguments representing the *R* and *Theta* polar coordinate location in degrees or radians (default). All arguments are *N* point vectors.

## X1, Y1, F1

These output arguments are processed and sorted single precision floating point data which are passed as the input points to the GRIDDATA function.

## Xyz

Upon return, a named variable that contains a 3-by-*n* array of Cartesian coordinates representing points on a sphere.

## Keywords

### DEGREES

By default, all angular inputs and keywords are assumed to be in radian units. Set the DEGREES keyword to change the angular input units to degrees.

### DUPLICATES

Set this keyword to a string indicating how duplicate data points are handled per the following table. The case (upper or lower) is ignored. The default setting for DUPLICATES is "First".

String	Meaning
"First"	Retain only the first encounter of the duplicate locations.
"Last"	Retain only the last encounter of the duplicate locations.
"All"	Retains all locations, which is invalid for any gridding technique that requires a TRIANGULATION. Some methods, such as Inverse Distance or Polynomial Regression with no search criteria can handle duplicates.
"Avg"	Retain the average F value of the duplicate locations.

Table 3-47: DUPLICATE Keyword Values

String	Meaning
"Midrange"	Retain the average of the minimum and maximum duplicate locations $((\text{Max}(F) + \text{Min}(F)) / 2)$ .
"Min"	Retain the minimum of the duplicate locations $(\text{Min}(F))$ .
"Max"	Retain the maximum of the duplicate locations $(\text{Max}(F))$ .

*Table 3-47: DUPLICATE Keyword Values (Continued)*

## EPSILON

The tolerance for finding duplicates. Points within EPSILON distance of each other are considered duplicates. For spherical coordinates, EPSILON is in units of angular distance, as set by the DEGREES keyword.

## EXCLUDE

An  $N$ -point vector specifying the indices of the points to exclude.

## POLAR

Set to indicate inputs are in polar coordinates.

## SPHERE

Set to indicate inputs are in spherical coordinates. In this case, the output argument  $XYZ$  is set to a 3-by- $n$  array containing the spherical coordinates converted to 3-dimensional Cartesian points on a sphere.

## Examples

The following example uses the data from the `irreg_grid1.txt` ASCII file included in the `examples/data` subdirectory of the IDL distribution. This file contains scattered elevation data of a model of an inlet. This scattered elevation data contains two duplicate locations. The `GRID_INPUT` procedure is used to omit the duplicate locations.

```

; Import the Data:
; Determine the path to the file.
file = FILE_SEARCH(!DIR, 'irreg_grid1.txt')
```

```

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
data = dataArray[*, 2]

; Display the Data:

; Scale the data to range from 1 to 253 so a color table can be
; applied. The values of 0, 254, and 255 are reserved as outliers.
scaled = BYTSCL(data, TOP = !D.TABLE_SIZE - 4) + 1B

; Load the color table. If you are on a TrueColor, set the
; DECOMPOSED keyword to the DEVICE command before running a
; color table related routine.
DEVICE, DECOMPOSED = 0
LOADCT, 38

; Open a display window and plot the data points.
WINDOW, 0
PLOT, x, y, /XSTYLE, /YSTYLE, LINESSTYLE = 1, $
    TITLE = 'Original Data, Scaled (1 to 253)', $
    XTITLE = 'x', YTITLE = 'y'

; Now display the data values with respect to the color table.
FOR i = 0L, (N_ELEMENTS(x) - 1) DO PLOTS, x[i], y[i], PSYM = -1, $
    SYMSIZE = 2., COLOR = scaled[i]

; Preprocess and sort the data. GRID_INPUT will
; remove any duplicate locations.
GRID_INPUT, x, y, data, xSorted, ySorted, dataSorted

; Display the results from GRID_INPUT:

; Scale the resulting data.
scaled = BYTSCL(dataSorted, TOP = !D.TABLE_SIZE - 4) + 1B

; Open a display window and plot the resulting data points.
WINDOW, 1
PLOT, xSorted, ySorted, /XSTYLE, /YSTYLE, LINESSTYLE = 1, $
    TITLE = 'The Data Preprocessed and Sorted, Scaled (1 to 253)', $
    XTITLE = 'x', YTITLE = 'y'

```

```
; Now display the resulting data values with respect to the color
; table.
FOR i = 0L, (N_ELEMENTS(xSorted) - 1) DO PLOTS, $
    xSorted[i], ySorted[i], PSYM = -1, COLOR = scaled[i], $
    SYMSIZE = 2.
```

[GRIDDATA](#)

## GRID\_TPS

The GRID\_TPS function uses thin plate splines to interpolate a set of values over a regular two dimensional grid, from irregularly sampled data values. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

Given  $n$  points,  $(x_i, y_i)$  in the plane, a thin plate spline can be defined as:

$$f(x, y) = a_0 + a_1x + a_2y + \frac{1}{2} \sum_{i=0}^{n-1} b_i r_i^2 \log r_i^2$$

with the constraints:

$$\sum_{i=1}^{n-1} b_i = \sum_{i=1}^{n-1} b_i x_i = \sum_{i=0}^{n-1} b_i y_i = 0$$

where  $r_i^2 = (x-x_i)^2 + (y-y_i)^2$ . A thin plate spline (TPS) is a smooth function, which implies that it has continuous first partial derivatives. It also grows almost linearly when far away from the points  $(x_i, y_i)$ . The TPS surface passes through the original points:  $f(x_i, y_i) = z_i$ .

### Note

---

GRID\_TPS requires at least 7 noncolinear points.

---

## Syntax

*Result* = GRID\_TPS (*Xp*, *Yp*, *Values* [, **COEFFICIENTS**=*variable*] [, **NGRID**=[*nx*, *ny*] [, **START**=[*x0*, *y0*] [, **DELTA**=[*dx*, *dy*] ] )

## Return Value

An array of dimension ( $nx, ny$ ) of interpolated values. If the values argument is a two-dimensional array, the output array has dimensions ( $nz, nx, ny$ ), where  $nz$  is the leading dimension of the values array allowing for the interpolation of arbitrarily sized vectors in a single call. Keywords can be used to specify the grid dimensions, size, and location.

**Note**

---

If the Cholesky factorization used within GRID\_TPS fails, then *Result* will be a scalar 0.

---

## Arguments

### **Xp**

A vector of  $x$  points.

### **Yp**

A vector of  $y$  points, with the same number of elements as the *Xp* argument.

### **Values**

A vector or two-dimensional array of values to interpolate. If values are a two-dimensional array, the leading dimension is the number of values for which interpolation is performed.

## Keywords

### **COEFFICIENTS**

A named variable in which to store the resulting coefficients of the thin plate spline function for the last set of Values. The first  $N$  elements, where  $N$  is the number of input points, contain the coefficients  $b_i$ , in the previous equation. Coefficients with subscripts  $n$ ,  $n+1$ , and  $n+2$ , contain the values of  $a_0$ ,  $a_1$ , and  $a_2$ , in the above equation.

### **DELTA**

A two-element array specifying the grid spacing in X and Y. If this keyword is not specified, or if one of the elements is set equal to zero, the grid spacing is determined from the values of the NGRID and START keywords, according to the following rules:

$$\text{DELTA}_0 = (\text{MAX}(Xp) - \text{START}_0) / (\text{NGRID}_0 - 1)$$

$$\text{DELTA}_1 = (\text{MAX}(Yp) - \text{START}_1) / (\text{NGRID}_1 - 1)$$

DELTA can also be set to a scalar value to be used for the grid size in both X and Y.

## NGRID

A two-element array of the size of the grid to interpolate ( $n_x, n_y$ ). If a scalar is passed, the value is used for both  $n_x$  and  $n_y$ . The default value is [25, 25].

## START

A two-element array of the location of grid point ( $x_0, y_0$ ). If a scalar is passed, the value is used for both  $x_0$  and  $y_0$ . The default is the minimum values in the  $xp$  and  $yp$  arrays.

## Examples

The following example creates a set of 25 random values defining a surface on a square, 100 units on a side, starting at the origin. Then, we use GRID\_TPS to create a regularly gridded surface, with dimensions of 101 by 101 over the square, which is then displayed. The same data set is then interpolated using TRIGRID, and the two results are displayed for comparison.

```

;X values
x = RANDOMU(seed, 25) * 100

;Y values
y = RANDOMU(seed, 25) * 100

;Z values
z = RANDOMU(seed, 25) * 10

z1 = GRID_TPS(x, y, z, NGRID=[101, 101], START=[0,0], DELTA=[1,1])

;Show the result
SHADE_SURF, z1, TITLE='TPS'

;Grid using TRIGRID
TRIANGULATE, x, y, tr, bounds

```

```
z2 = TRIGRID(x, y, z, tr, [1,1], [0,0,100, 100], $  
    EXTRAPOLATE=bounds)  
  
;Show triangulated surface  
SHADE_SURF, z2, TITLE='TRIGRID - Quintic'
```

# GRID3

The GRID3 function fits a smooth function to a set of 3D scattered nodes  $(x_i, y_i, z_i)$  with associated data values  $(f_i)$ . The function can be sampled over a set of user-specified points, or over an arbitrary 3D grid which can then be viewed using the SLICER3 procedure.

GRID3 uses the method described in Renka, R. J., “Multivariate Interpolation of Large Sets of Scattered Data,” *ACM Transactions on Mathematical Software*, Vol. 14, No. 2, June 1988, Pages 139-148, which has been referred to as the Modified Shepard’s Method. The function described by this method has the advantages of being equal to the values of  $f_i$ , at each  $(x_i, y_i, z_i)$ , and being smooth (having continuous first partial derivatives).

## Syntax

```
Result = GRID3( X, Y, Z, F, Gx, Gy, Gz [, DELTA=scalar/vector] [, DTOL=value]
  [, GRID=value] [, NGRID=value] [, START=[x, y, z]] )
```

## Return Value

If no optional or keyword parameters are supplied, GRID3 produces a regularly-sampled volume with dimensions of (25, 25, 25), made up of single-precision, floating-point values, enclosing the original data points.

## Arguments

### X, Y, Z and F

Arrays containing the locations of the data points, and the value of the variable to be interpolated at that point.  $X$ ,  $Y$ ,  $Z$ , and  $F$  must have the same number of elements (with a minimum of 10 elements per array) and are converted to floating-point if necessary.

### Note

---

For the greatest possible accuracy, the arrays  $X$ ,  $Y$ , and  $Z$  should be scaled to fit in the range [0,1].

---

### G<sub>x</sub>, G<sub>y</sub>, and G<sub>z</sub>

Optional arrays containing the locations within the volume to be sampled (if the GRID keyword is not set), or the locations along each axis of the sampling grid (if the

GRID keyword is set). If these parameters are supplied, the keywords DELTA, NGRID, and START are ignored.

If the keyword GRID is *not* set, the result has the same number of elements as  $G_x$ ,  $G_y$ , and  $G_z$ . The  $i$ th element of the result contains the value of the interpolate at  $(G_{xi}, G_{yi}, G_{zi})$ . The result has the same dimensions as  $G_x$ .

If the GRID keyword is set, the result of GRID3 is a three-dimensional, single-precision, floating-point array with dimensions of  $(N_x, N_y, N_z)$ , where  $N_x$ ,  $N_y$ , and  $N_z$  are the number of elements in  $G_x$ ,  $G_y$ , and  $G_z$ , respectively.

## Keywords

### DELTA

Set this keyword to a three-element vector or a scalar that specifies the grid spacing in the X, Y, and Z dimensions. The default spacing produces NGRID samples within the range of each axis.

### DTOL

The tolerance for detecting an ill-conditioned system of equations. The default value is 0.01, which is appropriate for small ranges of X, Y, and Z. For large ranges of X, Y, or Z, it may be necessary to decrease the value of DTOL. If you receive the error message “GRID3: Ill-conditioned matrix or all nodes co-planar,” try decreasing the value of DTOL.

### GRID

This keyword specifies the interpretation of  $G_x$ ,  $G_y$ , and  $G_z$ . The default value for GRID is zero if  $G_x$ ,  $G_y$ , and  $G_z$  are supplied, otherwise a regularly-gridded volume is produced.

### NGRID

The number of samples along each axis. NGRID can be set to a scalar, in which case each axis has the same number of samples, or to a three-element array containing the number of samples for each axis. The default value for NGRID is 25.

### START

A three-element array that specifies the starting value for each grid. The default value for START is the minimum value in the respective X, Y, and Z array.

## Examples

Produce a set random points within the (0,1) unit cube and simulate a function:

```

; Number of irregular samples:
N = 300

; Generate random values between 0 and 1:
X = RANDOMU(SEED, N)
Y = RANDOMU(SEED, N)
Z = RANDOMU(SEED, N)

; The function to simulate:
F = (X-.5)^2 + (Y-.5)^2 + Z

; Return a cube with 25 equal-interval samples along each axis:
Result = GRID3(X, Y, Z, F)

; Return a cube with 11 elements along each dimension, which
; samples each axis at (0, 0.1, ..., 1.0):
Result = GRID3(X, Y, Z, F, START=[0., 0., 0], $
    DELTA=0.1, NGRID=10)

```

The same result is produced by the statements:

```

; Create sample values:
S = FINDGEN(11) / 10.
Result = GRID3(X, Y, Z, F, S, S, S, /GRID)

```

# GRIDDATA

The GRIDDATA function interpolates scattered data values on a plane or a sphere to a regular grid, an irregular grid, a specified set of interpolates, or scattered data points. The returned value is a two-dimensional floating point array. Computations are performed in double-precision floating point. The following interpolation methods are supported:

- Inverse Distance (default)
- Natural Neighbor
- Kriging
- Nearest Neighbor
- Linear
- Polynomial Regression
- Minimum Curvature
- Quintic
- Modified Shepard's
- Radial Basis Function

---

## Note

GRIDDATA accepts complex input but only utilizes the real part of any complex number.

---

## Syntax

### Interleaved

*Result* = GRIDDATA( *X*, *F* )

### Planar

*Result* = GRIDDATA( *X*, *Y*, *F* )

### Sphere From Cartesian Coordinates

*Result* = GRIDDATA( *X*, *Y*, *Z*, *F*, /SPHERE )

### Sphere From Spherical Coordinates

*Result* = GRIDDATA( *Lon*, *Lat*, *F*, /SPHERE )

### Inverse Distance Keywords:

[, METHOD='InverseDistance' | /INVERSE\_DISTANCE ]  
 [, ANISOTROPY=*vector* ] [, /DEGREES ] [, DELTA=*vector* ]  
 [, DIMENSION=*vector* ] [, TRIANGLES=*array* [, EMPTY\_SECTORS=*value* ]

[, START=vector ]`

## Return Value

If any of the input arguments are double precision, *Result* is double precision; otherwise, *Result* is single precision. All computations are performed in double precision.

## Arguments

**X [, Y [, Z]]**

The point locations. If only one input coordinate parameter is supplied, the points are interleaved; for the Cartesian coordinate system the points are 2-by-*n* dimensions; and 3-by-*n* for a sphere in Cartesian coordinates.

## F

The function value at each location in the form of an  $n$ -element vector.

### Note

---

GRIDDATA will use the minimum number of points specified in any of the X, Y, Z, or F array arguments as the number of input points and function values.

---

## Lon, Lat

These arguments contain the locations (on a sphere) of the data points (similar to  $X$ , and  $Y$ ) but are in degrees or radians (default) depending on the use of the keyword DEGREES.

## Keywords

### ANISOTROPY

This keyword is a vector describing an ellipse (see the description for the SEARCH\_ELLIPSE keyword). All points on the circumference of the ellipse have an equal influence on a point at the center of the ellipse.

For example, assume that atmospheric data are being interpolated, with one dimension being altitude, and the other dimension representing distance from a point. If the vertical mixing is half that of the horizontal mixing, a point 100 units from an interpolate and at the same level has the same influence as a point 50 units above or below the interpolate at the same horizontal location. This effect requires setting the ANISOTROPY keyword to  $[2, 1, 0]$  which forms an ellipse with an X-axis length twice as long as its Y-axis length.

### DEGREES

By default, all angular inputs and keywords are assumed to be in radian units. Set the DEGREES keyword to change the angular input units to degrees.

### DELTA

A two-element array specifying the grid spacing in  $X$  and  $Y$ .

If this keyword is not specified, or if one of the elements is set equal to zero, the grid spacing is determined from the values of the DIMENSION and START keywords, according to the following rules:

- $\text{DELTA}_0 = (\max(x) - \text{START}_0) / (\text{DIMENSION}_0 - 1)$
- $\text{DELTA}_1 = (\max(y) - \text{START}_1) / (\text{DIMENSION}_1 - 1)$

DELTA can also be set to a scalar value to be used for the grid size in both *X* and *Y*.

This keyword is ignored if the GRID, XOUT and YOUT keywords are specified.

## DIMENSION

A two element array specifying the grid dimensions in *X* and *Y*. Default value is 25 for each dimension. This keyword can also be set to a scalar value to be used for the grid spacing in both *X* and *Y*.

This keyword is ignored if the GRID, XOUT and YOUT keywords are specified.

## EMPTY\_SECTORS

This keyword defines the search rules for the maximum number of sectors that may be empty when interpolating at each point. If this number or more sectors contain no data points, considering the search ellipse and/or the fault polygons, the resulting interpolant is the missing data value.

### Note

---

The TRIANGLES keyword is required when the EMPTY\_SECTORS, MAX\_PER\_SECTOR, MIN\_POINTS, or SEARCH\_ELLIPSE keywords are used.

---

## FAULT\_POLYGONS

Set this keyword to an array containing one or more polygon descriptions. A polygon description is an integer or longword array of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$ , where *n* is the number of vertices that define the polygon, and  $i_0 \dots i_{n-1}$  are indices into the FAULT\_XY vertices. The FAULT\_POLYGON array may contain multiple polygon descriptions that have been concatenated. To have this keyword ignore an entry in the FAULT\_POLYGONS array, set the vertex count, *n*, and all associated indices to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single connected polygon is generated from FAULT\_XY.

### Note

---

FAULT\_POLYGONS are not supported with spherical gridding.

---

## FAULT\_XY

The a 2-by- $n$  array specifying the coordinates of points on the fault lines/polygons.

### Note

FAULT\_XY is not supported with spherical gridding.

## FUNCTION\_TYPE

### Note

This keyword is only used with the Radial Basis Function method of interpolation.

Set this keyword to one of the values shown in the following table to indicate which basis function to use. Default is 0, the Inverse Multiquadric function.

Value	Function Type Used	Equation
0	Inverse Multiquadric	$B(h) = 1/(\sqrt{h^2 + R^2})$
1	Multilog	$B(h) = \log(h^2 + R^2)$
2	Multiquadric	$B(h) = \sqrt{h^2 + R^2}$
3	Natural Cubic Spline	$B(h) = (h^2 + R^2)^{3/2}$
4	Thin Plate Spline	$B(h) = (h^2 + R^2)\log(h^2 + R^2)$

**Note** - In the equations,  $h$  = the anisotropically scaled distance from the interpolant to the node, and  $R^2$  = the value of the SMOOTHING keyword.

## GRID

The GRID keyword controls how the XOUT and YOUT vectors specify where interpolates are desired.

If GRID is set, XOUT and YOUT must also be specified. Interpolation is performed on a regular or irregular grid specified by the vectors XOUT with  $m$  elements and YOUT with  $n$  elements. The *Result* is an  $m$ -by- $n$  grid with point  $[i, j]$  resulting from

the interpolation at (XOUT[*i*], YOUT[*j*]). When XOUT and YOUT are used, the DELTA, DIMENSION and START keywords are ignored.

## INVERSE\_DISTANCE

Selects the Inverse Distance method of interpolation.

## KRIGING

Selects the Kriging method of interpolation. The variogram type for the Kriging method is set by default, however the VARIOGRAM keyword can be used to set variogram parameters.

## LINEAR

Selects the Linear method of interpolation. The TRIANGLES keyword is required when the LINEAR keyword is used.

## MAX\_PER\_SECTOR

This keyword defines the search rules for the maximum number of data points to include in each sector when interpolating. Search rules effectively limit the number of data points used in computing each interpolate. For example, to use the nearest *n* nodes to compute each interpolant, specify MAX\_PER\_SECTOR = *n* and use the TRIANGLES keyword.

### Note

---

The TRIANGLES keyword is required when the EMPTY\_SECTORS, MAX\_PER\_SECTOR, MIN\_POINTS, or SEARCH\_ELLIPSE keywords are used.

---

## METHOD

A string containing one of the method names as shown in the following table. The default for METHOD is “InverseDistance”.

### Note

---

The interpolation method can be chosen using the METHOD keyword set to the specific string, or by setting the corresponding method name keyword.

---

### Note

---

There are no spaces between words in the method strings and the strings are case insensitive.

---

Method String	Meaning
"InverseDistance"	Data points closer to the grid points have more effect than those which are further away.
"Kriging"	Data points and their spatial variance are used to determine trends which are applied to the grid points.
"Linear"	Grid points are linearly interpolated from triangles formed by Delaunay triangulation.
"MinimumCurvature"	A plane of grid points is conformed to the data points while trying to minimize the amount of bending in the plane.
"ModifiedShepards"	Inverse Distance weighted with the least squares method.
"NaturalNeighbor"	Each interpolant is a linear combination of the three vertices of its enclosing Delaunay triangle and their adjacent vertices.
"NearestNeighbor"	The grid points have the same value as the nearest data point.
"PolynomialRegression"	Each interpolant is a least-squares fit of a polynomial in X and Y of the specified power to the specified data points.
"Quintic"	Grid points are interpolated with quintic polynomials from triangles formed by Delaunay triangulation.
"RadialBasisFunction"	The effects of data points are weighted by a function of their radial distance from a grid point.

Table 3-48: METHOD Keyword Values

## MIN\_CURVATURE

Selects the Minimum Curvature method of interpolation.

### Note

If the Cholesky factorization used within the Minimum Curvature method fails, then a scalar 0 will be returned instead of the two-dimensional array.

## MIN\_POINTS

If fewer than this number of data points are encountered in all sectors, the value of the resulting grid point is set to the value of the MISSING keyword.

The MIN\_POINTS keyword also indicates the number of closest points used for each local fit, if SEARCH\_ELLIPSE isn't specified.

---

### Note

The TRIANGLES keyword is required when the EMPTY\_SECTORS, MAX\_PER\_SECTOR, MIN\_POINTS, or SEARCH\_ELLIPSE keywords are used.

---

## MISSING

Set this keyword to the value that will be used for an element of the *Result* array if there is no calculated value for that element. The default is 0.

## NATURAL\_NEIGHBOR

Selects the Natural Neighbor method of interpolation.

---

### Note

The TRIANGLES keyword is required when the NATURAL\_NEIGHBOR keyword is used.

---

## NEAREST\_NEIGHBOR

Selects the Nearest Neighbor method of interpolation.

---

### Note

The TRIANGLES keyword is required when the NEAREST\_NEIGHBOR keyword is used.

---

## NEIGHBORHOOD

---

### Note

The NEIGHBORHOOD keyword is only used for the Modified Shepard's method of interpolation.

---

A two-element array,  $[Nq, Nw]$  defining the quadratic fit,  $Nq$ , and weighting,  $Nw$ , neighborhood sizes for the Modified Shepard's method. The default for  $Nq$  is the smaller of 13 and the number of points minus 1, with a minimum of 5. The default for

$N_w$  is the smaller of 19 and the number of points. The Modified Shepard's method first computes the coefficients of a quadratic fit for each input point, using its  $N_q$  closest neighbors.

When interpolating an output point, the quadratic fits from the  $N_w$  closest input points are weighted inversely by a function of distance and then combined. The size of the neighborhood used for Shepard's method interpolation may also be specified by the search rules keywords.

## POLYNOMIAL\_REGRESSION

Selects the Polynomial Regression method for interpolation. The power of the polynomial regression is set to 2 by default, however the POWER keyword can be used to change the power to 1 or 3.

The function fit to each interpolant corresponding to the POWER keyword set equal to 1, 2 (the default), and 3 respectively is as follows:

$$F(x,y) = a_0 + a_1x + a_2y$$

$$F(x,y) = a_0 + a_1x + a_2y + a_3x^2 + a_4y^2 + a_5xy$$

$$F(x,y) = a_0 + a_1x + a_2y + a_3x^2 + a_4y^2 + a_5xy + a_6x^3 + a_7y^3 + a_8x^2y + a_9xy^2$$

By inspection, a minimum of three data points are required to fit the linear polynomial, six data points for the second polynomial equation (where POWER = 2), and ten data points for the third polynomial (POWER = 3). If not enough data points exist for a given interpolant, the missing data values are set to the value of the MISSING keyword.

## POWER

The weighting power of the distance, or the maximum order in the polynomial fitting function. For polynomial regression, this value is either 1, 2 (the default), or 3.

### Note

---

The POWER keyword is only used for the Inverse Distance and Polynomial Regression methods of interpolation.

---

## QUINTIC

Selects the triangulation with Quintic interpolation method.

### Note

---

The TRIANGLES keyword is required when the QUINTIC keyword is used.

---

## RADIAL\_BASIS\_FUNCTION

Selects the Radial Basis Function method of interpolation.

## SEARCH\_ELLIPSE

This keyword defines the search rules as a scalar or vector of from 1 to 3 elements that specify an ellipse or circle in the form  $[R1]$ ,  $[R1, R2]$ , or  $[R1, R2, Theta]$ .  $R1$  is one radius,  $R2$  the other radius, and  $Theta$  describes the angle between the  $X$ -axis to the  $R1$ -axis, counterclockwise, in degrees or radians as specified by the DEGREES keyword. Only data points within this ellipse, centered on the location of the interpolate, are considered. If not specified, or 0, this distance test is not applied. Search rules effectively limit the number of data points used in computing each interpolate.

For example, to only consider data points within a distance of 5 units of each interpolant, specify the keyword as `SEARCH_ELLIPSE = 5`.

### Note

---

The TRIANGLES keyword is required when the EMPTY\_SECTORS, MAX\_PER\_SECTOR, MIN\_POINTS, or SEARCH\_ELLIPSE keywords are used.

---

## SECTORS

This keyword defines the search rules for the number of sectors used in applying the MAX\_SECTOR, EMPTY\_SECTORS, and MIN\_POINTS tests, an integer from 1 (the default setting) to 8.

## SHEPARDS

Selects the Modified Shepard's method of interpolation. The parameters for the Modified Shepard's method are set by default, however the NEIGHBORHOOD keyword can be used to modify the parameters.

### Note

---

The TRIANGLES keyword is required when the SHEPARDS keyword is used.

---

## SMOOTHING

A scalar value defining the smoothing radius. For the Radial Basis Function method, if SMOOTHING is not specified, the default value is equal to the average point spacing, assuming a uniform distribution. For the Inverse Distance method, the default value is 0, implying no smoothing.

**Note**

The SMOOTHING keyword is used only for the Inverse Distance and Radial Basis Function methods of interpolation.

**SPHERE**

If set, data points lie on the surface of a sphere.

When the SPHERE keyword is used with Cartesian input coordinates (x,y,z), the coordinates must lie on a unit sphere (i.e., center at 0,0,0 and radius = 1). If any points do not lie on the sphere (within some tolerance), they are forced to be on the sphere, and GRIDDATA issues a warning and continues execution.

Furthermore, if a point lies at the origin, GRIDDATA throws an error that Cartesian coordinates cannot be zero, and halts execution.

**START**

A scalar or a two-element array specifying the start of the grid in X and Y. Default value is [min(x), min(y)].

This keyword is ignored if the GRID, XOUT and YOUT keywords are specified.

**TRIANGLES**

A 3-by-*nt* longword array describing the connectivity of the input points, as returned by TRIANGULATE, where *nt* is the number of triangles. If duplicate point locations are input and the TRIANGLES keyword is present, only one of the points is considered.

**Note**

The TRIANGLES keyword is required for the Natural Neighbor, Nearest Neighbor, Modified Shepard's, Linear, and Quintic Interpolation methods.

**Note**

The TRIANGLES keyword is required when the EMPTY\_SECTORS, MAX\_PER\_SECTOR, MIN\_POINTS, or SEARCH\_ELLIPSE keywords are used.

**VARIOGRAM**

Specifies the variogram type and parameters for the Kriging method. This parameter is a vector of one to four elements in the form of: [ *Type*, *Range*, *Nugget*, *Scale*]. The *Type* is encoded as: 1 for linear, 2 for exponential, 3 for gaussian, 4 for spherical.

Defaults values are: *Type* is exponential, *Range* is 8 times the average point spacing assuming a uniform distribution, *Nugget* is zero, and *Scale* is 1.

**Note**

The VARIOGRAM keyword is only used with the Kriging method of interpolation.

The following functions are used to model the variogram functions:

Linear Covariance:

$$\text{Covariance} = \begin{array}{ll} N & \text{if } d = 0 \\ Sd & \text{if } d < R \\ 0 & \text{if } d > R \end{array}$$

Exponential Covariance:

$$\text{Covariance} = \begin{array}{ll} N + S & \text{if } d = 0 \\ Se^{(-3d/R)} & \text{if } d > 0 \end{array}$$

Gaussian Covariance:

$$\text{Covariance} = \begin{array}{ll} N + S & \text{if } d = 0 \\ Se^{(-3d^2/R^2)} & \text{if } d > 0 \end{array}$$

Spherical Covariance:

$$\text{Covariance} = \begin{array}{ll} N + S & \text{if } d = 0 \\ S - 1.5S(d/R) + 0.5S(d/R)^3 & \text{if } d < R \\ 0 & \text{if } d > R \end{array}$$

where  $d$  is the distance from one point to another,  $R$  is the range value,  $N$  is the nugget value, and  $S$  is the scale value.

## XOUT

If the GRID keyword is set, use XOUT to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. When XOUT and YOUT are used, the DELTA, DIMENSION and START keywords are ignored.

If GRID is not set (the default), the location vectors XOUT and YOUT directly contain the X and Y values of the interpolates, and must have the same number of elements. The *Result* has the same structure and number of elements as XOUT and YOUT, with point  $[i]$  resulting from the interpolation at (XOUT $[i]$ , YOUT $[i]$ ).

## YOUT

If the GRID keyword is set, use YOUT to specify irregularly spaced rectangular output grids. If YOUT is specified, XOUT must also be specified. When XOUT and YOUT are used, the DELTA, DIMENSION and START keywords are ignored.

If GRID is not set (the default), the location vectors XOUT and YOUT directly contain the X and Y values of the interpolates, and must have the same number of elements. The *Result* has the same structure and number of elements as XOUT and YOUT, with point  $[i]$  resulting from the interpolation at (XOUT $[i]$ , YOUT $[i]$ ).

## Examples

### Example 1

This example interpolates a data set measured on an irregular grid. Various types of the Inverse Distance interpolation method (the default method) are used in this example.

```
; Create a dataset of N points.
n = 100                                ;# of scattered points
seed = -121147L                         ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 768, TITLE = 'Inverse Distance'
!P.MULTI = [0, 1, 3, 0, 0]
```

```

; Inverse distance: Simplest default case which produces a 25 x
; 25 grid.
grid = GRIDDATA(x, y, f)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Simple Example'

; Default case, Inverse distance.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Larger Grid'

; Inverse distance + smoothing.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    SMOOTH = 0.05)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Smoothing'

; Set system variable back to default value.
!P.MULTI = 0

```

## Example 2

This example uses the same data as the previous one, however in this example we use the Radial Basis Function and the Modified Shepard's interpolation methods.

```

; Create a dataset of N points.
n = 100 ;# of scattered points
seed = -121147L ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form of a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 512, $
    TITLE = 'Different Methods of Gridding'
!P.MULTI = [0, 1, 2, 0, 0]

; Use radial basis function with multilog basis function.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    /RADIAL_BASIS_FUNCTION, FUNCTION_TYPE = 1)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Radial Basis Function'

; The following example requires triangulation.
TRIANGULATE, x, y, tr

```

```

; Use Modified Shepard's method.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /SHEPARDS)
SURFACE, grid, CHARSIZE = 3, TITLE = "Modified Shepard's Method"

; Set system variable back to default value.
!P.MULTI = 0

```

### Example 3

This example uses the same data as the previous ones, however in this example we use various types of the Polynomial Regression interpolation method.

```

; Create a dataset of N points.
n = 100 ;# of scattered points
seed = -121147L ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 768, $
    TITLE = 'Polynomial Regression'
!P.MULTI = [0, 1, 3, 0, 0]

; The following examples require the triangulation.
TRIANGULATE, x, y, tr

; Fit with a 2nd degree polynomial in x and y. This fit considers
; all points when fitting the surface, obliterating the individual
; peaks.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /POLYNOMIAL_REGRESSION)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Global Degree 2 Polynomial'

; Fit with a 2nd degree polynomial in x and y, but this time use
; only the 10 closest nodes to each interpolant. This provides a
; relatively smooth surface, but still shows the individual peaks.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /POLYNOMIAL_REGRESSION, MAX_PER_SECTOR = 10)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Local Polynomial, 10 Point'

```

```

; As above, but use only the nodes within a distance of 0.4 when
; fitting each interpolant.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /POLYNOMIAL_REGRESSION, SEARCH_ELLIPSE = 0.4)
SURFACE, grid, CHARSIZE = 3, $
    TITLE = 'Local Polynomial, Radius = 0.4'

!P.MULTI = 0          ; Set system variable back to default value.

```

## Example 4

This example uses the same data as the previous ones; however, in this example we show how to speed up the interpolation by limiting the interpolation to the local area around each interpolate.

```

; Create a dataset of N points.\.
n = 100                                ;# of scattered points
seed = -121147L                         ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Note: the inverse distance, kriging, polynomial regression, and
; radial basis function methods are, by default, global methods in
; which each input node affects each output node. With these
; methods, large datasets can require a prohibitively long time to
; compute unless the scope of the interpolation is limited to a
; local area around each interpolate by specifying search rules.
; In fact, the radial basis function requires time proportional to
; the cube of the number of input points.

; For example, with 2,000 input points, a typical workstation
; required 500 seconds to interpolate a 10,000 point grid using
; radial basis functions. By limiting the size of the fit to the
; 20 closest points to each interpolate, via the MIN_POINTS
; keyword, the time required dropped to less than a second.

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 512, $
    TITLE = 'Radial Basis Function'
!P.MULTI = [0, 1, 2, 0, 0]

```

```

; Slow way:
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
/RADIAL_BASIS_FUNCTION)
SURFACE, grid, CHARSIZE = 3, TITLE = 'All Points'

; The following example requires triangulation.
TRIANGULATE, x, y, tr

; Faster way:
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
/RADIAL_BASIS_FUNCTION, MIN_POINTS = 15, TRIANGLES = tr)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Nearest 15 Points'

; Set system variable back to default value.
!P.MULTI = 0

```

## Example 5

This example interpolates a spherical data set measured on an irregular grid. We use the Kriging and Natural Neighbors interpolation methods in this example.

```

; Create a 100 scattered points on a sphere and form a function
; of their latitude and longitude. Then grid them to a 2 degree
; grid over the sphere, display a Mollweide projection map, and
; overlay the contours of the result on the map.

; Create a dataset of N points.
n = 100
; A 2 degree grid with grid dimensions.
delta = 2
dims = [360, 180]/delta
; Longitude and latitudes (for uniformly placed data)
lon = RANDOMU(seed, n) * 360 - 180
lat = ACOS(2*RANDOMU(seed, n) - 1.) * !RADEG - 90
; The lon/lat grid locations
lon_grid = FINDGEN(dims[0]) * delta - 180
lat_grid = FINDGEN(dims[1]) * delta - 90

; Create a dependent variable in the form of a smoothly varying
; function.
f = SIN(2*lon*!DTOR) + COS(lat*!DTOR) ;

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 768, TITLE = 'Spherical Gridding'
!P.MULTI = [0, 1, 3, 0, 0]

; Kriging: Simplest default case.
z = GRIDDATA(lon, lat, f, /KRIGING, /DEGREES, START = 0, /SPHERE, $
DELTA = delta, DIMENSION = dims)

```

```

; Set system variable back to default value.
!P.MULTI = 0

```

## Example 6

The following example uses the data from the `irreg_grid1.txt` ASCII file. This file contains scattered elevation data of a model of an inlet. This scattered elevation data contains two duplicate locations.

The `GRID_INPUT` procedure is used to omit the duplicate locations for the `GRIDDATA` function. The `GRIDDATA` function is then used to grid the data using the Radial Basis Function method. This method is specified by setting the `METHOD` keyword the `RadialBasisFunction` string, although it could easily be done using the `RADIAL_BASIS_FUNCTION` keyword.

```

; Import the Data:

; Determine the path to the file.
file = FILEPATH('irreg_grid1.txt', $
    SUBDIRECTORY = ['examples', 'data'])

```

```

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
data = dataArray[*, 2]

; Display the Data:

; Scale the data to range from 1 to 253 so a color table can be
; applied. The values of 0, 254, and 255 are reserved as outliers.
scaled = BYTSCL(data, TOP = !D.TABLE_SIZE - 4) + 1B

; Load the color table. If you are on a TrueColor, set the
; DECOMPOSED keyword to the DEVICE command before running a
; color table related routine.
DEVICE, DECOMPOSED = 0
LOADCT, 38

; Open a display window and plot the data points.
WINDOW, 0
PLOT, x, y, /XSTYLE, /YSTYLE, LINESSTYLE = 1, $
      TITLE = 'Original Data, Scaled (1 to 253)', $
      XTITLE = 'x', YTITLE = 'y'

; Now display the data values with respect to the color table.
FOR i = 0L, (N_ELEMENTS(x) - 1) DO PLOTS, x[i], y[i], PSYM = -1, $
      SYMSIZE = 2., COLOR = scaled[i]

; Grid the Data and Display the Results:

; Preprocess and sort the data. GRID_INPUT will
; remove any duplicate locations.
GRID_INPUT, x, y, data, xSorted, ySorted, dataSorted

; Initialize the grid parameters.
gridSize = [51, 51]

; Use the equation of a straight line and the grid parameters to
; determine the x of the resulting grid.
slope = (MAX(xSorted) - MIN(xSorted))/(gridSize[0] - 1)
intercept = MIN(xSorted)
xGrid = (slope*FINDGEN(gridSize[0])) + intercept

```

```

; Use the equation of a straight line and the grid parameters to
; determine the y of the resulting grid.
slope = (MAX(ySorted) - MIN(ySorted))/(gridSize[1] - 1)
intercept = MIN(ySorted)
yGrid = (slope*FINDGEN(gridSize[1])) + intercept

; Grid the data with the Radial Basis Function method.
grid = GRIDDATA(xSorted, ySorted, dataSorted, $
    DIMENSION = gridSize, METHOD = 'RadialBasisFunction')

; Open a display window and contour the Radial Basis Function
; results.

scaled = BYTSCl(grid, TOP = !D.TABLE_SIZE - 4) + 1B
CONTOUR, scaled, xGrid, YGrid, /XSTYLE, /YSTYLE, /FILL, $
    LEVELS = BYTSCl(INDGEN(18), TOP = !D.TABLE_SIZE - 4) + 1B, $
    C_COLORS = BYTSCl(INDGEN(18), TOP = !D.TABLE_SIZE - 4) + 1B, $
    TITLE = 'The Resulting Grid with Radial Basis Function', $
    XTITLE = 'x', YTITLE = 'y'

```

## Example 7

The following example uses the data from the `irreg_grid1.txt` ASCII file. This file contains scattered elevation data of a model of an inlet. This scattered elevation data contains two duplicate locations. The same data is used in the previous example.

The `GRID_INPUT` procedure is used to omit the duplicate locations for the `GRIDDATA` function. The `GRIDDATA` function is then used to grid the data using the Radial Basis Function method. This method is specified by setting the `METHOD` keyword the `RadialBasisFunction` string, although it could easily be done using the `RADIAL_BASIS_FUNCTION` keyword.

Faulting is also applied in this example. First, a fault area is placed around the right side of the dataset. This fault area contains data points. The data points within this area are gridded separately from the points outside of the fault area.

Then, a fault area is defined within an region that does not contain any data points. Since this fault area does not contain any points, the grid within this region simply results to the value defined by the `MISSING` keyword. The points outside of the fault area are gridded independent of the fault region.

```

; Import the Data:

; Determine the path to the file.
file = FILEPATH('irreg_grid1.txt', $
    SUBDIRECTORY = ['examples', 'data'])

```

```

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
data = dataArray[*, 2]

; Grid the Data and Display the Results:

; Preprocess and sort the data. GRID_INPUT will
; remove any duplicate locations.
GRID_INPUT, x, y, data, xSorted, ySorted, dataSorted

; Initialize the grid parameters.
gridSize = [51, 51]

; Use the equation of a straight line and the grid parameters to
; determine the x of the resulting grid.
slope = (MAX(xSorted) - MIN(xSorted))/(gridSize[0] - 1)
intercept = MIN(xSorted)
xGrid = (slope*FINDGEN(gridSize[0])) + intercept

; Use the equation of a straight line and the grid parameters to
; determine the y of the resulting grid.
slope = (MAX(ySorted) - MIN(ySorted))/(gridSize[1] - 1)
intercept = MIN(ySorted)
yGrid = (slope*FINDGEN(gridSize[1])) + intercept

[GRID\\_INPUT](#)

# GS\_ITER

The GS\_ITER function solves an  $n$  by  $n$  linear system of equations using Gauss-Seidel iteration with over- and under-relaxation to enhance convergence.

---

**Note**

The equations must be entered in *diagonally dominant* form to guarantee convergence. A system is diagonally dominant if the diagonal element in a given row is greater than the sum of the absolute values of the non-diagonal elements in that row.

---

This routine is written in the IDL language. Its source code can be found in the file `gs_iter.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = GS_ITER( A, B [, /CHECK] [, /DOUBLE] [, LAMBDA=value{0.0 to 2.0}]  
                [, MAX_ITER=value] [, TOL=value] [, X_0=vector] )
```

## Return Value

Returns the solution to the linear system of equations of the specified dimensions.

## Arguments

### A

An  $n$  by  $n$  integer, single-, or double-precision floating-point array. On output,  $A$  is divided by its diagonal elements. Integer input values are converted to single-precision floating-point values.

### B

A vector containing the right-hand side of the linear system  $\mathbf{Ax}=\mathbf{b}$ . On output,  $B$  is divided by the diagonal elements of  $A$ .

## Keywords

### CHECK

Set this keyword to check the array  $A$  for diagonal dominance. If  $A$  is not in diagonally dominant form, `GS_ITER` reports the fact but continues processing on the chance that the algorithm may converge.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### LAMBDA

A scalar value in the range:  $[0.0, 2.0]$ . This value determines the amount of *relaxation*. Relaxation is a weighting technique used to enhance convergence.

- If  $LAMBDA = 1.0$ , no weighting is used. This is the default.
- If  $0.0 \leq LAMBDA < 1.0$ , convergence improves in oscillatory and non-convergent systems.
- If  $1.0 < LAMBDA \leq 2.0$ , convergence improves in systems already known to converge.

### MAX\_ITER

The maximum allowed number of iterations. The default value is 30.

### TOL

The relative error tolerance between current and past iterates calculated as:  $| ( \text{current-past} ) / \text{current} |$ . The default is  $1.0 \times 10^{-4}$ .

### X\_0

An  $n$ -element vector that provides the algorithm's starting point. The default is  $[1.0, 1.0, \dots, 1.0]$ .

## Example

```
; Define an array A:
A = [[ 1.0,  7.0, -4.0], $
      [ 4.0, -4.0,  9.0], $
      [12.0, -1.0,  3.0]]
```

```

; Define the right-hand side vector B:
B = [12.0, 2.0, -9.0]

; Compute the solution to the system:
RESULT = GS_ITER(A, B, /CHECK)

```

IDL prints:

```

Input matrix is not in Diagonally Dominant form.
Algorithm may not converge.
% GS_ITER: Algorithm failed to converge within given parameters.

```

Since the **A** represents a system of linear equations, we can reorder it into diagonally dominant form by rearranging the rows:

```

A = [[12.0, -1.0, 3.0], $
      [ 1.0, 7.0, -4.0], $
      [ 4.0, -4.0, 9.0]]

; Make corresponding changes in the ordering of B:
B = [-9.0, 12.0, 2.0]

; Compute the solution to the system:
RESULT = GS_ITER(A, B, /CHECK)

```

IDL prints:

```

-0.999982      2.99988      1.99994

```

# H\_EQ\_CT

The H\_EQ\_CT procedure histogram-equalizes the color tables for an image or a region of the display. A pixel-distribution histogram is obtained, the cumulative integral is taken and scaled, and the result is applied to the current color table.

Histogram equalization is used to change either an image or its associated color table to display minor variations within nearly uniform areas of the image. The histogram of the image is used to determine where the image or color table should be equalized to highlight these minor variations. See “[Working with Histograms](#)” in Chapter 8 of the *Image Processing in IDL* manual for more information on how histogram equalization effects images.

This routine is written in the IDL language. Its source code can be found in the file `h_eq_ct.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
H_EQ_CT [, Image]
```

## Arguments

### Image

A two-dimensional byte array representing the image whose histogram is to be used in determining the new color tables. If this value is omitted, the user is prompted to mark the diagonal corners of a region of the display. If *Image* is specified, it is assumed that the image is loaded into the current IDL window. *Image* must be scaled the same way as the image loaded to the display.

## Keywords

None.

## Example

The following example will apply histogram equalization to a color table associated with an image of mineral deposits to reveal previously indistinguishable features. This histogram equalization example is in *Direct Graphics*, which uses routines that directly work with the current color table. Since the concept of a current color table does not apply to *Object Graphics*, you must use histogram equalization routines that directly effect the image. See “[Working with Histograms](#)” in Chapter 8 of the *Image*

*Processing in IDL* manual for more information on histogram equalization with Object Graphics. Complete the following steps for a detailed description of the process.

### Example Code

---

See `histogramequalizing_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. Note that the `BLOCK` keyword is set when using `XLOADCT` to force the example routine to wait until the **Done** button is pressed to continue. If the `BLOCK` keyword was not set, the example routine would produce all of the displays at once and then end.

---

1. Determine the path to the `mineral.png` file:

```
file = FILEPATH('mineral.png', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image from the `mineral.png` file into IDL:

```
image = READ_PNG(file)
```

3. Determine the size of the imported image:

```
imageSize = SIZE(image, /DIMENSIONS)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program:

```
DEVICE, DECOMPOSED = 0
```

5. Initialize the image display:

```
LOADCT, 0
WINDOW, 0, XSIZE = 2*imageSize[0], YSIZE = imageSize[1], $
    TITLE = 'Histogram/Image'
```

6. Compute and display the histogram of the image. This step is not required to perform histogram equalization on a color table within IDL. It is done here to show how the histogram equalization affects the color table:

```
brightnessHistogram = BYTSCL(HISTOGRAM(image))
PLOT, brightnessHistogram, XSTYLE = 9, YSTYLE = 5, $
    POSITION = [0.05, 0.2, 0.45, 0.9], $
    XTITLE = 'Histogram of Image'
```

7. Display the image within the same window.

```
TV, image, 1
```

The following figure shows the resulting histogram and its related image.

Figure 3-39: Histogram (left) of the Mineral Image (right) in Direct Graphics

- Use the `H_EQ_CT` procedure to perform histogram equalization on the current color table:

```
H_EQ_CT, image
```

- Display the original image in another window with the updated color table:

```
WINDOW, 1, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'Histogram Equalized Color Table'
TV, image
```

Display the updated color table with the `XLOADCT` utility:

```
XLOADCT
```

Click on the **Done** button close the `XLOADCT` utility.

The following figure contains the results of the equalization on the image and its color table. After introducing intensity gradients within previously uniform regions of the image, the cracks are now more visible. However, some of the original features are not as clear. These regions can be clarified by interactively applying the amount of equalization to the color table.

*Figure 3-40: Resulting Image (left) and Color Table (right) of the Histogram Equalization in Direct Graphics*

The histogram equalizing process can also be interactively applied to a color table with the `H_EQ_INT` procedure. The `H_EQ_INT` procedure provides an interactive display, allowing you to use the cursor to control the amount of equalization. The equalization applied to the color table is scaled by a fraction, which is controlled by the movement of the cursor in the x-direction. If the cursor is all the way to the left side of the interactive display, the fraction equalized is close to zero, and the equalization has little effect on the color table. If the cursor is all the way to the right side of the interactive display, the fraction equalized is close to one, and the equalization is fully applied to the color table (which is similar to the results from the `H_EQ_CT` procedure). You can click on the right mouse button to set the amount of equalization and exit out of the interactive display.

10. Use the `H_EQ_INT` procedure to interactively perform histogram equalization on the current color table:

```
H_EQ_INT, image
```

Place the cursor at about 130 in the x-direction, which is about 0.5 equalized (about 50% of the equalization applied by the `H_EQ_CT` procedure). You do not have to be exact for this example. The y-direction location is arbitrary.

Click on the right mouse button.

The interactive display is similar to the following figure.

*Figure 3-41: Interactive Display for Histogram Equalization*

11. Display the image using the updated color table in another window:

```
WINDOW, 2, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'Interactively Equalized Color Table'
TV, image
```

Display the updated color table with the `XLOADCT` utility:

```
XLOADCT
```

Click on the **Done** button close the `XLOADCT` utility.

The following figure contains the results of the equalization on the image and its color table. The original details have returned and the cracks are still visible.

Figure 3-42: Resulting Image (left) and Color Table (right) of the Interactive Histogram Equalization in Direct Graphics

[H\\_EQ\\_INT](#)

# H\_EQ\_INT

The H\_EQ\_INT procedure interactively histogram-equalizes the color tables of an image or a region of the display. By moving the cursor across the screen, the amount of histogram-equalization can be varied.

Either the image parameter or a region of the display marked by the user is used to obtain a pixel-distribution histogram. The cumulative integral is taken and scaled and the result is applied to the current color tables.

This routine is written in the IDL language. Its source code can be found in the file `h_eq_int.pro` in the `lib` subdirectory of the IDL distribution.

## Using the H\_EQ\_INT Interface

A window is created and the histogram equalization function is plotted. A linear ramp is overplotted. Move the cursor from left to right to vary the amount of histogram equalization applied to the color tables from 0 to 100%. Press the right mouse button to exit.

## Syntax

```
H_EQ_INT [, Image]
```

## Arguments

### Image

A two-dimensional byte array representing the image whose histogram is to be used in determining the new color tables. If this value is omitted, the user is prompted to mark the diagonal corners of a region of the display. If *Image* is specified, it is assumed that the image is loaded into the current IDL window. *Image* must be scaled the same way as the image loaded to the display.

## H5\_\* Routines

For information, see [Chapter 3, “Hierarchical Data Format - HDF5”](#) in the *IDL Scientific Data Formats* manual.

# H5\_BROWSER

The H5\_BROWSER function presents a graphical user interface for viewing and reading HDF5 files. The browser provides a tree view of the HDF5 file or files, a data preview window, and an information window for the selected objects. The browser may be created as either a selection dialog with Open/Cancel buttons, or as a standalone browser that can import data to the IDL main program level.

---

**Note**

This function is not part of the standard HDF5 interface, but is provided as a programming convenience.

---

## Syntax

```
Result = H5_BROWSER([Files] [, /DIALOG_READ] )
```

## Return Value

If the DIALOG\_READ keyword is specified then the *Result* is a structure containing the selected group or dataset (as described in the H5\_PARSE function), or a zero if the **Cancel** button was pressed. If the DIALOG\_READ keyword is not specified then the *Result* is the widget ID of the HDF5 browser.

## Arguments

### Files

An optional scalar string or string array giving the name of the files to initially open. Additional files may be opened interactively. If *Files* is not provided then the user is automatically presented with a File Open dialog upon startup.

## Keywords

### DIALOG\_READ

If this keyword is set then the HDF5 browser is created as a modal Open/Cancel dialog instead of a standalone GUI. In this case, the IDL command line is blocked, and no further input is taken until the **Open** or **Cancel** button is pressed. If the GROUP\_LEADER keyword is specified, then that widget ID is used as the group leader, otherwise a default group leader base is created.

All keywords to WIDGET\_BASE, such as GROUP\_LEADER and TITLE, are passed on to the top-level base.

## Examples

The following example starts up the HDF5 browser on a sample file:

```
File = FILEPATH('hdf5_test.h5', SUBDIR=['examples','data'])
Result = H5_BROWSER(File)
```

### Using the HDF5 Browser Interface

When you call H5\_BROWSER with the preceding code, an interface similar to the following appears.

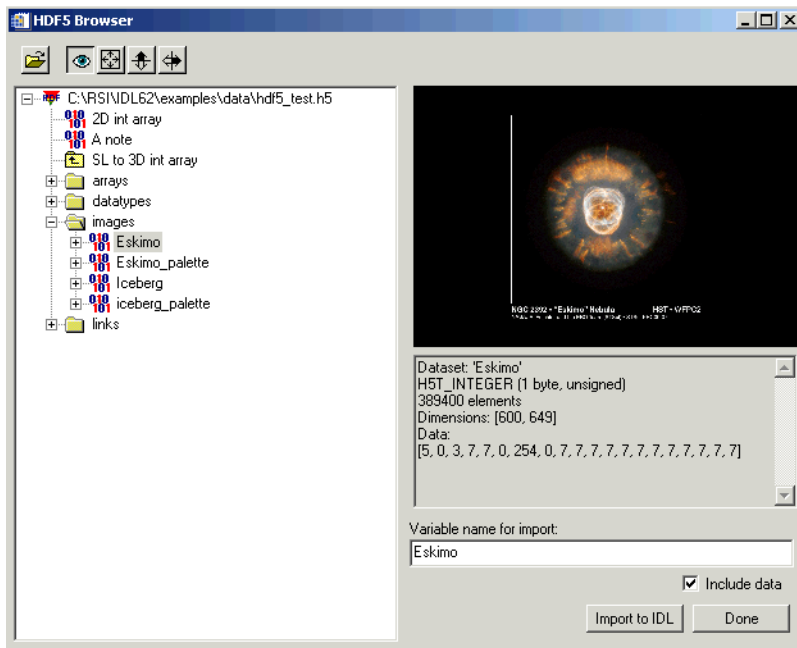

Figure 3-43: HDF5 Browser Dialog

The following steps import image data into IDL.

1. **Navigate to the image data.** Expand the top-level item, and the **images** item.

2. **Select an image file.** In this example, select **Eskimo**. A preview is automatically displayed.
3. **Import the image data.** Make sure the **Include data option** is selected, accept the default **Variable name for import** value and click **Import to IDL**.
4. **Import the image palette.** Repeat the previous two steps, but select **Eskimo palette**.
5. **Dismiss the dialog.** After importing all your data, click **Done**. The structure `Eskimo` and `Eskimo_Palette` appear in the variable watch window. (Position your cursor in the command line and hit the enter key if you need to refresh the variable watch window to display the structures.) The following figure show a subset of the variable watch window with the `Eskimo` structure expanded and the `_Data` element selected.

Name	Type	Value
ESKIMO	STRUCT	{ <Anonymous> }
_NAME	STRING	Eskimo
_ICONTYPE	STRING	binary
_TYPE	STRING	DATASET
_FILE	STRING	C:\RS\IDL62\examples\data\hdf5_test.h5
_PATH	STRING	/images
_DATA	BYTE	Array[600, 649]
_NDIMENSIONS	LONG	2
_DIMENSIONS	ULONG64	Array[2]
_NELEMENTS	ULONG64	389400
_DATATYPE	STRING	H5T_INTEGER

Figure 3-44: Eskimo Structure Expanded

6. **Access the imported data.** Use `structureName.fieldName` syntax to access data from the structure. For example, the following lines of code display the image (with its associated palette) in an `!Image` display:

```
!IMAGE, Eskimo._Data, RGB_TABLE=Eskimo_Palette._Data, /ORDER
```

The following table describes elements that are always available fields in a **HDF5 Browser** dialog.

<b>Open HDF5 file</b>	Click on this button to bring up a file selection dialog. Multiple files may be selected for parsing. All selected files are added to the tree view.
-----------------------	--

<b>Show preview</b>	Select this button to preview the data within the preview window. One-dimensional datasets are shown as line plots. Two-dimensional datasets are shown as images, along with any provided image palettes. For three- or higher-dimensional datasets, a two-dimensional slice is shown.
<b>Fit in window</b>	Select this button to scale the data larger or smaller to fit within the preview window. The aspect ratio of the image will be unchanged.
<b>Flip vertical</b>	Select this button to flip the previewed data from top to bottom.
<b>Flip horizontal</b>	If this toggle button is selected, then the preview image will be flipped from left to right.

If the `DIALOG_READ` keyword is present then the following options are available:

<b>Open</b>	Click on this button to close the HDF5 browser, and return an IDL structure containing the selected group or dataset, as described in the <code>H5_PARSE</code> function.
<b>Cancel</b>	Click on this button to close the HDF5 browser, and return a scalar zero for the result.

If the `DIALOG_READ` keyword is not present then the following options are available:

<b>Variable name for import</b>	Set this text string to the name of the IDL variable to construct when importing HDF5 data to IDL structures. If the entered name is not a valid IDL identifier, then a valid identifier will be constructed by converting all non-alphanumeric characters to underscores.
---------------------------------	--

<b>Cancel</b>	Click on this button to close the HDF5 browser, and return a scalar zero for the result.
<b>Include data</b>	If selected, then all data within the selected datasets will be read in from the HDF5 file and included in the IDL structure.
<b>Import to IDL</b>	Click on this button to import the currently selected HDF5 object into the IDL main program level. Imported variables will consist of a nested hierarchy of IDL structures, as described in the <code>H5_PARSE</code> function.
<b>Done</b>	Close the HDF5 browser.

# HANNING

The HANNING function is used to create a “window” for Fourier Transform filtering. It can be used to create both Hanning and Hamming windows.

This routine is written in the IDL language. Its source code can be found in the file `hanning.pro` in the `lib` subdirectory of the IDL distribution.

The Hanning window is defined as:

$$w(k) = \alpha - (1-\alpha)\cos(2 \pi k / N), \quad k = 0,1,\dots,N-1$$

where  $\alpha=0.5$  for the Hanning, and  $\alpha=0.54$  for the Hamming window.

---

**Note**

Because of the factor of  $1/N$  (rather than  $1/(N-1)$ ) in the above equation, the Hanning filter is not exactly symmetric, and does not go to zero at the last point. The factor of  $1/N$  is chosen to give the best behavior for spectral estimation of discrete data.

---

## Syntax

*Result* = HANNING( *N*<sub>1</sub> [, *N*<sub>2</sub>] [, ALPHA=*value*{0.5 to 1.0}] [, /DOUBLE] )

## Return Value

If only *N*<sub>1</sub> is specified, this function returns an array of dimensions [*N*<sub>1</sub>]. If both *N*<sub>1</sub> and *N*<sub>2</sub> are specified, this function returns an array of dimensions [*N*<sub>1</sub>, *N*<sub>2</sub>]. If any of the inputs are double-precision or if the DOUBLE keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### *N*<sub>1</sub>

The number of columns in the resulting array.

### *N*<sub>2</sub>

The number of rows in the resulting array.

## Keywords

### ALPHA

Set this keyword equal to the width parameter of a generalized Hamming window. ALPHA must be in the range of 0.5 to 1.0. If ALPHA = 0.5 (the default) the function is called a “Hanning” window. If ALPHA = 0.54, the result is called a “Hamming” window.

### DOUBLE

Set this keyword to force the computations to be done in double-precision arithmetic.

## Examples

```

; Construct a time series with three sine waves.
n = 1024
dt = 0.02
w = 2*!DPI*dt*DINDGEN(n)
x = -0.3d + SIN(2.8d * w) + SIN(6.25d * w) + SIN(11.0d * w)
; Find the power spectrum with and without the Hanning filter.
han = HANNING(n, /DOUBLE)
powerHan = ABS(FFT(han*x))^2
powerUnfilt = ABS(FFT(x))^2
freq = FINDGEN(n)/(n*dt)
; Plot the results.
PLOT, freq, powerHan, /XLOG, /YLOG, $
      XRANGE=[1,1./(2*dt)], XSTYLE=1, $
      TITLE='Power spectrum with Hanning (solid) and without
      (dashed)'
OPLOT, freq, powerUnfilt, LINESSTYLE=2

```

### Note

## HDF\_\* Routines

For information, see [Chapter 4, “Hierarchical Data Format”](#) in the *IDL Scientific Data Formats* manual.

# HDF\_BROWSER

The `HDF_BROWSER` function presents a graphical user interface (GUI) that allows the user to view the contents of a Hierarchical Data Format (HDF), HDF-EOS, or NetCDF file, and prepare a template for the extraction of HDF data and metadata into IDL. The output template is an IDL structure that may be used when reading HDF files with the `HDF_READ` routine. If you have several HDF files of identical form, the returned template from `HDF_BROWSER` may be reused to extract data from these files with `HDF_READ`. If you do not need a multi-use template, you may call `HDF_READ` directly.

## Syntax

```
Template = HDF_BROWSER([Filename] [, CANCEL=variable]  
[, GROUP=widget_id] [, PREFIX=string])
```

## Return Value

Returns a template structure containing heap variable references, or 0 if no file was selected. The user is required to clean up the heap variable references when done with them.

## Arguments

### Filename

A string containing the name of an HDF file to browse. If *Filename* is not specified, a dialog allows you to choose a file.

## Keywords

### CANCEL

Set this keyword to a named variable that will contain the byte value 1 (one) if the user clicked the “Cancel” button or the byte value 0 (zero) otherwise.

### GROUP

Set this keyword to the widget ID of a widget that calls `HDF_BROWSER`. When this ID is specified, a death of the caller results in the death of the `HDF_BROWSER`. The following example demonstrates how to use the `GROUP` keyword to properly call

HDF\_BROWSER from within a widget application. To run this example, save the following code as `browser_example.pro`:

```

PRO BROWSER_EXAMPLE_EVENT, ev

    WIDGET_CONTROL, ev.id, GET_VALUE=val
    CASE val of
        'Browser': BEGIN
            a=HDF_BROWSER (GROUP=ev.top)
            HELP, a, /st
        END
        'Exit': WIDGET_CONTROL, ev.top, /DESTROY
    ENDCASE

END

PRO BROWSER_EXAMPLE

a=WIDGET_BASE (/ROW)
b=WIDGET_BUTTON (a, VALUE='Browser')
c=WIDGET_BUTTON (a, VALUE='Exit')
WIDGET_CONTROL, a, /REALIZE
XMANAGER, 'browser_example', a

END

```

## PREFIX

When HDF\_BROWSER reviews the contents of an HDF file, it creates default output names for the various data elements. By default these default names begin with a prefix derived from the filename. Set this keyword to a string value to be used in place of the default prefix.

## Examples

```

template = HDF_BROWSER('test.hdf')
output_structure = HDF_READ(TEMPLATE=template)

or,

output_structure = HDF_READ('test.hdf', TEMPLATE=template)

```

## Using the HDF Browser Interface

When you call the `HDF_BROWSER` function from the command line or using the **Import HDF** macro, the **HDF Browser** window is displayed.

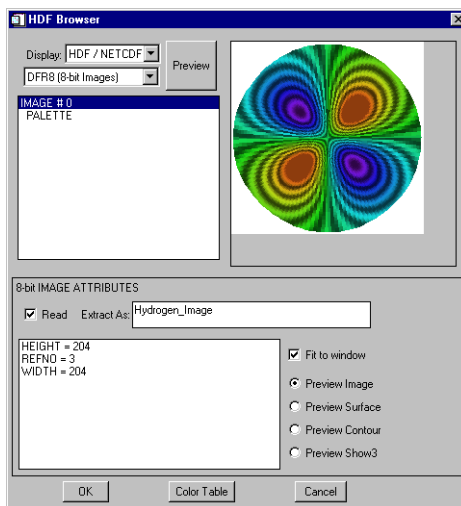

Figure 3-45: HDF Browser Window

Use the following steps when working with the **HDF Browser** dialog:

1. **Select the type of file you are opening.** The following table describes the **Display** field options:

<b>Display</b>	<p>Select one of the following options to indicate the type of file you are reading:</p> <ul style="list-style-type: none"> <li>• <b>HDF/NETCDF</b></li> <li>• <b>HDF-EOS</b></li> </ul> <p>This selection toggles the following droplist between <b>HDF Summary</b> and <b>HDF-EOS Summary</b>.</p>
----------------	--

<p><b>HDF Summary</b></p>	<p>Displays the number of items in each of the following categories:</p> <p><b>DF24 (24-bit Images)</b> — 24-bit images and their attributes</p> <p><b>DFR8 (8-bit Images)</b> — 8-bit images and their attributes</p> <p><b>DFP (Palettes)</b> — Image palettes</p> <p><b>SD (Variables/Attributes)</b> — Scientific Datasets and attributes</p> <p><b>AN (Annotations)</b> — Annotations</p> <p><b>GR (Generic Raster)</b> — Images</p> <p><b>GR Global (File) Attributes</b> — Image attributes</p> <p><b>VGroups</b> — Generic data groups</p> <p><b>VData</b> — Generic data and attributes</p>
<p><b>HDF-EOS Summary</b></p>	<p>Displays the number of items in each of the following categories:</p> <p><b>Point</b> — EOS point data and attributes</p> <p><b>Swath</b> — EOS swath data and attributes</p> <p><b>Grid</b> — EOS grid data and attributes</p>

2. **Select any element that contains data.** Attributes of the selected data appear in the lower textbox. Use other dialog options as follows:

<b>Preview</b>	<p>Select an image, 2D data set, or <math>3 \times n \times m</math> data set from the pulldown menu. Make a selection from the following and click <b>Preview</b> to create a display:</p> <p><b>Preview Image</b> — displays an image or a plot of a 2-D data set (the default)</p> <p><b>Preview Surface</b> — displays a surface plot</p> <p><b>Preview Contour</b> — displays a contour plot</p> <p><b>Preview Show3</b> — displays an image, surface, and contour plot</p> <p><b>Fit to Window</b> — fits the display to the visible area of window</p>
<b>Read</b>	<p>Import the selected data into IDL. Select this checkbox to extract the current data or metadata item from the HDF file.</p>
<b>Extract As</b>	<p>Enter name for the extracted data or metadata item. Default names are generated for all data items, but may be changed at any time.</p> <p><b>Note</b> - The <b>Read</b> checkbox must be selected for the item to be extracted.</p>
<b>Color Table</b>	<p>Select this option to apply a selected, pre-defined color table to the data.</p>
<b>OK</b>	<p>Complete any selected import actions.</p>
<b>Cancel</b>	<p>Dismiss the dialog without making changes.</p>

3. **Select additional data or complete the operation.** Continue selecting to read and name the data or metadata items you want to import into IDL and then select one of the following options:

<b>OK</b>	Generate the template used to import HDF data.
<b>Cancel</b>	Dismiss the dialog without making changes.

The result of these actions depends on the location from which you launched the **HDF Browser** dialog. The `HDF_READ` function, which reads data from a file according to the template specification, is automatically called when you access the **HDF Browser** dialog from the **Import HDF** macro. From the command line, you must explicitly read the HDF data with the template specification. After defining what data to access using the **HDF Browser** dialog, refer to the appropriate section:

- **Import HDF macro data access** — the HDF data is placed in a structure. You can access fields of the data using a `variable_name.element_name` syntax. See “[Using Macros to Import HDF Files](#)” in Chapter 6 of the *Using IDL* manual.
- **Command line binary data access** — the template is a structure defining the HDF data elements to be read. Access the data using `HDF_READ`, and specify the template as parameters of the data access operation.

## Version History

5.1	Introduced

[HDF\\_READ](#)

# HDF\_READ

The `HDF_READ` function extracts Hierarchical Data Format (HDF), HDF-EOS, and NetCDF data and metadata into an output structure based upon information provided through a graphical user interface or through a file template generated by `HDF_BROWSER`. If you do not specify a template, the **HDF Browser** dialog opens, allowing you to create one. See “Using the HDF Browser Interface” on page 917 for information about the dialog. The `HDF_READ` function returns a single level output structure that contains elements corresponding to those that were named and read in the HDF Browser dialog. Templates generated by `HDF_BROWSER` may be re-used for HDF files of identical format.

## Syntax

```
Result = HDF_READ( [Filename] [, DFR8=variable] [, DF24=variable]  
[, PREFIX=string] [, TEMPLATE =value] )
```

## Return Value

Returns an output structure containing the specified Hierarchical Data Format (HDF), HDF-EOS, and NetCDF data and metadata.

## Arguments

### Filename

A string containing the name of a HDF file to extract data from. If *Filename* is not specified, a dialog allows you to specify a file. Note that if a template is specified, the template must match the HDF file selected.

## Keywords

### DFR8

Set this keyword to a named variable that will contain a  $2 \times n$  string array of extracted DFR8 images and their palettes. The first column will contain the extracted DFR8 image names, while the second column will contain the extracted name of the associated palette. If no palette is associated with a DFR8 image the palette name will be set to the null string. If no DFR8 images were extracted from the HDF file, this returned string will be the null string array `["", ""]`.

## DF24

Set this keyword to a named variable that will contain a string array of the names of all the extracted DF24 24-bit images. This is useful in determining whether a  $(3,n,m)$  extracted data element is a 24-bit image or another type of data. If no DF24 24-bit images were extracted from the HDF file, the returned string will be the null string ("").

## PREFIX

When HDF\_READ is called without a template, it calls HDF\_BROWSER to review the contents of an HDF file and create the default output names for the various data elements. By default, these names begin with a prefix derived from the filename. Set this keyword to a string value to be used in place of the default prefix.

## TEMPLATE

Set this keyword to specify the HDF file template (generated by the function HDF\_BROWSER), that defines which data elements to extract from the selected HDF file. Templates may be used on any files that have a format identical to the file the template was created from.

## Examples

For information on how to use the **HDF Browser** dialog, which appears when a template is not specified, see [“Using the HDF Browser Interface”](#) on page 917.

```
template = HDF_BROWSER('my.hdf')
output_structure = HDF_READ(TEMPLATE=template)

or,

output_structure = HDF_READ('my.hdf')

or,

; Select 'my.hdf' with the file locator
output_structure = HDF_READ()

or,

output_structure = HDF_READ('just_like_my.hdf', TEMPLATE=template)
```

# HEAP\_FREE

The `HEAP_FREE` procedure recursively frees all heap variables (pointers or objects) referenced by its input argument. This routine examines the input variable, including all array elements and structure fields. When a valid pointer or object reference is encountered, that heap variable is marked for removal, and then is recursively examined for additional heap variables to be freed. In this way, all heap variables that are referenced directly or indirectly by the input argument are located. Once all such heap variables are identified, `HEAP_FREE` releases them in a final pass. Pointers are released as if the `PTR_FREE` procedure was called. Objects are released as with a call to `OBJ_DESTROY`.

As with the related `HEAP_GC` procedure, there are some disadvantages to using `HEAP_FREE`:

- When freeing object heap variables, `HEAP_FREE` calls `OBJ_DESTROY` without supplying any plain arguments or keywords. Depending on the objects being released, this may not be sufficient. In such cases, call `OBJ_DESTROY` explicitly with the proper arguments rather than using `HEAP_FREE`.
- `HEAP_FREE` releases the referenced heap variables in an unspecified order which depends on the current state of the internal data structure used by IDL to hold them. This can be confusing for object destructor methods that expect all of their contained data to be present. If your application requires a specific order for the release of its heap variables, you must explicitly free them in the correct order. `HEAP_FREE` cannot be used in such cases.
- The algorithm used by `HEAP_FREE` to release variables requires examination of every existing heap variable (that is, it is an  $O(n)$  algorithm). This may be slow if an IDL session has thousands of current heap variables.

For these reasons, RSI recommends that applications keep careful track of their heap variable usage, and explicitly free them at the proper time (for example, using the object destructor method) rather than resorting to simple-looking but potentially expensive expedients such as `HEAP_FREE` or `HEAP_GC`.

`HEAP_FREE` is recommended when:

- The data structures involved are highly complex, nested, or variable, and writing cleanup code is difficult and error prone.
- The data structures are opaque, and the code cleaning up does not have knowledge of the structure.

## Syntax

```
HEAP_FREE, Var [, /OBJ] [, /PTR] [, /VERBOSE]
```

## Arguments

### Var

The variable whose data is used as the starting point for heap variables to be freed.

## Keywords

### OBJ

Set this keyword to free object heap variables only.

### PTR

Set this keyword to free pointer heap variables only.

### Note

---

Setting both the PTR and OBJ keywords is the same as setting neither.

---

### VERBOSE

If this keyword is set, HEAP\_FREE writes a one line description of each heap variable, in the format used by the HELP procedure, as the variable is released. This is a debugging aid that can be used by program developers to check for heap variable leaks that need to be located and eliminated.

## Examples

```
; Create a structure variable.
mySubStructure = {pointer:PTR_NEW(INDGEN(100)), $
  obj:OBJ_NEW('Idl_Container')}
myStructure = {substruct:mySubStructure, $
  ptrs:[PTR_NEW(INDGEN(10)), PTR_NEW(INDGEN(11))]}

;Look at the heap.
HELP, /HEAP_VARIABLES

; Now free the heap variables contained in myStructure.
HEAP_FREE, myStructure, /VERBOSE
HELP, /HEAP_VARIABLES
```

## Version History

5.3	Introduced

[HEAP\\_GC](#)

# HEAP\_GC

The `HEAP_GC` procedure performs *garbage collection* on heap variables. It searches all current IDL variables (including common blocks, widget user values, etc.) for pointers and object references and determines which heap variables have become inaccessible. Pointer heap variables are freed (via `PTR_FREE`) and all memory used by the heap variable is released. Object heap variables are destroyed (via `OBJ_DESTROY`), also freeing all used memory.

The default action is to perform garbage collection on all heap variables regardless of type. Use the `POINTER` and `OBJECT` keywords to remove only specific types.

---

**Note**

Garbage collection is an expensive operation. When possible, applications should be written to avoid losing pointer and object references and avoid the need for garbage collection.

---

**Warning**

`HEAP_GC` uses a recursive algorithm to search for unreferenced heap variables. If `HEAP_GC` is used to manage certain data structures, such as large linked lists, a potentially large number of operations may be pushed onto the system stack. If so many operations are pushed that the stack runs out of room, IDL will crash.

---

## Syntax

```
HEAP_GC [, /OBJ | , /PTR] [, /VERBOSE]
```

## Arguments

None.

## Keywords

### OBJ

Set this keyword to perform garbage collection on object heap variables only.

### PTR

Set this keyword to perform garbage collection on pointer heap variables only.

**Note**

---

Setting *both* the PTR and OBJ keywords is the same as setting neither.

---

**VERBOSE**

If this keyword is set, HEAP\_GC writes a one line description of each heap variable, in the format used by the HELP procedure, as the variable is destroyed. This is a debugging aid that can be used by program developers to check for heap variable leaks that need to be located and eliminated.

[HEAP\\_FREE](#)

# HEAP\_NOSAVE

The `HEAP_NOSAVE` procedure is used to clear the *save attribute* of pointer or object heap variables. For more information about the heap variable save attribute, see the documentation for the [HEAP\\_SAVE](#) function, which provides a more general interface for managing the save attribute of heap variables.

## Syntax

`HEAP_NOSAVE, HeapVar`

## Arguments

### HeapVar

A pointer, object reference, or array of pointers or object references for which the referenced heap variables should have their save attributes cleared.

## Version History

6.1	Introduced
-----	------------

## See Also

[HEAP\\_SAVE](#)

# HEAP\_SAVE

The `HEAP_SAVE` function is used to query whether a pointer or object heap variable is savable. It can also be used to change the heap variable save attribute.

Every pointer and object heap variable has a *save attribute*, which is either set (True) or not set (False). This attribute determines whether the `SAVE` procedure will write the contents of the heap variable to a save file or not. When `SAVE` encounters a pointer or object reference, it checks the save attribute of the referenced heap variable and does one of the following:

1. If the save attribute is True (the default), it saves the referenced heap variable, and it recursively follows any pointer or object references the heap variable might contain to find any other heap variables it should also save.
2. If the save attribute is False, it does not save the referenced heap variable, and it does not follow any pointers or object references the heap variable might contain.

Later, when `RESTORE` or an `IDL_SAVEFILE` object is used to restore the pointer or object reference from the save file, one of the following will occur:

1. If the heap variable's save attribute is set, `RESTORE` will create a new heap variable containing the data from the saved heap variable, and the pointer or object reference will be set to refer to the new heap variable.
2. If the heap variable's save attribute is not set, the save file does not contain data for the heap variable. The heap variable is therefore not restored, and the pointer or object reference will be set to `NULL`.

IDL creates heap variables with their save attribute set to True by default; this is appropriate for the vast majority of IDL applications. Clearing the save attribute is not a very common operation, but there are situations in which it can be useful. For example, an object might use a pointer to hold data that it computes at runtime. Such data might be large, it might be subject to frequent change as the object state changes, or it might be easily recomputed. Rather than saving such data, you might choose to clear the save attribute so that the data won't be saved. When the pointer or object is restored it will be set to `NULL`, and the application can recompute the data as necessary.

## Syntax

*Result* = `HEAP_SAVE(HeapVar [, Set])`

## Return Value

Returns the value of the save attribute(s) of the heap variables referenced by *HeapVar*, as they exist when `HEAP_SAVE` is called, and before the *Set* parameter (if present) is applied. The result is of type byte, and has the same structure as *HeapVar*, with each element set to 1 (True) if the save attribute of the corresponding heap variable is set, and 0 (False) otherwise.

## Arguments

### HeapVar

A pointer, object reference, or array of pointers or object references to be processed.

### Set

A scalar value that is used to modify the save attributes of the heap variables referenced by *HeapVar*. Set this argument to 0 (zero) to clear the save attributes, or to a non-zero value to set the save attributes. If the *Set* argument is not present, `HEAP_SAVE` does not alter the save attributes.

### Note

---

The [HEAP\\_NOSAVE](#) procedure provides a shorthand method of clearing the save attributes of heap variables.

[HEAP\\_NOSAVE](#)

# HELP

The HELP procedure gives the user information on many aspects of the current IDL session. The specific area for which help is desired is selected by specifying the appropriate keyword. If no arguments or keywords are specified, the default is to show the current nesting of procedures and functions, all current variables at the current program level, and open files. Only one keyword can be specified at a time.

## Syntax

```
HELP, Expression1, ..., Expressionn [, /BREAKPOINTS] [, /BRIEF] [, /DEVICE]
  [, /DLM] [, /FILES] [, /FULL] [, /FUNCTIONS] [, /HEAP_VARIABLES]
  [, /KEYS] [, /LAST_MESSAGE] [, /LEVEL=value] [, /MEMORY]
  [, /MESSAGES] [, NAMES=string_of_variable_names] [, /OBJECTS]
  [, OUTPUT=variable] [, /PATH_CACHE] [, /PREFERENCES]
  [, /PROCEDURES] [, /RECALL_COMMANDS] [, /ROUTINES]
  [, /SHARED_MEMORY] [, /SOURCE_FILES] [, /STRUCTURES]
  [, /SYSTEM_VARIABLES] [, /TRACEBACK]
```

## Arguments

### Expression(s)

The arguments are interpreted differently depending on the keyword selected. If no keyword is selected, HELP displays basic information for its parameters. For example, to see the type and structure of the variable A, enter:

```
HELP, A
```

## Keywords

Note that the use of some of the following keywords causes any arguments to HELP to be ignored and HELP provides other types of information instead. If the description of the keyword does not explicitly mention the arguments, the arguments are ignored.

### BREAKPOINTS

Set this keyword to display the breakpoint table which shows the program module and location for each breakpoint.

## BRIEF

If set in conjunction with one of the following keywords, BRIEF produces very terse summary style output instead of the output normally displayed by those keywords:

- DLM
- MESSAGES
- ROUTINES
- STRUCTURES
- HEAP\_VARIABLES
- OBJECTS
- SOURCE\_FILES
- SYSTEM\_VARIABLES

## DEVICE

Set this keyword to show information about the currently selected graphics device. This information is dependent on the abilities of the current device, but the name of the device is always given. Arguments to HELP are ignored when DEVICE is specified.

## DLM

Set this keyword to display all known dynamically loadable modules and their state (loaded or not loaded).

## FILES

Set this keyword to display information about file units. If no arguments are supplied in the call to HELP, information on all open file units (except the special units 0, -1, and -2) is displayed. If arguments are provided, they are taken to be integer file unit numbers, and information on the specified file units is given.

For example, the command:

```
HELP, /FILES, -2, -1, 0
```

gives information below about the default file units:

```
Unit Attributes Name
-2 Write, Truncate, Tty, Reserved <stderr>
-1 Write, Truncate, Tty, Reserved <stdout>
0 Read, Tty, Reserved <stdin>
```

The attributes column tells about the characteristics of the file. For instance, the file connected to logical file unit 2 is called “stderr” and is the standard error file. It is opened for write access (Write), is a new file (Truncate), is a terminal (Tty), and cannot be closed by the CLOSE command (Reserved).

## FULL

By default, HELP filters its output in an attempt to display only the information likely to be of use to the IDL user. The filtering applied depends on the type of information being requested. By default:

- **Function keys:** Under UNIX, undefined function keys are not displayed. Under Windows, all function keys are displayed.
- **Structure Definitions And Objects:** Built-in IDL structure definitions (widget event structures, for example) are not displayed if they have not yet been used in the current IDL session. Structures and objects that have had their definition hidden using the `STRUCT_HIDE` procedure are not displayed.
- **Functions and Procedures:** Functions and procedures compiled with the `COMPILE_OPT HIDDEN` directive are not displayed.

Specify the FULL keyword to see all available information on a given topic without any filtering.

## FUNCTIONS

Normally, the `ROUTINES` or `SOURCE_FILES` keywords produce information on both functions and procedures. If `FUNCTIONS` is specified, only output on functions is produced. If `FUNCTIONS` is used without either `ROUTINES` or `SOURCE_FILES`, `ROUTINES` is assumed.

## HEAP\_VARIABLES

Set this keyword to display help information for all the current heap variables.

## KEYS

Set this keyword to show current function key definitions as set by `DEFINE_KEY`. Under UNIX, definitions for those function keys that are currently programmed to perform a function are displayed. Under Windows, definitions for all function keys are displayed. (Under UNIX, use the FULL keyword to display every available key, whether or not it is currently defined.)

If no arguments are supplied, information on all function keys is displayed. If arguments are provided, they must be scalar strings containing the names of function keys, and information on the specified keys is given.

## LAST\_MESSAGE

Set this keyword to display the last error message issued by IDL.

## LEVEL

By default, `HELP` displays information for variables in the scope of the currently executing routine. To change this behavior, set this keyword to a scalar integer indicating the scope in which the variables for displaying help should be found. The level value can be either absolute or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, <code>SCOPE_VARFETCH</code> clips the value not to go past <code>\$MAIN\$</code> .
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is <code>\$MAIN\$</code> , level 2 is the routine called from <code>\$MAIN\$</code> , and so forth. If you specify a level that is past the currently executing routine, <code>SCOPE_VARFETCH</code> clips the value to the level of the current routine.

Table 3-49: `HELP LEVEL` Keyword Values

For more information on scope level, see “`SCOPE_VARFETCH`” on page 2029.

## MEMORY

Set this keyword to see a report on the amount of dynamic memory (in bytes) currently in use by the IDL session; the maximum amount of dynamic memory allocated since the last call to `HELP, /MEMORY`; and the number of times dynamic

memory has been allocated and deallocated. Arguments to `HELP` are ignored when `MEMORY` is specified.

## MESSAGES

Set this keyword to display all known message blocks and the error space range into which they are loaded.

## NAMES

A string used to determine the names of the variables whose values are to be printed. A string match (equivalent to the `STRMATCH` function with the `FOLD_CASE` keyword set) is used to decide if a given variable will be displayed. The match string can contain any wildcard expression supported by `STRMATCH`, including “\*” and “?”.

For example, to print only the values of variables beginning with “A”, use the command `HELP, NAMES='a*'`. Similarly, `HELP, NAMES='?'` prints the values of all variables with a single-character name.

`NAMES` also works with the output from the following keywords:

- `DLM`
- `HEAP_VARIABLES`
- `MESSAGES`
- `OBJECTS`
- `PREFERENCES`
- `ROUTINES`
- `SOURCE_FILES`
- `STRUCTURES`
- `SYSTEM_VARIABLES`

## OBJECTS

Set this keyword to display information on defined object classes. If no arguments are provided, all currently-defined object classes are shown. If no arguments are provided, and the information you are looking for is not displayed, use the `FULL` keyword to prevent `HELP` from filtering the output. If arguments are provided, the definition of the object class for the heap variables referred to is displayed.

Information is provided on inherited superclasses and all *known methods*. A method is known to IDL only if it has been compiled in the current IDL session and called by its own class or a subclass. Methods that have not been compiled yet will not be shown. Thus, the list of methods displayed by `HELP` is not necessarily a complete list of all possible method for the object class.

If called within a class' method, the OBJECTS keyword also displays the instance data of the object on which it was called.

## OUTPUT

Set this keyword equal to a named variable that will contain a string array containing the formatted output of the HELP command. Each line of formatted output becomes a single element in the string array.

### Warning

---

The OUTPUT keyword is primarily for use in capturing HELP output in order to display it someplace else, such as in a text widget. This keyword is *not* intended to be used in obtaining programmatic information about the IDL session, and is formatted to be human readable. RSI reserves the right to change the format and content of this text *at any time, without warning*. If you find yourself using OUTPUT for a non-display purpose, consider using the STRUCTURE keyword to the [SIZE](#) function.

---

## PATH\_CACHE

Set this keyword to display a list of directories currently included in the IDL path cache, along with the number of .pro or .sav files found in those directories. See [PATH\\_CACHE](#) for details.

## PREFERENCES

Set this keyword to display information about the current status of IDL's preferences. IDL preferences are internal values used to configure certain aspects of the IDL environment. They serve as the initial values for many IDL system variables, as well as controlling other aspects of the user's environment.

Used by itself, the PREFERENCES keyword provides the following information:

- The path of the command-line preference file, if any.
- The path of the distribution preference file.
- The path of the user preference file.
- The number of preferences that are currently in a pending state. A preference is said to be pending if a new value has been set for it ([PREF\\_SET](#)) but not yet committed ([PREF\\_COMMIT](#)).

- The name and effective value of each preference and the source from which it is derived. In descending order of priority, the sources are command line, environment variable, user preference file, distribution preference file, and IDL default value.

Use **PREFERENCES** in conjunction with **BRIEF** for a terse display of the above. Use it with the **FULL** keyword in order to see the full information for each preference. In **FULL** mode, **HELP** displays the information above, as well as:

- A description of its purpose.
- Its category.
- If the preference serves as the initial value of a system variable, the name of the variable associated with the preference.
- When changes to the preference take effect.
- Values other than the effective value that are known for the preference. Because IDL preferences can have values from more than one source, the source with the highest priority is used as the effective value.

## PROCEDURES

Normally, the **ROUTINES** or **SOURCE\_FILES** keywords produce information on both functions and procedures. If **PROCEDURES** is specified, only output on procedures is produced. If **PROCEDURES** is used without either **ROUTINES** or **SOURCE\_FILES**, **ROUTINES** is assumed.

## RECALL\_COMMANDS

Set this keyword to display the saved commands in the command input buffer. By default, IDL saves the last 20 lines of input in a buffer from which they can be recalled for command line editing. Arguments to **HELP** are ignored when **RECALL** is specified.

The number of lines saved can be changed by assigning the desired number of lines to the **IDL\_RBUF\_SIZE** preference. For more information, see “**IDL\_RBUF\_SIZE**” on page 4854.

## ROUTINES

Set this keyword to show a list of all compiled procedures and functions with their parameter names. Keyword parameters accepted by each module are shown to the right of the routine name. If no arguments are provided, and the information you are looking for is not displayed, use the **FULL** keyword to prevent **HELP** from filtering the output.

## SHARED\_MEMORY

Set this keyword to display information about all current shared memory and memory mapped file segments mapped into the current IDL process via the [SHMMAP](#) procedure.

## SOURCE\_FILES

Set this keyword to display information on procedures and functions written in the IDL language that have been compiled during the current IDL session. Full path names (relative to the current directory) of compiled `.pro` files are displayed. If no arguments are provided, and the information you are looking for is not displayed, use the `FULL` keyword to prevent `HELP` from filtering the output.

## STRUCTURES

Set this keyword to display information on structure-type variables. If no arguments are provided, all currently-defined structures are shown. If no arguments are provided, and the information you are looking for is not displayed, use the `FULL` keyword to prevent `HELP` from filtering the output. If arguments are provided, the structure definition for those expressions is displayed. It is often more convenient to use `HELP, /STRUCTURES` instead of `PRINT` to look at the contents of a structure variable because it shows the names of the fields as well as the data.

## SYSTEM\_VARIABLES

Set this keyword to display information on all system variables. Arguments are ignored.

## TRACEBACK

Set this keyword to display the current nesting of procedures and functions.

## Examples

To see general information on the current IDL session, enter:

```
HELP
```

To see information on the structure definition of the system variable `!D`, enter:

```
HELP, !D, /STRUCTURES
```

## Version History

6.2	Added PREFERENCES keyword Deprecated ALL_KEYS and CALLS keywords

For information on deprecated keywords, see [Appendix J, “Obsolete Features”](#).

# HILBERT

The HILBERT function outputs a series that has all periodic terms phase-shifted by 90 degrees. This transform has the interesting property that the correlation between a series and its own Hilbert transform is mathematically zero.

This routine is written in the IDL language. Its source code can be found in the file `hilbert.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = HILBERT(*X* [, *D*])

## Return Value

The return value is a complex-valued vector with the same size as the input vector. HILBERT generates the fast Fourier transform using the FFT function, and shifts the first half of the transform products by +90 degrees and the second half by -90 degrees. The constant elements in the transform are not changed. Angle shifting is accomplished by multiplying or dividing by the complex number,  $i = (0.0000, 1.0000)$ . The shifted vector is then submitted to FFT for transformation back to the “time” domain and the output is divided by the number elements in the vector to correct for multiplication effect peculiar to the FFT algorithm.

### Note

---

Because HILBERT uses FFT, it exhibits the same side effects with respect to input arguments as that function.

---

## Arguments

### X

An  $n$ -element floating-point or complex-valued vector.

### D

A flag for rotation direction. Set  $D = +1$  for a positive rotation (the default). Set  $D = -1$  for a negative rotation.

## Keywords

None

[FFT](#)

# HIST\_2D

The HIST\_2D function returns the two dimensional density function (histogram) of two variables.

This routine is written in the IDL language. Its source code can be found in the file `hist_2d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = HIST_2D( V1, V2 [, BIN1=width] [, BIN2=height] [, MAX1=value]
                [, MAX2=value] [, MIN1=value] [, MIN2=value] )
```

## Return Value

Returns a longword array of dimensions  $(\text{MAX}(V1)+1, \text{MAX}(V2)+1)$ .  $\text{Result}(i,j)$  is equal to the number of simultaneous occurrences of  $V1 = i$  and  $V2 = j$  at the specified element.

## Arguments

### V1, V2

The arguments are arrays containing the variables.  $V1$  and  $V2$  may be of any numeric type except complex. If  $V1$  and  $V2$  do not contain the same number of elements, then the extra elements in the longer array are ignored.

## Keywords

### BIN1

Set this keyword equal to the size of each bin in the  $V1$  direction (column width). If this keyword is not specified, the size is set to 1.

### BIN2

Set this keyword equal to the size of each bin in the  $V2$  direction (row height). If this keyword is not specified, the size is set to 1.

## MAX1

Set this keyword equal to the maximum *V1* value to consider. If this keyword is not specified, then *V1* is searched for its largest value.

## MAX2

Set this keyword equal to the maximum *V2* value to consider. If this keyword is not specified, then *V2* is searched for its largest value.

## MIN1

Set this keyword to the minimum *V1* value to consider. If this keyword is not specified and if the smallest value of *V1* is greater than zero, then `MIN1=0` is used, otherwise the smallest value of *V1* is used.

## MIN2

Set this keyword to the minimum *V2* value to consider. If this keyword is not specified and if the smallest value of *V2* is greater than zero, then `MIN2=0` is used; otherwise, the smallest value of *V2* is used.

## Examples

To return the 2D histogram of two byte images:

```
R = HIST_2D(image1, image2)
```

To display the 2D histogram made from two floating point images, restricting the range from -1 to +1, and with 101 bins:

```
F1 = RANDOMN(seed, 256, 256)
F2 = RANDOMN(seed, 256, 256)
Result = HIST_2D(F1, F2, MIN1=-1, MAX1=1, $
    MIN2=-1, MAX2=1, BIN1=0.02, BIN2=0.02)
TVSCL, Result
```

## Version History

Pre 4.0	Introduced

[H\\_EQ\\_CT](#), [H\\_EQ\\_INT](#), [HIST\\_EQUAL](#), [HISTOGRAM](#)

# HIST\_EQUAL

The HIST\_EQUAL function returns a histogram-equalized byte array.

The HISTOGRAM function is used to obtain the density distribution of the input array. The histogram is integrated to obtain the cumulative density-probability function and finally the lookup function is used to transform to the output image.

---

**Note**

The first element of the histogram is always zeroed to remove the background.

---

This routine is written in the IDL language. Its source code can be found in the file `hist_equal.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = HIST_EQUAL( A [, BINSIZE=value] [, FCN=vector]
                    [, /HISTOGRAM_ONLY] [, MAXV=value] [, MINV=value]
                    [, OMAX=variable] [, OMIN=variable] [, PERCENT=value] [, TOP=value] )
```

## Return Value

This function returns a histogram-equalized array of type byte, with the same dimensions as the input array. If the HISTOGRAM\_ONLY keyword is set, then the output will be a vector of type LONG.

## Arguments

### A

The array to be histogram-equalized.

## Keywords

### BINSIZE

Set this keyword to the size of the bin to use. The default is BINSIZE=1 if A is a byte array, or, for other input types, the default is  $(MAXV - MINV)/5000$ .

## **FCN**

Set this keyword to the desired cumulative probability distribution function in the form of a 256-element vector. If a probability distribution function is not supplied, IDL uses a linear ramp, which yields equal probability bin results. This function is later normalized, so magnitude is inconsequential; the function should, however, increase monotonically.

## **HISTOGRAM\_ONLY**

Set this keyword to return a vector of type LONG containing the cumulative distribution histogram, rather than the histogram equalized array.

## **MAXV**

Set this keyword to the maximum value to consider. The default is 255 if *A* is a byte array, otherwise the maximum data value is used. Input elements greater than or equal to MAXV are output as 255.

## **MINV**

Set this keyword to the minimum value to consider. The default is 0 if *A* is a byte array, otherwise the minimum data value is used. Input elements less than or equal to MINV are output as 0.

## **OMAX**

Set this keyword to a named variable that, upon exit, will contain the maximum data value used in constructing the histogram.

## **OMIN**

Set this keyword to a named variable that, upon exit, will contain the minimum data value used in constructing the histogram.

## **PERCENT**

Set this keyword to a value between 0 and 100 to stretch the image histogram. The histogram will be stretched linearly between the limits that exclude the PERCENT fraction of the lowest values, and the PERCENT fraction of the highest values. This is an automatic, semi-robust method of contrast enhancement.

## TOP

The maximum value of the scaled result. If TOP is not specified, 255 is used. Note that the minimum value of the scaled result is always 0.

## Example

Create a sample image using the DIST function and display it:

```
image = DIST(100)
TV, image
```

Create a histogram-equalized version of the byte array, `image`, and display the new version. Use a minimum input value of 10, a maximum input value of 200, and limit the top value of the output array to 220:

```
new = HIST_EQUAL(image, MINV = 10, MAXV = 200, TOP = 220)
TV, new
```

### Note

Also see [“Working with Histograms”](#) in Chapter 8 of the *Image Processing in IDL* manual.

# HISTOGRAM

The HISTOGRAM function computes the density function of *Array*. In the simplest case, the density function, at subscript *i*, is the number of *Array* elements in the argument with a value of *i*.

Let  $F_i$  = the value of element *i*,  $0 \leq i < n$ . Let  $H_v$  = result of histogram function, an integer vector. The definition of the histogram function becomes:

$$H_v = \sum_{i=0}^{n-1} P(F_i, v), \quad v = 0, 1, 2, \dots, \left\lfloor \frac{\text{Max} - \text{Min}}{\text{Binsize}} \right\rfloor$$

$$P(F_i, v) = \begin{cases} 1, & v \leq (F_i - \text{Min})/\text{Binsize} < v + 1 \\ 0, & \text{Otherwise} \end{cases}$$

## Warning

---

There may not always be enough virtual memory available to find the density functions of arrays that contain a large number of bins.

---

For bivariate probability distributions, use the HIST\_2D function.

HISTOGRAM can optionally return an array containing a list of the original array subscripts that contributed to each histogram bin. This list, commonly called the reverse (or backwards) index list, efficiently determines which array elements are accumulated in a set of histogram bins. A typical application of the reverse index list is reverse histogram or scatter plot interrogation—a histogram bin or 2D scatter plot location is marked with the cursor and the original data items within that bin are highlighted.

## Syntax

```
Result = HISTOGRAM( Array [, BINSIZE=value] [, INPUT=variable]
  [, LOCATIONS=variable] [, MAX=value] [, MIN=value] [, /NAN]
  [, NBINS=value] [, OMAX=variable] [, OMIN=variable]
  [, /L64 | REVERSE_INDICES=variable] )
```

## Return Value

Returns a 32-bit or a 64-bit integer vector equal to the density function of the input *Array*.

## Arguments

### Array

The vector or array for which the density function is to be computed.

## Keywords

### BINSIZE

Set this keyword to the size of the bin to use. If this keyword is not specified, and NBINS is not set, then a bin size of 1 is used. If NBINS is set, the default is  $BINSIZE = (MAX - MIN) / (NBINS - 1)$ .

### Note

---

The data type of the value specified for BINSIZE should match the data type of the *Array* argument. Since BINSIZE is converted to the data type of *Array*, specifying mismatched data types may produce undesired results.

---

### INPUT

Set this keyword to a named variable that contains an array to be added to the output of HISTOGRAM. The density function of *Array* is added to the existing contents of INPUT and returned as the result. The array is converted to longword type if necessary and must have at least as many elements as are required to form the histogram. Multiple histograms can be efficiently accumulated by specifying partial sums via this keyword.

### L64

By default, the return value of HISTOGRAM is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases. L64 controls the type of *Result* as well as the output from the REVERSE\_INDICES keyword.

**Note**

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of `!VERSION.MEMORY_BITS` to see if your IDL is 64-bit or not.

## LOCATIONS

Set this keyword to a named variable in which to return the starting locations for each bin. The starting locations are given by  $\text{MIN} + v * \text{BINSIZE}$ , with  $v = 0, 1, \dots, \text{NBINS} - 1$ . `LOCATIONS` has the same number of elements as the `Result`, and has the same type as the input `Array`.

## MAX

Set this keyword to the maximum value to consider. If this keyword is not specified, `Array` is searched for its largest value. If this keyword is not specified, and `Array` is of type byte, 255 is used.

**Note**

The data type of the value specified for `MAX` should match the data type of the input array. Since `MAX` is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

**Note**

If `NBINS` is specified, the value for `MAX` will be adjusted to  $\text{NBINS} * \text{BINSIZE} + \text{MIN}$ . This ensures that the last bin has the same width as the other bins.

## MIN

Set this keyword to the minimum value to consider. If this keyword is not specified, and `Array` is of type byte, 0 is used. If this keyword is not specified and `Array` is not of byte type, `Array` is searched for its smallest value.

**Note**

The data type of the value specified for `MIN` should match the data type of the input array. Since `MIN` is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## NBINS

Set this keyword to the number of bins to use. If `BINSIZE` is specified, the number of bins in *Result* is `NBINS`, starting at `MIN` and ending at `MIN+(NBINS-1)*BINSIZE`. If `MAX` is specified, the bins will be evenly spaced between `MIN` and `MAX`. It is an error to specify `NBINS` with both `BINSIZE` and `MAX`.

## OMAX

Set this keyword to a named variable that will contain the maximum data value used in constructing the histogram.

## OMIN

A named variable that, upon exit, contains the minimum data value used in constructing the histogram.

## REVERSE\_INDICES

Set this keyword to a named variable in which the list of reverse indices is returned. When possible, this list is returned as a 32-bit integer vector whose number of elements is the sum of the number of elements in the histogram,  $N$ , and the number of array elements included in the histogram, plus one. If the number of elements is too large to be contained in a 32-bit integer, or if the `L64` keyword is set, `REVERSE_INDICES` is returned as a 64-bit integer.

The subscripts of the original array elements falling in the  $i^{\text{th}}$  bin,  $0 \leq i < N$ , are given by the expression: `R(R[i] : R[i+1]-1)`, where `R` is the reverse index list. If `R[i]` is equal to `R[i+1]`, no elements are present in the  $i^{\text{th}}$  bin.

For example, make the histogram of array `A`:

```
H = HISTOGRAM(A, REVERSE_INDICES = R)

;Set all elements of A that are in the ith bin of H to 0.
IF R[i] NE R[i+1] THEN A[R[R[I] : R[i+1]-1]] = 0
```

The above is usually more efficient than the following:

```
bini = WHERE(A EQ i, count)
IF count NE 0 THEN A[bini] = 0
```

## Examples

```
; Create a simple, 2D dataset:
D = DIST(200)
; Plot the histogram of D with a bin size of 1 and the default
; minimum and maximum:
PLOT, HISTOGRAM(D)
; Plot a histogram considering only those values from 10 to 50
; using a bin size of 4:
PLOT, HISTOGRAM(D, MIN = 10, MAX = 50, BINSIZE = 4)
```

The HISTOGRAM function can also be used to increment the elements of one vector whose subscripts are contained in another vector. To increment those elements of vector A indicated by vector B, use the command:

```
A = HISTOGRAM(B, INPUT=A, MIN=0, MAX=N_ELEMENTS(A)-1)
```

This method works for duplicate subscripts, whereas the following statement never adds more than 1 to any element, even if that element is duplicated in vector B:

```
A[B] = A[B]+1
```

For example, for the following commands:

```
A = LONARR(5)
B = [2,2,3]
PRINT, HISTOGRAM(B, INPUT=A, MIN=0, MAX=4)
```

IDL prints:

```
0 0 2 1 0
```

The commands:

```
A = LONARR(5)
A[B] = A[B]+1
PRINT, A
```

give the result:

```
0 0 1 1 0
```

The following example demonstrates how to use HISTOGRAM:

```

PRO t_histogram
data = [[-5, 4, 2, -8, 1], $
        [ 3, 0, 5, -5, 1], $
        [ 6, -7, 4, -4, -8], $
        [-1, -5, -14, 2, 1]]
hist = HISTOGRAM(data)
bins = FINDGEN(N_ELEMENTS(hist)) + MIN(data)
PRINT, MIN(hist)
PRINT, bins
PLOT, bins, hist, YRANGE = [MIN(hist)-1, MAX(hist)+1], PSYM = 10, $
    XTITLE = 'Bin Number', YTITLE = 'Density per Bin'
END

```

IDL prints:

```

0

-14.0000  -13.0000  -12.0000  -11.0000  -10.0000  -9.00000
-8.00000  -7.00000  -6.00000  -5.00000  -4.00000  -3.00000
-2.00000  -1.00000  0.00000  1.00000  2.00000  3.00000
 4.00000  5.00000  6.00000

```

# HLS

The HLS procedure creates a color table based on the HLS (Hue, Lightness, Saturation) color system.

Using the input parameters, a spiral through the double-ended HLS cone is traced. Points along the cone are converted from HLS to RGB. The current colortable (and the COLORS common block) contains the new colortable on exit.

This routine is written in the IDL language. Its source code can be found in the file `hls.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

HLS, *Litlo*, *Lithi*, *Satlo*, *Sathi*, *Hue*, *Loops* [, *Colr*]

## Arguments

### Litlo

Starting lightness, from 0 to 100%.

### Lithi

Ending lightness, from 0 to 100%.

### Satlo

Starting saturation, from 0 to 100%.

### Sathi

Ending saturation, from 0 to 100%.

### Hue

Starting Hue, from 0 to 360 degrees. Red = 0 degs, green = 120, blue = 240.

### Loops

The number of loops through the color spiral. This parameter does not have to be an integer. A negative value causes the loops to traverse the spiral in the opposite direction.

## Colr

An optional (256,3) integer array in which the new R, G, and B values are returned.  
Red = *Colr*[\*],0], green = *Colr*[\*],1], blue = *Colr*[\*],2].

## Keywords

None.

# HOUGH

The HOUGH function implements the Hough transform, used to detect straight lines within a two-dimensional image. This function can be used to return either the Hough transform, which transforms each nonzero point in an image to a sinusoid in the Hough domain, or the Hough backprojection, where each point in the Hough domain is transformed to a straight line in the image.

## Hough Transform Theory

The Hough transform is defined for a function  $A(x, y)$  as:

$$H(\theta, \rho) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} A(x, y) \delta(\rho - x \cos \theta - y \sin \theta) dx dy$$

where  $\delta$  is the Dirac delta-function. With  $A(x, y)$ , each point  $(x, y)$  in the original image,  $A$ , is transformed into a sinusoid  $\rho = x \cos \theta - y \sin \theta$ , where  $\rho$  is the perpendicular distance from the origin of a line at an angle  $\theta$  (The angle  $\theta$  will be limited to  $0 \leq \theta < \pi$  which could result in negative  $\rho$  values.):

Figure 3-46: Hough Transform

Points that lie on the same line in the image will produce sinusoids that all cross at a single point in the Hough transform. For the inverse transform, or backprojection, each point in the Hough domain is transformed into a straight line in the image.

Usually, the Hough function is used with binary images, in which case  $H(\theta, \rho)$  gives the total number of sinusoids that cross at point  $(\theta, \rho)$ , and hence, the total number of points making up the line in the original image. By choosing a threshold  $T$  for  $H(\theta, \rho)$ , and using the inverse Hough function, you can filter the original image to keep only lines that contain at least  $T$  points.

### How IDL Implements the Hough Transform

Consider an image  $A_{mn}$  of dimensions  $M$  by  $N$ , with array indices  $m = 0, \dots, M-1$  and  $n = 0, \dots, N-1$ .

The discrete formula for the HOUGH function for  $A_{mn}$  is:

$$H(\theta, \rho) = \sum_m \sum_n A_{mn} \delta(\rho, [\rho'])$$

where the brackets [ ] indicate rounding to the nearest integer, and

$$\rho' = (m\Delta x + x_{\min})\cos\theta + (n\Delta y + y_{\min})\sin\theta$$

The pixels are assumed to have spacing  $\Delta x$  and  $\Delta y$  in the x and y directions. The delta-function is defined as:

$$\delta(\rho, [\rho']) = \begin{cases} 1 & \rho = [\rho'] \\ 0 & \text{otherwise} \end{cases}$$

### How IDL Implements the Hough Backprojection

The backprojection,  $B_{mn}$ , contains all of the straight lines given by the  $(\theta, \rho)$  points given in  $H(\theta, \rho)$ . The discrete formula is

$$B_{mn} = \begin{cases} \sum_{\theta} \sum_{\rho} H(\theta, \rho) \delta(n, [am + b]) & |\sin\theta| > \frac{\sqrt{2}}{2} \\ \sum_{\theta} \sum_{\rho} H(\theta, \rho) \delta(m, [a'n + b']) & |\sin\theta| \leq \frac{\sqrt{2}}{2} \end{cases}$$

where the slopes and offsets are given by:

$$a = -\frac{\Delta x \cos \theta}{\Delta y \sin \theta} \qquad b = \frac{\rho - x_{\min} \cos \theta - y_{\min} \sin \theta}{\Delta y \sin \theta}$$

$$a' = \frac{1}{a} \qquad b' = \frac{\rho - x_{\min} \cos \theta - y_{\min} \sin \theta}{\Delta x \cos \theta}$$

## Syntax

### Hough Transform:

```
Result = HOUGH( Array [, /DOUBLE] [, DRHO=scalar] [, DX=scalar]
  [, DY=scalar] [, /GRAY] [, NRHO=scalar] [, NTHETA=scalar]
  [, RHO=variable] [, RMIN=scalar] [, THETA=variable] [, XMIN=scalar]
  [, YMIN=scalar] )
```

### Hough Backprojection:

```
Result = HOUGH( Array, /BACKPROJECT, RHO=variable, THETA=variable
  [, /DOUBLE] [, DX=scalar] [, DY=scalar] [, NX=scalar] [, NY=scalar]
  [, XMIN=scalar] [, YMIN=scalar] )
```

## Return Value

The result of this function is a two-dimensional floating-point array, or a complex array if the input image is complex. If *Array* is double-precision, or if the `DOUBLE` keyword is set, the result is double-precision, otherwise, the result is single-precision.

## Arguments

### Array

The two-dimensional array of size *M* by *N* which will be transformed. If the keyword `GRAY` is not set, then, for the forward transform, *Array* is treated as a binary image with all nonzero pixels considered as 1.

## Keywords

### BACKPROJECT

If set, the backprojection is computed, otherwise, the forward transform is computed. When BACKPROJECT is set, *Result* will be an array of dimension  $NX$  by  $NY$ .

#### Note

The Hough transform is not one-to-one: each point  $(x, y)$  is not mapped to a single  $(\theta, \rho)$ . Therefore, instead of the original image, the backprojection, or inverse transform, returns an image containing the set of all lines given by the  $(\theta, \rho)$  points.

### DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

### DRHO

Set this keyword equal to a scalar specifying the spacing  $\Delta\rho$  between  $\rho$  coordinates, expressed in the same units as *Array*. The default is  $1/\text{SQRT}(2)$  times the diagonal distance between pixels,  $[(DX^2 + DY^2)/2]^{1/2}$ . A larger value produces a coarser resolution by mapping multiple pixels onto a single  $\rho$ ; this is useful for images that do not contain perfectly straight lines. A smaller value may produce undersampling by trying to map fractional pixels onto  $\rho$ , and is not recommended. If BACKPROJECT is specified, this keyword is ignored.

### DX

Set this keyword equal to a scalar specifying the spacing between the horizontal (X) coordinates. The default is 1.0.

### DY

Set this keyword equal to a scalar specifying the spacing between the vertical (Y) coordinates. The default is 1.0.

### GRAY

Set this keyword to perform a weighted Hough transform, with the weighting given by the pixel values. If GRAY is not set, the image is treated as a binary image with all nonzero pixels considered as 1. If BACKPROJECT is specified, this keyword is ignored.

## NRHO

Set this keyword equal to a scalar specifying the number of  $\rho$  coordinates to use. The default is  $2 \text{ CEIL}([\text{MAX}(X^2 + Y^2)]^{1/2} / \text{DRHO}) + 1$ . If **BACKPROJECT** is specified, this keyword is ignored.

## NTHETA

Set this keyword equal to a scalar specifying the number of  $\theta$  coordinates to use over the interval  $[0, \pi]$ . The default is  $\text{CEIL}(\pi [\text{MAX}(X^2 + Y^2)]^{1/2} / \text{DRHO})$ . A larger value will produce smoother results, and is useful for filtering before backprojection. A smaller value will result in broken lines in the transform, and is not recommended. If **BACKPROJECT** is specified, this keyword is ignored.

## NX

If **BACKPROJECT** is specified, set this keyword equal to a scalar specifying the number of horizontal coordinates in the output array. The default is  $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$ . For the forward transform this keyword is ignored.

## NY

If **BACKPROJECT** is specified, set this keyword equal to a scalar specifying the number of vertical coordinates in the output array. The default is  $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$ . For the forward transform, this keyword is ignored.

## RHO

For the forward transform, set this keyword to a named variable that, on exit, will contain the radial ( $\rho$ ) coordinates, in units defined by the **DX** and **DY** keywords (pixels by default). If **BACKPROJECT** is specified, this keyword must contain the  $\rho$  coordinates of the input *Array*.

## RMIN

Set this keyword equal to a scalar specifying the minimum  $\rho$  coordinate to use for the forward transform. The default is  $-0.5(\text{NRHO} - 1) \text{ DRHO}$ . If **BACKPROJECT** is specified, this keyword is ignored.

## THETA

For the forward transform, set this keyword to a named variable containing a vector of angular ( $\theta$ ) coordinates (in radians) to use for the transform. If **NTHETA** is

specified instead, and THETA is set to a named variable, then on exit THETA will contain the  $\theta$  coordinates. If BACKPROJECT is specified, this keyword must contain the  $\theta$  coordinates of the input *Array*. HOUGH returns  $\theta$  in  $[0,\pi)$

## XMIN

Set this keyword equal to a scalar specifying the X coordinate of the lower-left corner of the input *Array*. The default is  $-(M-1)/2$ , where *Array* is an  $M$  by  $N$  array. If BACKPROJECT is specified, set this keyword equal to a scalar specifying the X coordinate of the lower-left corner of the *Result*. In this case the default is  $-DX (NX-1)/2$ .

## YMIN

Set this keyword equal to a scalar specifying the Y coordinate of the lower-left corner of the input *Array*. The default is  $-(N-1)/2$ , where *Array* is an  $M$  by  $N$  array. If BACKPROJECT is specified, set this keyword equal to a scalar specifying the Y coordinate of the lower-left corner of the *Result*. In this case the default is  $-DY (NY-1)/2$ .

## Examples

### Note

Also see [“Transforming to and from the Hough and Radon Domains”](#) in Chapter 7 of the *Image Processing in IDL* manual.

This example computes the Hough transform of a random set of pixels:

```
PRO hough_example

;Create an image with a random set of pixels
seed = 12345 ; remove this line to get different random images
array = RANDOMU(seed,128,128) GT 0.95

;Draw three lines in the image
x = FINDGEN(32)*4
array[x,0.5*x+20] = 1b
array[x,0.5*x+30] = 1b
array[-0.5*x+100,x] = 1b

;Create display window, set graphics properties
WINDOW, XSIZE=330,YSIZE=630, TITLE='Hough Example'
!P.BACKGROUND = 255 ; white
!P.COLOR = 0 ; black
!P.FONT=2
```

```

ERASE

XYOUTS, .1, .94, 'Noise and Lines', /NORMAL
;Display the image. 255b changes black values to white:
TVSCL, 255b - array, .1, .72, /NORMAL

;Calculate and display the Hough transform
result = HOUGH(array, RHO=rho, THETA=theta)
XYOUTS, .1, .66, 'Hough Transform', /NORMAL
TVSCL, 255b - result, .1, .36, /NORMAL

;Keep only lines that contain more than 20 points:
result = (result - 20) > 0

;Find the Hough backprojection and display the output
backproject = HOUGH(result, /BACKPROJECT, RHO=rho, THETA=theta)
XYOUTS, .1, .30, 'Hough Backprojection', /NORMAL
TVSCL, 255b - backproject, .1, .08, /NORMAL

END

```

The following figure displays the output of this example. The top image shows three lines drawn within a random array of pixels that represent noise. The center image shows the Hough transform, displaying sinusoids for points that lie on the same line in the original image. The bottom image shows the Hough backprojection, after setting the threshold to retain only those lines that contain more than 20 points. The Hough inverse transform, or backprojection, transforms each point in the Hough domain into a straight line in the image.

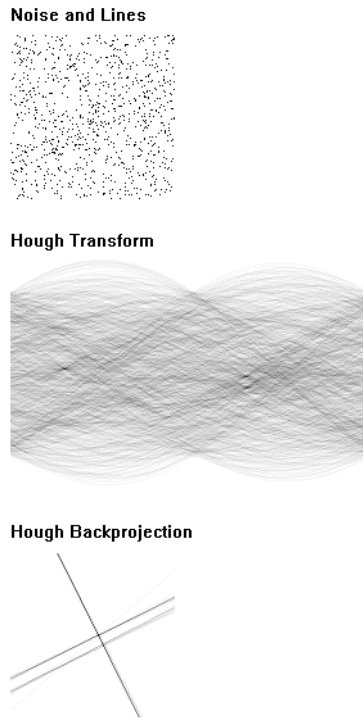

Figure 3-47: HOUGH example showing random pixels (top), Hough transform (center) and Hough backprojection (bottom)

# HQR

The HQR function returns all eigenvalues of an upper Hessenberg array. Using the output produced by the ELMHES function, this function finds all eigenvalues of the original real, nonsymmetric array.

HQR is based on the routine `hqr` described in section 11.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the LA\_HQR function instead.

---

## Syntax

*Result* = HQR( *A* [, /COLUMN] [, /DOUBLE] )

## Return Value

The result is an  $n$ -element complex vector.

## Arguments

### A

An  $n$  by  $n$  upper Hessenberg array. Typically, *A* would be an array resulting from an application of ELMHES.

---

**Note**

If HQR is complex then only the real part is used for the computation.

---

## Keywords

### COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To compute the eigenvalues of a real, non-symmetric unbalanced array, first define the array *A*:

```
A = [[ 1.0, 2.0, 0.0, 0.0, 0.0], $
      [-2.0, 3.0, 0.0, 0.0, 0.0], $
      [ 3.0, 4.0, 50.0, 0.0, 0.0], $
      [-4.0, 5.0, -60.0, 7.0, 0.0], $
      [-5.0, 6.0, -70.0, 8.0, -9.0]]

; Compute the upper Hessenberg form of the array:
hes = ELMHES(A)
; Compute the eigenvalues:
evals = HQR(hes)

; Sort the eigenvalues into ascending order based on their
; real components:
evals = evals(SORT(FLOAT(eval)))

;Print the result.
PRINT, evals
```

IDL prints:

```
( -9.00000, 0.00000) ( 2.00000, -1.73205)
( 2.00000, 1.73205) ( 7.00000, 0.00000)
( 50.0000, 0.00000)
```

This is the exact solution vector to five-decimal accuracy.

# HSV

The HSV procedure creates a color table based on the HSV (Hue and Saturation Value) color system.

Using the input parameters, a spiral through the single-ended HSV cone is traced. The color representation of pixel values is linearly interpolated from beginning and ending values of hue, saturation, and value. Points along the cone are converted from HSV to RGB. The current colortable (and the COLORS common block) contains the new colortable on exit.

This routine is written in the IDL language. Its source code can be found in the file `hsv.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

HSV, *Vlo*, *Vhi*, *Satlo*, *Sathi*, *Hue*, *Loops* [, *Colr*]

## Arguments

### **Vlo**

Starting value, from 0 to 100%.

### **Vhi**

Ending value, from 0 to 100%.

### **Satlo**

Starting saturation, from 0 to 100%.

### **Sathi**

Ending saturation, from 0 to 100%.

### **Hue**

Starting Hue, from 0 to 360 degrees. Red = 0 degs, green = 120, blue = 240.

## Loops

The number of loops through the color spiral. This parameter does not have to be an integer. A negative value causes the loops to traverse the spiral in the opposite direction.

## Colr

An optional (256,3) integer array in which the new R, G, and B values are returned. Red = *Colr*[\*],0], green = *Colr*[\*],1], blue = *Colr*[\*],2].

## Keywords

# IBETA

The IBETA function computes the incomplete beta function.

$$I_x(a, b) \equiv \frac{\int_0^x t^{a-1} (1-t)^{b-1} dt}{\int_0^1 t^{a-1} (1-t)^{b-1} dt}$$

This routine is written in the IDL language. Its source code can be found in the file `ibeta.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = IBETA( A, B, Z [, /DOUBLE] [, EPS=value] [, ITER=variable]
              [, ITMAX=value] )
```

## Return Value

If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of *A*, *B*, and *Z*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments are arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

If any of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### A

A scalar or array that specifies the parametric exponent of the integrand. *A* may be complex.

### B

A scalar or array that specifies the parametric exponent of the integrand. *B* may be complex.

## Z

A scalar or array, in the interval  $[0, 1]$ , that specifies the upper limit of integration.  $Z$  may be complex. If  $Z$  is not complex then the values must be in the range  $[0, 1]$ .

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double precision.

### EPS

Set this keyword to the desired relative accuracy, or tolerance. The default tolerance is  $3.0e-7$  for single precision, and  $3.0d-12$  for double precision.

### ITER

Set this keyword to a named variable that will contain the actual number of iterations performed.

### ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 100.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

### Example 1

Compute the incomplete beta function for the corresponding elements of  $A$ ,  $B$ , and  $Z$ .

```
; Define an array of parametric exponents:
A = [0.5, 0.5, 1.0, 5.0, 10.0, 20.0]
B = [0.5, 0.5, 0.5, 5.0, 5.0, 10.0]
```

```

; Define the upper limits of integration:
Z = [0.01, 0.1, 0.1, 0.5, 1.0, 0.8]
; Compute the incomplete beta functions:
result = IBETA(A, B, Z)
PRINT, result

```

IDL prints:

```
[0.0637686, 0.204833, 0.0513167, 0.500000, 1.00000, 0.950736]
```

## Example 2

This example shows the difference in accuracy between the incomplete beta function computed with a low tolerance and the incomplete beta function computed with a high tolerance. The resulting surfaces show the relative errors of each. The relative error of the low tolerance ranges from 0 to 0.002 percent. The relative error of the high tolerance ranges from 0 to 0.000000004 percent.

```

PRO UsingIBETAwithEPS

; Define an array of parametric exponents.
parameterA = (DINDGEN(101)/100. + 1.D) # REPLICATE(1.D, 101)
parameterB = REPLICATE(1.D, 101) # (DINDGEN(101)/10. + 1.D)

; Define the upper limits of integration.
upperLimits = REPLICATE(0.1D, 101, 101)

; Compute the incomplete beta functions.
betaFunctions = IBETA(parameterA, parameterB, upperLimits)

; Compute the incomplete beta functions with a less
; accurate tolerance set.
laBetaFunctions = IBETA(parameterA, parameterB, $
    upperLimits, EPS = 3.0e-4)

# ICONTOUR

The ICONTOUR procedure creates an iTool and associated user interface (UI) configured to display and manipulate contour data.

---

**Note**

If no arguments are specified, the ICONTOUR procedure creates an empty Contour tool.

---

This routine is written in the IDL language. Its source code can be found in the file `icontour.pro` in the `lib/itools` subdirectory of the IDL distribution.

For more information on using the iContour tool, see “[Working with Contours](#)” in the *iTool User’s Guide* manual.

## Using Palettes

Contour colors can be specified in several ways. By default, all contour levels are black. The `COLOR` keyword can be used to change the color of all contour levels. For example, you can change contour levels to red by setting `COLOR = [255, 0, 0]`. Individual color levels can be specified when the iContour tool is in palette color mode, which allows a color table to be used. You can activate the palette color mode from the IDL Command Line by setting either of the `RGB_TABLE` or `RGB_INDICES` keywords, or from the iContour tool’s property sheet by changing the **Use palette color** setting to `True`.

---

**Note**

If you are not in the palette color mode, the colors of individual levels may be modified in the contour level properties dialog. If you are in the palette color mode, the ability to edit individual colors in the contour level properties dialog is disabled. However, changing the **Use palette color** setting to `False` does not switch you back to previously set colors. It simply converts the colors referenced by indices to direct color values that can be individually modified. A common practice is to switch to palette color mode, select a palette, then change **Use palette color** to `False`. The colors of the palette are now loaded as individual contour colors that can each be edited in the contour level properties dialog.

---

If the iContour tool is in palette color mode, a colorbar can be inserted through the **Insert** menu. The colorbar displays a sample of the current palette associated with the contour display. The data values of the axis of the colorbar are based on the data range of the `Z` argument and the contour level values.

The minimum value of the colorbar axis represents the minimum of the data range. The maximum value of the axis is the greater of than the maximum of the data range and the highest contour level value.

### Note

When IDL computes default contour levels, the highest contour level may be above the maximum value of the data.

## Syntax

ICONTOUR[, Z[, X, Y]]

**iTool Common Keywords:** [, BACKGROUND\_COLOR=*value*]

[, DIMENSIONS=[*x, y*] [, /DISABLE\_SPLASH\_SCREEN]

[, IDENTIFIER=*variable*] [, LOCATION=[*x, y*]

 [, [XYZ]TITLE=*string*]

## Arguments

### X

A vector or two-dimensional array specifying the  $x$ -coordinates for the contour surface. If  $X$  is a vector, each element of  $X$  specifies the  $x$ -coordinate for a column of  $Z$  (e.g.,  $X[0]$  specifies the  $x$ -coordinate for  $Z[0, *]$ ). If  $X$  is a two-dimensional array, each element of  $X$  specifies the  $x$ -coordinate of the corresponding point in  $Z$  (i.e.,  $X_{ij}$  specifies the  $x$ -coordinate for  $Z_{ij}$ ).

### Y

A vector or two-dimensional array specifying the  $y$ -coordinates for the contour surface. If  $Y$  is a vector, each element of  $Y$  specifies the  $y$ -coordinate for a row of  $Z$  (e.g.,  $Y[0]$  specifies the  $y$ -coordinate for  $Z[* , 0]$ ). If  $Y$  is a two-dimensional array, each element of  $Y$  specifies the  $y$ -coordinate of the corresponding point in  $Z$  ( $Y_{ij}$  specifies the  $y$ -coordinate for  $Z_{ij}$ ).

### Z

A vector or two-dimensional array containing the values to be contoured. If the  $X$  and  $Y$  arguments are provided, the contour is plotted as a function of the  $(x, y)$  locations specified by their contents. Otherwise, the contour is generated as a function of the two-dimensional array index of each element of  $Z$ .

## Keywords

### Note

Keywords to the ICONTOUR routine that correspond to the names of *registered properties* of the iContour tool must be specified in full, without abbreviation.

### AM\_PM

Set this keyword to a vector of 2 strings indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL\_FORMAT keyword. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual for more information on format codes.

### ANISOTROPY

Set this keyword equal to a three-element vector  $[x, y, z]$  that represents the multipliers to be applied to the internally computed correction factors along each axis that account for anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range  $[x_{min}, y_{min}, z_{min}]$  to  $[x_{max}, y_{max}, z_{max}]$ , then the default correction factors are computed as follows:

```
dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
  xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
  ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
  zcorrection = maxRange / dz
```

This internally computed correction is then multiplied by the corresponding  $[x, y, z]$  values of the ANISOTROPY keyword. The default value for this keyword is  $[1,1,1]$ . IDL converts, maintains, and returns this data as double-precision floating-point.

## BACKGROUND\_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND\_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW\_NUMBER or VIEW\_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW\_GRID keyword, and the VIEW\_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND\_COLOR keyword would set the background color in the second view only.

## C\_COLOR

Set this keyword to a 3 by  $N$  array of RGB colors representing the colors to be applied at each contour level. If there are more contour levels than elements in this vector, the colors will be cyclically repeated. If C\_COLOR is set to 0, all contour levels will be drawn in the color specified by the COLOR keyword (this is the default).

However, the C\_COLOR keyword does not activate the palette color mode, which is recommended when working with contour levels and color. This mode can be activated with the RGB\_INDICES and RGB\_TABLE keywords. See [“Using Palettes”](#) on page 973 for more details.

## C\_FILL\_PATTERN

Set this keyword to an array of IDLgrPattern objects representing the patterns to be applied at each contour level if the FILL keyword is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this keyword is set to 0, all contour levels are filled with a solid color (this is the default).

## C\_LABEL\_INTERVAL

Set this keyword to a vector of values indicating the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C\_LABEL\_INTERVAL values will be repeated cyclically. The default is 0.4.

## C\_LABEL\_NOGAPS

Set this keyword to a vector of values indicating whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will

be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the `C_LABEL_NOGAPS` values will be repeated cyclically. By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

## **C\_LABEL\_OBJECTS**

Set this keyword to an array of object references to provide examples of labels to be drawn for each contour level. The objects specified via this keyword must inherit from one of the following classes:

- `IDLgrSymbol`
- `IDLgrText`

If a single object is provided, and it is an `IDLgrText` object, each of its strings will correspond to a contour level. If a vector of objects is used, any `IDLgrText` objects should have only a single string; each object will correspond to a contour level.

By default, with `C_LABEL_OBJECTS` set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values.

---

### **Note**

The objects specified via this keyword are used as descriptors only. The actual objects drawn as labels are generated by IDL.

---

The contour labels will have the same color as their contour level (see `C_COLOR`) unless the `C_USE_LABEL_COLOR` keyword is specified. The orientation of the label will be automatically computed unless the `C_USE_LABEL_ORIENTATION` keyword is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the `USE_TEXT_ALIGNMENTS` keyword is specified.

---

### **Note**

The object(s) set via this keyword will not be destroyed automatically when the contour is destroyed.

---

## **C\_LABEL\_SHOW**

Set this keyword to a vector of integers. For each contour value, if the corresponding value in the `C_LABEL_SHOW` vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements

in this vector, the `C_LABEL_SHOW` values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

## C\_LINestyle

Set this keyword to an array of linestyles representing the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this keyword is set to 0, all levels are drawn as solid lines (this is the default).

To use a pre-defined line style, set the `C_LINestyle` property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq \textit{repeat} \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

## C\_THICK

Set this keyword to an array of line thicknesses representing the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0 points. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this keyword is set to 0, all contour levels are drawn with a line thickness of 1.0 points (this is the default).

## **C\_USE\_LABEL\_COLOR**

Set this keyword to a vector of values (0 or 1) to indicate whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C\_USE\_LABEL\_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C\_COLOR property for the contour object will be used instead.

## **C\_USE\_LABEL\_ORIENTATION**

Set this keyword to a vector of values (0 or 1) to indicate whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (unrotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C\_USE\_LABEL\_ORIENTATION values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

## **C\_VALUE**

Set this keyword to a scalar value or a vector of values for which contour values are to be drawn. If this keyword is set to 0, contour levels will be evenly sampled across the range of the Z argument, using the value of the N\_LEVELS keyword to determine the number of samples. IDL converts, maintains, and returns this data as double-precision floating-point.

## **CLIP\_PLANES**

Set this keyword to an array of dimensions  $[4, N]$  specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

**COLOR**

Set this keyword to the color to be used to draw the contours. This color is specified as an RGB vector. The default is [0, 0, 0]. This value will be ignored if the C\_COLOR keyword is set to a vector.

**DAYS\_OF\_WEEK**

Set this keyword to a vector of 7 strings to indicate the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdWA format codes) with the LABEL\_FORMAT keyword. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual for more information on format codes.

**DEPTH\_OFFSET**

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer. The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH\_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

**Note**

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH\_OFFSET values. It is safest to use only a DEPTH\_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH\_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH\_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH\_OFFSET.

**Note**

DEPTH\_OFFSET has no effect unless the FILL keyword is also set.

**DIMENSIONS**

Set this keyword to a two-element vector of the form [width, height] to specify the dimensions of the drawing area of the specific tool in units specified by the UNITS keyword. If no value is provided, a default value of one half the screen size is used. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

**DISABLE\_SPLASH\_SCREEN**

Set this keyword to disable the iTools splash screen. By default, the first time an iTool is run, the splash screen is displayed.

**DOWNHILL**

Set this keyword to indicate that downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

**FILL**

Set this keyword to indicate that the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contours may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

**GRID\_UNITS**

Set this keyword to an integer specifying the units for the contour grid. This keyword applies only when there is a map projection inserted. It has the following values:

- 0 — None. The contour grid is in arbitrary units that are not tied to a map projection. The contour will not be warped to the current map projection.
- 1 — Meters. The contour grid is in meters, and is tied to a particular map projection. The contour will be automatically warped to the current map projection. You are responsible for choosing the dataspace map projection that matches the contour's map projection.
- 2 — Degrees. The contour grid is in degrees longitude/latitude, and will be automatically warped to the current map projection.

## HIDE

Set this keyword to a boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

## IDENTIFIER

Set this keyword to a named variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## LABEL\_FONT

Set this keyword to an instance of an `IDLgrFont` object to describe the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if `C_LABEL_SHOW` is set but the corresponding `C_LABEL_OBJECTS` text object is not provided), or for any text label objects provided via `C_LABEL_OBJECTS` that do not already have the font property set. The default value for this keyword is a `NULL` object reference, indicating that 12 pt. Helvetica will be used.

## LABEL\_FORMAT

Set this keyword to a string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: *Axis*, *Index*, and *Value* and an optional `DATA` keyword, where:

- *Axis* is simply the value 2 to indicate that values along the Z axis are being formatted, which allows a single callback routine to be used for both axis labeling and contour labeling.
- *Index* is the contour level index (indices start at 0).
- *Value* is the data value of the current contour level.
- `DATA` is the optional keyword allowing any user-defined value specified through the `LABEL_FRMTDATA` keyword to `ICONTOUR`.

## LABEL\_FRMTDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied formatting function specified via the LABEL\_FORMAT keyword, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

## LABEL\_UNITS

Set this keyword to a string indicating the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

---

### Note

The singular form of each of the time unit strings is also acceptable (for example, LEVEL\_UNITS='Day' is equivalent to LEVEL\_UNITS='Days').

---

## LOCATION

Set this keyword to a two-element vector of the form  $[x, y]$  to specify the location of the upper left-hand corner of the tool relative to the display screen, in units specified by the UNITS keyword.

**Note**

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2487 for additional information.

**MACRO\_NAMES**

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

**MAX\_VALUE**

Set this keyword to the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

**MONTHS**

Set this keyword to a vector of 12 strings indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C\_LABEL\_FORMAT keyword. See [“Format Codes”](#) in Chapter 18 of the *Building IDL Applications* manual for more information on format codes.

**MIN\_VALUE**

Set this keyword to the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

**N\_LEVELS**

Set this keyword to the number of contour levels to generate. This keyword is ignored if the C\_VALUE keyword is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this keyword to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

## NAME

Set this keyword to a string that specifies the name of this visualization.

## NO\_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

## OVERPLOT

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

## PLANAR

Set this keyword to indicate that the contoured data is to be projected onto a plane. Unlike the underlying IDLgrContour object, the default for ICONTOUR is planar (PLANAR = 1), which displays the contoured data in a plane. See the ZVALUE keyword to specify the Z value at which to display the planar Contour plot if it is displayed in a three dimensional data space.

## RGB\_INDICES

Set this keyword to a vector of indices into the color table to select colors to use for contour level colors. Setting the RGB\_INDICES keyword activates the palette color mode, which allows colors from a specified color table to be used for the contour levels. The values set for RGB\_INDICES are indices into the RGB\_TABLE array of colors. If the number of colors selected using RGB\_INDICES is less than the number of contour levels, the colors are repeated cyclically. If indices are not specified with the RGB\_INDICES keyword, a default vector is constructed based on the values of the contour levels within the contour data range scaled to the byte range of RGB\_TABLE.

See “Using Palettes” on page 973 for more details on the palette color mode.

## RGB\_TABLE

Set this keyword to either a 3 by 256 or 256 by 3 array containing color values to use for contour level colors. Setting the RGB\_TABLE keyword activates the palette color mode, which allows colors from a specified color table to be used for the contour levels. The colors for each level are selected from RGB\_TABLE using the

RGB\_INDICES vector. If indices are not specified with the RGB\_INDICES keyword then a default vector is constructed based on the values of the contour levels within the contour data range scaled to the byte range of RGB\_TABLE.

If the visualization is in palette color mode, but colors have not been specified with the RGB\_TABLE keyword, the contour plot uses a default grayscale ramp.

See “Using Palettes” on page 973 for more details on the palette color mode.

## SHADE\_RANGE

Set this keyword to a two-element array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

## SHADING

Set this keyword to an integer representing the type of shading to use:

- 0 = Flat (default): The color has a constant intensity for each face of the contour, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits.

The style is applied using the following rules:

- If the tool exists and /OVERPLOT is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either VIEW\_NEXT or VIEW\_NUMBER is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

## TICKINTERVAL

Set this keyword equal to a number indicating the distance between downhill tickmarks, in data units. If `TICKINTERVAL` is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

## TICKLEN

Set this keyword equal to a number indicating the length of the downhill tickmarks, in data units. If `TICKLEN` is not set, or if you explicitly set it to zero, IDL will compute the length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

## TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

## USE\_TEXT\_ALIGNMENTS

Set this keyword to indicate that, for any `IDLgrText` labels (as specified via the `C_LABEL_OBJECTS` keyword), the `ALIGNMENT` and `VERTICAL_ALIGNMENT` property values for the given `IDLgrText` object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the `ALIGNMENT` and `VERTICAL_ALIGNMENT` properties of the label `IDLgrText` object(s) will be set to default values (0.5 for each, indicating centered labels).

## VIEW\_GRID

Set this keyword to a two-element vector of the form `[columns, rows]` to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified then `VIEW_GRID` is ignored).

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then `/VIEW_NEXT` will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

**Note**

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

**VIEW\_NUMBER**

Set this keyword to change the currently-selected view to the view specified by the VIEW\_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

**Note**

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

**VIEW\_TITLE**

Set this keyword equal to a scalar string that will be placed in a text annotation centered horizontally in the current view, near the top. The text will be created with the properties (size, style, color, etc.) defined for text annotations in the current tool style.

**[XYZ]GRIDSTYLE**

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINSTYLE for a list of linestyles.

**[XYZ]MAJOR**

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely. ZMAJOR is ignored unless PLANAR is set to 0.

**[XYZ]MINOR**

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely. ZMINOR is ignored unless PLANAR is set to 0.

## [XYZ]RANGE

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. ZRANGE is ignored unless PLANAR is set to 0.

## [XYZ]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark. ZSUBTICKLEN is ignored unless PLANAR is set to 0.

## [XYZ]TEXT\_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black). ZTEXT\_COLOR is ignored unless PLANAR is set to 0.

## [XYZ]TICKFONT\_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

ZTICKFONT\_INDEX is ignored unless PLANAR is set to 0.

## [XYZ]TICKFONT\_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points. ZTICKFONT\_SIZE is ignored unless PLANAR is set to 0.

## [XYZ]TICKFONT\_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal

- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

ZTICKFONT\_STYLE is ignored unless PLANAR is set to 0.

## [XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

### If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

### If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

---

### Note

For more information, see “[[XYZ](#)]TICKFORMAT” on page 4790.

---

Used with the LABEL\_DATE function, this property can easily create axes with date/time labels.

ZTICKFORMAT is ignored unless PLANAR is set to 0.

## [XYZ]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

ZTICKINTERVAL is ignored unless PLANAR is set to 0.

## [XYZ]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

ZTICKLAYOUT is ignored unless PLANAR is set to 0.

### Note

---

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

## [XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2.

IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKLEN is ignored unless PLANAR is set to 0.

## [XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark. ZTICKNAME is ignored unless PLANAR is set to 0.

## [XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

ZTICKUNITS is ignored unless PLANAR is set to 0.

**Note**

---

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

---

**[XYZ]TICKVALUES**

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If **TICKVALUES** is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point. **ZTICKVALUES** is ignored unless **PLANAR** is set to 0.

**[XYZ]TITLE**

Set this keyword to a string representing the title of the specified axis. **ZTITLE** is ignored unless **PLANAR** is set to 0.

**ZVALUE**

For a planar contour plot, the height of the Z plane onto which the contour plot is projected. If the **ZVALUE** is zero, and **PLANAR** is true, then the contour visualization is considered to be 2D. If the **ZVALUE** is nonzero, then the contour visualization is considered to be 3D, and the dataspace associated with this contour will be automatically switched to 3D.

**Note**

---

This keyword will not have any visual effect unless **PLANAR** is true and the plot is in a 3D dataspace, for example by selecting the **Surface** operation to add a surface plot to the dataspace along with the contour plot.

---

**Examples**

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the **File** menu in the *iTool* window (as described in Examples 2 and 3). For detailed information on importing data via the *iTool* file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

**Example 1**

This example shows how to use the IDL Command Line to bring contour data into the *iContour* tool.

At the IDL Command Line, enter:

```
file = FILEPATH('convec.dat', SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [248, 248])
ICONTOUR, data
```

Double-click on a contour to display the contour properties. Change the **Number of levels** setting to 20, change **Use palette color** to **True**, and use the **Levels Color Table** setting to load the EOS B predefined color table through the **Load Predefined** button in the Palette Editor. Then, change the **Fill contours** setting to **True**.

The following figure displays the output of this example:

Figure 3-48: Earth Mantle Convection *iContour* Example

## Example 2

This example shows how to use the *iTool* **File** → **Open** command to load DICOM data into the *iContour* tool.

At the IDL Command Line, enter:

```
ICONTOUR
```

Select **File** → **Open** to display the Open dialog, then browse to find `mr_brain.dcm` in the `examples/data` directory in the IDL distribution, and click **Open**.

Double-click on a contour to display the contour properties. Then, change **Use palette color** to **True** and the **Fill contours** setting to **True**.

Smooth the data by selecting **Operations** → **Filter** → **Smooth**.

The following figure displays the output of this example:

Figure 3-49: Smoothed Brain MRI iContour Example

### Example 3

This example shows how to use the **File** → **Import** command to load binary data into the iContour tool.

At the IDL Command Line, enter:

```
ICONTOUR
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `idemosurf.dat` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Contour** and click **Finish**.

The Binary Template wizard is displayed. In the Binary Template, change **File's byte ordering** to **Little Endian**. Then, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** `Float (32 bit)`

- **Number of Dimensions:** 2
- **1st Dimension Size:** 200
- **2nd Dimension Size:** 200

Click **OK** to close the New Field dialog and the Binary Template dialog, and the contours are displayed.

Double-click on a contour to display the contour properties. Change the **Number of levels** setting to 10, change **Use palette color** to `True`, and use the **Levels Color Table** setting to load the `Rainbow18` predefined color table through the **Load Predefined** button in the Palette Editor. Then, change the **Fill contours** setting to `True`.

Change the **Projection** setting from `Planar` to `Three-D`.

The following figure displays the output of this example:

Figure 3-50: Filled Three-Dimensional `iContour` Example

## Version History

6.0	Introduced
-----	------------

6.1	Added BACKGROUND_COLOR, GRID_UNITS, MACRO_NAMES, and STYLE_NAME keywords
6.2	Added DISABLE_SPLASH_SCREEN and VIEW_TITLE keywords

# IDENTITY

The `IDENTITY` function returns an identity array (an array with ones along the main diagonal and zeros elsewhere) of the specified dimensions.

This routine is written in the IDL language. Its source code can be found in the file `identity.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = IDENTITY( N [, /DOUBLE] )
```

## Return Value

Returns an  $n$  by  $n$  identity array.

## Arguments

### N

The desired column and row dimensions.

## Keywords

### DOUBLE

Set this keyword to return a double-precision identity array.

## Examples

```
; Define an array, A:
A = [[ 2.0,  1.0,  1.0, 1.5], $
      [ 4.0, -6.0,  0.0, 0.0], $
      [-2.0,  7.0,  2.0, 2.5], $
      [ 1.0,  0.5,  0.0, 5.0]]

; Compute the inverse of A using the INVERT function:
inverse = INVERT(A)

; Verify the accuracy of the computed inverse using the
; mathematical identity, A x A^-1 - I(4) = 0, where A^-1 is the
; inverse of A and I(4) is the 4 by 4 identity array:
PRINT, A ## inverse - IDENTITY(4)
```

## Version History

5.0	Introduced

# IDL\_Container Object Class

See “[IDL\\_Container](#)” in Chapter 9.

# IDL\_VALIDNAME

The IDL\_VALIDNAME function determines whether a string may be used as a valid IDL variable name or structure tag name. Optionally, the routine can convert non-valid characters into underscores, returning a valid name string.

## Syntax

*Result* = IDL\_VALIDNAME(*String* [, /CONVERT\_ALL] [, /CONVERT\_SPACES])

## Return Value

Returns the input string, optionally converting all spaces or non-alphanumeric characters to underscores. If the input string cannot be used as a valid variable or structure tag name, a null string is returned.

## Arguments

### String

A string representing the IDL variable or structure tag name to be checked.

## Keywords

### CONVERT\_ALL

If this keyword is set, then *String* is converted into a valid IDL variable name using the following rules:

- All non-alphanumeric characters (except ‘\_’, ‘!’ and ‘\$’) are converted to underscores
- If the first character of *String* is a number or a ‘\$’, then an underscore is prepended to the string
- If the first character of *String* is not a valid character (‘\_’, ‘!’, ‘A’...’Z’) then that character is converted to an underscore
- If *String* is an empty string or a reserved word (such as “AND”) then an underscore is prepended to the string

**Tip**

The `CONVERT_ALL` keyword guarantees that a valid variable name is returned. It is useful in converting user-supplied strings into valid IDL variable names.

**CONVERT\_SPACES**

If this keyword is set, then all spaces within *String* are converted to underscores. If *String* contains any other non-alphanumeric characters, then a null string is returned, indicating that the string cannot be used as a valid variable name.

**Note**

`CONVERT_SPACES` behaves the same as `CREATE_STRUCT` when checking structure tag names.

**Examples**

The following table provides `IDL_VALIDNAME` examples and their results.

Example	Result
<code>result = IDL_VALIDNAME('abc')</code>	'abc'
<code>result = IDL_VALIDNAME(' a b c ')</code>	''
<code>result = IDL_VALIDNAME(' a b c ', /CONVERT_SPACES)</code>	'_a_b_c_'
<code>result = IDL_VALIDNAME('\$var')</code>	''
<code>result = IDL_VALIDNAME('\$var', /CONVERT_ALL)</code>	'_\$VAR'
<code>result = IDL_VALIDNAME('and')</code>	''
<code>result = IDL_VALIDNAME('and', /CONVERT_ALL)</code>	'_AND'

# IDLITSYS\_CREATETOOL

The IDLITSYS\_CREATETOOL function creates an instance of the specified tool registered within the IDL Intelligent Tools system.

This routine is written in the IDL language. Its source code can be found in the file `idlitsys_createtool.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

```
Result = IDLITSYS_CREATETOOL(StrTool [, DIMENSIONS=[width,height]]
  [, /DISABLE_SPLASH_SCREEN] [, IDENTIFIER=variable]
  [, INITIAL_DATA=data] [, LOCATION=[x,y]]
  [, MACRO_NAMES=string or string array] [, /NO_SAVEPROMPT]
  [, OVERPLOT=iToolID] [, STYLE_NAME=string]
  [, USER_INTERFACE=string] [, VIEW_GRID=vector] [, /VIEW_NEXT]
  [, VIEW_NUMBER=number] [, VISUALIZATION_TYPE=vistype] )
```

## Return Value

Returns an `iToolID` that can be used to reference the created tool at a later time.

## Arguments

### StrTool

The name of a tool that has been registered with the `iTools` system via the `ITREGISTER` routine.

## Keywords

### Note

---

Additional keywords/properties associated with the target visualization at the command line are passed to the underlying system to be applied to the created tool and visualizations.

---

### DIMENSIONS

Set this keyword to a two-element vector of the form `[width, height]` to specify the dimensions of the drawing area of the specific tool in device units. The minimum

width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

## **DISABLE\_SPLASH\_SCREEN**

Set this keyword to disable the iTools splash screen. By default, the first time an iTool is run, the splash screen is displayed.

## **IDENTIFIER**

Set this keyword to a named IDL variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## **INITIAL\_DATA**

Set this keyword to the data objects that are used to create the initial visualizations in the created tool.

## **LOCATION**

Set this keyword to a two-element vector of the form  $[x, y]$  to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

### **Note**

---

Some X Window managers explicitly ignore any request from the client for window placement. See “[Positioning Top-Level Bases](#)” on page 2487 for additional information.

---

## **MACRO\_NAMES**

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

## **NO\_SAVEPROMPT**

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

## OVERPLOT

Set this keyword to the `iToolID` of the tool in which the visualization is to be created. This `iToolID` can be obtained during the creation of a previous tool or from the `ITGETCURRENT` routine.

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits. The style is applied to all items within all views and the current tool style is updated with the new style.

## USER\_INTERFACE

Set this keyword equal to a string containing the name of a custom user interface that was previously registered using the `USER_INTERFACE` keyword to the `ITREGISTER` procedure. The following user interfaces are provided by default:

- `'Default'` — uses the standard iTools user interface.
- `'None'` — creates an iTool without a user interface and uses a graphics buffer object instead of a window. If you use this interface, by default `DISABLE_SPLASH_SCREEN` is set to `True`.

### Tip

This interface could be used for batch processing, where you can use a macro to automatically process the input data and output the results to a file. Note, however, that setting the user interface to `'None'` applies only to the newly created tool. If your macro operation starts a new tool or requires user input, those tools or dialogs will still appear.

Note also that you are responsible for closing any iTools created by your batch process. In a macro, consider using the **File** → **Exit** macro operation to close the tool after processing.

## VIEW\_GRID

Set this keyword to a two-element vector of the form `[columns, rows]` to specify the view layout within the new tool. This keyword is only used if a new tool is being created; it is ignored if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified.

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then /VIEW\_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

---

### Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

---

## VIEW\_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW\_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

---

### Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

---

## VISUALIZATION\_TYPE

Set this keyword to a string containing the name of a registered visualization type that should be used to visualize any data specified by the INITIAL\_DATA keyword. If this keyword is not specified, the iTool will select a visualization type based on the data type of the input data.

## Examples

See [Chapter 5, “Example: Simple iTool”](#) in the *iTool Developer’s Guide* manual.

## Version History

6.0	Introduced
Pre 6.1	Deprecated the PANEL_LOCATION keyword
6.1	Added MACRO_NAMES and STYLE_NAME keywords

---

6.2	Added DISABLE_SPLASH_SCREEN, USER_INTERFACE keywords
-----	--

---

For information on deprecated keywords, see [Appendix J, “Obsolete Features”](#).

[ITREGISTER](#), Chapter 5, “Creating an iTool Launch Routine” in the *iTool Developer’s Guide* manual

# IF...THEN...ELSE

The IF...THEN...ELSE statement conditionally executes a statement or block of statements.

---

**Note**

For information on using IF...THEN...ELSE and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

---

## Syntax

```
IF expression THEN statement [ ELSE statement ]
```

or

```
IF expression THEN BEGIN
```

```
  statements
```

```
ENDIF [ ELSE BEGIN
```

```
  statements
```

```
ENDELSE ]
```

## Examples

The following example illustrates the use of the IF statement using the ELSE clause. Notice that the IF statement is ended with ENDIF, and the ELSE statement is ended with ENDELSE. Also notice that the IF statement can be used with or without the BEGIN...END block:

```
A = 2
B = 4

IF (A EQ 2) AND (B EQ 3) THEN BEGIN
  PRINT, 'A = ', A
  PRINT, 'B = ', B
ENDIF ELSE BEGIN
  IF A NE 2 THEN PRINT, 'A <> 2' ELSE PRINT, 'B <> 3'
ENDELSE
```

IDL Prints:

```
B <> 3
```

## Version History

# IGAMMA

The IGAMMA function computes the incomplete gamma function.

$$P_x(a) \equiv \frac{\int_0^x e^{-t} t^{a-1} dt}{\int_0^{\infty} e^{-t} t^{a-1} dt}$$

IGAMMA uses either a power series representation or a continued fractions method. If  $Z$  is less than or equal to  $A+1$ , a power series representation is used. If  $Z$  is greater than  $A+1$ , a continued fractions method is used.

This routine is written in the IDL language. Its source code can be found in the file `igamma.pro` in the `lib` subdirectory of the IDL distribution.

This routine can also be used with the GAMMA function to calculate the following other variations of the incomplete gamma function.

- $\gamma_x(a) = P_x(a)\Gamma(a) = \int_0^x e^{-t} t^{a-1} dt$ , which can be calculated with IGAMMA and GAMMA:

```
igmaVariant1 = IGAMMA(A, Z) * GAMMA(A)
```

- $\Gamma_x(a) = \Gamma(a) - \gamma(a) = \int_x^{\infty} e^{-t} t^{a-1} dt$ , which can be calculated with IGAMMA and GAMMA:

```
igmaVariant2 = GAMMA(A) * (1 - IGAMMA(A, Z))
```

- $\gamma_x^*(a) = x^{-a} P_x(a) = (x^{-a} / (\Gamma(a))) \int_0^x e^{-t} t^{a-1} dt$ , which can be calculated with IGAMMA:

```
igmaVariant3 = x^(-A) * IGAMMA(A, Z)
```

## Syntax

```
Result = IGAMMA(A, Z [, /DOUBLE] [, EPS=value] [, ITER=variable]
           [, ITMAX=value] [, METHOD=variable] )
```

## Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $A$  and  $Z$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and

the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### A

A scalar or array that specifies the parametric exponent of the integrand. A may be complex.

### Z

A scalar or array that specifies the upper limit of integration. Z may be complex. If Z is not complex then the values must be greater than or equal to zero.

## Keywords

### DOUBLE

Set this keyword to return a double-precision result.

### EPS

Set this keyword to the desired relative accuracy, or tolerance. The default tolerance is  $3.0e-7$  for single precision, and  $3.0d-12$  for double precision.

### ITER

Set this keyword to a named variable that will contain the actual number of iterations performed.

### ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 100,000.

### METHOD

This keyword is obsolete. `METHOD` will still be accepted, but will always return 0.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

### Example 1

Compute the incomplete gamma function for the corresponding elements of `A` and `Z`.

```
; Define an array of parametric exponents:
A = [0.10, 0.50, 1.00, 1.10, 6.00, 26.00]

; Define the upper limits of integration:
Z = [0.0316228, 0.0707107, 5.00000, 1.04881, 2.44949, 25.4951]

; Compute the incomplete gamma functions:
result = IGAMMA(A, Z)

PRINT, result
```

IDL prints:

```
[0.742026, 0.293128, 0.993262, 0.607646, 0.0387318, 0.486387]
```

## Version History

4.0	Introduced
5.6	<code>A</code> and <code>Z</code> arguments accept complex input

# IIMAGE

The IIMAGE procedure creates an iTool and associated user interface (UI) configured to display and manipulate image data.

## Note

If no arguments are specified, the IIMAGE procedure creates an empty Image tool.

This routine is written in the IDL language. Its source code can be found in the file `iimage.pro` in the `lib/itools` subdirectory of the IDL distribution.

For more information on using the iImage tool, see “Working with Images” in the *iTool User’s Guide* manual.

## Syntax

IIMAGE[, Image[, X, Y]]

**iTool Common Keywords:** [, BACKGROUND\_COLOR=*value*]  
 [, DIMENSIONS=[*x, y*] [, /DISABLE\_SPLASH\_SCREEN]  
 [, IDENTIFIER=*variable*] [, LOCATION=[*x, y*]  
 [, MACRO\_NAMES=*string or string array*] [, NAME=*string*]  
 [, /NO\_SAVEPROMPT] [, OVERPLOT=*iToolID*] [, STYLE\_NAME=*string*]  
 [, TITLE=*string*] [, VIEW\_GRID=[*columns, rows*] [, /VIEW\_NEXT]  
 [, VIEW\_NUMBER=*integer*] [, VIEW\_TITLE=*string*]

**Image Keywords:** [, ALPHA\_CHANNEL=*array*] [, BLUE\_CHANNEL=*array*]  
 [, CHANNEL=*bitmask*] [, CLIP\_PLANES=*array*]  
 [, GREEN\_CHANNEL=*array*] [, GRID\_UNITS=*value*] [, /HIDE]  
 [, IMAGE\_DIMENSIONS=[*width, height*] [, IMAGE\_LOCATION=[*x, y*]  
 [, /INTERPOLATE] [, /ORDER] [, RED\_CHANNEL=*array*]  
 [, RGB\_TABLE=*array*] [, ZVALUE=*value*]

## Arguments

### Image

Either a vector, a two-dimensional, or a three-dimensional array representing the sample values to be displayed as an image.

If *Image* is a vector:

- The  $X$  and  $Y$  arguments must also be present and contain the same number of elements. In this case, a dialog will be presented that offers the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image).

If *Image* is a two-dimensional array:

- If either dimension is 3:

*Image* represents an array of  $x$ ,  $y$ , and  $z$  values (either  $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots, [x_n, y_n, z_n]]$  or  $[[x_0, x_1, \dots, x_n], [y_0, y_1, \dots, y_n], [z_0, z_1, \dots, z_n]]$  where  $n$  is the length of the other dimension). In this case, the  $X$  and  $Y$  arguments, if present, will be ignored. A dialog will be presented that allows the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image, using the  $z$  values as the image data values).

- If neither dimension is 3:

*Image* represents an array of sample values to be displayed as a color-indexed image. If  $X$  and  $Y$  are provided, the sample values are defined as a function of the corresponding  $(x, y)$  locations; otherwise, the sample values are implicitly treated as a function of the array indices of each element of *Image*.

If *Image* is a three-dimensional array:

- If one of the dimensions is 3:

*Image* is a  $3 \times n \times m$ ,  $n \times 3 \times m$ , or  $n \times m \times 3$  array representing the red, green, and blue channels of the image to be displayed.

- If one of the dimensions is 4:

*Image* is a  $4 \times n \times m$ ,  $n \times 4 \times m$ , or  $n \times m \times 4$  array representing the red, green, blue, and alpha channels of the image to be displayed.

## X

Either a vector or a two-dimensional array representing the  $x$ -coordinates of the image grid.

If the *Image* argument is a vector:

- $X$  must be a vector with the same number of elements as *Image*.

If the *Image* argument is a two-dimensional array (for which neither dimension is 3):

- If  $X$  is a vector:

Each element of  $X$  specifies the  $x$ -coordinates for a column of *Image* (e.g.,  $X[0]$  specifies the  $x$ -coordinate for  $Image[0, *]$ ).

- If  $X$  is a two-dimensional array:  
Each element of  $X$  specifies the  $x$ -coordinate of the corresponding point in  $Image$  ( $X_{ij}$  specifies the  $x$ -coordinate of  $Image_{ij}$ ).

## Y

Either a vector or a two-dimensional array representing the  $y$ -coordinates of the image grid.

If the  $Image$  argument is a vector:

- $Y$  must be a vector with the same number of elements.

If the  $Image$  argument is a two-dimensional array:

- If  $Y$  is a vector:  
Each element of  $Y$  specifies the  $y$ -coordinates for a column of  $Image$  (e.g.,  $Y[0]$  specifies the  $y$ -coordinate for  $Image[* , 0]$ ).
- If  $Y$  is a two-dimensional array:  
Each element of  $Y$  specifies the  $y$ -coordinate of the corresponding point in  $Image$  ( $Y_{ij}$  specifies the  $y$ -coordinate of  $Image_{ij}$ ).

## Keywords

### Note

---

Keywords to the IIMAGE routine that correspond to the names of *registered properties* of the iImage tool must be specified in full, without abbreviation.

---

## ALPHA\_CHANNEL

Set this keyword to a two-dimensional array representing the alpha channel pixel values for the image to be displayed. This keyword is ignored if the  $Image$  argument is present, and is intended to be used in conjunction with some combination of the RED\_CHANNEL, GREEN\_CHANNEL, and BLUE\_CHANNEL keywords.

## BACKGROUND\_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND\_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW\_NUMBER or VIEW\_NEXT keywords. The background color

is applied to the current view. For example, if multiple views have been created with the `VIEW_GRID` keyword, and the `VIEW_NUMBER` keyword is used to create a visualization in the second view, use of the `BACKGROUND_COLOR` keyword would set the background color in the second view only.

## BLUE\_CHANNEL

Set this keyword to a two-dimensional array representing the blue channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the `RED_CHANNEL`, `GREEN_CHANNEL`, and `ALPHA_CHANNEL` keywords.

## CHANNEL

Set this keyword to a hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, `'ff0000'X` represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value `'ffffff'X`.

## CLIP\_PLANES

Set this keyword to an array of dimensions  $[4, N]$  specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

---

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

---

## DIMENSIONS

Set this keyword to a two-element vector of the form  $[\text{width}, \text{height}]$  to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

## DISABLE\_SPLASH\_SCREEN

Set this keyword to disable the iTools splash screen. By default, the first time an iTool is run, the splash screen is displayed.

## GREEN\_CHANNEL

Set this keyword to a two-dimensional array representing the green channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the RED\_CHANNEL, BLUE\_CHANNEL, and ALPHA\_CHANNEL keywords.

## GRID\_UNITS

Set this keyword to an integer specifying the units for the image grid. This keyword applies only when there is a map projection inserted. It has the following values:

- 0 – None. The image grid is in arbitrary units that are not tied to a map projection. The image will not be warped to the current map projection.
- 1 – Meters. The image grid is in meters, and is tied to a particular map projection. The image will be warped to the current map projection.
- 2 – Degrees. The image grid is in degrees longitude/latitude, and will be automatically warped to the current map projection.

## HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

## IDENTIFIER

Set this keyword to a named IDL variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## IMAGE\_DIMENSIONS

Set this keyword to a 2-element vector, [*width*, *height*], to specify the image dimensions (in data units). By default, the dimensions match the pixel width of the image.

## IMAGE\_LOCATION

Set this keyword to a 2-element vector,  $[x, y]$ , to specify the image location (in data units). By default, the location is  $[0, 0]$ .

## INTERPOLATE

Set this keyword to one (1) to display the iImage tool using bilinear interpolation. The default is to use nearest neighbor interpolation.

## LOCATION

Set this keyword to a two-element vector of the form  $[x, y]$  to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

### Note

---

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2487 for additional information.

---

## MACRO\_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

## NAME

Set this keyword to a string to specify the name for this visualization. The name is used for tool-related display purposes only.

## NO\_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

## ORDER

Set this keyword to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

## OVERPLOT

Set this keyword to an `iToolID` to direct the graphical output of the particular tool to the tool specified by the provided `iToolID`.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

## RED\_CHANNEL

Set this keyword to a two-dimensional array representing the red channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the `GREEN_CHANNEL`, `BLUE_CHANNEL`, and `ALPHA_CHANNEL` keywords.

## RGB\_TABLE

Set this keyword to a 3 by 256 or 256 by 3 byte array of RGB color values. If no color tables are supplied, the tool will provide a default 256-entry linear grayscale ramp.

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits.

The style is applied using the following rules:

- If the tool exists and `/OVERPLOT` is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

## TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

## VIEW\_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified then `VIEW_GRID` is ignored).

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then `/VIEW_NEXT` will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

### Note

---

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

---

## VIEW\_NUMBER

Set this keyword to change the currently-selected view to the view specified by the `VIEW_NUMBER` before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

### Note

---

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

---

## VIEW\_TITLE

Set this keyword equal to a scalar string that will be placed in a text annotation centered horizontally in the current view, near the top. The text will be created with the properties (size, style, color, etc.) defined for text annotations in the current tool style.

## [XY]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when `[XY]TICKLEN` is set to 1.0). See `LINestyle` for a list of linestyles.

## **[XY]MAJOR**

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

## **[XY]MINOR**

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

## **[XY]RANGE**

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum.

## **[XY]SUBTICKLEN**

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

## **[XY]TEXT\_COLOR**

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

## **[XY]TICKFONT\_INDEX**

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

## **[XY]TICKFONT\_SIZE**

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

## [XY]TICKFONT\_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

## [XY]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

### If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

### If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

**Note**

---

For more information, see “[XYZ]TICKFORMAT” on page 4790.

---

Used with the LABEL\_DATE function, this property can easily create axes with date/time labels.

**[XY]TICKINTERVAL**

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

**[XY]TICKLAYOUT**

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

**Note**

---

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

**[XY]TICKLEN**

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

## [XY]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

## [XY]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- `Numeric`
- `Years`
- `Months`
- `Days`
- `Hours`
- `Minutes`
- `Seconds`
- `Time` - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- `""` - Use an empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the `Numeric` unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, `TICKUNITS = 'Day'` is equivalent to `TICKUNITS = 'Days'`).

---

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

---

## [XY]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

## [XY]TITLE

Set this keyword to a string representing the title of the specified axis.

## ZVALUE

Set this keyword to the height of the Z plane onto which the image will be projected. The default is zero. If the ZVALUE is zero then the image visualization is considered to be 2D. If the ZVALUE is nonzero, then the image visualization is considered to be 3D, and the dataspace associated with this image will be automatically switched to 3D.

## Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the **File** menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

### Example 1

This example shows how use the IDL Command Line to load data into the iImage tool.

At the IDL Command Line, enter:

```
file = FILEPATH('mineral.png', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_PNG(file)
IIMAGE, data, TITLE = 'Electron Image of Mineral Deposits'
```

Double-click the image to display image properties, and use the **Image Palette** setting to load the *Stern Special* predefined color table through the **Load Predefined** button in the Palette Editor.

Use the Text Annotation tool to insert a title at the top of the image. Select **Insert** → **Colorbars** to insert a color bar at the bottom of the image. Double-click on the colorbar to display its properties, and change the **Title** setting to *Stern Special*.

The following figure displays the output of this example:

Figure 3-51: Mineral image Example with Sterns Color Table

## Example 2

This example shows how to use the iTool **File** → **Open** command to load binary data into the iImage tool.

At the IDL Command Line, enter:

```
I IMAGE
```

Select **File** → **Open** to display the Open dialog, then browse to find `worldelv.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

In the Binary Template dialog, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** data (or a name of your choosing)
- **Type:** Byte (unsigned 8-bits)
- **Number of Dimensions:** 2
- **1st Dimension Size:** 360
- **2nd Dimension Size:** 360

Click **OK** to close the New Field dialog and the Binary Template dialog, and the image is displayed.

**Note**

For more information on using the Binary Template to import data, see “Using the [BINARY\\_TEMPLATE Interface](#)” on page 164.

Double-click the image to display image properties, and use the **Image Palette** setting to load the `STD_GAMMA-II` predefined color table through the **Load Predefined** button in the Palette Editor.

The following figure displays the output of this example:

*Figure 3-52: World Elevation ilmage Example*

**Example 3**

This example shows how to use the IDL Import Data Wizard to load image data into the `iImage` tool.

At the IDL Command Line, enter:

```
IIMAGE
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `n_vasinfecta.jpg` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Image** and click **Finish**.

Define the edges within the image by selecting **Operations** → **Filter** → **Sobel Filter**.

The following figure displays the output of this example:

*Figure 3-53: Sobel Filtered Neocosmospora Vasinfecta image Example*

## Version History

6.0	Introduced
6.1	Added BACKGROUND_COLOR, GRID_UNITS, MACRO_NAMES, and STYLE_NAME keywords
6.2	Added DISABLE_SPLASH_SCREEN and VIEW_TITLE keywords

# IMAGE\_CONT

The IMAGE\_CONT procedure overlays an image with a contour plot.

This routine is written in the IDL language. Its source code can be found in the file `image_cont.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
IMAGE_CONT, A [, /ASPECT] [, /INTERP] [, /WINDOW_SCALE]
```

## Arguments

### A

The two-dimensional array to display and overlay.

## Keywords

### ASPECT

Set this keyword to retain the image's aspect ratio. Square pixels are assumed. If WINDOW\_SCALE is set, the aspect ratio is automatically retained.

### INTERP

If this keyword is set, bilinear interpolation is used if the image is resized.

### WINDOW\_SCALE

Set this keyword to scale the window size to the image size. Otherwise, the image size is scaled to the window size. This keyword is ignored when outputting to devices with scalable pixels (e.g., PostScript).

## Examples

```
; Create an image to display:  
A = BYTSCL(DIST(356))  
  
; Display image and overplot contour lines:  
IMAGE_CONT, A, /WINDOW
```

# IMAGE\_STATISTICS

The IMAGE\_STATISTICS procedure computes sample statistics for a given array of values. An optional mask may be specified to restrict computations to a spatial subset of the input data.

## Syntax

```
IMAGE_STATISTICS, Data [, COUNT=variable] [, DATA_SUM=variable]
  [, /Labeled] [, LUT=array] [, MASK=array] [, MAXIMUM=variable]
  [, MEAN=variable] [, MINIMUM=variable] [, STDDEV=variable]
  [, SUM_OF_SQUARES=variable] [, VARIANCE=variable] [, /VECTOR]
  [, WEIGHT_SUM=variable] [, /WEIGHTED]
```

## Arguments

### Data

An  $N$ -dimensional input data array.

## Keywords

### COUNT

Set this keyword to a named variable to contain the number of samples that correspond to nonzero values within the mask.

### DATA\_SUM

Set this keyword to a named variable to contain the sum of the samples that lie within the mask.

### Labeled

When set, this keyword indicates values in the mask representing region labels, where each pixel of the mask is set to the index of the region in which that pixel belongs (see the LABEL\_REGION function in the *IDL Reference Guide*). If the Labeled keyword is set, each statistic's value is computed for each region index. Thus, a vector containing the results is provided for each statistic with one element per region. By default, this keyword is set to zero, indicating that all samples with a corresponding nonzero mask value are used to form a scalar result for each statistic.

**Note**

The Labeled keyword cannot be used with either the WEIGHT\_SUM or the WEIGHTED keywords.

**LUT**

Set this keyword to a one-dimensional array. For non-floating point input *Data*, the pixel values are looked up through this table before being used in any of the statistical computations. This allows an integer image array to be calibrated to any user specified intensity range for the sake of calculations. The length of this array must include the range of the input array. This keyword may not be set with floating point input data. When signed input data types are used, they are first cast to the corresponding IDL unsigned type before being used to access this array. For example, the integer value  $-1$  looks up the value 65535 in the LUT array.

**MASK**

An array of  $N$ , or  $N-1$  (when the VECTOR keyword is used) dimensions representing the mask array. If the Labeled keyword is set, MASK contains the region indices of each pixel; otherwise statistics are only computed for data values where the MASK array is non-zero.

**MAXIMUM**

Set this keyword to a named variable to contain the maximum value of the samples that lie within the mask.

**MEAN**

Set this keyword to a named variable to contain the mean of the samples that lie within the mask.

**MINIMUM**

Set this keyword to a named variable to contain the minimum value of the samples that lie within the mask.

**STDDEV**

Set this keyword to a named variable to contain the standard deviation of the samples that lie within the mask.

## SUM\_OF\_SQUARES

Set this keyword to a named variable to contain the sum of the squares of the samples that lie within the mask.

## VARIANCE

Set this keyword to a named variable to contain the variance of the samples that lie within the mask.

## VECTOR

Set this keyword to specify that the leading dimension of the input array is not to be considered spatial but consists of multiple data values at each pixel location. In this case, the leading dimension is treated as a vector of samples at the spatial location determined by the remainder of the array dimensions.

## WEIGHT\_SUM

Set the WEIGHT\_SUM keyword to a named variable to contain the sum of the weights in the mask.

---

**Note**

The WEIGHT\_SUM keyword cannot be used if the LABELED keyword is specified.

---

## WEIGHTED

If the WEIGHTED keyword is set, the values in the MASK array are used to weight individual pixels with respect to their count value. If a MASK array is not provided, all pixels are assigned a weight of 1.0.

---

**Note**

The WEIGHTED keyword cannot be used if the LABELED keyword is specified.

---

## Examples

See “[Calculating Image Statistics](#)” in Chapter 4 of the *Image Processing in IDL* manual.

## Version History

5.3	Introduced

# IMAGINARY

The IMAGINARY function returns the imaginary part of its complex-valued argument.

## Syntax

$$Result = \text{IMAGINARY}(Complex\_Expression)$$

## Return Value

If the complex-valued argument is double-precision, the result will be double-precision, otherwise the result will be single-precision floating-point.

## Arguments

### Complex\_Expression

The complex-valued expression for which the imaginary part is desired.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

```
; Create an array of complex values:
C = COMPLEX([1,2,3],[4,5,6])
```

```
; Print just the imaginary parts of each element in C:
PRINT, IMAGINARY(C)
```

IDL prints:

```
4.00000 5.00000 6.00000
```

# IMAP

The IMAP procedure creates an iTool and associated user interface (UI) configured to display and manipulate image and contour data that is georeferenced, as well as shapefile data that is interactively imported once an iMap tool is created.

## Note

---

If no arguments are specified, the IMAP procedure creates an empty iMap tool.

---

This procedure is written in the IDL language. Its source code can be found in the file `imap.pro` in the `lib/itools` subdirectory of the IDL distribution.

For more information on using the iMap tool, see [“Working with Maps”](#) in the *iTool User’s Guide* manual.

## Syntax

### Empty Map Projection

IMAP [, [MAP\\_PROJECTION=string](#)]

### Image Visualization

IMAP [, [Image\[, X, Y\]](#)] [, [GRID\\_UNITS=value](#)] [, [MAP\\_PROJECTION=string](#)]

### Contour Visualization

## Image Visualization Arguments

### Image

A vector, a two-dimensional array, or a three-dimensional array representing the sample values to be displayed as an image.

If *Image* is a vector:

- The *X* and *Y* arguments must also be present and contain the same number of elements. In this case, a dialog will be presented that offers the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image).

If *Image* is a two-dimensional array:

- If either dimension is 3:

*Image* represents an array of  $x$ ,  $y$ , and  $z$  values (either  $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots, [x_n, y_n, z_n]]$  or  $[[x_0, x_1, \dots, x_n], [y_0, y_1, \dots, y_n], [z_0, z_1, \dots, z_n]]$  where  $n$  is the length of the other dimension). In this case, the  $X$  and  $Y$  arguments, if present, will be ignored. A dialog will be presented that allows the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image, using the  $z$  values as the image data values).

- If neither dimension is 3:

*Image* represents an array of sample values to be displayed as a color-indexed image. If  $X$  and  $Y$  are provided, the sample values are defined as a function of the corresponding  $(x, y)$  locations; otherwise, the sample values are implicitly treated as a function of the array indices of each element of *Image*.

If *Image* is a three-dimensional array:

- If one of the dimensions is 3:

*Image* is a  $3 \times n \times m$ ,  $n \times 3 \times m$ , or  $n \times m \times 3$  array representing the red, green, and blue channels of the image to be displayed.

- If one of the dimensions is 4:

*Image* is a  $4 \times n \times m$ ,  $n \times 4 \times m$ , or  $n \times m \times 4$  array representing the red, green, blue, and alpha channels of the image to be displayed.

## X

Either a vector or a two-dimensional array representing the  $x$ -coordinates of the image grid.

If the *Image* argument is a vector:

- $X$  must be a vector with the same number of elements as *Image*.

If the *Image* argument is a two-dimensional array (for which neither dimension is 3):

- If  $X$  is a vector:

Each element of  $X$  specifies the  $x$ -coordinates for a column of *Image* (e.g.,  $X[0]$  specifies the  $x$ -coordinate for  $Image[0, *]$ ).

- If  $X$  is a two-dimensional array:

Each element of  $X$  specifies the  $x$ -coordinate of the corresponding point in *Image* ( $X_{ij}$  specifies the  $x$ -coordinate of  $Image_{ij}$ ).

## Y

Either a vector or a two-dimensional array representing the  $y$ -coordinates of the image grid.

If the *Image* argument is a vector:

- $Y$  must be a vector with the same number of elements.

If the *Image* argument is a two-dimensional array:

- If  $Y$  is a vector:

Each element of  $Y$  specifies the  $y$ -coordinates for a column of *Image* (e.g.,  $Y[0]$  specifies the  $y$ -coordinate for *Image*[\*, 0]).

- If  $Y$  is a two-dimensional array:

Each element of  $Y$  specifies the  $y$ -coordinate of the corresponding point in *Image* ( $Y_{ij}$  specifies the  $y$ -coordinate of *Image* <sub>$ij$</sub> ).

## Contour Visualization Arguments

### Z

A vector or two-dimensional array containing the values to be contoured. If the  $X$  and  $Y$  arguments are provided, the contour is plotted as a function of the  $(x, y)$  locations specified by their contents. Otherwise, the contour is generated as a function of the two-dimensional array index of each element of  $Z$ .

### X

A vector or two-dimensional array specifying the  $x$ -coordinates for the contour surface. If  $X$  is a vector, each element of  $X$  specifies the  $x$ -coordinate for a column of  $Z$  (e.g.,  $X[0]$  specifies the  $x$ -coordinate for  $Z[0, *]$ ). If  $X$  is a two-dimensional array, each element of  $X$  specifies the  $x$ -coordinate of the corresponding point in  $Z$  (i.e.,  $X_{ij}$  specifies the  $x$ -coordinate for  $Z_{ij}$ ).

### Y

A vector or two-dimensional array specifying the  $y$ -coordinates for the contour surface. If  $Y$  is a vector, each element of  $Y$  specifies the  $y$ -coordinate for a row of  $Z$  (e.g.,  $Y[0]$  specifies the  $y$ -coordinate for  $Z[* , 0]$ ). If  $Y$  is a two-dimensional array, each element of  $Y$  specifies the  $y$ -coordinate of the corresponding point in  $Z$  ( $Y_{ij}$  specifies the  $y$ -coordinate for  $Z_{ij}$ ).

## Keywords

### Note

Keywords to the IMAP routine that correspond to the names of *registered properties* of the iMap tool must be specified in full, without abbreviation.

## CONTOUR

Set this keyword to create a contour visualization from the supplied data. By default, the procedure creates an image visualization.

## MAP\_PROJECTION

Set this keyword to a string specifying the name of an IDL GCTP map projection to use for the initial projection. If this keyword is specified, the allowed map projection keywords are available. [Table 3-51](#) provides the projection names and the allowed keywords associated with them.

These properties are applied to the newly created dataspace, without affecting existing dataspace. If you create an image with IMAP and use this keyword to define a map projection, IDL uses these properties to set up the image's projection. For more information, see [“Registering an Image”](#) in Chapter 15 of the *iTool User's Guide* manual.

Projection Name	Allowed Keywords
UTM	CENTER_LATITUDE, ZONE
State Plane	ZONE
Albers Equal Area	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Lambert Conformal Conic	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING

Table 3-51: Map Projections and Their Allowed Keywords

Projection Name	Allowed Keywords
Mercator	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, CENTER_LONGITUDE, TRUE_SCALE_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Polar Stereographic	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Polyconic	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Equidistant Conic A	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PARALLEL, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Equidistant Conic B	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Transverse Mercator	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, MERCATOR_SCALE, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Stereographic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Lambert Azimuthal	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Azimuthal	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING

*Table 3-51: Map Projections and Their Allowed Keywords (Continued)*

<b>Projection Name</b>	<b>Allowed Keywords</b>
Gnomonic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Orthographic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Near Side Perspective	SPHERE_RADIUS, HEIGHT, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING

Wagner VII	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Oblated Equal Area	SPHERE_RADIUS, OEA_SHAPEM, OEA_SHAPEN, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING, OEA_ANGLE
Integerized Sinusoidal	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING, IS_ZONES, IS_JUSTIFY

*Table 3-51: Map Projections and Their Allowed Keywords (Continued)*

## **BACKGROUND\_COLOR**

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND\_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the

OVERPLOT, VIEW\_NUMBER, or VIEW\_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW\_GRID keyword, and the VIEW\_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND\_COLOR keyword would set the background color in the second view only.

## DIMENSIONS

Set this keyword to a two-element vector of the form [*width, height*] to specify the dimensions of the drawing area of the specific tool in units specified by the UNITS keyword. If no value is provided, a default value of one half the screen size is used. The minimum width of the window correlates to the width of the menu bar. The minimum window height is 100 pixels.

## DISABLE\_SPLASH\_SCREEN

Set this keyword to disable the iTools splash screen. By default, the first time an iTool is run, the splash screen is displayed.

## GRID\_UNITS

Set this keyword to an integer specifying the units for the image or contour grid. This keyword applies only when there is a map projection inserted. It has the following values:

- 0 — None. The image or contour grid is in arbitrary units that are not tied to a map projection. The image or contour will not be warped to the current map projection.
- 1 — Meters. The image or contour grid is in meters, and is tied to a particular map projection. The image or contour will be automatically warped to the current map projection. You are responsible for choosing the dataspace map projection that matches the image or contour's map projection.
- 2 — Degrees. The image or contour grid is in degrees longitude/latitude, and will be automatically warped to the current map projection.

## IDENTIFIER

Set this keyword to a named variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## LOCATION

Set this keyword to a two-element vector of the form  $[x, y]$  to specify the location of the upper left corner of the tool relative to the display screen, in units specified by the UNITS keyword.

### Note

---

Some X Window managers explicitly ignore any request from the client for window placement. See “[Positioning Top-Level Bases](#)” on page 2487 for additional information.

---

## MACRO\_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

## NAME

Set this keyword to a string that specifies the name of this visualization.

## NO\_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

## OVERPLOT

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits.

The style is applied using the following rules:

- If the tool exists and OVERPLOT is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either VIEW\_NEXT or VIEW\_NUMBER is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

## TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

## VIEW\_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created. For example, if OVERPLOT, VIEW\_NEXT, or VIEW\_NUMBER are specified, then VIEW\_GRID is ignored.

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently selected view before issuing any graphical commands. If the currently selected view is the last one in the layout, then VIEW\_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

### Note

---

The contents of the newly-selected view will be emptied unless OVERPLOT is set.

---

## VIEW\_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW\_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

### Note

---

The contents of the newly-selected view will be emptied unless OVERPLOT is set.

---

## **VIEW\_TITLE**

Set this keyword equal to a scalar string that will be placed in a text annotation centered horizontally in the current view, near the top. The text will be created with the properties (size, style, color, etc.) defined for text annotations in the current tool style.

## **[XY]GRIDSTYLE**

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XY]TICKLEN is set to 1.0). See **LINestyle** for a list of linestyles.

## **[XY]MAJOR**

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting **MAJOR** equal to zero suppresses major tickmarks entirely.

## **[XY]MINOR**

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting **MINOR** equal to zero suppresses minor tickmarks entirely.

## **[XY]RANGE**

Set this keyword to the desired data range of the axis, a two-element vector. The first element is the axis minimum, and the second is the axis maximum.

## **[XY]SUBTICKLEN**

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

## **[XY]TEXT\_COLOR**

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

## **[XY]TICKFONT\_INDEX**

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica

- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

## [XY]TICKFONT\_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

## [XY]TICKFONT\_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

## [XY]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

### If TICKUNITS are not specified:

The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

**If TICKUNITS are specified:**

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

**Note**

---

For more information, see “[XYZ]TICKFORMAT” on page 4790.

---

Used with the LABEL\_DATE function, this property can easily create axes with date/time labels.

**[XY]TICKINTERVAL**

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XY]RANGE and the number of major tick marks ([XY]MAJOR). The value of this keyword takes precedence over the value set for the [XY]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'] and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

**[XY]TICKLAYOUT**

Set this keyword to an integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

**Note**

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

**[XY]TICKLEN**

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

**[XY]TICKNAME**

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

**[XY]TICKUNITS**

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- Numeric
- Years
- Months
- Days
- Hours
- Minutes
- Seconds
- Time — Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.

- Use the empty string ("") to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the Numeric unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values.

---

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

---

**Note**

Note that the singular form of each of the time value strings is also acceptable (e.g., TICKUNITS = "Day" is equivalent to TICKUNITS = "Days").

---

## [XY]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

## [XY]TITLE

Set this keyword to a string representing the title of the specified axis.

## Map Projection Keywords:

### CENTER\_LATITUDE

Set this keyword to the latitude of the point on the earth's surface to be mapped to the center of the projection plane. Latitude is measured in degrees north of the equator and must be in the range -90 to +90. The default value is zero.

### CENTER\_LONGITUDE

Set this keyword to the longitude of the point on the earth's surface to be mapped to the center of the map projection. Longitude is measured in degrees east of the Greenwich meridian and must be in the range -360 to +360. The default value is zero.

---

**Note**

For the Hotine Oblique Mercator projection, the center latitude should not be set to 0, +90, or -90.

---

## DATUM

Set this keyword to a scalar string containing the name of the datum to use for the ellipsoid. The default value depends on the projection selected, but is either the Clarke 1866 ellipsoid or a sphere with a radius of 6370.997 kilometers.

Table 3-52 shows the datums (or spheroids) available for use with the DATUM keyword.

Name	Semimajor Axis (m)	Semiminor Axis (m)
Clarke 1866 (NAD27)	6378206.4	6356583.8
Clarke 1880	6378249.145	6356514.86955
Bessel	6377397.155	6356078.96284
International 1967	6378157.5	6356772.2
International 1909	6378388.0	6356911.94613
WGS 72	6378135.0	6356750.519915
Everest	6377276.3452	6356075.4133
WGS 66	6378145.0	6356759.769356
GRS 1980/WGS 84 (NAD 83)	6378137.0	6356752.31414
Airy	6377563.396	6356256.91
Modified Everest	6377304.063	6356103.039
Modified Airy	6377340.189	6356034.448
Walbeck	6378137.0	6356752.314245
Southeast Asia	6378155.0	6356773.3205
Australian National	6378160.0	6356774.719
Krassovsky	6378245.0	6356863.0188
Hough	6378270.0	6356794.343479
Mercury 1960	6378166.0	6356784.283666

Table 3-52: Datums Available for Use with the DATUM Keyword

Name	Semimajor Axis (m)	Semiminor Axis (m)
Modified Mercury 1968	6378150.0	6356768.337303
Sphere	6370997.0	6370997.0

*Table 3-52: Datums Available for Use with the DATUM Keyword (Continued)*

---

### Note

For many projections, you can specify your own datum by using either the SEMIMAJOR\_AXIS and SEMIMINOR\_AXIS keywords or the SPHERE\_RADIUS keyword.

---

## FALSE\_EASTING

Set this keyword to the false easting value (in meters) to be added to each  $x$ -coordinate for the forward transform, or subtracted from each  $x$  coordinate for the inverse transform.

## FALSE\_NORTHING

Set this keyword to the false northing value (in meters) to be added to each  $y$ -coordinate for the forward transform, or subtracted from each  $y$ -coordinate for the inverse transform.

## HEIGHT

Set this keyword to the height (in meters) above the earth's surface for satellite projections.

## HOM\_AZIM\_LONGITUDE

Set this keyword to the longitude in degrees of the central meridian point where the azimuth occurs.

## HOM\_AZIM\_ANGLE

Set this keyword to the azimuth angle, measured in degrees, east of a north-south line that intersects the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

## HOM\_LATITUDE1

Set this keyword to the latitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

---

**Note**

HOM\_LATITUDE1 cannot be equal to HOM\_LATITUDE2.

---

## HOM\_LATITUDE2

Set this keyword to the latitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

---

**Note**

HOM\_LATITUDE1 cannot be equal to HOM\_LATITUDE2.

---

## HOM\_LONGITUDE1

Set this keyword to the longitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

## HOM\_LONGITUDE2

Set this keyword to the longitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

## IS\_ZONES

Set this keyword to the number of longitudinal zones to include in the projection.

## IS\_JUSTIFY

Set this keyword to indicate what to do with rows with an odd number of columns. The following values are allowed:

- 0 — Indicates the extra column is on the right of the projection y-axis
- 1 — Indicates the extra column is on the left of the projection y-axis
- 2 — Calculates an even number of columns

## LIMIT

Set this keyword to a four-element vector of the form [*latmin*, *lonmin*, *latmax*, *lonmax*] that specifies the boundaries of the region to be mapped. The points [*lonmin*, *latmin*] and [*lonmax*, *latmax*] are the longitudes and latitudes of two points diagonal from each other on the region's boundary.

## MERCATOR\_SCALE

Set this keyword to the scale factor at the central meridian (for the Transverse Mercator projection) or the center of the projection (for the Hotine Oblique Mercator projection). For the Transverse Mercator projection, the default scale is 0.9996.

## OEA\_ANGLE

Set this keyword to the Oblated Equal Area oval rotation angle in degrees.

## OEA\_SHAPEM

Set this keyword to the Oblated Equal Area shape parameter *m*. The value of OEA\_SHAPEM determines the horizontal flatness of the oblong region, and is usually set to a value between one and three.

### Note

---

Setting both OEA\_SHAPEM and OEA\_SHAPEN equal to 2 is equivalent to using the Lambert Azimuthal projection.

---

## OEA\_SHAPEN

Set this keyword to the Oblated Equal Area oval shape parameter *n*. The value of OEA\_SHAPEN determines the vertical flatness of the oblong region, and is usually set to a value between one and three.

### Note

---

Setting both OEA\_SHAPEM and OEA\_SHAPEN equal to 2 is equivalent to using the Lambert Azimuthal projection.

---

## SEMIMAJOR\_AXIS

Set this keyword to the length in meters of the semimajor axis of the reference ellipsoid. The default is the semimajor axis length of either the Clarke 1866 datum (6378206.4 meters) or the Sphere radius (6370997.0 meters), depending on the projection.

## **SEMIMINOR\_AXIS**

Set this keyword to the length in meters of the semiminor axis of the reference ellipsoid. The default is the semiminor axis length of either the Clarke 1866 datum (6356583.8 meters) or the Sphere radius (6370997.0 meters), depending on the projection.

## **SOM\_INCLINATION**

Set this keyword to the orbit inclination angle in degrees of the ascending node, counter-clockwise from the equator.

## **SOM\_LONGITUDE**

Set this keyword to the longitude in degrees of the ascending orbit at the equator.

## **SOM\_PERIOD**

Set this keyword to the period in minutes of the satellite revolution.

## **SOM\_RATIO**

Set this keyword to the Landsat ratio to compensate for confusion at the northern end of orbit. A typical value is 0.5201613.

## **SOM\_FLAG**

Set this keyword to the end-of-path flag for Landsat, where 0 is the start and 1 is the end.

## **SOM\_LANDSAT\_NUMBER**

Set this keyword to the Landsat satellite number.

## **SOM\_LANDSAT\_PATH**

Set this keyword to the Landsat path number. Use 1 for Landsat 1, 2, and 3; use 2 for Landsat 4, 5 and 6.

## **SPHERE\_RADIUS**

Set this keyword to the radius in meters of the reference sphere. The default value is 6370997.

## STANDARD\_PARALLEL

Set this keyword to the latitude in degrees of the standard parallel along which the scale is true.

## STANDARD\_PAR1

Set this keyword to the latitude in degrees of the first standard parallel along which the scale is true.

---

**Note**

For Albers Equal Area and Lambert Conformal Conic projections, STANDARD\_PAR1 and STANDARD\_PAR2 should not be set to values that are equal and opposite.

---

## STANDARD\_PAR2

Set this keyword to the latitude in degrees of the second standard parallel along which the scale is true.

---

**Note**

For Albers Equal Area and Lambert Conformal Conic projections, STANDARD\_PAR1 and STANDARD\_PAR2 should not be set to values that are equal and opposite.

---

## TRUE\_SCALE\_LATITUDE

Set this keyword to the latitude in degrees of true scale.

## ZONE

Set this keyword to an integer specifying the zone for the UTM projection or the State Plane projection.

---

**Note**

For the UTM projection, you can also use the CENTER\_LONGITUDE and CENTER\_LATITUDE keywords to set the zone. Internally, the ZONE value will be computed from the longitude and latitude.

---

**Note**

UTM zones in the southern hemisphere must be specified by negative numbers (e.g., -53).

---

**Note**

---

For UTM, the zone number should be in the range -60 to -1 (Southern Hemisphere) or 1 to 60 (Northern Hemisphere).

---

**IIMAGE Keywords Accepted**

See [IIMAGE](#) for the description of the following keywords:

[ALPHA\\_CHANNEL](#), [BLUE\\_CHANNEL](#), [CHANNEL](#), [CLIP\\_PLANES](#),  
[GREEN\\_CHANNEL](#), [GRID\\_UNITS](#), [HIDE](#), [IMAGE\\_DIMENSIONS](#),  
[IMAGE\\_LOCATION](#), [INTERPOLATE](#), [ORDER](#), [RED\\_CHANNEL](#), [RGB\\_TABLE](#),  
[ZVALUE](#)

**ICONTOUR Keywords Accepted**

See [ICONTOUR](#) for the description of the following keywords:

[AM\\_PM](#), [ANISOTROPY](#), [C\\_COLOR](#), [C\\_FILL\\_PATTERN](#),  
[C\\_LABEL\\_INTERVAL](#), [C\\_LABEL\\_NOGAPS](#), [C\\_LABEL\\_OBJECTS](#),  
[C\\_LABEL\\_SHOW](#), [C\\_LINestyle](#), [C\\_THICK](#), [C\\_USE\\_LABEL\\_COLOR](#),  
[C\\_USE\\_LABEL\\_ORIENTATION](#), [C\\_VALUE](#), [CLIP\\_PLANES](#), [COLOR](#),  
[DAYS\\_OF\\_WEEK](#), [DEPTH\\_OFFSET](#), [DOWNHILL](#), [FILL](#), [GRID\\_UNITS](#), [HIDE](#),  
[LABEL\\_FONT](#), [LABEL\\_FORMAT](#), [LABEL\\_FRMTDATA](#), [LABEL\\_UNITS](#),  
[MAX\\_VALUE](#), [MIN\\_VALUE](#), [MONTHS](#), [N\\_LEVELS](#), [PLANAR](#),  
[RGB\\_INDICES](#), [RGB\\_TABLE](#), [SHADE\\_RANGE](#), [SHADING](#), [TICKINTERVAL](#),  
[TICKLEN](#), [USE\\_TEXT\\_ALIGNMENTS](#), [ZVALUE](#)

**Examples**

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Examples 2 and 3) or data can be imported via the **File** menu in the iTool window. For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

**Example 1**

```
IMAP, MAP_PROJECTION='Lambert'
```

This command opens a new iMap tool with the Lambert Conformal Conic projection loaded (Figure 3-54).

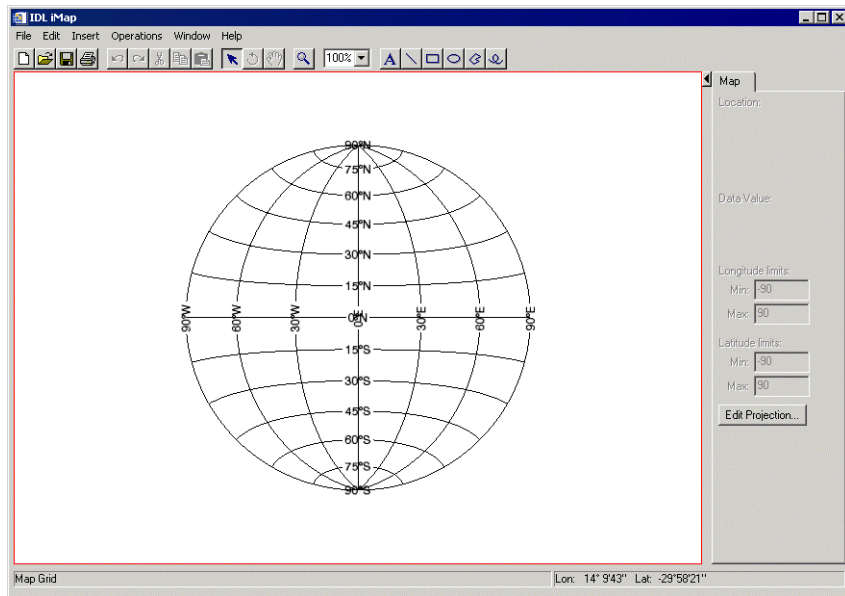

Figure 3-54: iMap Example — Empty Lambert Projection

## Example 2

```
file = FILEPATH('avhrr.png', SUBDIRECTORY=['examples','data'])
data = READ_PNG(file, r, g, b)
IMAP, data, LIMIT=[-90,-180,90,180], $
    MAP_PROJECTION='Mollweide', RGB_TABLE=[[r],[g],[b]], $
    IMAGE_TRANSPARENCY=50, GRID_UNITS=2, $
    IMAGE_LOCATION=[-180,-90], IMAGE_DIMENSIONS=[360,180]
```

This series of commands opens a new iMap tool and loads an image of the world, registered in degrees, into a Mollweide map projection (Figure 3-55).

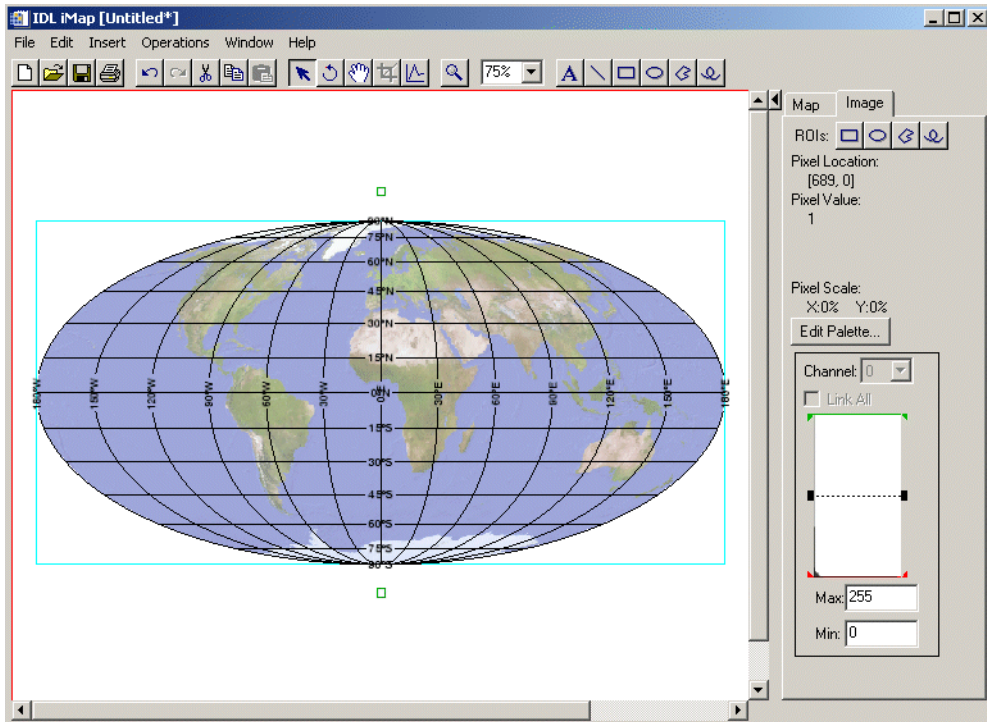

Figure 3-55: iMap Example — World Image with Mollweide Projection

### Example 3

This example builds on Example 2, adding contours to the world image in the Mollweide projection.

```
loadct, 39
tv!ct, r, g, b, /get

clons = FINDGEN(360) - 179.5
clats = FINDGEN(180) - 89.5
cdata = SIN(clons/30) # COS(clats/30)
IMAP, cdata, clons, clats, /CONTOUR, /OVERPLOT, $
    RGB_TABLE=[[r],[g],[b]], GRID_UNITS=2, $
    N_LEVELS=10, C_THICK=REPLICATE(2,10)
```

This series of commands plots the contour data atop Example 2's display (Figure 3-55).

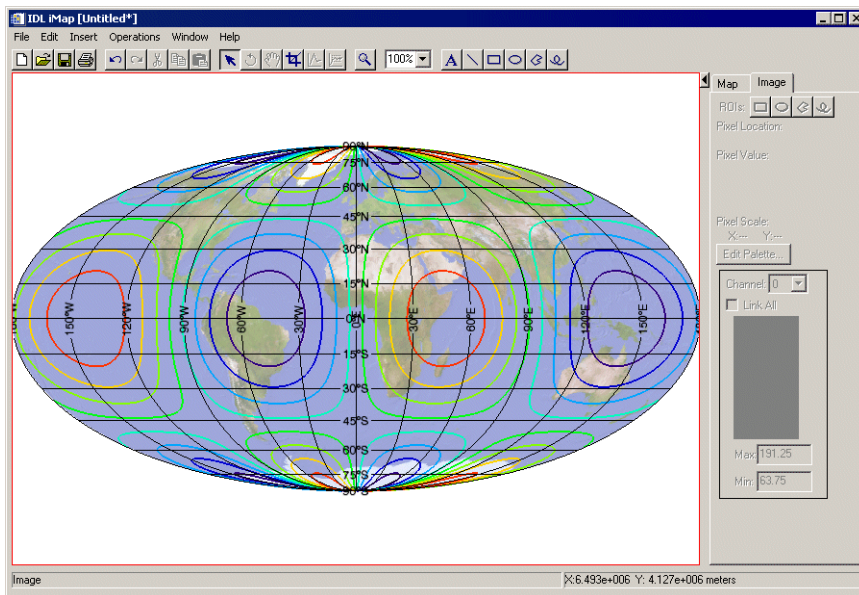

Figure 3-56: iMap Example — Overplotted Contour Data in Rainbow Colors

## Version History

6.1	Introduced
6.2	Added DISPLAY_SPLASH_SCREEN and VIEW_TITLE keywords

# INDGEN

The INDGEN function returns an integer array with the specified dimensions.

## Syntax

```
Result = INDGEN(D1 [, ..., D8] [, /BYTE | , /COMPLEX | , /DCOMPLEX | ,  
/ DOUBLE | , /FLOAT | , /L64 | , /LONG | , /STRING | , /UINT | , /UL64 | ,  
/ ULONG] [, TYPE=value] )
```

## Return Value

Each element of the returned integer array is set to the value of its one-dimensional subscript.

## Arguments

### *D*<sub>*i*</sub>

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### **BYTE**

Set this keyword to create a byte array.

### **COMPLEX**

Set this keyword to create a complex, single-precision, floating-point array.

### **DCOMPLEX**

Set this keyword to create a complex, double-precision, floating-point array.

## DOUBLE

Set this keyword to create a double-precision, floating-point array.

## FLOAT

Set this keyword to create a single-precision, floating-point array.

## L64

Set this keyword to create a 64-bit integer array.

## LONG

Set this keyword to create a longword integer array.

## STRING

Set this keyword to create a string array.

## TYPE

The type code to set the type of the result. See the description of the [SIZE](#) function for a list of IDL type codes.

## UINT

Set this keyword to create an unsigned integer array.

## UL64

Set this keyword to create an unsigned 64-bit integer array.

## ULONG

Set this keyword to create an unsigned longword integer array.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C](#), “[Thread Pool Keywords](#)” for details.

## Examples

Create *I*, a 5-element vector of integer values with each element set to the value of its subscript by entering:

```
I = INDGEN(5)
```

## INT\_2D

The INT\_2D function computes the double integral of a bivariate function using iterated Gaussian quadrature. The algorithm's transformation data is provided in tabulated form with 15 decimal accuracy.

This routine is written in the IDL language. Its source code can be found in the file `int_2d.pro` in the `lib` subdirectory of the IDL distribution.

### Syntax

```
Result = INT_2D( Fxy, AB_Limits, PQ_Limits, Pts [, /DOUBLE] [, /ORDER] )
```

### Return Value

Returns a double value containing the integral.

### Arguments

#### Fxy

A scalar string specifying the name of a user-supplied IDL function that defines the bivariate function to be integrated. For dy/dx integration (the default, or if the ORDER keyword is explicitly set to zero), the Fxy function must be able to accept a scalar value for X and a vector for Y, and must return a vector of the same length as Y. For dx/dy integration (if the ORDER keyword is set), the Fxy function must be able to accept a vector for X and a scalar value for Y, and must return a vector of the same length as X.

For example, if we wish to integrate the following function:

$$f(x, y) = e^{-x^2 - y^2}$$

We define a function FXY to express this relationship in the IDL language:

```
FUNCTION fxy, X, Y
  RETURN, EXP(-X^2. -Y^2.)
END
```

#### AB\_Limits

A two-element vector containing the lower (A) and upper (B) limits of integration with respect to the variable  $x$ .

## PQ\_Limits

A scalar string specifying the name of a user-supplied IDL function that defines the lower (P(x)) and upper (Q(x)) limits of integration with respect to the variable y. The function must accept x and return a two-element vector result.

For example, we might write the following IDL function to represent the limits of integration with respect to y:

```
FUNCTION PQ_limits, X
    RETURN, [-SQRT(16.0 - X^2), SQRT(16.0 - X^2)]
END
```

## Pts

The number of transformation points used in the computation. Possible values are: 6, 10, 20, 48, or 96.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ORDER

A scalar value of either 0 or 1. If set to 0, the integral is computed using a dy-dx order of integration. If set to 1, the integral is computed using a dx-dy order of integration.

## Examples

### Example 1

Compute the double integral of the bivariate function.

$$I = \int_{x=0.0}^{x=2.0} \int_{y=0.0}^{y=x^2} y \cdot \cos(x^5) dy dx$$

```
; Define the Fxy function.
FUNCTION Fxy, x, y
    RETURN, y*COS(x^5)
END
```

```

; Define the limits of integration for y as a function of x:
FUNCTION PQ_Limits, x
    RETURN, [0.0, x^2]
END

; Define limits of integration for x:
AB_Limits = [0.0, 2.0]

; Using the function and limits defined above, integrate with 48
; and 96 point formulas using a dy-dx order of integration and
; double-precision arithmetic:
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 48, /DOUBLE)
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 96, /DOUBLE)

```

INT\_2D with 48 transformation points yields: 0.055142668

INT\_2D with 96 transformation points yields: 0.055142668

## Example 2

Compute the double integral of the bivariate function:

$$I = \int_{x=0.0}^{x=2.0} \int_{y=0.0}^{y=x^2} y \cdot \cos(x^5) dx dy$$

```

; Define the Fxy function.
FUNCTION Fxy, x, y
    RETURN, y*COS(x^5)
END

; Define the limits of integration for y as a function of x:
FUNCTION PQ_Limits, y
    RETURN, [sqrt(y), 2.0]
END

; Define limits of integration for x:
AB_Limits = [0.0, 4.0]

; Using the function and limits defined above, integrate with 48
; and 96 point formulas using a dy-dx order of integration and
; double-precision arithmetic:
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 48, /DOUBLE, /ORDER)
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 96, /DOUBLE, /ORDER)

```

INT\_2D with 48 transformation points yields: 0.055142678

INT\_2D with 96 transformation points yields: 0.055142668

The exact solution (7 decimal accuracy) is: 0.055142668

## Version History

## INT\_3D

The INT\_3D function computes the integral of a trivariate function using iterated Gaussian quadrature. The algorithm's transformation data is provided in tabulated form with 15 decimal accuracy.

This routine is written in the IDL language. Its source code can be found in the file `int_3d.pro` in the `lib` subdirectory of the IDL distribution.

### Syntax

```
Result = INT_3D( Fxyz, AB_Limits, PQ_Limits, UV_Limits, Pts [, /DOUBLE] )
```

### Return Value

Returns the triple integral.

### Arguments

#### Fxyz

A scalar string specifying the name of a user-supplied IDL function that defines the trivariate function to be integrated. The function must accept X, Y, and Z, and return a scalar result.

For example, if we wish to integrate the following function:

$$f(x, y, z) = z \cdot (x^2 + y^2 + z^2)^{3/2}$$

We define a function FXY to express this relationship in the IDL language:

```
FUNCTION fxyz, X, Y, Z
  RETURN, z*(x^2+y^2+z^2)^1.5
END
```

#### AB\_Limits

A two-element vector containing the lower (A) and upper (B) limits of integration with respect to the variable  $x$ .

## PQ\_Limits

A scalar string specifying the name of a user-supplied IDL function that defines the lower (P(x)) and upper (Q(x)) limits of integration with respect to the variable y. The function must accept x and return a two-element vector result.

For example, we might write the following IDL function to represent the limits of integration with respect to y:

```
FUNCTION PQ_limits, X
    RETURN, [-SQRT(4.0 - X^2), SQRT(4.0 - X^2)]
END
```

## UV\_Limits

A scalar string specifying the name of a user-supplied IDL function that defines the lower (U(x,y)) and upper (V(x,y)) limits of integration with respect to the variable z. The function must accept x and y and return a two-element vector result.

For example, we might write the following IDL function to represent the limits of integration with respect to z:

```
FUNCTION UV_limits, X, Y
    RETURN, [0, SQRT(4.0 - X^2 - Y^2)]
END
```

## Pts

The number of transformation points used in the computation. Possible values are: 6, 10, 20, 48, or 96.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

Compute the triple integral of the trivariate function

$$I = \int_{x=-2}^{x=2} \int_{y=-\sqrt{4-x^2}}^{y=\sqrt{4-x^2}} \int_{z=0}^{z=\sqrt{4-x^2-y^2}} z \cdot (x^2 + y^2 + z^2)^{3/2} dz dy dx$$

Using the functions and limits defined above, integrate with 10, 20, 48, and 96 point formulas (using double-precision arithmetic):

```
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 10,$
/D)
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 20,$
/D)
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 48,$
/D)
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 96,$
/D)
```

INT\_3D with 10 transformation points yields: 57.444248

INT\_3D with 20 transformation points yields: 57.446201

INT\_3D with 48 transformation points yields: 57.446265

INT\_3D with 96 transformation points yields: 57.446266

The exact solution (6 decimal accuracy) is: 57.446267

# INT\_TABULATED

The INT\_TABULATED function integrates a tabulated set of data  $\{ X_i, F_i \}$  on the closed interval  $[\text{MIN}(X), \text{MAX}(X)]$ , using a five-point Newton-Cotes integration formula.

---

**Warning**

Data that is highly oscillatory requires a sufficient number of samples for an accurate integral approximation.

---

This routine is written in the IDL language. Its source code can be found in the file `int_tabulated.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = INT\_TABULATED( *X*, *F* [, /DOUBLE] [, /SORT] )

## Return Value

Returns the area under the curve represented by the function.

## Arguments

### X

The tabulated single- or double-precision floating-point *X*-value data. Data may be irregularly gridded and in random order. (If the data is randomly ordered, set the **SORT** keyword.)

---

**Warning**

Each *X* value must be unique; if duplicate *X* values are detected, the routine will exit and display a warning message.

---

---

**Note**

*X* is returned modified if **SORT** is set.

---

### F

The tabulated single- or double-precision floating-point *F*-value data. Upon input to the function,  $X_i$  and  $F_i$  must have corresponding indices for all values of  $i$ . If *X* is reordered, *F* is also reordered.

**Note**

---

$F$  is returned modified if **`SORT`** is set.

---

## Keywords

### **DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

### **SORT**

Set this keyword to sort the tabulated  $x$ -value data into ascending order. If **`SORT`** is set, both  $X$  and  $F$  values are returned sorted.

## Examples

Define 11  $x$ -values on the closed interval  $[0.0, 0.8]$ :

```
X = [0.0, .12, .22, .32, .36, .40, .44, .54, .64, .70, .80]
```

Define 11  $f$ -values corresponding to  $x_i$ :

```
F = [0.200000, 1.30973, 1.30524, 1.74339, 2.07490, 2.45600, $
     2.84299, 3.50730, 3.18194, 2.36302, 0.231964]
result = INT_TABULATED(X, F)
```

In this example, the  $f$ -values are generated from a known function

$$f = 0.2 + 25x - 200x^2 + 675x^3 - 900x^4 + 400x^5$$

which allows the determination of an exact solution. A comparison of methods yields the following results:

- The Multiple Application Trapezoid Method yields: 1.5648
- The Multiple Application Simpson's Method yields: 1.6036
- `INT_TABULATED` yields: 1.6271

The exact solution (4 decimal accuracy) is: 1.6405

# INTARR

The INTARR function returns an integer vector or array.

## Syntax

*Result* = INTARR(  $D_1$  [, ...,  $D_8$ ] [, /NOZERO] )

## Return Value

Returns the integer array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, INTARR sets every element of the result to zero. If NOZERO is nonzero, this zeroing is not performed and INTARR executes faster.

## Examples

Create I, a 3-element by 3-element integer array with each element set to 0 by entering:

```
I = INTARR(3, 3)
```

# INTERPOL

The INTERPOL function performs linear, quadratic, or spline, interpolation on vectors with a regular or irregular grid.

This routine is written in the IDL language. Its source code can be found in the file `interpol.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*For regular grids:* `Result = INTERPOL( V, N [, /LSQUADRATIC] [, /QUADRATIC] [, /SPLINE] )`

*For irregular grids:* `Result = INTERPOL( V, X, U [, /LSQUADRATIC] [, /QUADRATIC] [, /SPLINE] )`

## Return Value

The result is a single- or double-precision floating-point vector, or a complex vector if the input vector is complex.

## Arguments

### V

An input vector of any type except string.

### N

The number of points in the result when both input and output grids are regular. The abscissa values for the output grid will contain the same endpoints as the input.

### X

The abscissa values for *V*, in the irregularly-gridded case. *X* must have the same number of elements as *V*, and the values *must* be strictly ascending or descending.

### U

The abscissa values for the result. The result will have the same number of elements as *U*. *U* does not need to be monotonic.

## Keywords

### LSQUADRATIC

If set, interpolate using a least squares quadratic fit to the equation  $y = a + bx + cx^2$ , for each 4 point neighborhood  $(x[i-1], x[i], x[i+1], x[i+2])$  surrounding the interval of the interpolate,  $x[i] \leq u < x[i+1]$ .

### QUADRATIC

If set, interpolate by fitting a quadratic  $y = a + bx + cx^2$ , to the three point neighborhood  $(x[i-1], x[i], x[i+1])$  surrounding the interval  $x[i] \leq u < x[i+1]$ .

### SPLINE

If set, interpolate by fitting a cubic spline to the 4 point neighborhood  $(x[i-1], x[i], x[i+1], x[i+2])$  surrounding the interval,  $x[i] \leq u < x[i+1]$ .

#### Note

---

If LSQUADRATIC or QUADRATIC or SPLINE is not set, the default is to use linear interpolation.

---

## Examples

Create a floating-point vector of 61 elements in the range [-3, 3].

```
X = FINDGEN(61)/10 - 3

; Evaluate V[x] at each point:
V = SIN(X)

; Define X-values where interpolates are desired:
U = [-2.50, -2.25, -1.85, -1.55, -1.20, -0.85, -0.50, -0.10, $
     0.30, 0.40, 0.75, 0.85, 1.05, 1.45, 1.85, 2.00, 2.25, 2.75 ]

; Interpolate:
result = INTERPOL(V, X, U)

; Plot the function:
PLOT, X, V

; Plot the interpolated values:
OPLOT, U, result
```

[BILINEAR](#), [INTERPOLATE](#), [KRIG2D](#)

# INTERPOLATE

The INTERPOLATE function returns an array of linear, bilinear or trilinear interpolates, depending on the dimensions of the input array *P*.

Interpolates outside the bounds of *P* can be set to a user-specified value by using the MISSING keyword.

## Syntax

```
Result = INTERPOLATE( P, X [, Y [, Z]] [, CUBIC=value{-1 to 0}] [, /GRID]
[, MISSING=value ] )
```

## Return Value

Linear interpolates are returned in the one-dimensional case, bilinear in the two-dimensional case and trilinear interpolates in the three-dimensional case. The returned array has the same type as *P* and its dimensions depend on those of the location parameters *X*, *Y*, and *Z*, as explained below.

## Arguments

### P

The array of data values. *P* can be an array of any dimensions. Interpolation occurs in the *M* rightmost indices of *P*, where *M* is the number of interpolation arrays.

### X, Y, Z

Arrays of numeric type containing the locations for which interpolates are desired. For linear interpolation (*P* is a vector), the result has the same dimensions as *X*. The *i*-th element of the result is *P* interpolated at location  $X_i$ . The *Y* and *Z* parameters should be omitted.

For bilinear interpolation *Z* should not be present.

### Note

---

INTERPOLATE considers location points with values between zero and *n*, where *n* is the number of values in the input array *P*, to be valid. Location points outside this range are considered missing data. Location points  $x$  in the range  $n-1 \leq x < n$  return the last data value in the array *P*.

---

If the keyword GRID is not set, all location arrays must have the same number of elements. See the description of the GRID keyword below for more details on how interpolates are computed from  $P$  and these arrays.

## Keywords

### CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal,  $f$ , is a band-limited signal, with no frequency component larger than  $\omega_0$ , and  $f$  is sampled with spacing less than or equal to  $1/(2\omega_0)$ , then  $f$  can be reconstructed by convolving with a sinc function:  $\text{sinc}(x) = \sin(\pi x) / (\pi x)$ .

The number of neighboring points used varies according to the dimension:

- 1-dimensional: 4 points
- 2-dimensional: 16 points
- 3-dimensional: not supported

#### Note

---

Cubic convolution interpolation is significantly slower than bilinear interpolation. Also note that cubic interpolation is not supported for three-dimensional data.

---

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 "Image Reconstruction by Parametric Cubic Convolution", Computer Vision, Graphics & Image Processing 23, 256.

## GRID

The **GRID** keyword controls how the location arrays specify where interpolates are desired. This keyword has no effect in the case of linear interpolation.

**If **GRID** is not set:** The location arrays,  $X$ ,  $Y$ , and, if present,  $Z$  must have the same number of elements. The result has the same structure and number of elements as  $X$ .

In the case of bilinear interpolation, the result is obtained as follows: Let  $l = \lfloor X_i \rfloor$  and  $k = \lfloor Y_i \rfloor$ . Element  $i$  of the result is computed by interpolating between  $P(l, k)$ ,  $P(l+1, k)$ ,  $P(l, k+1)$ , and  $P(l+1, k+1)$  to obtain the estimated value at  $(X_i, Y_i)$ . Trilinear interpolation is a direct extension of the above.

**If **GRID** is set:** Let  $N_x$  be the number of elements in  $X$ , let  $N_y$  be the number of elements in  $Y$ , and  $N_z$  be the number of elements in  $Z$ . The result has dimensions  $(N_x, N_y)$  for bilinear interpolation, and  $(N_x, N_y, N_z)$  for trilinear interpolation. For bilinear interpolation, element  $(i, j)$  of the result contains the value of  $P$  interpolated at position  $(X_i, Y_j)$ . For trilinear interpolation, element  $(i, j, k)$  of the result is  $P$  interpolated at  $(X_i, Y_j, Z_k)$ .

## MISSING

The value to return for elements outside the bounds of  $P$ . If this keyword is not specified, interpolated positions that fall outside the bounds of the array  $P$ —that is, elements of the  $X$ ,  $Y$ , or  $Z$  arguments that are either less than zero or greater than the largest subscript in the corresponding dimension of  $P$ —are set equal to the value of the nearest element of  $P$ .

### Note

---

If **MISSING** value is set to a complex number, IDL uses only the real part.

---

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

The example below computes bilinear interpolates with the keyword GRID set:

```
p = FINDGEN(4,4)
PRINT, INTERPOLATE(p, [.5, 1.5, 2.5], [.5, 1.5, 2.5], /GRID)
```

and prints the 3 by 3 array:

```
2.50000  3.50000  4.50000
6.50000  7.50000  8.50000
10.5000  11.5000  12.5000
```

corresponding to the locations:

```
(.5,.5), (1.5, .5), (2.5, .5),
(.5,1.5), (1.5, 1.5), (2.5, 1.5),
(.5,2.5), (1.5, 2.5), (2.5, 2.5)
```

Another example computes interpolates, with GRID not set and a parameter outside the bounds of *P*:

```
PRINT, INTERPOLATE(p, [.5, 1.5, 2.5, 3.1], [.5, 1.5, 2.5, 2])
```

and prints the result:

```
2.50000  7.50000  12.5000  11.0000
```

corresponding to the locations (.5,.5), (1.5, 1.5), (2.5, 2.5) and (3.1, 2.0). Note that the last location is outside the bounds of *P* and is set from the value of the last column.

The following command uses the MISSING keyword to set such values to -1:

```
PRINT, INTERPOLATE(p, [.5, 1.5, 2.5, 3.1], [.5, 1.5, 2.5, 2], $
MISSING = -1)
```

and gives the result:

```
2.50000  7.50000  12.5000  -1.00000
```

# INTERVAL\_VOLUME

The `INTERVAL_VOLUME` procedure is used to generate a tetrahedral mesh from volumetric data. The generated mesh spans the portion of the volume where the volume data samples fall between two constant data values. This can also be thought of as a mesh constructed to fill the volume between two isosurfaces which are drawn according to the two supplied constant data values. The algorithm is very similar to the `ISOSURFACE` algorithm and expands upon the `SHADE_VOLUME` algorithm. A topologically-consistent tetrahedral mesh is returned by decomposing the volume into oriented tetrahedra. This also allows the algorithm to find the interval volume of any tetrahedral mesh.

If an auxiliary array is provided, its data is interpolated onto the output vertices and is returned. This auxiliary data array may have multiple values at each vertex. Any size-leading dimension is allowed as long as the number of values in the subsequent dimensions matches the number of elements in the input data array.

For more information on the `INTERVAL_VOLUME` algorithm, see the paper, "Interval Volume Tetrahedrization", Nielson and Sung, *Proceedings: IEEE Visualization*, 1997.

## Syntax

```
INTERVAL_VOLUME, Data, Value0, Value1, Outverts, Outconn
  [, AUXDATA_IN=array, AUXDATA_OUT=variable]
  [, GEOM_XYZ=array, TETRAHEDRA=array]
  [, PROGRESS_CALLBACK=string] [, PROGRESS_METHOD=string]
  [, PROGRESS_OBJECT=objref] [, PROGRESS_PERCENT=percent{0 to 100}]
  [, PROGRESS_USERDATA=value]
```

## Arguments

### Data

Input three-dimensional array of scalars that define the volume data.

### Value0

Input scalar iso-value. This value specifies one of the limits for the interval volume. The generated interval volume encloses all volume samples between and including *Value0* and *Value1*. *Value0* may be greater than or less than *Value1*, but the two values may not be exactly equal. This value also cannot be a NaN, but can be +/- INF.

## Value1

Input scalar iso-value. This value specifies the other limit for the interval volume. The generated interval volume encloses all volume samples between and including *Value0* and *Value1*. *Value1* may be greater than or less than *Value0*, but the two values may not be exactly equal. This value also cannot be a NaN, but can be +/- INF.

## Outverts

A named variable to contain an output [3, n] array of floating point vertices making up the tetrahedral mesh.

## Outconn

A named variable to contain an output array of tetrahedral mesh connectivity values. This array is one-dimensional and consists of a series of four vertex indices, where each group of four indices describes a tetrahedron. The connectivity values are indices into the vertex array returned in *Outverts*. If no tetrahedra are extracted, this argument returns the array [-1].

## Keywords

### AUXDATA\_IN

This keyword defines the input array of auxiliary data with trailing dimensions being the number of values in *Data*.

---

**Note**

If you specify the `AUXDATA_IN` then you must specify `AUXDATA_OUT`.

---

### AUXDATA\_OUT

Set this keyword to a named variable that will contain an output array of auxiliary data sampled at the locations in *Outverts*.

---

**Note**

If you specify `AUXDATA_OUT` then you must specify `AUXDATA_IN`.

---

### GEOM\_XYZ

This keyword defines a [3, n] input array of vertex coordinates (one for each value in the *Data* array). This array is used to define the spatial location of each scalar. If this

keyword is omitted, *Data* must be a three-dimensional array and the scalar locations are assumed to be on a uniform grid.

---

**Note**

If you specify GEOM\_XYZ then you must specify TETRAHEDRA.

---

## PROGRESS\_CALLBACK

Set this keyword to a scalar string containing the name of the IDL function that the INTERVAL\_VOLUME procedure calls at PROGRESS\_PERCENT intervals as it generates the interval volume.

The PROGRESS\_CALLBACK function returns a zero to signal INTERVAL\_VOLUME to stop generating the interval volume. This causes INTERVAL\_VOLUME to return a single vertex and a connectivity array of [-1], which specifies an empty mesh. If the callback function returns any non-zero value, INTERVAL\_VOLUME continues to generate the interval volume.

The PROGRESS\_CALLBACK function must specify a single argument, *Percent*, which INTERVAL\_VOLUME sets to an integer between 0 and 100, inclusive.

The PROGRESS\_CALLBACK function may specify an optional USERDATA keyword parameter, which INTERVAL\_VOLUME sets to the variable provided in the PROGRESS\_USERDATA keyword.

The following code shows an example of a progress callback function:

```
FUNCTION myProgressCallback, $
    percent, USERDATA = myStruct

oProgressBar = myStruct.oProgressBar

; This method updates the progress bar
; graphic and returns TRUE if the user
; has NOT pressed the cancel button.
keepGoing = oProgressBar->$
    UpdateProgressValue(percent)

RETURN, keepGoing

END
```

## PROGRESS\_METHOD

Set this keyword to a scalar string containing the name of a function method that the INTERVAL\_VOLUME procedure calls at PROGRESS\_PERCENT intervals as it generates the interval. If this keyword is set, then the PROGRESS\_OBJECT

keyword must be set to an object reference that is an instance of a class that defines the specified method.

The `PROGRESS_METHOD` function method callback has the same specification as the callback described in the `PROGRESS_CALLBACK` keyword, except that it is defined as an object class method:

```
FUNCTION myClass::myProgressCallback, $
    percent, USERDATA = myStruct
```

## PROGRESS\_OBJECT

Set this keyword to an object reference that is an instance of a class that defines the method specified with the `PROGRESS_METHOD` keyword. If this keyword is set, then the `PROGRESS_METHOD` keyword must also be set.

## PROGRESS\_PERCENT

Set this keyword to a scalar in the range [1, 100] to specify the interval between invocations of the callback function. The default value is 5 and IDL silently clamps other values to the range [1, 100].

For example, a value of 5 (the default) specifies `INTERVAL_VOLUME` will call the callback function when the interval volume process is 0% complete, 5% complete, 10% complete, ..., 95% complete, and 100% complete.

## PROGRESS\_USERDATA

Set this property to any IDL variable that `INTERVAL_VOLUME` passes to the callback function in the callback function's `USERDATA` keyword parameter. If this keyword is specified, then the callback function must be able to accept keyword parameters.

## TETRAHEDRA

This keyword defines an input array of tetrahedral connectivity values. If this array is not specified, the connectivity is assumed to be a rectilinear grid over the input three-dimensional array. If this keyword is specified, the input data array need not be a three-dimensional array. Each tetrahedron is represented by four values in the connectivity array. Every four values in the array correspond to the vertices of a single tetrahedron.

### Note

---

If you specify `TETRAHEDRA` then you must specify `GEOM_XYZ`.

---

## Examples

The following example generates an interval volume and displays the surface of the volume:

```
RESTORE, FILEPATH('clouds3d.dat', $
    SUBDIRECTORY=['examples','data'])
INTERVAL_VOLUME, rain, 0.1, 0.6, verts, conn
conn = TETRA_SURFACE(verts, conn)
oRain = OBJ_NEW('IDLgrPolygon', verts, POLYGONS=conn, $
    COLOR=[255,255,255], SHADING=1)
XOBJVIEW, oRain, BACKGROUND=[150,200,255]
```

# INVERT

The INVERT function uses the Gaussian elimination method to compute the inverse of a square array. Errors from singular or near-singular arrays are accumulated in the optional *Status* argument.

**Note**

---

If you are working with complex inputs, use the LA\_INVERT function instead.

---

## Syntax

*Result* = INVERT( *Array* [, *Status*] [, /DOUBLE] )

## Return Value

The result is a single- or double-precision array of floating or complex values.

## Arguments

### Array

The array to be inverted. *Array* must have two dimensions of equal size (i.e., a square array) and can be of any type except string. Note that the resulting array will be composed of single- or double-precision floating-point or complex values, depending on whether the DOUBLE keyword is set.

### Status

A named variable to receive the status of the operation. Possible status values are:

- 0 = Successful completion.
- 1 = Singular array (which indicates that the inversion is invalid).
- 2 = Warning that a small pivot element was used and that significant accuracy was probably lost.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```

; Create an array A:
A = [[ 5.0, -1.0, 3.0], $
      [ 2.0,  0.0, 1.0], $
      [ 3.0,  2.0, 1.0]]
result = INVERT(A)

```

```

; We can check the accuracy of the inversion by multiplying the
; inverted array by the original array. The result should be a 3 x
; 3 identity array.
PRINT, result # A

```

IDL prints:

```

1.00000      0.00000      0.00000
0.00000      1.00000      0.00000
0.00000  9.53674e-07      1.00000

```

# IOCTL

The IOCTL function provides a thin wrapper over the UNIX `ioctl(2)` system call. IOCTL performs special functions on the specified file. The set of functions actually available depends on your version of UNIX and the type of file (tty, tape, disk file, etc.) referred to.

To use IOCTL, read the C programmer's documentation describing the `ioctl(2)` function for the desired device and convert all constants and data to their IDL equivalents.

## Syntax

```
Result = IOCTL( File_Unit [, Request, Arg] [, /BY_VALUE] [, /MT_OFFLINE]
              [, /MT_REWIND] [, MT_SKIP_FILE=[-]number_of_files]
              [, MT_SKIP_RECORD=[-]number_of_records] [, /MT_WEOF]
              [, /SUPPRESS_ERROR] )
```

## Return Value

The value returned by the system `ioctl` function is returned as the value of the IDL IOCTL function.

## Arguments

### File\_Unit

The IDL logical unit number (LUN) for the open file on which the `ioctl` request is made.

### Request

A longword integer that specifies the `ioctl` request code. These codes are usually contained in C language header files provided by the operating system, and are not generally portable between UNIX versions. If one of the "MT" keywords is used, this argument can be omitted.

### Arg

A named variable through which data is passed to and from `ioctl`. IOCTL requests usually request data from the system or supply the system with information. The user must make *Arg* the correct type and size. Errors in typing or sizing *Arg* can corrupt

the IDL address space and/or make IDL crash. If one of the MT keywords is used, this argument can be omitted.

## Keywords

Note that the keywords below that start with “MT” can be used to issue commonly used magnetic tape `ioctl()` calls. When these keywords are used, the *Request* and *Arg* arguments are ignored and can be omitted. Magnetic tape operations not available via these keywords can still be executed by supplying the appropriate *Request* and *Arg* values. When issuing magnetic tape IOCTL calls, be aware that different devices have different rules for which `ioctl` calls are allowed, and when. The documentation for your computer system explains those rules.

### BY\_VALUE

If this keyword is set, *Arg* is converted to a scalar longword and this longword is passed by value. Normally, *Arg* is passed to `ioctl` by reference (i.e., by address).

### MT\_OFFLINE

Set this keyword to rewind and unload a tape.

### MT\_REWIND

Set this keyword to rewind a tape.

### MT\_SKIP\_FILE

Use this keyword to skip files on a tape. A positive value skips forward that number of files. A negative value skips backward.

### MT\_SKIP\_RECORD

Use this keyword to skip records on tape. A positive value skips forward that number of files. A negative value skips backward.

### MT\_WEOF

Set this keyword to write an EOF (“tape mark”) on the tape at the current location.

### SUPPRESS\_ERROR

Set this keyword to log errors quietly and cause a value of -1 to be returned. The default is for IDL to notice any failures associated with the use of `ioctl` and issue the appropriate IDL error and halt execution.

## Examples

The following example prints the size of the terminal being used by the current IDL session. It is known to work under SunOS 4.1.2. Changes may be necessary for other operating systems or even other versions of SunOS.

```
; Variable to receive result. This structure is described in
; Section 4 of the SunOS manual pages under termios(4):
winsize = {row:0u, col:0u, xpixel:0u, ypixel:0u}

; The request code for obtaining the tty size, as determined by
; reading the termios(4) documentation, and reading the system
; include files in the /usr/include/sys directory:
TIOCGWINSZ = 21608L

; Make the information request. -1 is the IDL logical file unit for
; the standard output:
ret = IOCTL(-1, TIOCGWINSZ, winsize)

; Output the results:
PRINT,winsize.row, winsize.col, $
  format='("TTY has ", I0," rows and ", I0," columns.")'
```

The following points should be noted in this example:

- Even though we only want the number of rows and columns, we must include all the fields required by the `TIOCGWINSZ ioctl` in the `winsize` variable (as documented in the `termio(4)` manual page). Not providing a large enough result buffer would cause IDL's memory to be corrupted.
- The value of `TIOCGWINSZ` was determined by examining the system header files provided in the `/usr/include/sys` directory. Such values are not always portable between major operating system releases.

# I PLOT

The IPLOT procedure creates an iTool and the associated user interface (UI) configured to display and manipulate plot data.

## Note

If no arguments are specified, the IPLOT procedure creates an empty Plot tool.

This routine is written in the IDL language. Its source code can be found in the file `iplot.pro` in the `lib/itools` subdirectory of the IDL distribution.

For more information on using the iPlot tool, see [“Working with Plots”](#) in the *iTool User’s Guide* manual.

## Syntax

### Cartesian

IPLOT, [X,] Y

or

IPLOT, X, Y, Z

### Polar

IPLOT[, R], *Theta*, /POLAR

**iTool Common Keywords:** [, `BACKGROUND_COLOR=`*value*] [, `DIMENSIONS=[`*x, y*`]` [, `/DISABLE_SPLASH_SCREEN`] [, `IDENTIFIER=`*variable*`]` [, `LOCATION=[`*x, y*`]` [, `MACRO_NAMES=`*string or string array*`]` [, `NAME=`*string*`]` [, `/NO_SAVEPROMPT`] [, `OVERPLOT=iToolID`] [, `STYLE_NAME=`*string*`]` [, `TITLE=`*string*`]` [, `VIEW_GRID=[`*columns, rows*`]` [, `/VIEW_NEXT`] [, `VIEW_NUMBER=`*integer*`]` [, `VIEW_TITLE=`*string*`]`

**Plot Keywords:** [, `CLIP_PLANES=`*array*`]` [, `COLOR =` *RGB vector*`]` [, `ERRORBAR_COLOR=`*vector*`]` [, `ERRORBAR_CAPSIZE=`*float* {0.0 to 1.0}] [, `/FILL_BACKGROUND`] [, `FILL_COLOR=`*vector*`]` [, `FILL_LEVEL=`*value*`]` [, `/HIDE`] [, `/HISTOGRAM`] [, `LINestyle=`*integer*`]` [, `MAX_VALUE=`*value*`]` [, `MIN_VALUE=`*value*`]` [, `NSUM=`*value*`]` [, `/POLAR`] [, `RGB_TABLE=`*byte array*`]` [, `/SCATTER`] [, `SYM_COLOR=`*RGB vector*`]` [, `SYM_INCREMENT=`*integer*`]` [, `SYM_INDEX=`*integer*`]` [, `SYM_SIZE=`*float* {0.0 to 1.0}] [, `SYM_THICK=`*float* {1.0 to 10.0}] [, `THICK=`*float* {1.0 to 10.0}] [, `TRANSPARENCY=`*float* {0.0 to 100.0}]

```
[, /USE_DEFAULT_COLOR] [, VERT_COLORS=byte vector]
[, /XY_SHADOW] [, /[XYZ]_ERRORBARS] [, /[XYZ]_LOG]
[, [XYZ]ERROR=vector or array] [, /XZ_SHADOW] [, /YZ_SHADOW]
```

**Axis Keywords:** [, [XYZ]GRIDSTYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}]  
 [, [XYZ]MAJOR=*integer*] [, [XYZ]MINOR=*integer*]  
 [, [XYZ]RANGE=[*min, max*]] [, [XYZ]SUBTICKLEN=*ratio*]  
 [, [XYZ]TEXT\_COLOR=*RGB vector*]  
 [, [XYZ]TICKFONT\_INDEX={0 | 1 | 2 | 3 | 4}]  
 [, [XYZ]TICKFONT\_SIZE=*integer*]  
 [, [XYZ]TICKFONT\_STYLE={0 | 1 | 2 | 3}]  
 [, [XYZ]TICKFORMAT=*string or string array*]  
 [, [XYZ]TICKINTERVAL=*value*] [, [XYZ]TICKLAYOUT={0 | 1 | 2}]  
 [, [XYZ]TICKLEN=*value*] [, [XYZ]TICKNAME=*string array*]  
 [, [XYZ]TICKUNITS=*string*] [, [XYZ]TICKVALUES=*vector*]  
 [, [XYZ]TITLE=*string*]

## Arguments

### R

If the POLAR keyword is set, *R* is a vector representing the radius of the polar plot. If *R* is specified, *Theta* is plotted as a function of *R*. If *R* is not specified, *Theta* is plotted as a function of the vector index of *Theta*.

### Theta

If the POLAR keyword is set, *Theta* is a vector representing the angle (in radians) of the polar plot.

### X

A vector representing the *x*-coordinates of the plot.

### Y

A vector or a two-dimensional array. If *Y* is:

- a vector, it represents the *y*-coordinates of the plot. If *X* is not specified, *Y* is plotted as a function of the vector index of *Y*. If *X* is specified, *Y* is plotted as a function of *X*.
- a 2-by-*n* array, *Y*[0, \*] represents the *x*-coordinates and *Y*[1, \*] represents the *y*-coordinates of the plot.

- a 3-by- $n$  array,  $Y[0, *]$  represents the  $x$ -coordinates,  $Y[1, *]$  represents the  $y$ -coordinates, and  $Y[2, *]$  represents the  $z$ -coordinates of the plot.

## Z

A vector representing the  $z$ -coordinates of the plot.

## Keywords

### Note

---

Keywords to the IPLOT routine that correspond to the names of *registered properties* of the iPlot tool must be specified in full, without abbreviation.

---

## BACKGROUND\_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND\_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW\_NUMBER or VIEW\_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW\_GRID keyword, and the VIEW\_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND\_COLOR keyword would set the background color in the second view only.

## CLIP\_PLANES

Set this keyword to an array of dimensions [4,  $N$ ] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

---

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

---

## COLOR

Set this keyword to an RGB value specifying the color to be used as the foreground color for this plot. The default is [0, 0, 0] (black).

## DIMENSIONS

Set this keyword to a two-element vector of the form [*width*, *height*] to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

## DISABLE\_SPLASH\_SCREEN

Set this keyword to disable the iTools splash screen. By default, the first time an iTool is run, the splash screen is displayed.

## ERRORBAR\_COLOR

Set this keyword to an RGB value specifying the color for the error bar. The default value is [0, 0, 0] (black).

## ERRORBAR\_CAPSIZE

Set this keyword to a floating-point value specifying the size of the error bar endcaps. This value ranges from 0 to 1.0, where a value of 1.0 results in an endcap that is 10% of the data range.

## FILL\_BACKGROUND

*This keyword is only available for 2D plots.*

Set this keyword to fill the area under the plot. This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

## FILL\_COLOR

*This keyword is only available for 2D plots.*

Set this keyword to an RGB value specifying the color for the filled area. The default value is [128,128,128] (white). This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

## FILL\_LEVEL

*This keyword is only available for 2D plots.*

Set this keyword to a floating-point value specifying the y-value for the lower boundary of the fill region. This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

## HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

## HISTOGRAM

*This keyword is only available for 2D plots.*

Set this keyword to force only horizontal and vertical lines to be used to connect the plotted points. By default, the points are connected using a single straight line. This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

## IDENTIFIER

Set this keyword to a named IDL variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## LINESTYLE

Set this keyword to indicate the line style that should be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE keyword equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq \textit{repeat} \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

## LOCATION

Set this keyword to a two-element vector of the form [*x*, *y*] to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

### Note

---

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2487 for additional information.

---

## MACRO\_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the *iTool* and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

## MAX\_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of `MAX_VALUE` are treated as missing data and are not plotted.

### Note

---

The IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

---

## MIN\_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of `MIN_VALUE` are treated as missing data and are not plotted.

**Note**

---

The IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

---

**NAME**

Set this keyword to a string to specify the name for this visualization.

**NO\_SAVEPROMPT**

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

**NSUM**

Set this keyword to the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

**OVERPLOT**

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

**POLAR**

Set this keyword to display the plot as a polar plot. If this keyword is set, the arguments will be interpreted as *R* and *Theta* or simply *Theta* for a single argument. If *R* is not supplied the plot will use a vector of indices for the *R* argument.

**RGB\_TABLE**

Set this keyword to either a 3 by 256 or 256 by 3 byte array containing color values to use for vertex colors. If the values supplied are not of type byte, they are scaled to the byte range using BYTSCL. Use the VERT\_COLORS keyword to specify indices that select colors from the values specified with RGB\_TABLE.

**SCATTER**

Set this keyword to generate a scatter plot. This action is equivalent to setting LINESTYLE = 6 (no line) and SYM\_INDEX = 3 (Period symbol).

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits.

The style is applied using the following rules:

- If the tool exists and /OVERPLOT is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either VIEW\_NEXT or VIEW\_NUMBER is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

## SYM\_COLOR

Set this keyword to an RGB value specifying the color for the plot symbol.

### Note

---

This color is applied to the symbol only if the [USE\\_DEFAULT\\_COLOR](#) keyword is explicitly set equal to zero.

---

## SYM\_INCREMENT

Set this keyword to an integer value specifying the number of vertices to increment between symbol instances. The default value is 1, which places a symbol on every vertex.

## SYM\_INDEX

Set this keyword to one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = Arrow Head

## **SYM\_SIZE**

Set this keyword to a floating-point value from 0.0 to 1.0 specifying the size of the plot symbol. A value of 1.0 results in a symbol that is 10% of the width/height of the plot.

## **SYM\_THICK**

Set this keyword to floating-point value from 1 to 10 points specifying the thickness of the plot symbol.

## **THICK**

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. The default is 1.0 points.

## **TITLE**

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

## **TRANSPARENCY**

Set this keyword to floating-point value specifying the transparency of the filled area. Valid values range from 0.0 to 100.0. The default value is 0.0 (opaque).

## **USE\_DEFAULT\_COLOR**

Set this keyword to use the color of the plot line for any plot symbols (this is the default). If this keyword is explicitly set to 0, the color specified by the [SYM\\_COLOR](#) keyword is used for symbols.

## **VERT\_COLORS**

Set this keyword to a vector of indices into the color table to select colors to use for each vertex (plot data point). Alternately, set this keyword to a 3 by  $N$  byte array containing color values to use for each vertex. If the values supplied are not of type byte, they are scaled to the byte range using BYTSCL. If indices are supplied but no colors are provided with the RGB\_TABLE keyword, then a default grayscale ramp is

used. If a 3 by  $N$  array of colors is provided, the colors are used directly and the color values provided with `RGB_TABLE` are ignored. If the number of indices or colors specified is less than the number of vertices, the colors are repeated cyclically.

**Note**

---

`VERT_COLORS` can be an array of RGB triplets or RGBA colors.

---

## VIEW\_GRID

Set this keyword to a two-element vector of the form `[columns, rows]` to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified then `VIEW_GRID` is ignored).

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then `/VIEW_NEXT` will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

**Note**

---

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

---

## VIEW\_NUMBER

Set this keyword to change the currently-selected view to the view specified by the `VIEW_NUMBER` before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

**Note**

---

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

---

## VIEW\_TITLE

Set this keyword equal to a scalar string that will be placed in a text annotation centered horizontally in the current view, near the top. The text will be created with the properties (size, style, color, etc.) defined for text annotations in the current tool style.

## **XY\_SHADOW**

*This keyword is only available for 3D plots.*

Set this keyword to display a shadow of the plot in a three-dimensional plot. The shadow lies in the XY plane at the minimum value of the data space range of the z-axis. This keyword has no effect for two-dimensional plots.

## **[XYZ]\_ERRORBARS**

Set this keyword to show error bars. The Z\_ERRORBARS keyword is for three-dimensional plots only.

## **[XYZ]GRIDSTYLE**

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINSTYLE for a list of linestyles.

## **[XYZ]\_LOG**

Set this keyword to specify a logarithmic axis. The minimum value of the axis range must be greater than zero. The Z\_LOG keyword is for three-dimensional plots only.

## **[XYZ]ERROR**

Set this keyword to either a vector or a 2 by  $N$  array of error values to be displayed as error bars for the [XYZ] dimension of the plot. The length of this array must be equal in length to the number of vertices of the plot or it will be ignored. If this keyword is set to a vector, the value will be applied as both a negative and positive error and the error bar will be symmetric about the plot vertex. If this keyword is set to a 2 by  $N$  array the [0, \*] values define the negative error and the [1, \*] values define the positive error, allowing asymmetric error bars. The ZERROR keyword is for three-dimensional plots only.

## **[XYZ]MAJOR**

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely. ZMAJOR is for three-dimensional plots only.

## **[XYZ]MINOR**

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting

MINOR equal to zero suppresses minor tickmarks entirely. ZMINOR is for three-dimensional plots only.

### **[XYZ]RANGE**

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. ZRANGE is for three-dimensional plots only.

### **[XYZ]SUBTICKLEN**

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark. ZSUBTICKLEN is for three-dimensional plots only.

### **[XYZ]TEXT\_COLOR**

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black). ZTEXT\_COLOR is for three-dimensional plots only.

### **[XYZ]TICKFONT\_INDEX**

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

ZTICKFONT\_INDEX is for three-dimensional plots only.

### **[XYZ]TICKFONT\_SIZE**

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points. ZTICKFONT\_SIZE is for three-dimensional plots only.

## [XYZ]TICKFONT\_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

ZTICKFONT\_STYLE is for three-dimensional plots only.

## [XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

### If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

### If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

**Note**

---

For more information, see “[XYZ]TICKFORMAT” on page 4790.

---

Used with the [LABEL\\_DATE](#) function, this property can easily create axes with date/time labels.

ZTICKFORMAT is for three-dimensional plots only.

**[XYZ]TICKINTERVAL**

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

ZTICKINTERVAL is for three-dimensional plots only.

**[XYZ]TICKLAYOUT**

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

ZTICKLAYOUT is for three-dimensional plots only.

**Note**

---

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

## [XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKLEN is for three-dimensional plots only.

## [XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark. ZTICKNAME is for three-dimensional plots only.

## [XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

ZTICKUNITS is for three-dimensional plots only.

**Note**

---

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

---

## [XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKVALUES is for three-dimensional plots only.

## [XYZ]TITLE

Set this keyword to a string representing the title of the specified axis. ZTITLE is for three-dimensional plots only.

## XZ\_SHADOW

*This keyword is only available for 3D plots.*

Set this keyword to display a shadow of the plot in a three-dimensional plot. The shadow lies in the XZ plane at the minimum value of the data space range of the y-axis. This keyword has no effect for two-dimensional plots.

## YZ\_SHADOW

*This keyword is only available for 3D plots.*

Set this keyword to display a shadow of the plot in a three-dimensional plot. The shadow lies in the YZ plane at the minimum value of the data space range of the x-axis. This keyword has no effect for two-dimensional plots.

## Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the File menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

## Example 1

This example shows how to use the IDL Command Line to load data and variables into the iPlot tool.

At the IDL Command Line, enter:

```
file = FILEPATH('elnino.dat', SUBDIRECTORY = ['examples','data'])
data = READ_BINARY(file, DATA_TYPE = 4, DATA_DIMS = [500, 1], $
    ENDIAN = 'little')
time = DINDGEN(500)*0.25d + 1871
IPLOT, time, data, TITLE = 'El Nino', COLOR = [255, 128, 0]
```

Place a title on the time axis of your plot by selecting the axis, right-clicking to display the context menu, selecting **Properties** to display the property sheet, and typing `Year` in the **Title** field.

Place a title on the temperature axis of your plot by selecting the axis, displaying the property sheet, and entering the following in the **Title** field:

```
Temperature Anomaly (!Uo!NC)
```

Annotate your plot by selecting the Text Annotation tool, clicking near the top of the plot, and typing `El Nino`.

Add the special character to the annotation by selecting the annotation text, displaying the property sheet, selecting the lower-case `n` in `Nino` in the **Title** field, and replacing it with the following:

```
!Z(U+0F1)
```

---

### Note

U+0F1 is unicode for the ñ character.

---

The following figure displays the output of this example:

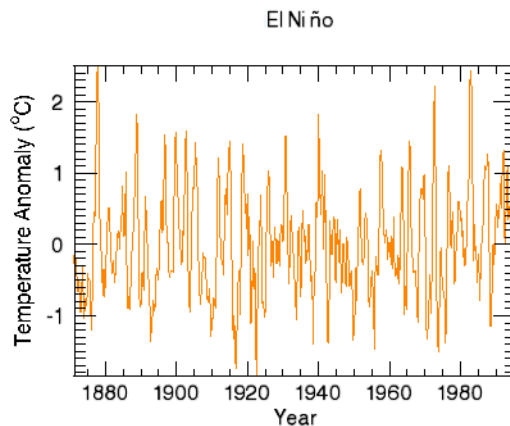

Figure 3-57: El Niño iPlot Example

## Example 2

This example shows how to use the **File** → **Open** command to load binary data into the iPlot tool.

At the IDL Command Line, enter:

```
IPLOT
```

Select **File** → **Open** command to display the Open dialog, then browse to find `dirty_sine.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

In the Binary Template dialog, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** data (or a name of your choosing)
- **Type:** Byte (unsigned 8-bits)
- **Number of Dimensions:** 1
- **1st Dimension Size:** 256

Click **OK** to close the New Field dialog and the Binary Template dialog, and the surface is displayed.

**Note**

For more information on using the Binary Template to import data, see [“Using the BINARY\\_TEMPLATE Interface”](#) on page 164.

Annotate your plot by selecting the Text Annotation tool, clicking near the curve, and typing `Noisy Sine Wave`.

The following figure displays the output of this example:

*Figure 3-58: Noisy Sine Data iPlot Example*

**Example 3**

This example shows how to use the **File** → **Import** command to load ASCII data into the iPlot tool.

At the IDL Command Line, enter:

```
I PLOT
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `sine_waves.txt` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Plot** and click **Finish**.

Then, the ASCII Template wizard is displayed.

1. At Step 1, click **Next>>** to accept the displayed data type/range definition.

2. At Step 2, click **Next**>> to accept the displayed delimiter/fields definition.
3. At Step 3, click **Finish** to accept the displayed field specification. The `sine_waves.txt` plot is displayed in the iPlot window.

The plot consists of two overlapping sine waves. To make it easier to distinguish between the two, change the appearance of the noisy sine wave to a dotted line pattern by selecting the noisy sine wave, right-clicking to display the context menu, selecting **Properties**, and changing the **Linestyle** property to a dotted line.

The following figure displays the output of this example:

Figure 3-59: Overlapping Sine Waves iPlot Example

## Version History

6.0	Introduced
6.1	Added <code>BACKGROUND_COLOR</code> , <code>MACRO_NAMES</code> , and <code>STYLE_NAME</code> keywords
6.2	Added <code>DISPLAY_SPLASH_SCREEN</code> and <code>VIEW_TITLE</code> keywords

# ISHFT

The ISHFT function performs the bit shift operation on bytes, integers and longwords.

## Syntax

$$Result = ISHFT(P_1, P_2)$$

## Return Value

If  $P_2$  is positive,  $P_1$  is left shifted  $P_2$  bit positions with 0 bits filling vacated positions. If  $P_2$  is negative,  $P_1$  is right shifted with 0 bits filling vacated positions.

## Arguments

**$P_1$**

The scalar or array to be shifted.

**$P_2$**

The scalar or array containing the number of bit positions and direction of the shift.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Bit shift each element of the integer array [1, 2, 3, 4, 5] three bits to the left and store the result in B by entering:

```
B = ISHFT([1, 2, 3, 4, 5], 3)
```

The resulting array B is [8, 16, 24, 32, 40].

# ISOCONTOUR

The ISOCONTOUR procedure interprets the contouring algorithm found in the IDLgrContour object. The algorithm allows for contouring on arbitrary meshes and returns line or orientated tessellated polygonal output. The interface will also allow secondary data values to be interpolated and returned at the output vertices as well.

## Syntax

```
ISOCONTOUR, Values, Outverts, Outconn
  [, AUXDATA_IN=array, AUXDATA_OUT=variable]
  [, C_LABEL_INTERVAL=vector of values] [, C_LABEL_SHOW=vector of
  integers] [, C_VALUE=scalar or vector] [, /DOUBLE] [, /FILL]
  [, GEOMX=vector] [, GEOMY=vector] [, GEOMZ=vector]
  [, LEVEL_VALUES=variable] [, N_LEVELS=levels]
  [, OUT_LABEL_OFFSETS=variable] [, OUT_LABEL_POLYLINES=variable]
  [, OUT_LABEL_STRINGS=variable] [, OUTCONN_INDICES=variable]
  [, POLYGONS=array of polygon descriptions]
```

## Arguments

### Values

A vector or two-dimensional array specifying the values to be contoured. If the data is of double-precision floating-point type, or if the DOUBLE keyword is set, computations are done in double precision and the result is a double-precision value. If the data is of any other type, it is converted (if necessary) to single-precision floating-point; all computations are then done in single precision and the result is a single-precision value.

### Outconn

Output variable to contain the connectivity information of the contour geometry in the form: [n0, i(0, 0), i(0, 1)..., i(0, n0-1), n1, i(1, 0), ...].

### Outverts

Output variable to contain the contour vertices. The vertices are returned in double-precision floating point if the DOUBLE keyword is specified with a non-zero value. Otherwise, the vertices are returned in single-precision floating point.

## Keywords

### AUXDATA\_IN

The auxiliary values to be interpolated at contour vertices. If  $p$  is the dimensionality of the auxiliary values, set this argument to a  $p$ -by- $n$  array (if the *Values* argument is a vector of length  $n$ ), or to a  $p$ -by- $m$ -by- $n$  array (if the *Values* argument is an  $m$ -by- $n$  two-dimensional array).

### AUXDATA\_OUT

If the AUXDATA\_IN keyword was specified, set this keyword to a named output variable to contain the interpolated auxiliary values at the contour vertices. If  $p$  is the dimensionality of the auxiliary values, the output is a  $p$ -by- $n$  array of values, where  $n$  is the number of vertices in *Outverts*.

### C\_LABEL\_INTERVAL

Set this keyword to a vector of values indicating the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C\_LABEL\_INTERVAL values will be repeated cyclically. The default is 0.4.

### C\_LABEL\_SHOW

Set this keyword to a vector of integers. For each contour value, if the corresponding value in the C\_LABEL\_SHOW vector is non-zero, the contour line for that contour value will be labeled (with the corresponding label information returned via the OUT\_LABEL\_POLYS, OUT\_LABEL\_OFFSETS, and OUT\_LABEL\_STRINGS keywords). If the number of contour levels exceeds the number of elements in this vector, the C\_LABEL\_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

### C\_VALUE

Set this keyword to a scalar value or a vector of values for which contour levels are to be generated. If this keyword is set to 0, contour levels will be evenly sampled across the range of the *Values* argument, using the value of the N\_LEVELS keyword to determine the number of samples.

## DOUBLE

Set this keyword to use double-precision to compute the contours. IDL converts any data supplied by the *Values* argument or GEOMX, GEOMY, and GEOMZ keywords to double precision and returns the *Outverts* argument in double precision. The default behavior is to convert the input to single precision and return the *Outverts* in single precision.

## FILL

Set this keyword to generate an output connectivity as a set of polygons (Outconn is in the form used by the IDLgrPolygon POLYGONS keyword). The resulting representation is as a set of filled contours. The default is to generate line contours (Outconn is in the form used by the IDLgrPolyline POLYLINES keyword).

## GEOMX

Set this keyword to a vector or two-dimensional array specifying the *X* coordinates of the geometry with which the contour values correspond. If *X* is a vector, it must match the number of elements in the *Values* argument, or it must match the first of the two dimensions of the *Values* argument (in which case the *X* coordinates will be repeated for each row of data values).

If necessary, data in the supplied vector or array will be converted to match the data type of the *Values* argument.

## GEOMY

Set this keyword to a vector or two-dimensional array specifying the *Y* coordinates of the geometry with which the contour values correspond. If *Y* is a vector, it must match the number of elements in the *Values* argument, or it must match the second of the two dimensions of the *Values* argument (in which case the *Y* coordinates will be repeated for each column of data values).

If necessary, data in the supplied vector or array will be converted to match the data type of the *Values* argument.

## GEOMZ

Set this keyword to a vector or two-dimensional array specifying the *Z* coordinates of the geometry with which the contour values correspond.

If GEOMZ is a vector or an array, it must match the number of elements in the *Values* argument.

If GEOMZ is not set, the geometry will be derived from the *Values* argument (if it is set to a two-dimensional array). In this case connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

If necessary, data in the supplied vector or array will be converted to match the data type of the *Values* argument.

## LEVEL\_VALUES

Set this keyword to a named output variable to receive a vector of values corresponding to the values used to generate the contours. The length of this vector is equal to the number of contour levels generated. This vector is returned in double precision floating point.

## N\_LEVELS

Set this keyword to the number of contour levels to generate. This keyword is ignored if the C\_VALUE keyword is set to a vector, in which case the number of levels is derived from the number of elements in that vector. Set this keyword to 0 to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

## OUT\_LABEL\_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of offsets (parameterized to the corresponding contour line) indicating the positions of the contour labels.

### Note

---

The C\_LABEL\_SHOW keyword should be specified if this keyword is used.

---

## OUT\_LABEL\_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of polyline indices, [P0, P1, ...], that indicate which contour lines are labeled. Pi corresponds to the *i*th polyline specified via the Outconn argument. Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL\_POLYS vector.

### Note

---

The C\_LABEL\_SHOW keyword should be specified if this keyword is used.

---

## OUT\_LABEL\_STRINGS

Set this keyword to a named variable that upon return will contain a vector of strings, [str0, str1, ...], that indicate the label strings.

### Note

The C\_LABEL\_SHOW keyword should be specified if this keyword is used.

## OUTCONN\_INDICES

Set this keyword to a named output variable to receive an array of beginning and ending indices of connectivity for each contour level.

The output array is of the form: [start<sub>0</sub>, end<sub>0</sub>, start<sub>1</sub>, end<sub>1</sub>, ..., start<sub>nc-1</sub>, end<sub>nc-1</sub>], where *nc* is the number of contour levels. If a level has no contour lines, the start and stop pair is set to 0 and 0 for that level.

## POLYGONS

Set this keyword to an array of polygonal descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument). A polygonal description is an integer or long array of the form: [n, i<sub>0</sub>, i<sub>1</sub>, ..., i<sub>n-1</sub>], where *n* is the number of vertices that define the polygon, and i<sub>0</sub>...i<sub>n-1</sub> are indices into the GEOMX, GEOMY, and GEOMZ keywords that represent the polygonal vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n* to 0. To end the drawing list, even if additional array space is available, set *n* to -1.

## Version History

5.5	Introduced
5.6	Added C_LABEL_INTERVAL, C_LABEL_SHOW, OUT_LABEL_OFFSETS, OUT_LABEL_POLYLINES, and OUT_LABEL_STRINGS keywords

# ISOSURFACE

The ISOSURFACE procedure algorithm expands on the SHADE\_VOLUME algorithm. It returns topologically consistent triangles by using oriented tetrahedral decomposition internally. This also allows the algorithm to isosurface any arbitrary tetrahedral mesh. If the user provides an optional auxiliary array, the data in this array is interpolated onto the output vertices and is returned as well. This auxiliary data array is allowed to have more than one value at each vertex. Any size leading dimension is allowed as long as the number of values in the subsequent dimensions matches the number of elements in the input Data array.

## Syntax

```
ISOSURFACE, Data, Value, Outverts, Outconn
  [, GEOM_XYZ=array, TETRAHEDRA=array]
  [, AUXDATA_IN=array, AUXDATA_OUT=variable]
  [, PROGRESS_CALLBACK=string] [, PROGRESS_METHOD=string]
  [, PROGRESS_OBJECT=objref] [, PROGRESS_PERCENT=percent{0 to 100}]
  [, PROGRESS_USERDATA=value]
```

## Arguments

### Data

Input three-dimensional array of scalars which are to be contoured.

### Value

Input scalar contour value. This value specifies the constant-density surface (also called an iso-surface) to be extracted.

### Outverts

A named variable to contain an output  $[3, n]$  array of floating point vertices making up the triangle surfaces.

### Outconn

A named variable to contain an output array of polygonal connectivity values (see IDLgrPolygon, POLYGONS keyword). If no polygons were extracted, this argument returns the array  $[-1]$ .

## Keywords

### AUXDATA\_IN

Input array of auxiliary data with trailing dimensions being the number of values in Data.

---

**Note**

If AUXDATA\_IN is specified then AUXDATA\_OUT must also be specified.

---

### AUXDATA\_OUT

Set this keyword to a named variable that will contain an output array of auxiliary data sampled at the locations in Outverts.

---

**Note**

If AUXDATA\_OUT is specified then AUXDATA\_IN must also be specified.

---

### GEOM\_XYZ

A [3,n] input array of vertex coordinates (one for each value in the Data array). This array is used to define the spatial location of each scalar. If this keyword is omitted, Data must be a three-dimensional array and the scalar locations are assumed to be on a uniform grid.

---

**Note**

If GEOM\_XYZ is specified then TETRAHEDRA must also be specified if either is to be specified.

---

### PROGRESS\_CALLBACK

Set this keyword to a scalar string containing the name of the IDL function that ISOSURFACE calls at PROGRESS\_PERCENT intervals as it generates the isosurface.

The PROGRESS\_CALLBACK function returns a zero to signal ISOSURFACE to stop generating the isosurface. This causes ISOSURFACE to return a single vertex and a connectivity array of [-1], which specifies an empty polygon. If the callback function returns any non-zero value, ISOSURFACE continues to generate the isosurface.

The `PROGRESS_CALLBACK` function must specify a single argument, *Percent*, which `ISOSURFACE` sets to an integer between 0 and 100, inclusive.

The `PROGRESS_CALLBACK` function may specify an optional `USERDATA` keyword parameter, which `ISOSURFACE` sets to the variable provided in the `PROGRESS_USERDATA` keyword.

The following code shows an example of a progress callback function:

```
FUNCTION myProgressCallback, percent,$      USERDATA = myStruct
oProgressBar = myStruct.oProgressBar

; This method updates the progress bar
; graphic and returns TRUE if the user has
; NOT pressed the cancel button.
keepGoing = oProgressBar-> $
    UpdateProgressValue(percent)

RETURN, keepGoing

END
```

## PROGRESS\_METHOD

Set this keyword to a scalar string containing the name of a function method that `ISOSURFACE` calls at `PROGRESS_PERCENT` intervals as it generates the isosurface. If this keyword is set, then the `PROGRESS_OBJECT` keyword must be set to an object reference that is an instance of a class that defines the specified method.

The `PROGRESS_METHOD` function method callback has the same specification as the callback described in the `PROGRESS_CALLBACK` keyword, except that it is defined as an object class method:

```
FUNCTION myClass::myProgressCallback, $
    percent, USERDATA = myStruct
```

## PROGRESS\_OBJECT

Set this keyword to an object reference that is an instance of a class that defines the method specified with the `PROGRESS_METHOD` keyword. If this keyword is set, then the `PROGRESS_METHOD` keyword must also be set.

## PROGRESS\_PERCENT

Set this keyword to a scalar in the range [1, 100] to specify the interval between invocations of the callback function. The default value is 5 and IDL silently clamps other values to the range [1, 100].

For example, a value of 5 (the default) specifies ISOSURFACE will call the callback function when the isosurface process is 0% complete, 5% complete, 10% complete, ..., 95% complete, and 100% complete.

## PROGRESS\_USERDATA

Set this property to any IDL variable that ISOSURFACE passes to the callback function in the callback function's USERDATA keyword parameter. If this keyword is specified, then the callback function must be able to accept keyword parameters.

## TETRAHEDRA

An input array of tetrahedral connectivity values. If this array is not specified, the connectivity is assumed to be a rectilinear grid over the input three-dimensional array. If this keyword is specified, the input data array need not be a three-dimensional array. Each tetrahedron is represented by four values in the connectivity array. Every four values in the array correspond to the vertices of a single tetrahedron.

## Version History

5.5	Introduced
6.0	Added PROGRESS_CALLBACK, PROGRESS_METHOD, PROGRESS_OBJECT, PROGRESS_PERCENT, and PROGRESS_USERDATA keywords

# ISURFACE

The ISURFACE procedure creates an iTool and the associated user interface (UI) configured to display and manipulate surface data.

## Note

If no arguments are specified, the ISURFACE procedure creates an empty Surface tool.

This routine is written in the IDL language. Its source code can be found in the file `isurface.pro` in the `lib/itools` subdirectory of the IDL distribution.

For more information on using the iSurface tool, see “[Working with Surfaces](#)” in the *iTool User’s Guide* manual.

## Syntax

ISURFACE[, Z [, X, Y]]

**iTool Common Keywords:** [, [BACKGROUND\\_COLOR=](#)*value*]

```

## Arguments

### X

A vector or two-dimensional array specifying the  $x$ -coordinates of the grid.

If  $X$  is a vector:

- If  $Y$  and  $Z$  are vectors and have the same length as  $X$ :  
Each element of  $X$  specifies the  $x$ -coordinates of a point in space (e.g.,  $X[0]$  specifies the  $x$ -coordinate for  $Y[0]$  and  $Z[0]$ ). The gridding wizard will automatically launch in this case.
- If  $Z$  is a two-dimensional array:  
Each element of  $X$  specifies the  $x$ -coordinates for a column of  $Z$  (e.g.,  $X[0]$  specifies the  $x$ -coordinate for  $Z[0, *]$ ).

If  $X$  is a two-dimensional array, each element of  $X$  specifies the  $x$ -coordinate of the corresponding point in  $Z$  ( $X_{ij}$  specifies the  $x$ -coordinate of  $Z_{ij}$ ).

### Y

A vector or two-dimensional array specifying the  $y$ -coordinates of the grid.

If  $Y$  is a vector:

- If  $X$  and  $Z$  are vectors and have the same length as  $Y$ :  
Each element of  $Y$  specifies the  $y$ -coordinates of a point in space (e.g.,  $Y[0]$  specifies the  $y$ -coordinate for  $X[0]$  and  $Z[0]$ ). The gridding wizard will automatically launch in this case.
- If  $Z$  is a two-dimensional array:  
Each element of  $Y$  specifies the  $y$ -coordinates for a column of  $Z$  (e.g.,  $Y[0]$  specifies the  $y$ -coordinate for  $Z[* , 0]$ ).

If  $Y$  is a two-dimensional array, each element of  $Y$  specifies the  $y$ -coordinate of the corresponding point in  $Z$  ( $Y_{ij}$  specifies the  $y$ -coordinate of  $Z_{ij}$ ).

## Z

A vector or two-dimensional array specifying the data to be displayed.

If  $Z$  is a vector,

- If  $X$  and  $Y$  are vectors and have the same length as  $Z$ :  
Each element of  $Z$  specifies the  $z$ -coordinates of a point in space (e.g.,  $Z[0]$  specifies the  $z$ -coordinate for  $X[0]$  and  $Y[0]$ ). The gridding wizard will automatically launch in this case.

If  $Z$  is a two-dimensional array,

- If  $X$  and  $Y$  are provided:  
The surface is defined as a function of the  $(x, y)$  locations specified by their contents.
- If  $X$  and  $Y$  are not provided:  
The surface is generated as a function of the array indices of each element of  $Z$ .

## Keywords

### Note

---

Keywords to the ISURFACE routine that correspond to the names of *registered properties* of the iSurface tool must be specified in full, without abbreviation.

---

## BACKGROUND\_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND\_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW\_NUMBER or VIEW\_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW\_GRID keyword, and the VIEW\_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND\_COLOR keyword would set the background color in the second view only.

## BOTTOM

Set this keyword to an RGB color for drawing the bottom of the surface. Set this keyword to a scalar to draw the bottom with the same color as the top.

## CLIP\_PLANES

Set this keyword to an array of dimensions  $[4, N]$  specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

### Note

---

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

---

## COLOR

Set this keyword to the color to be used as the foreground color for this model. The color is specified as an RGB vector. The default is  $[225, 184, 0]$ .

## DEPTH\_OFFSET

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH\_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

---

**Note**

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple `DEPTH_OFFSET` values. It is safest to use only a `DEPTH_OFFSET` value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of `DEPTH_OFFSET` values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of `DEPTH_OFFSET` values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use `DEPTH_OFFSET`.

---

**Note**

`DEPTH_OFFSET` has no effect unless the value of the `STYLE` keyword is 2 or 6 (Filled or LegoFilled).

---

## DIMENSIONS

Set this keyword to a two-element vector of the form [width, height] to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

## DISABLE\_SPLASH\_SCREEN

Set this keyword to disable the iTools splash screen. By default, the first time an iTool is run, the splash screen is displayed.

## EXTENDED\_LEGO

Set this keyword to force the iSurface tool to display the last row and column of data when lego display styles are selected.

## HIDDEN\_LINES

Set this keyword to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

## HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

## IDENTIFIER

Set this keyword to a named IDL variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## LINestyle

Set this keyword to indicate the line style that should be used to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the `LINestyle` keyword equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq \textit{repeat} \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

## LOCATION

Set this keyword to a two-element vector of the form [*x*, *y*] to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

**Note**

Some X Window managers explicitly ignore any request from the client for window placement. See “[Positioning Top-Level Bases](#)” on page 2487 for additional information.

**MACRO\_NAMES**

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the `iTool` and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

**NAME**

Set this keyword to a string to specify the name for this visualization. The name is used for tool-related display purposes only.

**NO\_SAVEPROMPT**

Set this keyword to cause the `iTool` *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

**OVERPLOT**

Set this keyword to an `iToolID` to direct the graphical output of the particular tool to the tool specified by the provided `iToolID`.

Set this keyword equal to one to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

**RGB\_TABLE**

Set this keyword to a two-dimensional array containing RGB triplets defining the colors to be used in a color indexed texture image or by vertex colors. The values should be within the range of  $0 \leq \text{value} \leq 255$ . The array must be a 3 by  $N$  array where  $m$  must not exceed 256.

**SHADING**

Set this keyword to an integer representing the type of shading to use if `STYLE` is set to 2 (Filled).

- 0 = Flat (default): The color has a constant intensity for each face of the surface, based on the normal vector.

- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

## SHOW\_SKIRT

Set this keyword to enable skirt drawing. The default is to disable skirt drawing.

## SKIRT

Set this keyword to the  $Z$  value at which a skirt is to be defined around the array. The  $Z$  value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given  $Z$  value, and the same  $X$  and  $Y$  values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see `SHOW_SKIRT` above). IDL converts, maintains, and returns this data as double-precision floating-point.

## STYLE

Set this keyword to an integer value that indicates the style to be used to draw the surface. Valid values are:

- 0 = Points
- 1 = Wire mesh
- 2 = Filled (the default)
- 3 = RuledXZ
- 4 = RuledYZ
- 5 = Lego
- 6 = LegoFilled: for outline or shaded and stacked histogram-style plots.

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits.

The style is applied using the following rules:

- If the tool exists and `/OVERPLOT` is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

## **TEXTURE\_ALPHA**

Set the keyword to a two-dimensional array containing the alpha channel of an image to be used as a texture image. Use of this keyword requires that `TEXTURE_RED`, `TEXTURE_GREEN`, and `TEXTURE_BLUE` be set to arrays of identical size and type.

## **TEXTURE\_BLUE**

Set the keyword to a two-dimensional array containing the blue channel of an image to be used as a texture image. Use of this keyword requires that `TEXTURE_RED` and `TEXTURE_GREEN` be set to arrays of identical size and type.

## **TEXTURE\_GREEN**

Set the keyword to a two-dimensional array containing the green channel of an image to be used as a texture image. Use of this keyword requires that `TEXTURE_RED` and `TEXTURE_BLUE` be set to arrays of identical size and type.

## **TEXTURE\_HIGHRES**

An integer value that determines the type of texture tiling, if any, that will be used to maintain the full pixel resolution of the original texture image. Set this property to one of the following options:

- 0 = If the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to this resolution.
- 1 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. As a large image could easily consume all available video memory, this mode employs texture Level of Detail (LoD). Rather than loading the entire image into the texture

tiles at the full resolution, the image tiles are downsampled based on the level of zoom. If the entire image is visible the texture tiles will contain highly downsampled data from the image to conserve video memory. As a portion of the image is zoomed in on, progressively higher resolution image data is loaded into the visible tiles, until the maximum resolution is reached. The tiles that are not visible during zooming are not loaded with high resolution data.

---

**Note**

This mode is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic when `TEXTURE_HIGHRES=0`.

---

- 2 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. However, the highest resolution data is loaded into all tiles. LoD tiling is disabled. This mode should only be used if the video memory is sufficient for the image size.

If not set, and the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to the maximum resolution supported by the 3-D hardware on your system. The default value is 0.

---

**Note**

`TEXTURE_HIGHRES` is supported only when `STYLE=2` (Filled).

---

## TEXTURE\_IMAGE

Set this keyword to an array containing an image to be texture mapped onto the surface. If this keyword is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the `COLOR` or `VERTEX_COLORS` property. The image array can be a two-dimensional array of color indexes or a three-dimensional array specifying RGB values at each pixel ( $3 \times n \times m$ ,  $n \times 3 \times m$ , or  $n \times m \times 3$ ). Setting `TEXTURE_IMAGE` to a three-dimensional array contains an alpha channel ( $4 \times n \times m$ ,  $n \times 4 \times m$ , or  $n \times m \times 4$ ) allows you to create a transparent `iSurface` object. The `TEXTURE_IMAGE` keyword will override any values passed to `TEXTURE_RED`, `TEXTURE_GREEN`, `TEXTURE_BLUE`, or `TEXTURE_ALPHA`.

## TEXTURE\_INTERP

Set this keyword to a nonzero value to indicate that bilinear sampling is to be used with texture mapping. The default method is nearest-neighbor sampling.

## TEXTURE\_RED

Set the keyword to a two-dimensional array containing the red channel of an image to be used as a texture image. Use of this keyword requires that TEXTURE\_GREEN and TEXTURE\_BLUE be set to arrays of identical size and type.

## THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. The default is 1.0 points.

## TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

## USE\_TRIANGLES

Set this keyword to force the iSurface tool to use triangles instead of quads to draw the surface and skirt.

## VERT\_COLORS

Set this keyword to a vector, two-dimensional array of equal size to Z, or a two-dimensional array containing RGB triplets representing colors to be used at each vertex. If this keyword is set to a vector or a two-dimensional array of equal size to Z, these values are indices into a color table that can be specified by the RGB\_TABLE keyword. If the RGB\_TABLE keyword is not set, a grayscale color is used. If more vertices exist than elements in VERT\_COLORS, the elements of VERT\_COLORS are cyclically repeated. If this keyword is omitted, the surface is drawn in the color specified by the COLOR keyword or the default color.

### Note

---

VERT\_COLORS can be an array of RGB triplets or RGBA colors.

---

## VIEW\_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if OVERPLOT, VIEW\_NEXT, or VIEW\_NUMBER are specified then VIEW\_GRID is ignored).

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then /VIEW\_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

---

**Note**

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

---

## VIEW\_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW\_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

---

**Note**

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

---

## VIEW\_TITLE

Set this keyword equal to a scalar string that will be placed in a text annotation centered horizontally in the current view, near the top. The text will be created with the properties (size, style, color, etc.) defined for text annotations in the current tool style.

## [XYZ]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINSTYLE for a list of linestyles.

## [XYZ]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

## **[XYZ]MINOR**

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

## **[XYZ]RANGE**

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum.

## **[XYZ]SUBTICKLEN**

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

## **[XYZ]TEXT\_COLOR**

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

## **[XYZ]TICKFONT\_INDEX**

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

## **[XYZ]TICKFONT\_SIZE**

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

## **[XYZ]TICKFONT\_STYLE**

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal

- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

## [XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

### If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

### If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

### Note

---

For more information, see “[\[XYZ\]TICKFORMAT](#)” on page 4790.

---

Used with the LABEL\_DATE function, this property can easily create axes with date/time labels.

## [XYZ]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

## [XYZ]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

### Note

---

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

## [XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

## [XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

## [XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

---

### Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

---

## [XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

## [XYZ]TITLE

Set this keyword to a string representing the title of the specified axis.

## ZERO\_OPACITY\_SKIP

Set this keyword to gain finer control over the rendering of textured surface pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this keyword is set to 1, any texels are “skipped” and not rendered at all. If this keyword is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this keyword is 1.

### Note

---

This keyword has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

---

## Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the File menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

### Example 1

This example shows how to use the IDL Command Line to load data into the iSurface tool.

At the IDL Command Line, enter:

```
file = FILEPATH('surface.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [350, 450], DATA_TYPE = 2, $
  ENDIAN = 'little')
ISURFACE, data, TITLE = 'Maroon Bells Elevation', $
  COLOR = [255, 128, 0]
```

Place a title on the elevation axis of your plot by selecting the axis, right-clicking to display the context menu, selecting **Properties** to display the property sheet, and typing `Elevation (m)` in the **Title** field.

Use the **Operations** → **Statistics...** option to display the iTools Statistics dialog. Within this dialog, observe the Z value's Maximum, which is 4241 at [29, 253]. Close the iTools Statistics dialog by selecting **File** → **Close**.

Annotate your plot by selecting the Text Annotation tool, clicking near the top of the highest peak in the display, and typing Highest Point (4241 m). Draw a line annotation between the text annotation and the highest peak on the surface.

The following figure displays the output of this example:

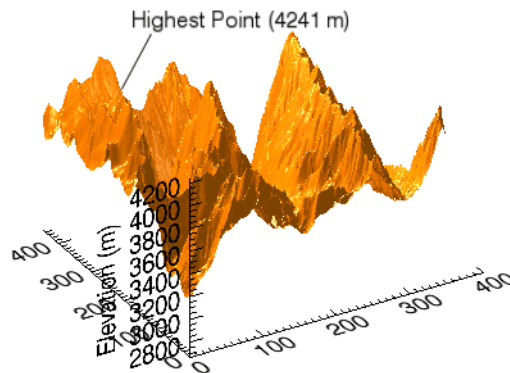

Figure 3-60: Maroon Bells iSurface Example

## Example 2

This example shows how to use the **File** → **Open** command to load binary data into the iSurface tool.

At the IDL Command Line, enter:

```
ISURFACE
```

Select **File** → **Open** to display the Open dialog, then browse to find `idemosurf.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

The Binary Template wizard is displayed. In the Binary Template, change **File's byte ordering** to `Little Endian`. Then, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** `Float (32 bit)`

- **Number of Dimensions:** 2
- **1st Dimension Size:** 200
- **2nd Dimension Size:** 200

Click **OK** to close the New Field dialog and the Binary Template dialog, and the surface is displayed.

---

**Note**

For more information on using the Binary Template to import data, see [“Using the BINARY\\_TEMPLATE Interface”](#) on page 164.

---

Insert a contour onto the surface by clicking the **Surface Contour** button on the toolbar, then clicking and dragging on the surface to position the contour at the desired height.

The following figure displays the output of this example:

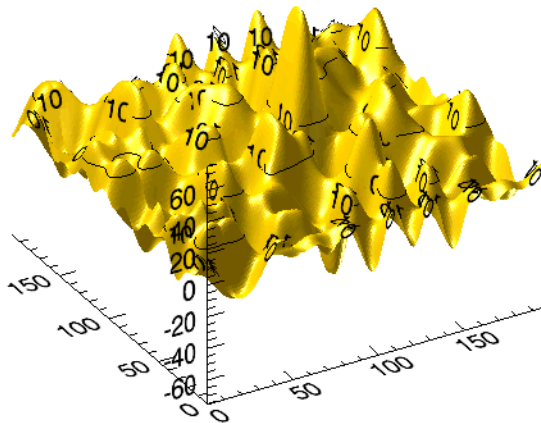

Figure 3-61: Binary Surface Data iSurface Example

### Example 3

This example shows how to use the **File** → **Import** command to load ASCII data into the iSurface tool.

At the IDL Command Line, enter:

```
ISURFACE
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `irreg_grid1.txt` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Surface** and click **Finish**.

Then, the ASCII Template wizard is displayed.

1. At Step 1, click **Next>>** to accept the displayed Data Type/Range definitions.
2. At Step 2, click **Next>>** to accept the displayed Delimiter/Fields definitions.
3. At Step 3, click **Finish** to accept the displayed Field Specifications.

---

**Note**

For more information on using the ASCII Template to import data, see [“Using the ASCII Template Dialog”](#) under ASCII\_TEMPLATE in this manual.

---

At the iTool’s Create Visualization window, you have the option of launching the Gridding wizard or not creating a visualization. Choose **Launch the gridding wizard** and click **Ok**.

4. At Step 1, click **Next>>** to accept the interpolation of data values and locations.
5. At Step 2, click **Next>>** to accept the dimensions, start and spacing.
6. At Step 3, select **Inverse Distance** as the gridding method, click **Preview** to preview the possible results, and click **Finish** to display the surface.

Double-click the surface to display the Properties sheet, and change the **Fill shading** setting from `Flat` to `Gouraud`.

Use the Rotate tool on the Toolbar to rotate the surface slightly forward to better display the surface convolutions.

The following figure displays the output of this example.

Figure 3-62: ASCII Surface Data *iSurface* Example

## Version History

6.0	Introduced
6.1	Added BACKGROUND_COLOR, MACRO_NAMES, and STYLE_NAME keywords
6.2	Added DISABLE_SPLASH_SCREEN and VIEW_TITLE keywords

# ITCURRENT

The ITCURRENT procedure is used to set the current tool in the IDL Intelligent Tools system. This routine is used with the identifier of the tool to make it current in the system. If the identifier is valid, the specified tool becomes current.

When a tool is set as current, the visible display or the focus state of the tool does not change. Only the internal setting of the current tool changes.

Besides using this procedure to set the current tool, a tool is made current when it is created or when it is placed in focus in the current windowing system.

This routine is written in the IDL language. Its source code can be found in the file `itcurrent.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

ITCURRENT, *iToolID*

## Arguments

### **iToolID**

The identifier of the existing iTool to be set as current.

## Keywords

None.

## Example

Enter the following at the IDL Command Line:

```
IPlot, IDENTIFIER = PlotID1
current1 = ITGETCURRENT()
PRINT, 'The current tool is ', current1
```

An iPlot tool is created, and the newly created iPlot tool becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/IPlot_8
```

Enter the following at the IDL Command Line:

```
I PLOT, IDENTIFIER = PlotID2
current2 = ITGETCURRENT()
PRINT, 'The current tool is ', current2
```

A second iPlot tool is created, and this newly created iPlot tool becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/IPLOT_9
```

Enter the following at the IDL Command Line:

```
I SURFACE, IDENTIFIER = SurfaceID1
current3 = ITGETCURRENT()
PRINT, 'The current tool is ', current3
```

An iSurface tool is created, and the newly created iSurface tool becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/ISURFACE_5
```

Enter the following at the IDL Command Line:

```
ITCURRENT, PlotID1
current = ITGETCURRENT()
PRINT, 'The current tool is ', current
END
```

The iPlot tool created at the beginning of the example (PlotID1) becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/IPLOT_8
```

Note that the system ID of the current tool (IPLOT\_8) is the same as that of the current tool at the beginning of the exercise.

## Version History

6.0	Introduced
-----	------------

## See Also

[ITDELETE](#), [ITGETCURRENT](#), [ITRESET](#)

# ITDELETE

The ITDELETE procedure is used to delete a tool in the IDL Intelligent Tools system. If a valid identifier is provided, the tool represented by the identifier is destroyed. If no identifier is provided, the current tool is destroyed.

When a tool is destroyed, all resources specific to that tool are released and the tool ceases to exist.

This routine is written in the IDL language. Its source code can be found in the file `itdelete.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

```
ITDELETE[, iToolID]
```

## Arguments

### **`iToolID`**

This optional argument contains the identifier for the specific `iTool` to delete. If not provided, the current tool is destroyed.

## Keywords

None.

## Example

Enter the following at the IDL Command Line:

```
I PLOT, IDENTIFIER = PlotID1  
I SURFACE, IDENTIFIER = SurfaceID1
```

Two tools are created: an `iPlot` tool and an `iSurface` tool.

Next, enter the following at the IDL Command Line:

```
ITDELETE, plotID1
```

The `iPlot` tool is deleted, leaving only the `iSurface` tool.

## Version History

6.0	Introduced
-----	------------

## See Also

[ITCURRENT](#), [ITGETCURRENT](#), [ITRESET](#)

# ITGETCURRENT

The ITGETCURRENT function is used to get the identifier of, and optionally and object reference to, the current tool in the IDL Intelligent Tools system.

## Note

---

You can also retrieve the identifier of an iTool by specifying the IDENTIFIER keyword in the call to the routine that creates the tool (*e.g.* IPLOT or IIMAGE).

---

This routine is written in the IDL language. Its source code can be found in the file `itgetcurrent.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

*Result* = ITGETCURRENT( [, **TOOL**=*variable*] )

## Return Value

Returns the identifier of the current tool in the iTool system. If no tool exists, an empty string ( ' ' ) is returned.

## Arguments

None.

## Keywords

### TOOL

Set this keyword to a named variable in which to return the object reference to the current tool object, or a null object if no tool exists.

## Example

Suppose you have several iPlot tools running in your IDL session, and want to retrieve the iTool identifier for one of them. Select the iPlot tool using the mouse, and issue the following IDL command:

```
idPlot = ITGETCURRENT()
```

The `idPlot` variable would contain the iTool identifier for the selected tool.

Controlling the contents of an existing *iTool* from the IDL command line sometimes requires the use of the *iTool*'s *object reference* rather than its identifier. For example, suppose you have created an *iPlot* tool using the following command:

```
IPLOT, SIN(FINDGEN(361) * !DTOR), COLOR=[0, 0, 255], THICK=2
```

To rotate the plot from the IDL command line, you could use the following statements:

```
idPlot = ITGETCURRENT(TOOL=oPlot)
void = oPlot->DoAction('OPERATIONS/OPERATIONS/ROTATE/ROTATERIGHT')
```

The process of controlling an *iTool* from the IDL command line is discussed in detail in [Appendix A, “Controlling \*iTools\* from the IDL Command Line”](#) in the *iTool Developer's Guide* manual.

## Version History

6.0	Introduced
6.1	Added TOOL keyword

## See Also

[ITCURRENT](#), [ITDELETE](#), [ITRESET](#)

[Appendix A, “Controlling \*iTools\* from the IDL Command Line”](#) in the *iTool Developer's Guide* manual

# ITREGISTER

The ITREGISTER procedure is used to register iTool object classes or other iTool functionality with the IDL Intelligent Tools system. Functionality that is registered with the iTools system is available to all iTools. See the Register methods of the [IDLitTool](#) class for information on how to register functionality with an individual iTool.

This routine is written in the IDL language. Its source code can be found in the file `itregister.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

```
ITREGISTER, Name, ItemName [, /ANNOTATION] [, /DEFAULT]
           [, /FILE_READER] [, /FILE_WRITER] [, TYPES=string] [, /UI_PANEL]
           [, /UI_SERVICE] [, /USER_INTERFACE] [, /VISUALIZATION]
```

## Arguments

### Name

A string containing the name used to refer to the associated class once registration is completed. Subsequent calls to create items of this type will use this name to identify the associated class.

The *Name* argument and the keywords specified (if any) are used to define the iTool *identifier* for the component being registered. If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item. This means that calling ITREGISTER more than once with the same combination of *Name* argument and keywords will replace the previously registered item.

### Note

---

If no keywords are supplied, *Name* is the name of an iTool.

---

### ItemName

A string containing the class name of the object class or user interface routine that is to be associated with *Name*. When an item of name *Name* is requested from the system, an object of this class is created or the specified routine is called.

**Note**

---

If no keywords are supplied, *ItemName* is the name of an iTool class.

---

## Keywords

**Note**

---

Keywords supplied in the call to ITREGISTER but not listed here are passed directly to the underlying objects' registration routines.

---

### ANNOTATION

Set this keyword to indicate that an annotation is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the annotation type, and *ItemName* is the class name of the annotation type's object class.

### DEFAULT

Set this keyword to specify that the item being registered should be the *default item* of its type. Making an item the default places the item first in the list of items of its type. When the iTool system chooses an item, it will use the first item in the list that matches the data type of the selected data. When items are displayed in a list for the user to select from, the default item will appear at the top of the list.

For example, if you register a visualization type with the DEFAULT keyword set, your visualization type will be used by the iTool (assuming the selected data is of the proper type) unless you specifically choose a different visualization type.

**Note**

---

If you register more than one item with the DEFAULT keyword set, the *last* item registered will appear *first* in the list of items of that type.

---

### FILE\_READER

Set this keyword to indicate that a file reader is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the file reader, and *ItemName* is the class name of the file reader's object class.

## FILE\_WRITER

Set this keyword to indicate that a file writer is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the file writer, and *ItemName* is the class name of the file writer's object class.

## TYPES

This keyword is only used in conjunction with the `UI_PANEL` keyword.

Set this keyword equal to a string or string array containing iTTool types with which the UI panel should be associated. When the registered type of a UI panel matches the registered type of an iTTool, the panel will be displayed as part of the iTTool's interface.

## UI\_PANEL

Set this keyword to indicate that a UI panel is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the panel and *ItemName* is the routine that should be called when the panel is created.

To specify that the UI panel is associated with a particular iTTool or iTTools, set the `TYPES` keyword to the iTTool types that should expose this panel.

## UI\_SERVICE

Set this keyword to indicate that a UI service is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the UI service and *ItemName* is the routine that should be called to execute the service.

## USER\_INTERFACE

Set this keyword to indicate that a user interface is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the user interface, and *ItemName* is the name of the user interface procedure.

## VISUALIZATION

Set this keyword to indicate that a visualization is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the visualization type, and *ItemName* is the class name of the visualization type's object class.

## Examples

Suppose you have an iTool class definition file named `myTool__define.pro`, located in a directory included in IDL's `!PATH` system variable. Register this class with the iTool system with the following command:

```
ITREGISTER, 'My First Tool', 'myTool'
```

Tools defined by the `myTool` class definition file can now be created by the iTool system by specifying the tool name `My First Tool`.

Similarly, suppose you have a user interface service defined in a file named `myUIFileOpen.pro`. Register this UI service with the iTool system with the following command:

```
ITREGISTER, 'My File Open', 'myUIFileOpen', /UI_SERVICE
```

Finally, suppose you have a user interface panel defined in a file named `myPanel.pro`, and that you want this panel to be added to the user interface of iTools registered with the `TYPES` property set to `MYTOOL`. Register this UI panel with the iTool system with the following command:

```
ITREGISTER, 'My Panel', 'myPanel', /UI_PANEL, TYPES = 'MYTOOL'
```

## Version History

6.0	Introduced
6.1	Added <code>ANNOTATION</code> , <code>DEFAULT</code> , <code>FILE_READER</code> , <code>FILE_WRITER</code> , and <code>USER_INTERFACE</code> keywords

# ITRESET

The ITRESET procedure resets the IDL iTools session. When called, all active tools and overall system management is destroyed and associated resources released.

This routine is written in the IDL language. Its source code can be found in the file `itreset.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

```
ITRESET[, /NO_PROMPT]
```

## Arguments

None

## Keywords

### NO\_PROMPT

Set this keyword to disable prompting the user before resetting the system. If this keyword is set, the user is not presented with a prompt and the reset is performed immediately.

## Examples

The iTool Data Manager system maintains your data during the entire IDL session, unless ITRESET is used. This example shows how the data is maintained and how ITRESET is used to clear the iTool Data Manager.

Read in plot data and load it into an iPlot tool at the IDL Command Line:

```
file = FILEPATH('dirty_sine.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [256, 1])
I PLOT, data
```

Delete this tool with the ITDELETE procedure at the IDL Command Line:

```
ITDELETE
```

Read in surface data and load it into an iSurface tool at the IDL Command Line:

```
file = FILEPATH('elevbin.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [64, 64])
```

```
ISURFACE, data
```

Use **Window** → **Data Manager...** to access the Data Manager Browser. The browser contains both plot and surface parameters. Although the iPlot tool was deleted, its data remains in the Data Manager. Click **Dismiss**.

Use **File** → **New** → **iPlot** to create an empty iPlot tool. If you want to load the plot data in the Data Manager into this tool, use **Insert** → **Visualization** to access the Insert Visualization dialog, which allows you to specify the plot data to be displayed.

At the IDL Command Line, enter:

```
ITRESET, /NO_PROMPT
```

The two iTools are deleted and the data in the Data Manager is released. To verify the data is released, create an empty iSurface tool at the IDL Command Line:

```
ISURFACE
```

Use **Window** → **Data Manager...** to access the Data Manager Browser. No data appears in the browser. The iTool Data Manager is empty. Click **Dismiss**.

At the IDL Command Line, enter:

```
ITRESET, /NO_PROMPT
```

# ITRESOLVE

The ITRESOLVE procedure resolves all IDL code within the iTools directory, as well as all other IDL code required for the iTools framework. This procedure is useful for constructing SAVE files containing user code that requires the iTools framework.

This routine is written in the IDL language. Its source code can be found in the file `itresolve.pro` in the `lib/itools` subdirectory of the IDL distribution.

## Syntax

```
ITRESOLVE [, PATH=string]
```

## Arguments

None.

## Keywords

### PATH

Set this keyword to a string containing the full path to the iTools directory. The default is to use the `lib/itools` subdirectory within which the ITRESOLVE procedure resides.

## Examples

Suppose you wish to create a SAVE file that contains all of the code necessary to run an iTool you have created with the name `mytool`. First compile all of your own code:

```
.COMPILE mytool
```

Now compile all of the iTools code:

```
ITRESOLVE
```

Finally, create the SAVE file:

```
SAVE, FILE='mytool.sav', /ROUTINES, /COMPRESS
```

# IVOLUME

The IVOLUME procedure creates an iTool and associated user interface (UI) configured to display and manipulate volume data.

---

## Note

If no arguments are specified, the IVOLUME procedure creates an empty Volume tool.

---

This routine is written in the IDL language. Its source code can be found in the file `ivolume.pro` in the `lib/itools` subdirectory of the IDL distribution.

For more information on using the iVolume tool, see “[Working with Volumes](#)” in the *iTool User’s Guide* manual.

---

## Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

---

## Syntax

IVOLUME[, Vol<sub>0</sub>[, Vol<sub>1</sub>][, Vol<sub>2</sub>, Vol<sub>3</sub>]]

 [, [XYZ]TITLE=*string*]

## Arguments

### Note

---

The volume data provided in the  $Vol_0$ ,  $Vol_1$ ,  $Vol_2$ , and  $Vol_3$  arguments are scaled into byte values (ranging from 0 to 255) with the BYTSCL function to facilitate using the volume data as indices into the RGB and OPACITY tables. This scaling is done for display purposes only; the iVolume tool maintains the original data as supplied with the arguments for use in other operations. The minimum and maximum values used by the BYTSCL function may be adjusted in the volume's property sheet. By default, the tool uses the minimum and maximum values of all volume parameters to uniformly byte-scale the data.

---

### $Vol_0$ , $Vol_1$ , $Vol_2$ , $Vol_3$

A three-dimensional array of any numeric type containing volume data. Arrays of strings, structures, object references, and pointers are not allowed. If more than one volume is specified, they must all have the same dimensions.

The number of volumes present and the value of the `COMPOSITE_FUNCTION` keyword determine how the volume data is rendered by the `iVolume` tool. The number of volume arguments determine how the `src` and `srcalpha` values for the `COMPOSITE_FUNCTION` are computed:

- If  $Vol_0$  is the only argument present, the values of `src` and `srcalpha` are taken directly from the `RGB` and `OPACITY` tables, as indexed by each volume data sample:

```
src = RGB_TABLE0 [VOL0]
srcalpha = OPACITY_TABLE0 [VOL0]
```

- If  $Vol_0$  and  $Vol_1$  are the only arguments present, the two volumes are blended together using independent tables:

```
src = (RGB_TABLE0 [VOL0] * RGB_TABLE1 [VOL1]) / 256
srcalpha = (OPACITY_TABLE0 [VOL0] * OPACITY_TABLE1 [VOL1]) / 256
```

- If all the arguments are present,  $Vol_0$  indexes the red channel of `RGB_TABLE0`,  $Vol_1$  indexes the green channel of `RGB_TABLE0`, and  $Vol_2$  indexes the blue channel of `RGB_TABLE0`. The  $Vol_3$  argument indexes `OPACITY_TABLE0`:

```
src = (RGB_TABLE [VOL0, 0], RGB_TABLE [VOL1, 1], $
      RGB_TABLE [VOL2, 2]) / 256
srcalpha = (OPACITY_TABLE0 [VOL3]) / 256.
```

---

### Note

If all the arguments are present, the composite function cannot be set to the average-intensity projection (`COMPOSITE_FUNCTION = 3`).

---

## Keywords

---

### Note

Keywords to the `IVOLUME` routine that correspond to the names of *registered properties* of the `iVolume` tool must be specified in full, without abbreviation.

---

## AMBIENT

Use this keyword to set the color and intensity of the volume's base ambient lighting. Color is specified as an RGB vector. The default is [255, 255, 255]. `AMBIENT` is applicable only when `LIGHTING_MODEL` is set.

## AUTO\_RENDER

Set this keyword to 1 to always render the volume. The default is to not render the volume each time the tool window is drawn.

## BACKGROUND\_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND\_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW\_NUMBER or VIEW\_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW\_GRID keyword, and the VIEW\_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND\_COLOR keyword would set the background color in the second view only.

## BOUNDS

Set this keyword to a six-element vector of the form  $[x_{min}, y_{min}, z_{min}, x_{max}, y_{max}, z_{max}]$ , which represents the sub-volume to be rendered. This keyword is the same as the SUBVOLUME keyword.

## CLIP\_PLANES

Set this keyword to an array of dimensions  $[4, N]$  specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form  $[A, B, C, D]$ , where  $Ax + By + Cz + D = 0$ . Portions of this object that fall in the half space  $Ax + By + Cz + D > 0$  will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

---

**Note**

Clipping planes are equivalent to the obsolete cutting planes. If defined, CUTTING\_PLANES will be applied first, then the CLIP\_PLANES (until a maximum number of planes is reached).

---

---

**Note**

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

---

## COMPOSITE\_FUNCTION

The composite function determines the value of a pixel on the viewing plane by analyzing the voxels falling along the corresponding ray, according to one of the following compositing functions:

- 0 = Alpha (default): Alpha-blending. The recursive equation  $dest' = src * sr calpha + dest * (1 - sr calpha)$  is used to compute the final pixel color.
- 1 = MIP: Maximum intensity projection. The value of each pixel on the viewing plane is set to the brightest voxel, as determined by its opacity. The most opaque voxel's color appropriation is then reflected by the pixel on the viewing plane.
- 2 = Alpha sum: Alpha-blending. The recursive equation  $dest' = src + dest * (1 - sr calpha)$  is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.
- 3 = Average: Average-intensity projection. The resulting image is the average of all voxels along the corresponding ray.

---

### Note

This option (COMPOSITE\_FUNCTION = 3) is not supported for 4-channel volumes.

---

The COMPOSITE\_FUNCTION setting is used only when RENDER\_QUALITY is set to 2 (High).

## DEPTH\_CUE

Set this keyword to a two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH\_CUE property is set to [-1, 1],

an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between  $Z_{bright}$  and  $Z_{dim}$  determines the result of the rendering:

- $Z_{bright} < Z_{dim}$ : Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$ : Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$ : Disables depth cueing.

You can disable depth cueing by setting  $z_{bright} = z_{dim}$ . The default is [0.0, 0.0].

## DIMENSIONS

Set this keyword to a two-element vector of the form [width, height] to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

## DISABLE\_SPLASH\_SCREEN

Set this keyword to disable the iTools splash screen. By default, the first time an iTools is run, the splash screen is displayed.

## EXTENTS\_TRANSPARENCY

Set this keyword to an integer that specifies the percent transparency of the volume's boundary wire frame or walls.

## HIDE

Set this keyword to a boolean value indicating whether the volume should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

## HINTS

Set this keyword to specify one of the following acceleration hints:

- 0 = Disables all acceleration hints (default).
- 1 = Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this

process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.

- 2 = Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
- 3 = Selects the two acceleration options described above.

## IDENTIFIER

Set this keyword to a named IDL variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

## INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used to determine the data value for each step on a ray. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

## LIGHTING\_MODEL

Set this keyword to use the current lighting model during rendering in conjunction with a local gradient evaluation.

### Note

---

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

---

## LOCATION

Set this keyword to a two-element vector of the form  $[x, y]$  to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

**Note**

Some X Window managers explicitly ignore any request from the client for window placement. See “[Positioning Top-Level Bases](#)” on page 2487 for additional information.

**MACRO\_NAMES**

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

**NAME**

Set this keyword to a string to specify the name for this visualization. The name is used for tool-related display purposes only.

**NO\_SAVEPROMPT**

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

**OPACITY\_TABLE0**

Set this keyword to a 256-element byte array to specify an opacity table for  $Vol_0$  if  $Vol_0$  or  $Vol_0$  and  $Vol_1$  are present. If all the volume arguments are present, this keyword represents the opacity of the resulting RGBA volume. A value of 0 indicates complete transparency and a value of 255 indicates complete opacity. The default table is a linear ramp.

**OPACITY\_TABLE1**

Set this keyword to a 256-element byte array to specify an opacity table for  $Vol_1$  when  $Vol_0$  and  $Vol_1$  are present. A value of 0 indicates complete transparency and a value of 255 indicates complete opacity. The default table is a linear ramp.

**OVERPLOT**

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

## RENDER\_EXTENTS

Set this keyword to draw a boundary around the rendered volume. The default (`RENDER_EXTENTS = 2`) is to draw a translucent boundary box. Possible values for this keyword are:

- 0 = Do not draw anything around the volume.
- 1 = Draw a wireframe around the volume.
- 2 = Draw a translucent box around the volume

## RENDER\_STEP

Set this keyword to a three element vector of the form  $[x, y, z]$  to specify the stepping factor through the voxel matrix. This keyword is only valid if render quality is set to high (`RENDER_QUALITY = 2`). The default render step is  $[1, 1, 1]$ .

## RENDER\_QUALITY

Set this keyword to determine the quality of the rendered volume. The default (`RENDER_QUALITY = 1`) is low quality. Possible values for this keyword are:

- 1 = Low - Renders volume with a stack of two-dimensional texture maps.
- 2 = High - Use ray-casting rendering, see the `COMPOSITE_FUNCTION` for more details.

## RGB\_TABLE0

Set this keyword to a 3 by 256 or 256 by 3 byte array of RGB color values to specify a color table for  $Vol_0$  if  $Vol_0$  or  $Vol_0$  and  $Vol_1$  are present. If all the arguments are present, this keyword represents the RGB color values of all of these volumes. The default is a linear ramp

## RGB\_TABLE1

Set this keyword to a 3 by 256 or 256 by 3 byte array of RGB color values to specify a color table for  $Vol_1$  when  $Vol_0$  and  $Vol_1$  are present. The default is a linear ramp.

## STYLE\_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If a style of the specified name does not exist, IDL generates an error and the routine exits.

The style is applied using the following rules:

- If the tool exists and `/OVERPLOT` is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

## SUBVOLUME

Set this keyword to a six-element vector of the form  $[x_{min}, y_{min}, z_{min}, x_{max}, y_{max}, z_{max}]$ , which represents the sub-volume to be rendered. This keyword is the same as the `BOUNDS` keyword.

## TITLE

Set this keyword to a string to specify the title for this particular tool. The title is displayed in the title bar of the tool.

## TWO\_SIDED

Set this keyword to force the lighting model to use a two-sided voxel gradient. The two-sided gradient is different from the one-sided gradient (default) in that the absolute value of the inner product of the light direction and the surface gradient is used instead of clamping to 0.0 for negative values.

## VIEW\_GRID

Set this keyword to a two-element vector of the form  $[columns, rows]$  to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified then `VIEW_GRID` is ignored).

## VIEW\_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then `/VIEW_NEXT` will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

**Note**

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

**VIEW\_NUMBER**

Set this keyword to change the currently-selected view to the view specified by the `VIEW_NUMBER` before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

**Note**

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

**VIEW\_TITLE**

Set this keyword equal to a scalar string that will be placed in a text annotation centered horizontally in the current view, near the top. The text will be created with the properties (size, style, color, etc.) defined for text annotations in the current tool style.

**VOLUME\_DIMENSIONS**

A 3-element vector specifying the volume dimensions in terms of user data units. For example, specifying `[0.1, 0.1, 0.1]` would cause the volume to be rendered into a region that is 0.1 data units long on each side of the volume cube. If this parameter is not specified, the volume is rendered into a region the same size as the number of samples, with an origin of `[0, 0, 0]`. In this case, a volume with sample size of `[20, 25, 20]` would render into the region `[0:19, 0:24, 0:19]` in user data units. Use the `VOLUME_LOCATION` keyword to specify a different origin.

**VOLUME\_LOCATION**

A 3-element vector specifying the volume location in user data units. Use this keyword to render the volume so that the first sample voxel appears at the specified location, instead of at `[0, 0, 0]`, the default. Specify the location in terms of coordinates after the application of the `VOLUME_DIMENSIONS` values. For example, if the value of the `VOLUME_DIMENSIONS` keyword is `[0.1, 0.1, 0.1]` and you want the volume to be centered at the origin, set the `VOLUME_LOCATION` keyword to `[-0.05, -0.05, -0.05]`.

## **[XYZ]GRIDSTYLE**

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See **LINestyle** for a list of linestyles.

## **[XYZ]MAJOR**

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

## **[XYZ]MINOR**

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

## **[XYZ]RANGE**

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum.

## **[XYZ]SUBTICKLEN**

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

## **[XYZ]TEXT\_COLOR**

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

## **[XYZ]TICKFONT\_INDEX**

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

## [XYZ]TICKFONT\_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

## [XYZ]TICKFONT\_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

## [XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 18 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

### If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

**If TICKUNITS are specified:**

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

**Note**

---

For more information, see “[XYZ]TICKFORMAT” on page 4790.

---

Used with the LABEL\_DATE function, this property can easily create axes with date/time labels.

**[XYZ]TICKINTERVAL**

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

**[XYZ]TICKLAYOUT**

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

**Note**

---

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

---

**[XYZ]TICKLEN**

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

**[XYZ]TICKNAME**

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

**[XYZ]TICKUNITS**

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.

- ""- Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

---

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

---

## [XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

## [XYZ]TITLE

Set this keyword to a string representing the title of the specified axis.

## ZBUFFER

Set this keyword to clip the rendering to the current Z-buffer and then update the buffer.

## ZERO\_OPACITY\_SKIP

Set this keyword to skip voxels with an opacity of 0. This keyword can increase the output contrast of MIP (MAXIMUM\_INTENSITY) projections by allowing the background to show through. If this keyword is set, voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the keyword) continues to render voxels with an opacity of zero.

## Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the **File** menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to [“Data Import Methods”](#) in Chapter 2 of the *iTool User’s Guide* manual.

## Example 1

This example shows how to use the IDL Command Line to bring data into the iVolume tool.

At the IDL Command Line, enter:

```
file = FILEPATH('clouds3d.dat', $
  SUBDIRECTORY = ['examples', 'data'])
RESTORE, file
IVOLUME, clouds
```

Derive an interval volume by selecting **Operations** → **Volume** → **Interval Volume**. In the Interval Volume Value Selector dialog, change the minimum value to 0.2 and the **Decimate: % of original surface** slider to 20, then click **OK**.

The following figure displays the output of this example:

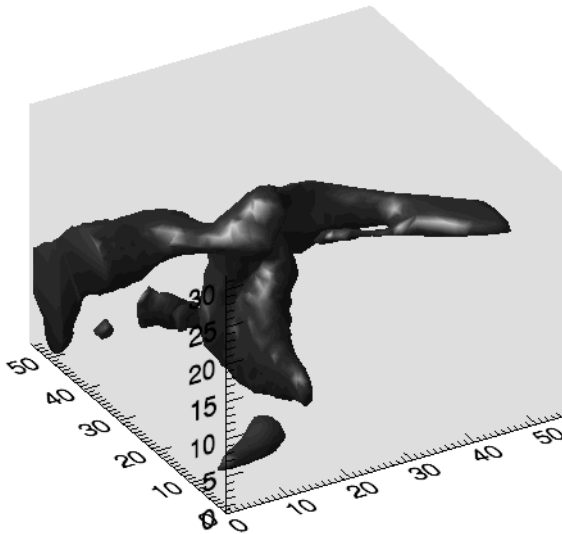

Figure 3-63: Cloud Interval Volume iVolume Example

## Example 2

This example shows how to use the iTool **File** → **Open** command to load binary data into the iVolume tool.

At the IDL Command Line, enter:

## IVOLUME

Select **File** → **Open** to display the Open dialog, then browse to find `head.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

In the Binary Template dialog, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** `Byte` (unsigned 8-bits)
- **Number of Dimensions:** 3
- **1st Dimension Size:** 80
- **2nd Dimension Size:** 100
- **3rd Dimension Size:** 57

Click **OK** to close the New Field dialog and the Binary Template dialog, and the image is displayed.

**Note**

---

For more information on using the Binary Template to import data, see [“Using the BINARY\\_TEMPLATE Interface”](#) on page 164.

---

Select **Operations** → **Volume** → **Isosurface**, and insert an isosurface with a value of 60, decimated to 20% of the original surface.

The following figure displays the output of this example:

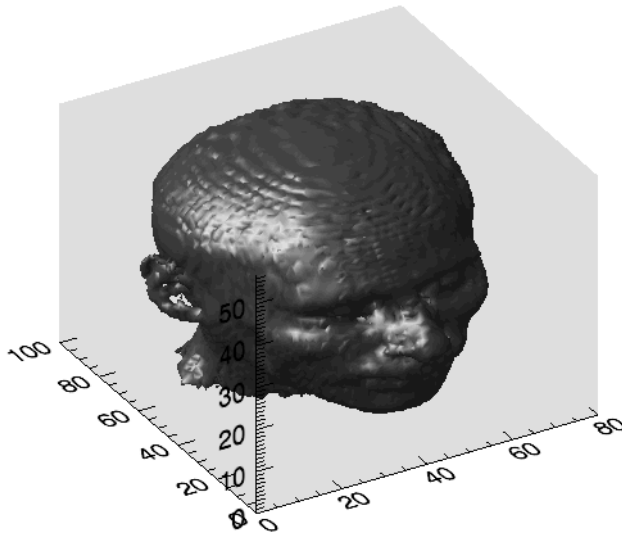

Figure 3-64: Human Head MRI Isosurface iVolume Example

### Example 3

This example shows how to use the **File** → **Import** command to load binary data into the iVolume tool.

At the IDL Command Line, enter:

```
IVOLUME
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `jet.dat` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Volume** and click **Finish**.

The Binary Template wizard is displayed. In the Binary Template, change **File's byte ordering** to **Little Endian**. Then, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** data (or a name of your choosing)

- **Type:** Byte (unsigned 8-bits)
- **Number of Dimensions:** 3
- **1st Dimension Size:** 81
- **2nd Dimension Size:** 40
- **3rd Dimension Size:** 101

Click **OK** to close the New Field dialog and the Binary Template dialog, and the volume is displayed.

Select **Operations** → **Volume** → **Image Plane** to display a plane in the  $x$ -direction. Double-click on the plane to access its properties through the property sheet. Change the **Orientation** setting to  $z$ . You can drag the image to see it at different  $z$  values by clicking on the edge of the image plane.

The following figure displays the output of this example:

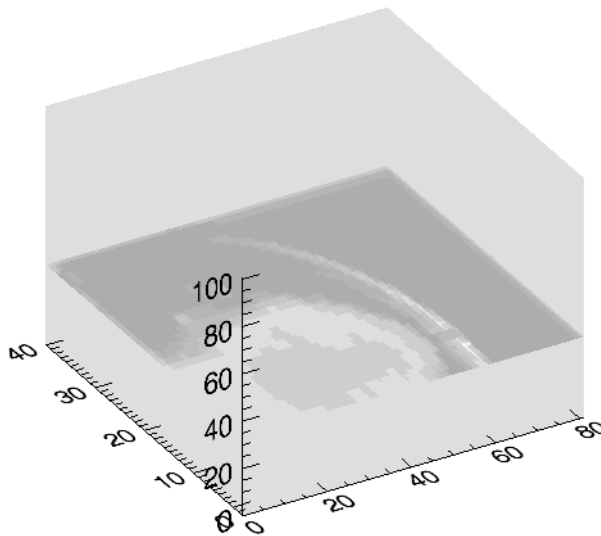

Figure 3-65: Plasma Jet Image Plane iVolume Example

## Example 4

This example shows how to use a second volume argument to cut away a section of the first volume argument.

First, load the MRI head data into IDL. At the IDL Command Line, enter:

```
file = FILEPATH('head.dat', SUBDIRECTORY = ['examples', 'data'])
data0 = READ_BINARY(file, DATA_DIMS = [80, 100, 57])
```

Then, create the second volume that will cut away the upper left corner of the head. At the IDL Command Line, enter:

```
data1 = BYTARR(80, 100, 57) + 1B
data1[0:39, *, 28:56] = 0B
```

Derive the color and opacity tables for the second volume. At the IDL Command Line, enter:

```
rgbTable1 = [[BYTARR(256)], [BYTARR(256)], [BYTARR(256)]]
rgbTable1[1, *] = [255, 255, 255]
opacityTable1 = BYTARR(256)
opacityTable1[1] = 255
```

Now, display the two volumes. At the IDL Command Line, enter:

```
IVOLUME, data0, data1, RGB_TABLE1 = rgbTable1, $
    OPACITY_TABLE1 = opacityTable1, /AUTO_RENDER
```

The following figure displays the output of this example:

Figure 3-66: Cut Away *i*Volume Example

## Example 5

This example shows how to use all the volume arguments to display an RGB (Red, Green, Blue) volume.

First, create the volumes to contain primary colors (black, red, green, blue, yellow, cyan, magenta, and white) in each corner. At the IDL Command Line, enter:

```
vol0 = BYTARR(32, 32, 32)
vol1 = BYTARR(32, 32, 32)
vol2 = BYTARR(32, 32, 32)
vol3 = BYTARR(32, 32, 32)
vol0[0:15, *, *] = 255
vol1[*, 0:15, *] = 255
vol2[*, *, 0:15] = 255
vol3[*, *, *] = 128
```

Then, derive the color and opacity tables. At the IDL Command Line, enter:

```
loadct, 15
tv1ct, r, g, b, /get
rgbtable = BINDGEN(3, 256)
rgbtable[0, *] = r
rgbtable[1, *] = g
rgbtable[2, *] = b
opacityTable = BINDGEN(256)
```

Now, display the two volumes. At the IDL Command Line, enter:

```
IVOLUME, vol0, vol1, vol2, vol3, RGB_TABLE0 = rgbTable, $
    OPACITY_TABLE0 = opacityTable, /AUTO_RENDER
```

The following figure displays the output of this example:

Figure 3-67: RGB iVolume Example

### Note

The white corner of this example volume is actually gray to distinguish it from the white background.

## Version History

6.0	Introduced
6.1	Added BACKGROUND_COLOR, EXTENTS_TRANSPARENCY, MACRO_NAMES, and STYLE_NAME keywords
6.1	Deprecated the CUTTING_PLANE keyword
6.2	Added DISABLE_SPLASH_SCREEN and VIEW_TITLE keywords

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

# JOURNAL

The JOURNAL procedure provides a record of an interactive session by saving, in a file, all text entered from the terminal in response to the IDL prompt. The first call to JOURNAL starts the logging process. The read-only system variable !JOURNAL is set to the file unit used. To stop saving commands and close the file, call JOURNAL with no parameters. If logging is in effect and JOURNAL is called with a parameter, the parameter is simply written to the journal file.

## Syntax

```
JOURNAL [, Arg]
```

## Arguments

### Arg

A string containing the name of the journal file to be opened or text to be written to an open journal file. If *Arg* is not supplied, and a journal file is not already open, the file `idlsave.pro` is used. Once journaling is enabled, a call to JOURNAL with *Arg* supplied causes *Arg* to be written into the journal file. Calling JOURNAL without *Arg* while journaling is in progress closes the journal file and ends the logging process.

## Keywords

None.

## Examples

To begin journaling to the file `myjournal.pro`, enter:

```
JOURNAL, 'myjournal.pro'
```

Any commands entered at the IDL prompt are recorded in the file until IDL is exited or the JOURNAL command is entered without an argument.

As an example of Journaling in IDL, consider the following IDL statements:

```
; Start journaling to file demo.pro:
JOURNAL, 'demo.pro'
; Prompt for input:
PRINT, 'Enter a number:'
```

```

; Read the user response into variable Z:
READ, Z
; Send an IDL comment to the journal file using JOURNAL:
JOURNAL, '; This was inserted with JOURNAL.'
; Send another comment using PRINTF:
PRINTF, '!JOURNAL, '; This was inserted with PRINTF.'
; End journaling:
JOURNAL

```

If these statements are executed by a user named Doug on a Sun workstation named quixote, the resulting journal file `demo.pro` will look like the following:

```

; IDL Version 5.3 (sunos sparc)
; Journal File for doug@quixote
; Working directory: /home/doug/IDL
; Date: Mon Sept 9 14:38:24 1999

PRINT, 'Enter a number:'
; Enter a number:
READ, Z
; 87
; This was inserted with JOURNAL.
; This was inserted with PRINTF.
PRINTF, '!JOURNAL, '; This was inserted with PRINTF.'

```

Note that the input data to the `READ` statement is shown as a comment. In addition, the statement to insert the text using `JOURNAL` does not appear, while the statement using `PRINTF` does appear.

# JULDAY

The JULDAY function calculates the Julian Day Number (which begins at noon) for the specified date. This is the inverse of the CALDAT procedure.

---

**Note**

The Julian calendar, established by Julius Caesar in the year 45 BCE, was corrected by Pope Gregory XIII in 1582, excising ten days from the calendar. The CALDAT procedure reflects the adjustment for dates after October 4, 1582. See the example below for an illustration.

---

---

**Note**

A small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, seconds. This offset is given by the larger of EPS and EPS\*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR (using double precision). For typical Julian dates, this offset is approximately  $6 \times 10^{-10}$  (which corresponds to  $5 \times 10^{-5}$  seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

---

---

**Note**

Calendar dates must be in the range 1 Jan 4716 B.C.E. to 31 Dec 5000000, which corresponds to Julian values -1095 and 1827933925, respectively.

---

This routine is written in the IDL language. Its source code can be found in the file `julday.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = JULDAY(*Month, Day, Year, Hour, Minute, Second*)

## Return Value

*Result* is of type double-precision if Hour, Minute, or Second is specified, otherwise *Result* is of type long integer. If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of the arrays, returning an array with the same dimensions as the smallest array. If the inputs contain both scalars and arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

## Arguments

### Month

Number of the desired month (1 = January, ..., 12 = December). *Month* can be either a scalar or an array.

### Day

Number of the day of the month (1-31). *Day* can be either a scalar or an array.

### Year

Number of the desired year (e.g., 1994). *Year* can be either a scalar or an array.

### Hour

Number of the hour of the day (0-23). *Hour* can be either a scalar or an array.

### Minute

Number of the minute of the hour (0-59). *Minute* can be either a scalar or an array.

### Second

Number of the second of the minute (0-59). *Second* can be either a scalar or an array.

## Examples

In 1582, Pope Gregory XIII adjusted the Julian calendar to correct for its inaccuracy of slightly more than 11 minutes per year. As a result, the day following October 4, 1582 was October 15, 1582. `JULDAY` follows this convention, as illustrated by the following commands:

```
PRINT, JULDAY(10,4,1582), JULDAY(10,5,1582), JULDAY(10,15,1582)
```

IDL prints:

```
2299160      2299161      2299161
```

Using arrays, this can also be calculated as follows:

```
PRINT, JULDAY(10, [4, 5, 15], 1582)
```

If you are using `JULDAY` to calculate an absolute number of days elapsed, be sure to account for the Gregorian adjustment.

# KEYWORD\_SET

The `KEYWORD_SET` function returns a Boolean value based on the value of the specified expression. It returns a True (1) if its argument is defined and nonzero, and False (0) otherwise. The exact rules used to determine this are given in [Return Value](#) below.

## Syntax

*Result* = `KEYWORD_SET(Expression)`

## Return Value

This function returns True (1) if:

- *Expression* is a scalar or 1-element array with a non-zero value.
- *Expression* is a structure.
- *Expression* is an ASSOC file variable.

`KEYWORD_SET` returns False (0) if:

- *Expression* is undefined.
- *Expression* is a scalar or 1-element array with a zero value.

## Arguments

### Expression

The expression to be tested. *Expression* is usually a named variable.

## Keywords

None.

## Examples

Suppose that you are writing an IDL procedure that has the following procedure definition line:

```
PRO myproc, KEYW1 = keyw1, KEYW2 = keyw2
```

The following command could be used to execute a set of commands only if the keyword `KEYW1` is set (i.e., it is present and nonzero):

```
IF KEYWORD_SET(keyw1) THEN BEGIN
```

The commands to be executed only if `KEYW1` is set would follow.

## KRIG2D

The KRIG2D function interpolates a regularly- or irregularly-gridded set of points  $z = f(x, y)$  using kriging.

The parameters of the data model – the range, nugget, and sill – are highly dependent upon the degree and type of spatial variation of your data, and should be determined statistically. Experimentation, or preferably rigorous analysis, is required.

For  $n$  data points, a system of  $n+1$  simultaneous equations are solved for the coefficients of the surface. For any interpolation point, the interpolated value is:

$$f(x, y) = \sum w_i \cdot C(x_i, y_i, x, y)$$

The following formulas are used to model the variogram functions:

$d(i, j)$  = the distance from point  $i$  to point  $j$ .

$V$  = the variance of the samples.

$C(i, j)$  = the covariance of sample  $i$  with sample  $j$ .

$C(x_0, y_0, x_1, y_1)$  = the covariance of point  $(x_0, y_0)$  with point  $(x_1, y_1)$ .

Exponential covariance:

$$C(d) = \begin{cases} C_1 \cdot e^{(-3 \cdot d/A)} & \text{if } d \neq 0 \\ C_1 + C_0 & \text{if } d = 0 \end{cases}$$

Spherical covariance:

$$C(d) = \begin{cases} 1.0 - (1.5 \cdot d/A) + (0.5 \cdot (d/A)^3) & \text{if } d < a \\ C_1 + C_0 & \text{if } d = 0 \\ 0 & \text{if } d > a \end{cases}$$

---

### Note

The accuracy of this function is limited by the single-precision floating-point accuracy of the machine.

---

This routine is written in the IDL language. Its source code can be found in the file `krig2d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = KRIG2D( Z [, X, Y] [, EXPONENTIAL=vector] [, SPHERICAL=vector]
  [, /REGULAR] [, XGRID=[xstart, xspacing]] [, XVALUES=array]
  [, YGRID=[ystart, yspacing]] [, YVALUES=array] [, GS=[xspacing, yspacing]]
  [, BOUNDS=[xmin, ymin, xmax, ymax]] [, NX=value] [, NY=value] )
```

## Return Value

Returns a two dimensional floating-point array containing the interpolated surface, sampled at the grid points.

## Arguments

### Z, X, Y

Arrays containing the Z, X, and Y coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

## Keywords

### Model Parameter Keywords:

#### EXPONENTIAL

Set this keyword to a two- or three-element vector of model parameters [A,C0, C1] to use an exponential semivariogram model. The model parameters are as follows:

- A — The *range*. At distances beyond A, the semivariogram or covariance remains essentially constant.
- C0 — The *nugget*, which provides a discontinuity at the origin.
- C1 — If specified, C1 is the covariance value for a zero distance, and the variance of the random sample z variable. If only a two element vector is supplied, C1 is set to the sample variance. (C0 + C1) = the *sill*, which is the variogram value for very large distances.

## SPHERICAL

Set this keyword to a two- or three-element vector of model parameters [A, C0, C1] to use a spherical semivariogram model. The model parameters are as follows:

- A — The *range*. At distances beyond A, the semivariogram or covariance remains essentially constant.
- C0 — The *nugget*, which provides a discontinuity at the origin.
- C1 — If specified, C1 is the covariance value for a zero distance, and the variance of the random sample *z* variable. If only a two element vector is supplied, C1 is set to the sample variance.  $(C0 + C1)$  = the *sill*, which is the variogram value for very large distances.

### Input Grid Keywords:

## REGULAR

If set, the Z parameter is a two dimensional array of dimensions  $(n,m)$ , containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, Z. If REGULAR is set, and no grid specifications are present, the grid is set to (0, 1, 2, ...).

## XGRID

A two-element array, [*xstart*, *xspacing*], defining the input grid in the *x* direction. Do not specify both XGRID and XVALUES.

## XVALUES

An *n*-element array defining the *x* locations of  $Z[i,j]$ . Do not specify both XGRID and XVALUES.

## YGRID

A two-element array, [*ystart*, *yspacing*], defining the input grid in the *y* direction. Do not specify both YGRID and YVALUES.

## YVALUES

An *n*-element array defining the *y* locations of  $Z[i,j]$ . Do not specify both YGRID and YVALUES.

## Output Grid Keywords:

### BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in  $x$  and  $y$  of the output grid:  $[xmin, ymin, xmax, ymax]$ . If not specified, the grid limits are set to the extent of  $x$  and  $y$ .

### GS

The output grid spacing. If present, GS must be a two-element vector  $[xs, ys]$ , where  $xs$  is the horizontal spacing between grid points and  $ys$  is the vertical spacing. The default is based on the extents of  $x$  and  $y$ . If the grid starts at  $x$  value  $xmin$  and ends at  $xmax$ , then the default horizontal spacing is  $(xmax - xmin)/(NX-1)$ .  $ys$  is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

### NX

The output grid size in the  $x$  direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

### NY

The output grid size in the  $y$  direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

## Examples

```

; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Get a 26 by 26 grid over the rectangle bounding x and y:
; Range is 0.25 and nugget is 0. These numbers are dependent on
; your data model:
E = [ 0.25, 0.0]

; Get the surface:
R = KRIG2D(Z, X, Y, EXPON = E)

```

Alternatively, get a surface over the unit square, with spacing of 0.05:

```
R = KRIG2D(Z, X, Y, EXPON=E, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])
```

# KURTOSIS

The KURTOSIS function computes the statistical kurtosis of an  $n$ -element vector. Kurtosis is defined as the degree to which a statistical frequency curve is peaked. KURTOSIS calls the IDL function MOMENT.

## Note

---

KURTOSIS subtracts 3 from the raw kurtosis value since 3 is the kurtosis for a Gaussian (normal) distribution. For resulting values, positive values of the kurtosis (leptokurtic) indicate pointed or peaked distributions. Negative values (platykurtic) indicate flattened or non-peaked distributions.

---

## Syntax

*Result* = KURTOSIS(*X* [, /DOUBLE] [, /NAN] )

## Return Value

Returns the floating point or double precision statistical kurtosis. If the variance of the vector is zero, the kurtosis is not defined, and KURTOSIS returns !VALUES.F\_NAN as the result.

## Arguments

**X**

An  $n$ -element, floating-point or double-precision vector.

## Keywords

**DOUBLE**

If this keyword is set, computations are performed in double precision arithmetic.

**NAN**

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:  
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]  
; Compute the kurtosis:  
result = KURTOSIS(x)  
; Print the result:  
PRINT, result
```

IDL prints

```
-1.18258
```

## KW\_TEST

The KW\_TEST function tests the hypothesis that three or more sample populations have the same mean of distribution against the hypothesis that they differ. The populations may be of equal or unequal lengths. The output is a vector containing the test statistic, H, and value indicating the probability of obtaining a value equal to or greater than H from a Chi-square distribution.

This test is an extension of the Rank Sum Test implemented in the RS\_TEST function. When each sample population contains at least five observations, the H test statistic is approximated very well by a Chi-square distribution with DF degrees of freedom. The hypothesis that three or more sample populations have the same mean of distribution is rejected if two or more populations differ with statistical significance. This type of test is often referred to as the Kruskal-Wallis H-Test.

The test statistic H is defined as follows:

$$H = \frac{12}{N_T(N_T + 1)} \sum_{i=0}^{M-1} \frac{R_i^2}{N_i} - 3(N_T + 1)$$

where  $N_i$  is the number of observations in the  $i^{th}$  sample population,  $N_T$  is the total number of observations in all sample populations, and  $R_i$  is the overall rank sum of the  $i^{th}$  sample population.

This routine is written in the IDL language. Its source code can be found in the file `kw_test.pro` in the `lib` subdirectory of the IDL distribution.

### Syntax

*Result* = KW\_TEST( X [, DF=variable] [, MISSING=nonzero\_value] )

### Return Value

The result is a two-element vector containing the test statistic H and the one-tailed probability of obtaining a value of H or greater from a Chi-square distribution.

## Arguments

### X

An integer, single-, or double-precision floating-point array of  $m$ -columns (with  $m \geq 3$ ) and  $n$ -rows. The columns of this two-dimensional array correspond to the sample populations.

If the sample populations are of unequal length, any columns of  $X$  that are shorter than the longest column must be “filled in” by appending a user-specified missing data value. This method requires the use of the `MISSING` keyword. See the *Example* section below for an example of this case.

## Keywords

### DF

Use this keyword to specify a named variable that will contain the number of degrees of freedom used to compute the probability of obtaining a value of  $H$  or greater from the corresponding Chi-square distribution

### MISSING

Set this keyword equal to a non-zero numeric value that has been appended to some columns of  $X$  to make them all a common length of  $n$ .

## Examples

Test the hypothesis that three sample populations have the same mean of distribution against the hypothesis that they differ at the 0.05 significance level. Assume we have the following sample populations:

```
sp0 = [24.0, 16.7, 22.8, 19.8, 18.9]
```

```
sp1 = [23.2, 19.8, 18.1, 17.6, 20.2, 17.8]
```

```
sp2 = [18.2, 19.1, 17.3, 17.3, 19.7, 18.9, 18.8, 19.3]
```

Since the sample populations are of unequal lengths, a missing value must be appended to `sp0` and `sp1`. In this example the missing value is `-1.0` and the 3-column, 8-row input array  $X$  is defined as:

```
X = [[24.0, 23.2, 18.2], $
      [16.7, 19.8, 19.1], $
      [22.8, 18.1, 17.3], $
      [19.8, 17.6, 17.3], $
```

```
[18.9, 20.2, 19.7], $  
[-1.0, 17.8, 18.9], $  
[-1.0, -1.0, 18.8], $  
[-1.0, -1.0, 19.3]]  
PRINT, KW_TEST(X, MISSING = -1)
```

IDL prints:

```
[1.65862, 0.436351]
```

The computed probability (0.436351) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that the three sample populations  $sp_0$ ,  $sp_1$ , and  $sp_2$  have the same mean of distribution.

# L64INDGEN

The L64INDGEN function creates a 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$\text{Result} = \text{L64INDGEN}(D_1 [, \dots, D_8])$$

## Return Value

The return value is the specified 64-bit integer array.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create L, a 10-element by 10-element 64-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
L = L64INDGEN(10, 10)
```

# LA\_CHOLDC

The LA\_CHOLDC procedure computes the Cholesky factorization of an  $n$ -by- $n$  symmetric (or Hermitian) positive-definite array as:

$$\text{If } A \text{ is real: } A = U^T U \text{ or } A = L L^T$$

$$\text{If } A \text{ is complex: } A = U^H U \text{ or } A = L L^H$$

where  $U$  and  $L$  are upper and lower triangular arrays. The  $T$  represents the transpose while  $H$  represents the Hermitian, or transpose complex conjugate.

LA\_CHOLDC is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	spotrf
Double	dpotrf
Complex	cpotrf
Double complex	zpotrf

Table 3-53: LAPACK Routine Basis for LA\_CHOLDC

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

LA\_CHOLDC, *Array* [, /DOUBLE] [, STATUS=*variable*] [, /UPPER]

## Arguments

### Array

A named variable containing the real or complex array to be factorized. Only the lower triangular portion of *Array* is used (or upper if the UPPER keyword is set). This procedure returns *Array* as a lower triangular array from the Cholesky decomposition (upper triangular if the UPPER keyword is set).

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

### STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The array is not positive definite and the factorization could not be completed. The `STATUS` value specifies the order of the leading minor which is not positive definite.

#### Note

---

If `STATUS` is not specified, any error messages will output to the screen.

---

### UPPER

If this keyword is set, then only the upper triangular portion of *Array* is used, and the upper triangular array is returned. The default is to use the lower triangular portion and to return the lower triangular array.

## Examples

The following example program computes the Cholesky decomposition of a given symmetric positive-definite array:

```

PRO ExLA_CHOLDC
; Create a symmetric positive-definite array.
n = 10
seed = 12321
array = RANDOMU(seed, n, n)
array = array ## TRANSPOSE(Array)

; Compute the Cholesky decomposition.
lower = array      ; make a copy
LA_CHOLDC, lower

```

```
; Zero out the upper triangular portion.
for i = 0,n - 2 Do lower[i+1:*,i] = 0

; Reconstruct the array and check the difference
arecon = lower ## TRANSPOSE(lower)
PRINT, 'LA_CHOLDC Error:', MAX(ABS(arecon - array))
END
```

When this program is compiled and run, IDL prints:

```
LA_CHOLDC Error:
4.76837e-007
```

[CHOLDC](#), [LA\\_CHOLMPROVE](#), [LA\\_CHOLSOL](#)

# LA\_CHOLMPROVE

The LA\_CHOLMPROVE function uses Cholesky factorization to improve the solution to a system of linear equations,  $AX = B$  (where  $A$  is symmetric or Hermitian), and provides optional error bounds and backward error estimates.

The LA\_CHOLMPROVE function may also be used to improve the solutions for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the improved solution vector for that set of equations.

LA\_CHOLMPROVE is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sporfs
Double	dporfs
Complex	cporf
Double complex	zporfs

Table 3-54: LAPACK Routine Basis for LA\_CHOLMPROVE

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_CHOLMPROVE( Array, Achol, B, X
  [, BACKWARD_ERROR=variable] [, /DOUBLE]
  [, FORWARD_ERROR=variable] [, /UPPER] )
```

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### Array

The original  $n$ -by- $n$  array of the linear system  $AX = B$ .

## Achol

The  $n$ -by- $n$  Cholesky factorization of *Array*, created by the LA\_CHOLDC procedure.

## B

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

## X

An  $n$ -element input vector, or a  $k$ -by- $n$  array, containing the approximate solutions to the linear system, created by the LA\_CHOLSOL function.

## Keywords

### BACKWARD\_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If  $B$  is a vector containing a single linear system, then BACKWARD\_ERROR will be a scalar. If  $B$  is an array containing  $k$  linear systems, then BACKWARD\_ERROR will be a  $k$ -element vector. The backward error is the smallest relative change in any element of  $A$  or  $B$  that makes  $X$  an exact solution.

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE = 0.

### FORWARD\_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If  $B$  is a vector containing a single linear system, then FORWARD\_ERROR will be a scalar. If  $B$  is an array containing  $k$  linear systems, then FORWARD\_ERROR will be a  $k$ -element vector. For each linear system, if  $X_{true}$  is the true solution corresponding to  $X$ , then the forward error is an estimated upper bound for the magnitude of the largest element in  $(X - X_{true})$  divided by the magnitude of the largest element in  $X$ .

## UPPER

Set this keyword if *A* contains the upper triangular array, rather than the lower triangular array.

---

### Note

If the UPPER keyword is set in LA\_CHOLDC and LA\_CHOLSOL then the UPPER keyword must also be set in LA\_CHOLMPROVE.

---

## Examples

The following example program computes an improved solution to a set of 10 equations:

```

PRO ExLA_CHOLMPROVE
; Create a symmetric positive-definite array.
n = 10
seed = 12321
a = RANDOMU(seed, n, n, /DOUBLE)
a = a ## TRANSPOSE(a)

; Create the right-hand side vector b:
b = RANDOMU(seed, n, /DOUBLE)

; Compute the Cholesky decomposition.
achol = a ; make a copy
LA_CHOLDC, achol

; Compute the first approximation to the solution:
x = LA_CHOLSOL(achol, b)

; Improve the solution and print the error estimate:
xmprove = LA_CHOLMPROVE(a, achol, b, x, $
    FORWARD_ERROR = fError)
PRINT, 'LA_CHOLMPROVE error:', $
    MAX(ABS(a ## xmprove - b))
PRINT, 'LA_CHOLMPROVE Error Estimate:', fError
END

```

When this program is compiled and run, IDL prints:

```

LA_CHOLMPROVE error:    3.9412917e-15
LA_CHOLMPROVE error estimate:    5.1265892e-12

```

[LA\\_CHOLDC](#), [LA\\_CHOLSOL](#)

# LA\_CHOLSOL

The LA\_CHOLSOL function is used in conjunction with the LA\_CHOLDC to solve a set of  $n$  linear equations in  $n$  unknowns,  $AX = B$ , where  $A$  must be a symmetric (or Hermitian) positive-definite array. The parameter  $A$  is input not as the original array, but as its Cholesky decomposition, created by the routine LA\_CHOLDC.

The LA\_CHOLSOL function may also be used to solve for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the solution vector for that set of equations.

LA\_CHOLSOL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	spotrs
Double	dpotrs
Complex	cpotrs
Double complex	zpotrs

Table 3-55: LAPACK Routine Basis for LA\_CHOLSOL

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

*Result* = LA\_CHOLSOL( *A*, *B* [, /DOUBLE] [, /UPPER] )

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### A

The  $n$ -by- $n$  Cholesky factorization of an array, created by the LA\_CHOLDC procedure.

**B**

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

**Keywords****DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

**UPPER**

Set this keyword if  $A$  contains the upper triangular array, rather than the lower triangular array.

**Note**

---

If the `UPPER` keyword is set in the `LA_CHOLDC` then the `UPPER` keyword must also be set in `LA_CHOLSOL`.

---

**Examples**

Given the following system of equations:

$$6u + 15v + 55w = 9.5$$

$$15u + 55v + 225w = 50$$

$$55u + 225v + 979w = 237$$

The solution can be derived by using the following program:

```
PRO ExLA_CHOLSOL
; Define the coefficient array:
a = [[6.0, 15.0, 55.0], $
     [15.0, 55.0, 225.0], $
     [55.0, 225.0, 979.0]]

; Define the right-hand side vector b:
b = [9.5, 50.0, 237.0]

; Compute the Cholesky decomposition of a:
achol = a      ; make a copy
```

```
LA_CHOLDC, achol

; Compute and print the solution:
x = LA_CHOLSOL(achol, b)
PRINT, 'LA_CHOLSOL solution:', x
END
```

When this program is compiled and run, IDL prints:

```
LA_CHOLSOL Solution:
-0.499999      -1.00000      0.500000
```

The exact solution vector is [-0.5, -1.0, 0.5].

# LA\_DETERM

The LA\_DETERM function uses LU decomposition to compute the determinant of a square array.

This routine is written in the IDL language. Its source code can be found in the file `la_determ.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LA_DETERM( A [, /CHECK] [, /DOUBLE] [, ZERO=value] )
```

## Return Value

The result is a scalar of the same type as the input array.

## Arguments

### A

An  $n$ -by- $n$  real or complex array.

## Keywords

### CHECK

Set this keyword to check  $A$  for any singularities. The determinant of a singular array is returned as zero if this keyword is set. Run-time errors may result if  $A$  is singular and this keyword is not set.

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

### ZERO

Use this keyword to set the absolute value of the floating-point zero. A floating-point zero on the main diagonal of a triangular array results in a zero determinant. For single-precision inputs, the default value is  $1.0 \times 10^{-6}$ . For double-precision inputs,

the default value is  $1.0 \times 10^{-12}$ . Setting this keyword to a value less than the default may improve the precision of the result.

## Examples

The following program computes the determinant of a square array:

```
PRO ExLA_DETERM
; Create a square array.
array = [[1d, 2, 1], $
         [4, 10, 15], $
         [3, 7, 1]]
; Compute the determinant.
adeterm = LA_DETERM(array)
PRINT, 'LA_DETERM:', adeterm
END
```

When this program is compiled and run, IDL prints:

```
A_DETERM:
-15.000000
```

## Version History

[DETERM](#), [LA\\_LUDC](#)

# LA\_EIGENPROBLEM

The LA\_EIGENPROBLEM function uses the QR algorithm to compute all eigenvalues  $\lambda$  and eigenvectors  $v \neq 0$  of an  $n$ -by- $n$  real nonsymmetric or complex non-Hermitian array  $A$ , for the eigenproblem  $Av = \lambda v$ . The routine can also compute the left eigenvectors  $u \neq 0$ , which satisfy  $u^H A = \lambda u^H$ .

LA\_EIGENPROBLEM may also be used for the generalized eigenproblem:

$$Av = \lambda Bv \text{ and } u^H A = \lambda u^H B$$

where  $A$  and  $B$  are square arrays,  $v$  are the right eigenvectors, and  $u$  are the left eigenvectors.

LA\_EIGENPROBLEM is based on the following LAPACK routines:

Output Type	Standard LAPACK Routine	Generalized LAPACK Routine
Float	sggevx	sggevx
Double	dgeevx	dggevx
Complex	cgeevx	cggevx
Double complex	zgeevx	zggevx

Table 3-56: LAPACK Routine Basis for LA\_EIGENPROBLEM

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_EIGENPROBLEM( A [, B] [, ALPHA=variable] [, BALANCE=value]
  [, BETA=variable] [, /DOUBLE] [, EIGENVECTORS=variable]
  [, LEFT_EIGENVECTORS=variable] [, NORM_BALANCE = variable]
  [, PERMUTE_RESULT=variable] [, SCALE_RESULT=variable]
  [, RCOND_VALUE=variable] [, RCOND_VECTOR=variable]
  [, STATUS=variable] )
```

## Return Value

The result is a complex  $n$ -element vector containing the eigenvalues.

## Arguments

### A

The real or complex array for which to compute eigenvalues and eigenvectors.

### B

An optional real or complex  $n$ -by- $n$  array used for the generalized eigenproblem. The elements of  $B$  are converted to the same type as  $A$  before computation.

## Keywords

### ALPHA

For the generalized eigenproblem with the  $B$  argument, set this keyword to a named variable in which the numerator of the eigenvalues will be returned as a complex  $n$ -element vector. For the standard eigenproblem this keyword is ignored.

#### Tip

---

The ALPHA and BETA values are useful for eigenvalues which underflow or overflow. In this case the eigenvalue problem may be rewritten as  $\alpha Av = \beta Bv$ .

---

### BALANCE

Set this keyword to one of the following values:

- BALANCE = 0: No balancing is applied to  $A$ .
- BALANCE = 1: Both permutation and scale balancing are performed.
- BALANCE = 2: Permutations are performed to make the array more nearly upper triangular.
- BALANCE = 3: Diagonally scale the array to make the columns and rows more equal in norm.

The default is BALANCE = 1, which performs both permutation and scaling balances. Balancing a nonsymmetric (or non-Hermitian) array is recommended to reduce the sensitivity of eigenvalues to rounding errors.

## BETA

For the generalized eigenproblem with the  $B$  argument, set this keyword to a named variable in which the denominator of the eigenvalues will be returned as a real or complex  $n$ -element vector. For the standard eigenproblem this keyword is ignored.

---

### Tip

The ALPHA and BETA values are useful for eigenvalues which underflow or overflow. In this case, the eigenvalue problem may be rewritten as  $\alpha Av = \beta Bv$ .

---

## DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

## EIGENVECTORS

Set this keyword to a named variable in which the eigenvectors will be returned as a set of row vectors. If this variable is omitted then eigenvectors will not be computed unless the `RCOND_VALUE` or `RCOND_VECTOR` keywords are present.

---

### Note

For the standard eigenproblem the eigenvectors are normalized and rotated to have norm 1 and largest component real. For the generalized eigenproblem the eigenvectors are normalized so that the largest component has  $\text{abs}(\text{real}) + \text{abs}(\text{imaginary}) = 1$ .

---

## LEFT\_EIGENVECTORS

Set this keyword to a named variable in which the left eigenvectors will be returned as a set of row vectors. If this variable is omitted then left eigenvectors will not be computed unless the `RCOND_VALUE` or `RCOND_VECTOR` keywords are present.

---

### Note

Note - For the standard eigenproblem the eigenvectors are normalized and rotated to have norm 1 and largest component real. For the generalized eigenproblem the eigenvectors are normalized so that the largest component has  $\text{abs}(\text{real}) + \text{abs}(\text{imaginary}) = 1$ .

---

## NORM\_BALANCE

Set this keyword to a named variable in which the one-norm of the balanced matrix will be returned. The one-norm is defined as the maximum value of the sum of absolute values of the columns. For the standard eigenproblem, this will be returned as a scalar value; for the generalized eigenproblem this will be returned as a two-element vector containing the  $A$  and  $B$  norms.

## PERMUTE\_RESULT

Set this keyword to a named variable in which the result for permutation balancing will be returned as a two-element vector  $[ilo, ihi]$ . If permute balancing is not done then the values will be  $ilo = 1$  and  $ihi = n$ .

## RCOND\_VALUE

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvalues will be returned as an  $n$ -element vector. If RCOND\_VALUE is present then left and right eigenvectors must be computed.

## RCOND\_VECTOR

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvectors will be returned as an  $n$ -element vector. If RCOND\_VECTOR is present then left and right eigenvectors must be computed.

## SCALE\_RESULT

Set this keyword to a named variable in which the results for permute and scale balancing will be returned. For the standard eigenproblem, this will be returned as an  $n$ -element vector. For the generalized eigenproblem, this will be returned as a  $n$ -by-2 array with the first row containing the permute and scale factors for the left side of  $A$  and  $B$  and the second row containing the factors for the right side of  $A$  and  $B$ .

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- STATUS = 0: The computation was successful.
- STATUS > 0: The QR algorithm failed to compute all eigenvalues; no eigenvectors or condition numbers were computed. The STATUS value indicates that eigenvalues  $ilo:STATUS$  (starting at index 1) did not converge; all other eigenvalues converged.

**Note**

---

If STATUS is not specified, any error messages will be output to the screen.

---

## Examples

Find the eigenvalues and eigenvectors for an array using the following program:

```

PRO ExLA_EIGENPROBLEM
; Create a random array:
n = 4
seed = 12321
array = RANDOMN(seed, n, n)

; Compute all eigenvalues and eigenvectors:
eigenvalues = LA_EIGENPROBLEM(array, $
    EIGENVECTORS = eigenvectors)
PRINT, 'LA_EIGENPROBLEM Eigenvalues:'
PRINT, eigenvalues

; Check the results using the eigenvalue equation:
maxErr = 0d
FOR i = 0, n - 1 DO BEGIN
    ; A*z = lambda*z
    alhs = array ## eigenvectors[*,i]
    arhs = eigenvalues[i]*eigenvectors[*,i]
    maxErr = maxErr > MAX(ABS(alhs - arhs))
ENDFOR
PRINT, 'LA_EIGENPROBLEM Error:', maxErr

; Now try the generalized eigenproblem:
b = IDENTITY(n) + 0.01*RANDOMN(seed, n, n)
eigenvalues = LA_EIGENPROBLEM(Array, B)
PRINT, 'LA_EIGENPROBLEM Generalized Eigenvalues:'
PRINT, EIGENVALUES
END

```

When this program is compiled and run, IDL prints:

```

LA_EIGENPROBLEM eigenvalues:
( -0.593459, 0.566318) ( -0.593459, -0.566318)
( 1.06216, 0.00000) ( 1.61286, 0.00000)
LA_EIGENPROBLEM error: 4.0978193e-07
LA_EIGENPROBLEM generalized eigenvalues:
( -0.574766, 0.567452) ( -0.574766, -0.567452)
( 1.57980, 0.00000) ( 1.08711, 0.00000)

```

# LA\_EIGENQL

The LA\_EIGENQL function computes selected eigenvalues  $\lambda$  and eigenvectors  $z \neq 0$  of an  $n$ -by- $n$  real symmetric or complex Hermitian array  $A$ , for the eigenproblem  $Az = \lambda z$ .

LA\_EIGENQL may also be used for the generalized symmetric eigenproblems:

$$Az = \lambda Bz \text{ or } ABz = \lambda z \text{ or } BAz = \lambda z$$

where  $A$  and  $B$  are symmetric (or Hermitian) and  $B$  is positive definite.

LA\_EIGENQL is based on the following LAPACK routines:

Output Type	Standard Eigenproblem	Generalized
Float	ssyevx, ssyevr, ssyevd	ssygvx, ssygvd
Double	dsyevx, dsyevr, dsyevd	dsygvx, dsygvd
Complex	cheevx, cheevr, cheevd	chegvx, chegvd
Double complex	zheevx, zheevr, zheevd	zhegvx, zhegvd

Table 3-57: LAPACK Routine Basis for LA\_EIGENQL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_EIGENQL( A [, B] [, /DOUBLE] [, EIGENVECTORS=variable]
  [, FAILED=variable] [, GENERALIZED=value] [, METHOD=value]
  [, RANGE=vector] [, SEARCH_RANGE=vector] [, STATUS=variable]
  [, TOLERANCE=value] )
```

## Return Value

The result is a real vector containing the eigenvalues in ascending order.

## Arguments

### A

The real or complex  $n$ -by- $n$  array for which to compute eigenvalues and eigenvectors.  $A$  must be symmetric (or Hermitian).

### B

An optional real or complex  $n$ -by- $n$  array used for the generalized eigenproblem.  $B$  must be symmetric (or Hermitian) and positive definite. The elements of  $B$  are converted to the same type as  $A$  before computation.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

### EIGENVECTORS

Set this keyword to a named variable in which the eigenvectors will be returned as a set of row vectors. If this variable is omitted then eigenvectors will not be computed. All eigenvectors will be returned unless the `RANGE` or `SEARCH_RANGE` keywords are used to restrict the eigenvalue range.

### FAILED

Set this keyword to a named variable in which to return the indices of eigenvectors that did not converge. This keyword is only available for `METHOD = 0`, and will be ignored for other methods.

#### Note

---

Index numbers within `FAILED` start at 1.

---

### GENERALIZED

For the generalized eigenproblem with the optional  $B$  argument, set this keyword to indicate which problem to solve. Possible values are:

- `GENERALIZED = 0` (the default): Solve  $Az = \lambda Bz$ .

- GENERALIZED = 1: Solve  $ABz = \lambda z$ .
- GENERALIZED = 2: Solve  $BAz = \lambda z$ .

This keyword is ignored if argument  $B$  is not present.

## METHOD

Set this keyword to indicate which computation method to use. Possible values are:

- METHOD = 0 (the default): Use tridiagonal decomposition to compute some or all of the eigenvalues and (optionally) eigenvectors.
- METHOD = 1: Use the Relatively Robust Representation (RRR) algorithm to compute some or all of the eigenvalues and (optionally) eigenvectors. This method is unavailable for the generalized eigenproblem with the optional  $B$  argument, and will default to METHOD = 0.

---

### Note

The RRR method may produce *NaN* and *Infinity* floating-point exception messages during normal execution.

---

- METHOD = 2: Use a divide-and-conquer algorithm to compute all of the eigenvalues and (optionally) all eigenvectors. This method is available for either the standard or generalized eigenproblems. For METHOD = 2 the RANGE, SEARCH\_RANGE, and TOLERANCE keywords are ignored, and all eigenvalues are returned.

## RANGE

Set this keyword to a two-element vector containing the indices of the smallest and largest eigenvalues to be returned. The default is  $[0, n-1]$ , which returns all eigenvalues and eigenvectors. This keyword is ignored for METHOD = 2.

## SEARCH\_RANGE

Set this keyword to a two-element floating-point vector containing the lower and upper bounds of the interval to be searched for eigenvalues. The default is to return all eigenvalues and eigenvectors. This keyword is ignored for METHOD = 2. If both RANGE and SEARCH\_RANGE are specified, only the SEARCH\_RANGE values are used.

---

### Note

If the search range does not contain any eigenvalues, then Result, EIGENVECTORS, and FAILED will each be set to a scalar zero.

---

## STATUS

Set this keyword to a named variable that will contain the status of the computation. In all cases STATUS = 0 indicates successful computation. For the standard eigenproblem, possible nonzero values are:

- METHOD = 0, STATUS > 0: STATUS eigenvectors failed to converge. The FAILED keyword contains the indices of the eigenvectors that did not converge.
- METHOD = 1, STATUS < 0 or STATUS > 0: An internal error occurred during the computation.
- METHOD = 2, STATUS > 0: STATUS off-diagonal elements of an intermediate tridiagonal matrix did not converge to zero.

For the generalized eigenproblem, possible nonzero values are:

- METHOD = 0,  $0 < \text{STATUS} \leq n$ : STATUS eigenvectors failed to converge. The FAILED keyword contains the indices of the eigenvectors that did not converge.
- METHOD = 0, STATUS > n: The factorization of  $B$  could not be completed and the computation failed. The value of (STATUS -  $n$ ) specifies the order of the leading minor of  $B$  which is not positive definite.
- METHOD = 2,  $0 < \text{STATUS} \leq n$ : STATUS off-diagonal elements of an intermediate tridiagonal matrix did not converge to zero.
- METHOD = 2, STATUS > n: The factorization of  $B$  could not be completed and the computation failed. The value of (STATUS -  $n$ ) specifies the order of the leading minor of  $B$  which is not positive definite.

---

### Note

If STATUS is not specified, any error messages will be output to the screen.

---

## TOLERANCE

Set this keyword to a scalar giving the absolute error tolerance for the eigenvalues and eigenvectors. For the most accurate eigenvalues, TOLERANCE should be set to  $2 * XMIN$ , where  $XMIN$  is the magnitude of the smallest usable floating-point value. For METHOD = 0, if TOLERANCE is less than or equal to zero, or is unspecified, then a tolerance value of  $EPS * \|T\|_1$  will be used, where  $T$  is the tridiagonal matrix obtained from  $A$ . For METHOD = 1, if TOLERANCE is less than or equal to  $N * EPS * \|T\|_1$ , or is unspecified, then a tolerance value of  $N * EPS * \|T\|_1$  will be used.

For values of *EPS* and *XMIN*, see the [MACHAR](#). This keyword is ignored for *METHOD* = 2.

### Tip

If the *LA\_EIGENQL* routine fails to converge, try setting the *TOLERANCE* to a larger value.

## Examples

Find the eigenvalues and eigenvectors for a symmetric array using the following program:

```

PRO ExLA_EIGENQL
; Create a random symmetric array:
n = 10
seed = 12321
array = RANDOMN(seed, n, n)
array = array + TRANSPOSE(array)

; Compute all eigenvalues and eigenvectors:
eigenvalues = LA_EIGENQL(array, $
    EIGENVECTORS=eigenvectors)

; Check the results using the eigenvalue equation:
maxErr = 0d
FOR i=0,n-1 DO BEGIN
    ; a*z = lambda*z
    alhs = array ## eigenvectors[* ,i]
    arhs = eigenvalues[i]*eigenvectors[* ,i]
    maxErr = maxErr > MAX(ABS(alhs - arhs))
ENDFOR
PRINT, 'LA_EIGENQL error:', maxErr

; Compute the three largest eigenvalues:
eigenvalues = LA_EIGENQL(array, $
    EIGENVECTORS = eigenvectors, $
    RANGE = [n-3,n-1])
PRINT, 'LA_EIGENQL eigenvalues:', eigenvalues

; Now try the generalized eigenproblem:
b = IDENTITY(n) + 0.01*RANDOMN(seed,n,n)
; Make B symmetric and positive definite:
b = b ## TRANSPOSE(b)

; Compute the three largest generalized eigenvalues:
eigenvalues = LA_EIGENQL(array, b, RANGE=[n-3,n-1])
PRINT, 'LA_EIGENQL Generalized Eigenvalues:'

```

```
PRINT, Eigenvalues
END
```

When this program is compiled and run, IDL prints:

```
LA_EIGENQL error: 1.3560057e-06
LA_EIGENQL eigenvalues: 3.82993 4.69785 5.61567
LA_EIGENQL generalized eigenvalues:
3.83750 4.74803 5.57692
```

# LA\_EIGENVEC

The LA\_EIGENVEC function uses the QR algorithm to compute all or some of the eigenvectors  $v \neq 0$  of an  $n$ -by- $n$  real nonsymmetric or complex non-Hermitian array  $A$ , for the eigenproblem  $Av = \lambda v$ . The routine can also compute the left eigenvectors  $u \neq 0$ , which satisfy  $u^H A = \lambda u^H$ .

## Note

The left and right eigenvectors returned by LA\_EIGENVEC are normalized to norm 1. Unlike the LA\_EIGENPROBLEM, they are not rotated to have largest component real. Therefore, you may notice slight differences in results between LA\_EIGENVEC and LA\_EIGENPROBLEM.

LA\_EIGENVEC is based on the following LAPACK routines:

Output Type	Eigenvectors	Condition Numbers	Undo Balancing
Float	strevc	strsna	sgebak
Double	dtrevc	dtrsna	dgebak
Complex	ctrevc	ctrsna	cgebak
Double complex	ztrevc	ztrsna	zgebak

Table 3-58: LAPACK Routine Basis for LA\_EIGENVEC

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_EIGENVEC( T, QZ [, BALANCE=value] [, /DOUBLE]
  [, EIGENINDEX=variable] [, LEFT_EIGENVECTORS=variable]
  [, PERMUTE_RESULT=[ilo, ihi]] [, SCALE_RESULT=vector]
  [, RCOND_VALUE=variable] [, RCOND_VECTOR=variable]
  [, SELECT=vector])
```

## Return Value

The result is a complex array containing the eigenvectors as a set of row vectors.

## Arguments

### T

The upper quasi-triangular array containing the Schur form, created by LA\_HQR.

### QZ

The array of Schur vectors, created by LA\_HQR.

## Keywords

### BALANCE

If balancing was applied in the call to LA\_ELMHES, then set this keyword to the same value that was used, in order to apply the backward balancing transform to the eigenvectors. If BALANCE is not specified, then the default is BALANCE = 1.

#### Note

---

If BALANCE is not zero, then both PERMUTE\_RESULT and SCALE\_RESULT must be supplied.

---

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if T is double precision, otherwise the default is DOUBLE = 0.

### EIGENINDEX

If keyword SELECT is used, then set this keyword to a named variable in which the indices of the eigenvalues that correspond to the selected eigenvectors will be returned. If the SELECT keyword is not used then EIGENINDEX will be set to LINDGEN(n).

#### Tip

---

This keyword is most useful for real input arrays when the SELECT keyword is present. In this case, a value of SELECT[j] equal to 1 may produce two eigenvectors if the eigenvalue is part of a complex-conjugate pair.

---

## LEFT\_EIGENVECTORS

Set this keyword to a named variable in which the left eigenvectors will be returned as a set of row vectors. If this variable is omitted then left eigenvectors will not be computed unless the RCOND\_VALUE keyword is present.

## PERMUTE\_RESULT

Set this keyword to a two-element vector containing the  $[ilo, ihi]$  permutation results from the LA\_ELMHES procedure. This keyword must be present if BALANCE = 1 or BALANCE = 2.

## RCOND\_VALUE

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvalues will be returned as an  $n$ -element vector. If RCOND\_VALUE is present then left and right eigenvectors must be computed.

## RCOND\_VECTOR

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvectors will be returned as an  $n$ -element vector.

## SCALE\_RESULT

Set this keyword to an  $n$ -element vector containing the permute and scale balancing results from the LA\_ELMHES procedure. This keyword must be present if BALANCE is not zero.

## SELECT

Set this keyword to an  $n$ -element vector of zeroes or ones that indicates which eigenvectors to compute. There are two cases:

- The original array was real: If the  $j$ -th eigenvalue (as created by LA\_HQR) is real, then if SELECT[ $j$ ] is set to 1, then the  $j$ -th eigenvector will be computed. If the  $j$ -th and  $(j+1)$  eigenvalues form a complex-conjugate pair, then if either SELECT[ $j$ ] or SELECT[ $j+1$ ] is set to 1, then the complex-conjugate pair of  $j$ -th and  $(j+1)$  eigenvectors will be computed.
- The original array was complex: If SELECT[ $j$ ] is set to 1, then the  $j$ -th eigenvector will be computed.

If SELECT is omitted then all eigenvectors are returned.

## Examples

Compute the eigenvalues and selected eigenvectors of a random array using the following program:

```

PRO ExLA_EIGENVEC
; Create a random array:
n = 10
seed = 12321
array = RANDOMN(seed, n, n)

; Reduce to upper Hessenberg and compute Q:
H = LA_ELMHES(array, q, $
PERMUTE_RESULT = permute, SCALE_RESULT = scale)

; Compute eigenvalues, T, and QZ arrays:
eigenvalues = LA_HQR(h, q, PERMUTE_RESULT = permute)

; Compute eigenvectors corresponding to
; the first 3 eigenvalues.
select = [1, 1, 1, REPLICATE(0, n - 3)]
eigenvectors = LA_EIGENVEC(H, Q, $
EIGENINDEX = eigenindex, $
PERMUTE_RESULT = permute, SCALE_RESULT = scale, $
SELECT = select)

PRINT, 'LA_EIGENVEC eigenvalues:'
PRINT, eigenvalues[eigenindex]
END

```

When this program is compiled and run, IDL prints:

```

LA_EIGENVEC eigenvalues:
(-0.278633, 2.55055) (-0.278633, -2.55055)
(2.31208, 0.000000)

```

[EIGENVEC](#), [LA\\_ELMHES](#), [LA\\_HQR](#)

# LA\_ELMHES

The LA\_ELMHES function reduces a real nonsymmetric or complex non-Hermitian array to upper Hessenberg form  $H$ . If the array is real then the decomposition is  $A = Q H Q^T$ , where  $Q$  is orthogonal. If the array is complex Hermitian then the decomposition is  $A = Q H Q^H$ , where  $Q$  is unitary. The superscript T represents the transpose while superscript H represents the Hermitian, or transpose complex conjugate.

LA\_ELMHES is based on the following LAPACK routines:

Output Type	Balance & Reduce	Norm	Optional Q
Float	sgebal, sgehrd	slange	sorghr
Double	dgebal, dgehrd	dlange	dorghr
Complex	cgebal, cgehrd	clange	cunghr
Double complex	zgebal, zgehrd	zlange	zunghr

Table 3-59: LAPACK Routine Basis for LA\_ELMHES

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_ELMHES( Array [, Q] [, BALANCE=value] [, /DOUBLE]
  [, NORM_BALANCE=variable] [, PERMUTE_RESULT=variable]
  [, SCALE_RESULT=variable] )
```

## Return Value

The result is an array of the same type as  $A$  containing the upper Hessenberg form. The Hessenberg array is stored in the upper triangle and the first subdiagonal. Elements below the subdiagonal should be ignored but are not automatically set to zero.

## Arguments

### Array

The  $n$ -by- $n$  real or complex array to reduce to upper Hessenberg form.

### Q

Set this optional argument to a named variable in which the array  $Q$  will be returned. The  $Q$  argument may then be input into LA\_HQR to compute the Schur vectors.

## Keywords

### BALANCE

Set this keyword to one of the following values:

- BALANCE = 0: No balancing is applied to *Array*.
- BALANCE = 1: Both permutation and scale balancing are performed.
- BALANCE = 2: Permutations are performed to make the array more nearly upper triangular.
- BALANCE = 3: Diagonally scale the array to make the columns and rows more equal in norm.

The default is BALANCE = 1, which performs both permutation and scaling balances. Balancing a nonsymmetric array is recommended to reduce the sensitivity of eigenvalues to rounding errors.

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE = 0.

### NORM\_BALANCE

Set this keyword to a named variable in which the one-norm of the balanced matrix will be returned. The one-norm is defined as the maximum value of the sum of absolute values of the columns.

## PERMUTE\_RESULT

Set this keyword to a named variable in which the result for permutation balancing will be returned as a two-element vector  $[ilo, ihi]$ . If permute balancing is not done then the values will be  $ilo = 1$  and  $ihi = n$ .

## SCALE\_RESULT

Set this keyword to a named variable in which the result for permute and scale balancing will be returned as an  $n$ -element vector.

## Examples

See `LA_EIGENVEC` for an example of using this procedure.

## LA\_GM\_LINEAR\_MODEL

The `LA_GM_LINEAR_MODEL` function is used to solve a general Gauss-Markov linear model problem:

$$\text{minimize}_x \|y\|_2 \text{ with constraint } d = Ax + By$$

where  $A$  is an  $m$ -column by  $n$ -row array,  $B$  is a  $p$ -column by  $n$ -row array, and  $d$  is an  $n$ -element input vector with  $m \leq n \leq m+p$ .

The following items should be noted:

- If  $A$  has full column rank  $m$  and the array  $(A \ B)$  has full row rank  $n$ , then there is a unique solution  $x$  and a minimal 2-norm solution  $y$ .
- If  $B$  is square and nonsingular then the problem is equivalent to a weighted linear least-squares problem,  $\text{minimize}_x \|B^{-1}(Ax - d)\|_2$ .
- If  $B$  is the identity matrix then the problem reduces to the ordinary linear least-squares problem,  $\text{minimize}_x \|Ax - d\|_2$ .

`LA_GM_LINEAR_MODEL` is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sggglm
Double	dggglm
Complex	cggglm
Double complex	zggglm

Table 3-60: LAPACK Routine Basis for `LA_GM_LINEAR_MODEL`

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

### Syntax

`Result = LA_GM_LINEAR_MODEL( A, B, D, Y [, /DOUBLE] )`

### Return Value

The result ( $x$ ) is an  $m$ -element vector whose type is identical to  $A$ .

## Arguments

### A

The  $m$ -by- $n$  array used in the constraint equation.

### B

The  $p$ -by- $n$  array used in the constraint equation.

### D

An  $n$ -element input vector used in the constraint equation.

### Y

Set this argument to a named variable, which will contain the  $p$ -element output vector.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

## Examples

Given the constraint equation  $d = Ax + By$ , (where  $A$ ,  $B$ , and  $d$  are defined in the program below) the following example program solves the general Gauss-Markov problem:

```

PRO ExLA_GM_LINEAR_MODEL
; Define some example coefficient arrays:
a = [[2, 7, 4], $
      [5, 1, 3], $
      [3, 3, 6], $
      [4, 5, 2]]
b = [[-3, 2], $
      [1, 5], $
      [2, 9], $
      [4, 1]]

```

```

; Define a sample left-hand side vector D:
d = [-1, 2, -3, 4]

; Find and print the solution x:
x = LA_GM_LINEAR_MODEL(a, b, d, y)
PRINT, 'LA_GM_LINEAR_MODEL solution:'
PRINT, X
PRINT, 'LA_GM_LINEAR_MODEL 2-norm solution:'
PRINT, Y
END

```

When this program is compiled and run, IDL prints:

```

LA_GM_LINEAR_MODEL solution:
    1.04668    0.350346    -1.28445
LA_GM_LINEAR_MODEL 2-norm solution:
    0.151716    0.0235733

```

[LA\\_LEAST\\_SQUARE\\_EQUALITY](#), [LA\\_LEAST\\_SQUARES](#)

# LA\_HQR

The LA\_HQR function uses the multishift QR algorithm to compute all eigenvalues of an  $n$ -by- $n$  upper Hessenberg array. The LA\_ELMHES routine can be used to reduce a real or complex array to upper Hessenberg form suitable for input to this procedure. LA\_HQR may also be used to compute the matrices  $T$  and  $QZ$  from the Schur decomposition  $A = (QZ) T (QZ)^H$ .

LA\_HQR is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	shseqr
Double	dhseqr
Complex	chseqr
Double complex	zhseqr

Table 3-61: LAPACK Routine Basis for LA\_HQR

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

*Result* = LA\_HQR( $H$  [,  $Q$ ] [, /DOUBLE] [, PERMUTE\_RESULT=[*ilo*, *ihi*]] [, STATUS=*variable*] )

## Return Value

The result is an  $n$ -element complex vector.

## Arguments

### H

An  $n$ -by- $n$  upper Hessenberg array, created by the LA\_ELMHES procedure. If argument  $Q$  is present, then on return  $H$  is replaced by the Schur form  $T$ . If argument  $Q$  is not present then  $H$  is unchanged.

**Q**

Set this optional argument to the array  $Q$  created by the LA\_ELMHES procedure. If argument  $Q$  is present, then on return  $Q$  is replaced by the Schur vectors  $QZ$ .

**Keywords****DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $H$  is double precision, otherwise the default is `DOUBLE = 0`.

**PERMUTE\_RESULT**

Set this keyword to a two-element vector containing the  $[ilo, ihi]$  permutation results from the LA\_ELMHES procedure. The default is  $[1, n]$ , indicating that permute balancing was not done on  $H$ .

**STATUS**

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The algorithm failed to find all eigenvalues in  $30*(ihi - ilo + 1)$  iterations. The `STATUS` value indicates that eigenvalues `ilo:STATUS` (starting at index  $I$ ) did not converge; all other eigenvalues converged.

**Note**

---

If `STATUS` is not specified, any error messages will output to the screen.

---

**Examples**

See LA\_EIGENVEC for an example of using this procedure.

# LA\_INVERT

The LA\_INVERT function uses LU decomposition to compute the inverse of a square array.

LA\_INVERT is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgetrf, sgetri
Double	dgetrf, dgetri
Complex	cgetrf, cgetri
Double complex	zgetrf, zgetri

Table 3-62: LAPACK Routine Basis for LA\_INVERT

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

*Result* = LA\_INVERT( *A* [, /DOUBLE] [, STATUS=*variable*] )

## Return Value

The result is an array of the same dimensions as the input array.

## Arguments

### A

The *n*-by-*n* array to be inverted.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *A* is double precision, otherwise the default is DOUBLE = 0.

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The array is singular and the inverse could not be computed. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

---

### Note

If `STATUS` is not specified, any error messages will be output to the screen.

---

## Examples

The following program computes the inverse of a square array:

```
PRO ExLA_INVERT
; Create a square array.
array = [[1d, 2, 1], $
         [4, 10, 15], $
         [3, 7, 1]]
; Compute the inverse and check the error.
ainv = LA_INVERT(array)
PRINT, 'LA_INVERT Identity Matrix:'
PRINT, ainv ## array
END
```

When this program is compiled and run, IDL prints:

```
A_INVERT Identity Matrix:
1.00000000  1.7763568e-015  6.6613381e-016
0.00000000  1.00000000    1.2212453e-015
0.00000000  0.00000000    1.00000000
```

## Version History

# LA\_LEAST\_SQUARE\_EQUALITY

The LA\_LEAST\_SQUARE\_EQUALITY function is used to solve the linear least-squares problem:

$$\text{Minimize}_x \|Ax - c\|_2 \text{ with constraint } Bx = d$$

where  $A$  is an  $n$ -column by  $m$ -row array,  $B$  is an  $n$ -column by  $p$ -row array,  $c$  is an  $m$ -element input vector, and  $d$  is a  $p$ -element input vector with  $p \leq n \leq m+p$ . If  $B$  has full row rank  $p$  and the array  $\begin{pmatrix} A \\ B \end{pmatrix}$  has full column rank  $n$ , then a unique solution exists.

LA\_LEAST\_SQUARE\_EQUALITY is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sggls
Double	dggls
Complex	cggls
Double complex	zggls

Table 3-63: LAPACK Routine Basis for LA\_LEAST\_SQUARE\_EQUALITY

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_LEAST_SQUARE_EQUALITY(A, B, C, D [, /DOUBLE]
[, RESIDUAL=variable])
```

## Return Value

The result ( $x$ ) is an  $n$ -element vector.

## Arguments

### A

The  $n$ -by- $m$  array used in the least-squares minimization.

**B**

The  $n$ -by- $p$  array used in the equality constraint.

**C**

An  $m$ -element input vector containing the right-hand side of the least-squares system.

**D**

A  $p$ -element input vector containing the right-hand side of the equality constraint.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

### RESIDUAL

Set this keyword to a named variable in which to return a scalar giving the residual sum-of-squares for `Result`. If  $n = m + p$  then `RESIDUAL` will be zero.

## Examples

Given the following system of equations:

$$\begin{aligned} 2t + 5u + 3v + 4w &= 9 \\ 7t + u + 3v + 5w &= 1 \\ 4t + 3u + 6v + 2w &= 2 \end{aligned}$$

with constraints,

$$\begin{aligned} -3t + u + 2v + 4w &= -4 \\ 2t + 5u + 9v + 1w &= 4 \end{aligned}$$

find the solution using the following program:

```
PRO ExLA_LEAST_SQUARE_EQUALITY
; Define the coefficient array:
a = [[2, 5, 3, 4], $
      [7, 1, 3, 5], $
      [4, 3, 6, 2]]
```

```

; Define the constraint array:
b = [[-3, 1, 2, 4], $
      [2, 5, 9, 1]]

; Define the right-hand side vector c:
c = [9, 1, 2]

; Define the constraint right-hand side d:
d = [-4, 4]

; Find and print the minimum norm solution of a:
x = LA_LEAST_SQUARE_EQUALITY(a, b, c, d)
PRINT, 'LA_LEAST_SQUARE_EQUALITY solution:'
PRINT, x
END

```

When this program is compiled and run, IDL prints:

```

LA_LEAST_SQUARE_EQUALITY solution:
      0.651349      2.72695      -1.14638      -0.620036

```

# LA\_LEAST\_SQUARES

The LA\_LEAST\_SQUARES function is used to solve the linear least-squares problem:

$$\text{Minimize}_x \|Ax - b\|_2$$

where  $A$  is a (possibly rank-deficient)  $n$ -column by  $m$ -row array,  $b$  is an  $m$ -element input vector, and  $x$  is the  $n$ -element solution vector. There are three possible cases:

- If  $m \geq n$  and the rank of  $A$  is  $n$ , then the system is overdetermined and a unique solution may be found, known as the least-squares solution.
- If  $m < n$  and the rank of  $A$  is  $m$ , then the system is under determined and an infinite number of solutions satisfy  $Ax - b = 0$ . In this case, the solution is found which minimizes  $\|x\|_2$ , known as the minimum norm solution.
- If  $A$  is rank deficient, such that the rank of  $A$  is less than  $\text{MIN}(m, n)$ , then the solution is found which minimizes both  $\|Ax - b\|_2$  and  $\|x\|_2$ , known as the minimum-norm least-squares solution.

The LA\_LEAST\_SQUARES function may also be used to solve for multiple systems of least squares, with each column of  $b$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the solution vector for that set of equations.

LA\_LEAST\_SQUARES is based on the following LAPACK routines:

Output Type	LAPACK Routines
Float	sgels, sgelsy, sgelss, sgelsd
Double	dgels, dgelsy, dgelss, dgelsd
Complex	cgels, cgelsy, cgelss, cgelsd
Double complex	zgels, zgelsy, zgelss, zgelsd

Table 3-64: LAPACK Routine Basis for LA\_LEAST\_SQUARES

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_LEAST_SQUARES( A, B [, /DOUBLE] [, METHOD=value]
  [, RANK=variable] [, RCONDITION=value] [, RESIDUAL=variable]
  [, STATUS=variable] )
```

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### A

The  $n$ -by- $m$  array used in the least-squares system.

### B

An  $m$ -element input vector containing the right-hand side of the linear least-squares system, or a  $k$ -by- $m$  array, where each of the  $k$  columns represents a different least-squares system.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

### METHOD

Set this keyword to indicate which computation method to use. Possible values are:

- `METHOD = 0` (the default): Assume that array  $A$  has full rank equal to  $\min(m, n)$ . If  $m \geq n$ , find the least-squares solution to the overdetermined system. If  $m < n$ , find the minimum norm solution to the under determined system. Both cases use QR or LQ factorization of  $A$ .
- `METHOD = 1`: Assume that array  $A$  may be rank deficient; use a complete orthogonal factorization of  $A$  to find the minimum norm least-squares solution.

- **METHOD = 2:** Assume that array  $A$  may be rank deficient; use singular value decomposition (SVD) to find the minimum norm least-squares solution.
- **METHOD = 3:** Assume that array  $A$  may be rank deficient; use SVD with a divide-and-conquer algorithm to find the minimum norm least-squares solution. The divide-and-conquer method is faster than regular SVD, but may require more memory.

## RANK

Set this keyword to a named variable in which to return the effective rank of  $A$ . If **METHOD = 0** or the array is full rank, then **RANK** will have the value  $\text{MIN}(m, n)$ .

## RCONDITION

Set this keyword to the reciprocal condition number used as a cutoff value in determining the effective rank of  $A$ . Arrays with condition numbers larger than  $1/\text{RCONDITION}$  are assumed to be rank deficient. If **RCONDITION** is set to zero or omitted, then array  $A$  is assumed to be of full rank. This keyword is ignored for **METHOD = 0**.

## RESIDUAL

If  $m > n$  and the rank of  $A$  is  $n$  (the system is overdetermined), then set this keyword to a named variable in which to return the residual sum-of-squares for *Result*. If  $B$  is an  $m$ -element vector then **RESIDUAL** will be a scalar; if  $B$  is a  $k$ -by- $m$  array then **RESIDUAL** will be a  $k$ -element vector containing the residual sum-of-squares for each system of equations. If  $m \leq n$  or  $A$  is rank deficient ( $\text{rank} < n$ ) then the values in **RESIDUAL** will be zero.

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- **STATUS = 0:** The computation was successful.
- **STATUS > 0:** For **METHOD=2** or **METHOD=3**, this indicates that the SVD algorithm failed to converge, and **STATUS** off-diagonal elements of an intermediate bidiagonal form did not converge to zero. For **METHOD=0** or **METHOD=1** the **STATUS** will always be zero.

## Examples

Given the following under determined system of equations:

$$\begin{aligned} 2t + 5u + 3v + 4w &= 3 \\ 7t + u + 3v + 5w &= 1 \\ 4t + 3u + 6v + 2w &= 6 \end{aligned}$$

The following program can be used to find the solution:

```
PRO ExLA_LEAST_SQUARES
; Define the coefficient array:
a = [[2, 5, 3, 4], $
      [7, 1, 3, 5], $
      [4, 3, 6, 2]]

; Define the right-hand side vector b:
b = [3, 1, 6]

; Find and print the minimum norm solution of a:
x = LA_LEAST_SQUARES(a, b)
PRINT, 'LA_LEAST_SQUARES solution:', x
END
```

When this program is compiled and run, IDL prints:

```
LA_LEAST_SQUARES solution:
-0.0376844      0.350628      0.986164      -0.409066
```

# LA\_LINEAR\_EQUATION

The LA\_LINEAR\_EQUATION function uses LU decomposition to solve a system of linear equations,  $AX = B$ , and provides optional error bounds and backward error estimates.

The LA\_LINEAR\_EQUATION function may also be used to solve for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the solution vector for that set of equations.

This routine is written in the IDL language. Its source code can be found in the file `la_linear_equation.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LA_LINEAR_EQUATION( Array, B [, BACKWARD_ERROR=variable]  
[, /DOUBLE] [, FORWARD_ERROR=variable] [, STATUS=variable])
```

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### Array

The  $n$ -by- $n$  array of the linear system  $AX = B$ .

### B

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

## Keywords

### BACKWARD\_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If  $B$  is a vector containing a single linear system, then BACKWARD\_ERROR will be a scalar. If  $B$  is an array containing  $k$  linear systems,

then `BACKWARD_ERROR` will be a  $k$ -element vector. The backward error is the smallest relative change in any element of  $A$  or  $B$  that makes  $X$  an exact solution.

## DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if `Array` is double precision, otherwise the default is `DOUBLE = 0`.

## FORWARD\_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If  $B$  is a vector containing a single linear system, then `FORWARD_ERROR` will be a scalar. If  $B$  is an array containing  $k$  linear systems, then `FORWARD_ERROR` will be a  $k$ -element vector. For each linear system, if  $X_{true}$  is the true solution corresponding to  $X$ , then the forward error is an estimated upper bound for the magnitude of the largest element in  $(X - X_{true})$  divided by the magnitude of the largest element in  $X$ .

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The computation failed because one of the diagonal elements of the LU decomposition is zero. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

### Note

---

If `STATUS` is not specified, any error messages will be output to the screen.

---

## Examples

Given the system of equations:

$$\begin{aligned} 4u + 16000v + 17000w &= 100.1 \\ 2u + \quad 5v + \quad 8w &= 0.1 \\ 3u + \quad 6v + \quad 10w &= 0.01 \end{aligned}$$

The following program can be used to find the solution:

```

PRO ExLA_LINEAR_EQUATION
; Define the coefficient array:
a = [[4, 16000, 17000], $
      [2, 5, 8], $
      [3, 6, 10]]

; Define the right-hand side vector b:
b = [100.1, 0.1, 0.01]

; Compute and print the solution to ax=b:
x = LA_LINEAR_EQUATION(a, b)
PRINT, 'LA_LINEAR_EQUATION solution:', x
end

```

When this program is compiled and run, IDL prints:

```

LA_LINEAR_EQUATION solution:
-0.397432    -0.334865     0.321148

```

The exact solution to 6 decimal places is [-0.397432, -0.334865, 0.321149].

[LA\\_LUDC](#), [LA\\_LUMPROVE](#), [LA\\_LUSOL](#)

# LA\_LUDC

The LA\_LUDC procedure computes the LU decomposition of an  $n$ -column by  $m$ -row array as:

$$A = P L U$$

where  $P$  is a permutation matrix,  $L$  is lower trapezoidal with unit diagonal elements (lower triangular if  $n = m$ ), and  $U$  is upper trapezoidal (upper triangular if  $n = m$ ).

LA\_LUDC is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgetrf
Double	dgetrf
Complex	cgetrf
Double complex	zgetrf

Table 3-65: LAPACK Routine Basis for LA\_LUDC

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

LA\_LUDC, *Array*, *Index* [, /DOUBLE] [, STATUS=*variable*]

## Arguments

### Array

A named variable containing the real or complex array to decompose. This procedure returns *Array* as its LU decomposition.

### Index

An output vector with  $\text{MIN}(m, n)$  elements that records the row permutations which occurred as a result of partial pivoting. For  $1 < j < \text{MIN}(m, n)$ , row  $j$  of the matrix was interchanged with row *Index*[ $j$ ].

**Note**

---

Row numbers within *Index* start at one rather than zero.

---

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

### STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: One of the diagonal elements of *U* is zero. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

**Note**

---

If `STATUS` is not specified, any error messages will output to the screen.

---

## Examples

The following example uses the LU decomposition on a given array, then determines the residual error of using the resulting lower and upper arrays to recompute the original array:

```

PRO ExLA_LUDC
; Create a random array:
n = 20
seed = 12321
array = RANDOMN(seed, n, n)

; Compute LU decomposition.
aludc = array          ; make a copy
LA_LUDC, aludc, index

; Extract the lower and upper triangular arrays.
l = IDENTITY(n)

```

```

u = FLTARR(n, n)
FOR j = 1,n - 1 DO l[0:j-1,j] = aludc[0:j-1,j]
FOR j=0,n - 1 DO u[j:*,j] = aludc[j:*,j]

; Reconstruct array, but with rows permuted.
arecon = l ## u
; Adjust from LAPACK back to IDL indexing.
Index = Index - 1
; Permute the array rows back into correct order.
; Note that we need to loop in reverse order.
FOR i = n - 1,0,-1 DO BEGIN & $
    temp = arecon[* ,i]
    arecon[* , i] = arecon[* ,index[i]]
    arecon[* , index[i]] = temp
ENDFOR
PRINT, 'LA_LUDC Error:', MAX(ABS(arecon - array))
END

```

When this program is compiled and run, IDL prints:

```
LA_LUDC error: 4.76837e-007
```

# LA\_LUMPROVE

The LA\_LUMPROVE function uses LU decomposition to improve the solution to a system of linear equations,  $AX = B$ , and provides optional error bounds and backward error estimates.

The LA\_LUMPROVE function may also be used to improve the solutions for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the improved solution vector for that set of equations.

LA\_LUMPROVE is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgerfs
Double	dgetrfs
Complex	cgetrfs
Double complex	zgetrfs

Table 3-66: LAPACK Routine Basis for LA\_LUMPROVE

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

```
Result = LA_LUMPROVE(Array, Aludc, Index, B, X
  [, BACKWARD_ERROR=variable] [, /DOUBLE]
  [, FORWARD_ERROR=variable])
```

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### Array

The original  $n$ -by- $n$  array of the linear system.

## Aludc

The  $n$ -by- $n$  LU decomposition of *Array*, created by the LA\_LUDC procedure.

## Index

An  $n$ -element input vector, created by the LA\_LUDC procedure, containing the row permutations which occurred as a result of partial pivoting.

## B

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

## X

An  $n$ -element input vector, or a  $k$ -by- $n$  array, containing the approximate solutions to the linear system, created by the LA\_LUSOL function.

## Keywords

### BACKWARD\_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If  $B$  is a vector containing a single linear system, then BACKWARD\_ERROR will be a scalar. If  $B$  is an array containing  $k$  linear systems, then BACKWARD\_ERROR will be a  $k$ -element vector. The backward error is the smallest relative change in any element of  $A$  or  $B$  that makes  $X$  an exact solution.

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE = 0.

### FORWARD\_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If  $B$  is a vector containing a single linear system, then FORWARD\_ERROR will be a scalar. If  $B$  is an array containing  $k$  linear systems, then FORWARD\_ERROR will be a  $k$ -element vector. For each linear system, if  $X_{true}$  is the true solution corresponding to  $X$ , then the forward error is an estimated

upper bound for the magnitude of the largest element in  $(X - X_{true})$  divided by the magnitude of the largest element in  $X$ .

## Examples

The solution to a given system of equations can be derived and improved by using the following program:

```

PRO ExLA_LUMPROVE
; Define the coefficient array:
  a= [[4, 16000, 17000], $
      [2, 5, 8], $
      [3, 6, 10]]
; Compute the LU decomposition:
aludc = a
; make a copy
LA_LUDC, aludc, index

; Define the right-hand side vector B:
b = [100.1, 0.1, 0.01]
; Find the solution to Ax=b:
x = LA_LUSOL(aludc, index, b)
PRINT, 'LA_LUSOL Solution:', x

; Improve the solution:
xnew = LA_LUMPROVE(a, aludc, index, b, x)
PRINT, 'LA_LUMPROVE Solution:', xnew
END

```

When this program is compiled and run, IDL prints:

```

LA_LUSOL Solution:
-0.397355    -0.334742    0.321033
LA_LUMPROVE Solution:
-0.397432    -0.334865    0.321148

```

The exact solution to 6 decimal places is [-0.397432, -0.334865, 0.321149].

# LA\_LUSOL

The LA\_LUSOL function is used in conjunction with the LA\_LUDC procedure to solve a set of  $n$  linear equations in  $n$  unknowns,  $AX = B$ . The parameter  $A$  is not the original array, but its LU decomposition, created by the routine LA\_LUDC.

The LA\_LUSOL function may also be used to solve for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the solution vector for that set of equations.

LA\_LUSOL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgetrs
Double	dgetrs
Complex	cgetrs
Double complex	zgetrs

Table 3-67: LAPACK Routine Basis for LA\_LUSOL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

*Result* = LA\_LUSOL( *A*, *Index*, *B* [, /DOUBLE] )

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### A

The  $n$ -by- $n$  LU decomposition of an array, created by the LA\_LUDC procedure.

### Note

LA\_LUSOL cannot accept any non-square output generated by LA\_LUDC.

## Index

An  $n$ -element input vector, created by the LA\_LUDC procedure, containing the row permutations which occurred as a result of partial pivoting.

## B

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if  $A$  is double precision, otherwise the default is `DOUBLE = 0`.

## Examples

Given the system of equations:

$$\begin{aligned} 4u + 16000v + 17000w &= 100.1 \\ 2u + 5v + 8w &= 0.1 \\ 3u + 6v + 10w &= 0.01 \end{aligned}$$

find the solution can be derived by using the following program:

```
PRO ExLA_LUSOL
; Define the coefficient array:
a = [[4, 16000, 17000], $
      [2, 5, 8], $
      [3, 6, 10]]
; Compute the LU decomposition:
aludc = a
; make a copy
LA_LUDC, aludc, index

; Define the right-hand side vector B:
b = [100.1, 0.1, 0.01]

; Compute and print the solution to Ax=b:
x = LA_LUSOL(aludc, index, b)
PRINT, 'LA_LUSOL Solution:', x
END
```

When this program is compiled and run, IDL prints:

```
LA_LUSOL solution:   -0.397355   -0.334742   0.321033
```

The exact solution to 6 decimal places is [-0.397432, -0.334865, 0.321149].

## LA\_SVD

The LA\_SVD procedure computes the singular value decomposition (SVD) of an  $n$ -columns by  $m$ -row array as the product of orthogonal and diagonal arrays:

$$A \text{ is real: } A = U S V^T$$

$$A \text{ is complex: } A = U S V^H$$

where  $U$  is an orthogonal array containing the left singular vectors,  $S$  is a diagonal array containing the singular values, and  $V$  is an orthogonal array containing the right singular vectors. The superscript  $T$  represents the transpose while the superscript  $H$  represents the Hermitian, or transpose complex conjugate.

If  $n < m$  then  $U$  has dimensions  $(n \times m)$ ,  $S$  has dimensions  $(n \times n)$ , and  $V^H$  has dimensions  $(n \times n)$ . If  $n \geq m$  then  $U$  has dimensions  $(m \times m)$ ,  $S$  has dimensions  $(m \times m)$ , and  $V^H$  has dimensions  $(n \times m)$ . The following diagram shows the array dimensions:

$$\begin{bmatrix} A \end{bmatrix} = \begin{bmatrix} U \end{bmatrix} \cdot \begin{bmatrix} S \end{bmatrix} \cdot \begin{bmatrix} V^T \end{bmatrix} \quad n < m$$

$$\begin{bmatrix} A \end{bmatrix} = \begin{bmatrix} U \end{bmatrix} \cdot \begin{bmatrix} S \end{bmatrix} \cdot \begin{bmatrix} V^T \end{bmatrix} \quad n \geq m$$

LA\_SVD is based on the following LAPACK routines:

Output Type	LAPACK Routine	
	QR Iteration	Divide-and-conquer
Float	sgesvd	sgesdd
Double	dgesvd	dgesdd
Complex	cgesvd	cgesdd
Double complex	zgesvd	zgesdd

Table 3-68: LAPACK Routine Basis for LA\_SVD

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

LA\_SVD, *Array*, *W*, *U*, *V* [, /DOUBLE] [, /DIVIDE\_CONQUER]  
[, STATUS=*variable*]

## Arguments

### Array

The real or complex array to decompose.

### W

On output, *W* is a vector with  $\text{MIN}(m, n)$  elements containing the singular values.

### U

On output, *U* is an orthogonal array with  $\text{MIN}(m, n)$  columns and *m* rows used in the decomposition of *Array*. If *Array* is complex then *U* will be complex, otherwise *U* will be real.

### V

On output, *V* is an orthogonal array with  $\text{MIN}(m, n)$  columns and *n* rows used in the decomposition of *Array*. If *Array* is complex then *V* will be complex, otherwise *V* will be real.

### Note

---

To reconstruct *Array*, you will need to take the transpose or Hermitian of *V*.

---

## Keywords

### DIVIDE\_CONQUER

If this keyword is set, then the divide-and-conquer method is used to compute the singular vectors, otherwise, QR iteration is used. The divide-and-conquer method is faster at computing singular vectors of large matrices, but uses more memory and may produce less accurate singular values.

## DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The computation did not converge. The `STATUS` value specifies how many superdiagonals did not converge to zero.

### Note

---

If `STATUS` is not specified, any error messages will output to the screen.

---

## Examples

Construct a sample input array *A*, consisting of smoothed random values:

```

PRO ExLA_SVD
; Create a smoothed random array:
n = 100
m = 200
seed = 12321
a = SMOOTH(RANDOMN(seed, n, m, /DOUBLE), 5)

; Compute the SVD and check reconstruction error:
LA_SVD, a, w, u, v
arecon = u ## DIAG_MATRIX(w) ## TRANSPOSE(v)
PRINT, 'LA_SVD error:', MAX(ABS(arecon - a))

; Keep only the 15 largest singular values
wfiltered = w
wfiltered[15:*] = 0.0
; Reconstruct the array:
afiltered = u ## DIAG_MATRIX(wfiltered) ## TRANSPOSE(v)
percentVar = 100*(w^2)/TOTAL(w^2)
PRINT, 'LA_SVD Variance:', TOTAL(percentVar[0:14])
END

```

When this program is compiled and run, IDL prints:

```
LA_SVD error:  1.0103030e-014  
LA_SVD variance:      82.802816
```

---

**Note**

More than 80% of the variance is contained in the 15 largest singular values.

# LA\_TRIDC

The LA\_TRIDC procedure computes the LU decomposition of a tridiagonal ( $n \times n$ ) array as  $Array = L U$ , where  $L$  is a product of permutation and unit lower bidiagonal arrays, and  $U$  is upper triangular with nonzero elements only in the main diagonal and the first two superdiagonals.

LA\_TRIDC is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgttrf
Double	dgttrf
Complex	cgttrf
Double complex	zgttrf

Table 3-69: LAPACK Routine Basis for LA\_TRIDC

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

LA\_TRIDC, AL, A, AU, U2, Index [, /DOUBLE] [, STATUS=variable]

## Arguments

### AL

A named vector of length  $(n - 1)$  containing the subdiagonal elements of an array. This procedure returns  $AL$  as the  $(n - 1)$  elements of the lower bidiagonal array from the LU decomposition.

### A

A named vector of length  $n$  containing the main diagonal elements of an array. This procedure returns  $A$  as the  $n$  diagonal elements of the upper array from the LU decomposition.

## AU

A named vector of length  $(n - 1)$  containing the superdiagonal elements of an array. This procedure returns *AU* as the  $(n - 1)$  superdiagonal elements of the upper array.

## U2

An output vector that contains the  $(n - 2)$  elements of the second superdiagonal of the upper array.

## Index

An output vector that records the row permutations which occurred as a result of partial pivoting. For  $1 < j < n$ , row  $j$  of the matrix was interchanged with row *Index*[ $j$ ].

---

**Note**

Row numbers within *Index* start at one rather than zero.

---

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *AL* is double precision, otherwise the default is `DOUBLE = 0`.

### STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: One of the diagonal elements of *U* is zero. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

---

**Note**

If `STATUS` is not specified, any error messages will output to the screen.

---

## Examples

Create a test program to compute the LU decomposition of a tridiagonal array:

```

PRO EX_LA_TRIDC
  ; Create a random tridiagonal array.
  n = 9
  seed = 12321
  AL = RANDOMN(seed, n-1)
  A = RANDOMN(seed, n)
  AU = RANDOMN(seed, n-1)

  ; Construct tridiagonal array.
  Array = DIAG_MATRIX(AL, -1) + DIAG_MATRIX(A) + $
          DIAG_MATRIX(AU, 1)

  ; Compute the LU decomposition.
  LA_TRIDC, AL, A, AU, U2, Index

  ; Adjust from LAPACK back to IDL indexing.
  Index = Index - 1

  ; Create upper and lower arrays.
  Upper = DIAG_MATRIX(A) + $
          DIAG_MATRIX(AU, 1) + DIAG_MATRIX(U2, 2)
  Lower = DIAG_MATRIX(AL, -1) + IDENTITY(n)

  ; To conserve storage, LA_TRIDC keeps all lower diagonal
  ; elements in AL, regardless of row. The Index array
  ; tells which subdiagonals need to be shifted down.
  ; Loop starts at 1 since there aren't any subdiagonals
  ; to the left of the first diagonal element.
  FOR i = 1, n-2 DO BEGIN
    IF (Index[i] NE i) THEN $
      Lower[0:i-1, [i, i+1]] = Lower[0:i-1, [i+1, i]]
  ENDFOR

  ; Permute the row order.
  FOR i = n-2, 0, -1 DO BEGIN
    IF (Index[i] NE i) THEN $
      Lower[* , [i, i+1]] = Lower[* , [i+1, i]]
  ENDFOR

  ; Reconstruct the array and check the difference:
  Arecon = Lower ## Upper
  PRINT, 'LA_TRIDC error:', MAX(ABS(Arecon - Array))
END

```

When this program is compiled and run, IDL prints:

```
LA_TRIDC error: 1.50427e-008
```

[LA\\_TRIMPROVE](#), [LA\\_TRISOL](#)

# LA\_TRIMPROVE

The LA\_TRIMPROVE function improves the solution to a system of linear equations with a tridiagonal array,  $AX = B$ , and provides optional error bounds and backward error estimates.

The LA\_TRIMPROVE function may also be used to improve the solutions for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the improved solution vector for that set of equations.

LA\_TRIMPROVE is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgtrfs
Double	dgtrfs
Complex	cgtrfs
Double complex	zgtrfs

Table 3-70: LAPACK Routine Basis for LA\_TRIMPROVE

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

*Result* = LA\_TRIMPROVE( *AL*, *A*, *AU*, *DAL*, *DA*, *DAU*, *DU2*, *Index*, *B*, *X*  
 [, [BACKWARD\\_ERROR=variable](#)] [, /[DOUBLE](#)]  
 [, [FORWARD\\_ERROR=variable](#)] )

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### AL

A vector of length  $(n - 1)$  containing the subdiagonal elements of the original array.

**A**

A vector of length  $n$  containing the main diagonal elements of the original array.

**AU**

A vector of length  $(n - 1)$  containing the superdiagonal elements of the original array.

**DAL**

The  $(n - 1)$  elements of the lower bidiagonal array, created by the LA\_TRIDC procedure.

**DA**

The  $n$  diagonal elements of the upper triangular array, created by the LA\_TRIDC procedure.

**DAU**

The  $(n - 1)$  superdiagonal elements of the upper triangular array, created by the LA\_TRIDC procedure.

**DU2**

The  $(n - 2)$  elements of the second superdiagonal of the upper triangular array, created by the LA\_TRIDC procedure.

**Index**

An input vector, created by the LA\_TRIDC procedure, containing the row permutations which occurred as a result of partial pivoting.

**B**

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

**X**

An  $n$ -element input vector, or a  $k$ -by- $n$  array, containing the approximate solutions to the linear system, created by the LA\_TRISOL function.

## Keywords

### BACKWARD\_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If  $B$  is a vector containing a single linear system, then `BACKWARD_ERROR` will be a scalar. If  $B$  is an array containing  $k$  linear systems, then `BACKWARD_ERROR` will be a  $k$ -element vector. The backward error is the smallest relative change in any element of  $A$  or  $B$  that makes  $X$  an exact solution.

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if `AL` is double precision, otherwise the default is `DOUBLE = 0`.

### FORWARD\_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If  $B$  is a vector containing a single linear system, then `FORWARD_ERROR` will be a scalar. If  $B$  is an array containing  $k$  linear systems, then `FORWARD_ERROR` will be a  $k$ -element vector. For each linear system, if  $X_{true}$  is the true solution corresponding to  $X$ , then the forward error is an estimated upper bound for the magnitude of the largest element in  $(X - X_{true})$  divided by the magnitude of the largest element in  $X$ .

## Examples

Given the tridiagonal system of equations:

$$\begin{array}{rcl} -4t + u & & = 6 \\ 2t - 4u + v & & = -8 \\ & 2u - 4v + w & = -5 \\ & & 2v - 4w = 8 \end{array}$$

the solution can be found and improved by using the following program:

```
PRO ExLA_TRIMPROVE
; Define array a:
aupper = [1, 1, 1]
adiag = [-4, -4, -4, -4]
alower = [2, 2, 2]
; Define right-hand side vector b:
b = [6, -8, -5, 8]
```

```

; Decompose a:
dlower = alower
darray = adiaq
dupper = aupper
LA_TRIDC, dlower, darray, dupper, u2, index

; Compute and improve the solution:
x = LA_TRISOL(dlower, darray, dupper, u2, index, b)
xnew = LA_TRIMPROVE(Alower, Adiaq, Aupper, $
    dlower, darray, dupper, u2, index, b, x)
PRINT, 'LA_TRISOL improved solution:'
PRINT, xnew
END

```

When this program is compiled and run, IDL prints:

```

LA_TRISOL improved solution:
-1.00000      2.00000      2.00000      -1.00000

```

# LA\_TRIQL

The LA\_TRIQL procedure uses the QL and QR variants of the implicitly-shifted QR algorithm to compute the eigenvalues and eigenvectors of a symmetric tridiagonal array. The LA\_TRIRED routine can be used to reduce a real symmetric (or complex Hermitian) array to tridiagonal form suitable for input to this procedure.

LA\_TRIQL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	ssteqr
Double	dsteqr
Complex	csteqr
Double complex	zsteqr

*Table 3-71: LAPACK Routine Basis for LA\_TRIQL*

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

LA\_TRIQL, D, E [, A] [, /DOUBLE] [, STATUS=*variable*]

## Arguments

### D

A named vector of length  $n$  containing the real diagonal elements, optionally created by the LA\_TRIRED procedure. Upon output,  $D$  is replaced by a real vector of length  $n$  containing the eigenvalues.

### E

The  $(n - 1)$  real subdiagonal elements, optionally created by the LA\_TRIRED procedure. On output, the values within  $E$  are destroyed.

### A

An optional named variable that returns the eigenvectors as a set of  $n$  row vectors. If the eigenvectors of a tridiagonal array are desired,  $A$  should be input as an identity

array. If the eigenvectors of an array that has been reduced by LA\_TRIRED are desired, *A* should be input as the Array output from LA\_TRIRED. If *A* is not input, then eigenvectors are not computed. *A* may be either real or complex.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `DOUBLE = 0` if none of the inputs are double precision. If *A* is not input, then the default is `/DOUBLE` if *D* is double precision. If *A* is input, then the default is `/DOUBLE` if *A* is double precision (real or complex).

### STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The algorithm failed to find all eigenvalues in  $30n$  iterations. The `STATUS` value specifies how many elements of *E* have not converged to zero.

### Note

---

If `STATUS` is not specified, any error messages will be output to the screen.

---

## Examples

The following example program computes the eigenvalues and eigenvectors of a given symmetric array:

```

PRO ExLA_TRIQL
; Create a symmetric random array:
n = 4
seed = 12321
Array = RANDOMN(seed, n, n)
array = array + TRANSPOSE(array)

; Reduce to tridiagonal form
q = array      ; make a copy
LA_TRIRED, q, d, e

```

```
; Compute eigenvalues and eigenvectors
eigenvalues = d
eigenvectors = q
LA_TRIQL, eigenvalues, e, eigenvectors
PRINT, 'LA_TRIQL eigenvalues:'
PRINT, eigenvalues
END
```

When this program is compiled and run, IDL prints:

```
LA_TRIQL eigenvalues:
-2.87710      -0.663354      2.92018      3.59648
```

[LA\\_TRIRED](#), [TRIQLDOUBLE](#)

# LA\_TRIRED

The LA\_TRIRED procedure reduces a real symmetric or complex Hermitian array to real tridiagonal form  $T$ . If the array is real symmetric then the decomposition is  $A = Q T Q^T$ , where  $Q$  is orthogonal. If the array is complex Hermitian then the decomposition is  $A = Q T Q^H$ , where  $Q$  is unitary. The superscript  $T$  represents the transpose while superscript  $H$  represents the Hermitian, or transpose complex conjugate.

LA\_TRIRED is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	ssytrd, sorgtr
Double	dsytrd, dorgtr
Complex	chetrd, cungr
Double complex	zhetrd, zungr

Table 3-72: LAPACK Routine Basis for LA\_TRIRED

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

LA\_TRIRED, *Array*, *D*, *E* [, /DOUBLE] [, /UPPER]

## Arguments

### Array

A named variable containing the real or complex array to decompose. Only the lower triangular portion of *Array* is used (or upper if the /UPPER keyword is set). This procedure returns *Array* as the real orthogonal (or complex unitary)  $Q$  array used to reduce the original array to tridiagonal form.

### D

An  $n$ -element output vector containing the real diagonal elements of the tridiagonal array. Note that  $D$  is always real.

## E

An  $(n - 1)$  element output vector containing the real subdiagonal elements of the tridiagonal array. Note that  $E$  is always real.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

### UPPER

If this keyword is set, then only the upper triangular portion of *Array* is used, and the upper triangular array is returned. The default is to use the lower triangular portion and return the lower triangular array.

## Examples

See `LA_TRIQL` for an example of using this procedure.

# LA\_TRISOL

The LA\_TRISOL function is used in conjunction with the LA\_TRIDC procedure to solve a set of  $n$  linear equations in  $n$  unknowns,  $AX = B$ , where  $A$  is a tridiagonal array. The parameter  $A$  is input not as the original array, but as its LU decomposition, created by the routine LA\_TRIDC.

The LA\_TRISOL function may also be used to solve for multiple systems of linear equations, with each column of  $B$  representing a different set of equations. In this case, the result is a  $k$ -by- $n$  array where each of the  $k$  columns represents the solution vector for that set of equations.

LA\_TRISOL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgttrs
Double	dgttrs
Complex	cgttrs
Double complex	zgttrs

Table 3-73: LAPACK Routine Basis for LA\_TRISOL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

## Syntax

*Result* = LA\_TRISOL( *AL*, *A*, *AU*, *U2*, *Index*, *B* [, /DOUBLE] )

## Return Value

The result is an  $n$ -element vector or  $k$ -by- $n$  array.

## Arguments

### AL

The  $(n - 1)$  elements of the lower bidiagonal array, created by the LA\_TRIDC procedure.

**A**

The  $n$  diagonal elements of the upper triangular array, created by the LA\_TRIDC procedure.

**AU**

The  $(n - 1)$  superdiagonal elements of the upper triangular array, created by the LA\_TRIDC procedure.

**U2**

The  $(n - 2)$  elements of the second superdiagonal of the upper triangular array, created by the LA\_TRIDC procedure.

**Index**

An input vector, created by the LA\_TRIDC procedure, containing the row permutations which occurred as a result of partial pivoting.

**B**

An  $n$ -element input vector containing the right-hand side of the linear system, or a  $k$ -by- $n$  array, where each of the  $k$  columns represents a different linear system.

**Keywords****DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if `AL` is double precision, otherwise the default is `DOUBLE = 0`.

**Examples**

For an example of using this routine see [LA\\_TRIMPROVE](#).

# LABEL\_DATE

The LABEL\_DATE function can be used, in conjunction with the [XYZ]TICKFORMAT keyword to IDL plotting routines, to easily label axes with dates and times.

This routine is written in the IDL language. Its source code can be found in the file `label_date.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LABEL_DATE( [, DATE_FORMAT=string/string array]
                    [, AM_PM=2-element vector of strings]
                    [, DAYS_OF_WEEK=7-element vector of strings]
                    [, MONTHS=12-element vector of strings] [, OFFSET=value] [, /ROUND_UP] )
```

and then,

```
PLOT, x, y, XTICKFORMAT = 'LABEL_DATE'
```

## Return Value

Returns a date formatting definition.

## Arguments

If LABEL\_DATE is being called to initialize string formats, it should be called with no arguments and the DATE\_FORMAT keyword should be set.

## Keywords

### Note

---

The settings for LABEL\_DATE remain in effect for all subsequent calls to LABEL\_DATE. To restore any default settings, call LABEL\_DATE again with the appropriate keyword set to either a null string (") or to 0, depending upon the data type of that keyword.

---

## AM\_PM

Set this keyword to a two-element string array that contains the names to be used with '%A'. The default is ['am','pm'].

## DATE\_FORMAT

Set this keyword to a format string or array of format strings. Each string corresponds to an axis level as provided by the [XYZ]TICKUNITS keyword to the plotting routine. If there are fewer strings than axis levels, then the strings are cyclically repeated. A string can contain any of the following codes:

Code	Description
%M	Month name.
%N	Month number (2 digits).
%D	Day of month (2 digits).
%Y	Year (4 digits, or 5 digits for negative years).
%Z	Last 2 digits of the year.
%W	Day of the week.
%A	AM or PM (%H is then 12-hour instead of 24-hour).
%H	Hours (2 digits).
%I	Minutes (2 digits).
%S	Seconds (2 digits), followed optionally by %n where n is an integer 0-9 representing the number of digits after the decimal point for seconds; the default is no decimal places.
%%	Represents the % character.

*Table 3-74: DATE\_FORMAT Codes*

Other items you can include can consist of:

- Any other text characters in the format string.
- Any vector font positioning and font change commands. For more information, see [“Embedded Formatting Commands”](#) in Appendix H.

If DATE\_FORMAT is not specified then the default is the standard 24-character system format, '%W %M %D %H:%I:%S %Y'.

The following table contains some examples of DATE\_FORMAT strings and the resulting output:

DATE_FORMAT String	Example Result
'%D/%N/%Y'	11/12/1993
'%M!C%Y' <b>Note</b> - !C is the code for a newline character.	Dec 1993
'%H:%I:%S'	21:33:58
'%H:%I:%S%3'	21:33:58.125
'%W, %M %D, %H %A'	Sat, Jan 01, 9 pm
'%S seconds'	60 seconds

Table 3-75: DATE\_FORMAT Examples

## DAYS\_OF\_WEEK

Set this keyword to a seven-element string array that contains the names to be used with '%W'. The default is the three-letter English abbreviations, ['Sun', 'Mon', 'Tue', 'Wed', 'Thu', 'Fri', 'Sat'].

## MONTHS

Set this keyword to a twelve-element string array that contains the names to be used with '%M'. The default is the three-letter English abbreviations, ['Jan', 'Feb', ..., 'Dec'].

## OFFSET

Set this keyword to a value representing the offset to be added to each tick value before conversion to a label. This keyword is usually used when your axis values are measured relative to a certain starting time. In this case, OFFSET should be set to the Julian date of the starting time.

## ROUND\_UP

Set this keyword to force times to be rounded up to the nearest minute after the 30 second mark in the DATE\_FORMAT string. The default is for times to be truncated to the smallest time unit.

**Note**

---

If ROUND\_UP is set, it will remain set unless set back to 0.

---

## Examples

This example creates a sample plot that has a date axis from Jan 1 to June 30, 2000:

```
; Create format strings for a two-level axis:
dummy = LABEL_DATE (DATE_FORMAT=['%D-%M', '%Y'])

; Generate the Date/Time data
time = TIMEGEN (START=JULDAY(1,1,2000), FINAL=JULDAY(6,30,2000))

; Generate the Y-axis data
data = RANDOMN(seed, N_ELEMENTS(time))

; Plot the data
PLOT, time, data, XTICKUNITS = ['Time', 'Time'], $
    XTICKFORMAT='LABEL_DATE', XSTYLE=1, XTICKS=6, YMARGIN=[6,2]
```

The following examples show how to display one-dimensional and two-dimensional date/time data.

### Displaying Date/Time Data on a Plot Display

Date/time data usually comes from measuring data values at specific times. For example, the displacement (in inches) of an object might be recorded at every second for 37 seconds after the initial recording of 59 minutes and 30 seconds after 2 o'clock pm (14 hundred hours) on the 30th day of March in the year 2000 as follows

```
number_samples = 37
date_time = TIMEGEN(number_samples, UNITS = 'Seconds', $
    START = JULDAY(3, 30, 2000, 14, 59, 30))
displacement = SIN(10.*!DTOR*FINDGEN(number_samples))
```

**Note**

---

See “[Date/Time Data](#)” in Chapter 13 of the *Building IDL Applications* manual for information on date- and time-based data.

---

Normally, this type of data would be imported into IDL from a data file. However, this section is designed specifically to show how to display date/time data, not how to import data from a file; therefore, the data for this example is created with the above IDL commands.

Before displaying this one-dimensional data with the PLOT routine, the format of the date/time values is specified through the LABEL\_DATE routine as follows

```
date_label = LABEL_DATE (DATE_FORMAT = ['%I:%S'])
```

where %I represents minutes and %S represents seconds.

The resulting format is specified in the call to the PLOT routine with the XTICKFORMAT keyword:

```
PLOT, date_time, displacement, /XSTYLE, $  
  ; displaying titles.  
  TITLE = 'Measured Signal', $  
  XTITLE = 'Time (seconds)', $  
  YTITLE = 'Displacement (inches)', $  
  ; applying date/time formats to X-axis labels.  
  XTICKFORMAT = 'LABEL_DATE', $  
  XTICKUNITS = 'Time', $  
  XTICKINTERVAL = 5
```

The XTICKUNITS keyword is set to note the tick labels contain date/time data. The XTICKINTERVAL keyword is set to place the major tick marks at every five second interval.

These keyword settings produce the following results:

*Figure 3-68: Displaying Date/Time data with PLOT*

The above display shows the progression of the date/time variable, but it does not include all of the date/time data we generated with the TIMEGEN routine. This data also includes hour, month, day, and year information. IDL can display this information with additional levels to the date/time axis. You can control the number of levels to draw and the units used at each level with the XTICKUNITS keyword. You can specify the formatting for these levels by changing the DATE\_FORMAT keyword setting to the LABEL\_DATE routine:

```
date_label = LABEL_DATE (DATE_FORMAT = $
                        ['%I:%S', '%H', '%D %M, %Y'])
```

where %H represents hours, %D represents days, %M represents months, and %Y represents years. Notice DATE\_FORMAT is specified with a three element vector. Date/time data can be displayed on an axis with three levels. The format of these levels are specified through this vector.

In this example, the first level (closest to the axis) will contain minute and second values separated by a colon (%I:%S). The second level (just below the first level) will contain the hour values (%H). The third level (the final level farthest from the axis) will contain the day and month values separated by a space and year value separated from the day and month values by a comma (%D %M, %Y).

Besides the above change to the LABEL\_DATE routine, you must also change the settings of the keywords to the PLOT routine to specify a multiple level axis:

```
PLOT, date_time, displacement, /XSTYLE, $
; displaying titles.
TITLE = 'Measured Signal', $
XTITLE = 'Time (seconds)', $
YTITLE = 'Displacement (inches)', $
; applying date/time formats to X-axis labels.
POSITION = [0.2, 0.25, 0.9, 0.9], $
XTICKFORMAT = ['LABEL_DATE', 'LABEL_DATE', 'LABEL_DATE'], $
XTICKUNITS = ['Time', 'Hour', 'Day'], $
XTICKINTERVAL = 5
```

The POSITION keyword is set to allow the resulting display to contain all three levels and the title of the date/time axis. The XTICKFORMAT is now set to a string array containing an element for each level of the axis. The XTICKUNITS keyword is set to note the unit of each level.

These keyword settings produce the results shown in the following figure.

Figure 3-69: Displaying Three Levels of Date/Time data with PLOT

Notice the three levels of the X-axis. These levels are arranged as specified by the previous call to the LABEL\_DATE routine.

### Using System Variables to Display Date/Time Data

The settings we used to display our date/time data could have been specified through system variables instead of keywords. The following table shows the relationship between these keywords and their system variables:

Keywords	System Variables
[XYZ]TICKUNITS	![XYZ].TICKUNITS
[XYZ]TICKINTERVAL	![XYZ].TICKINTERVAL
[XYZ]TICKLAYOUT	![XYZ].TICKLAYOUT

Table 3-76: Relationship Between Keywords and System Variables

Usually, keywords are used more frequently than system variables, but system variables are better when trying to establish a consistent display style. For example, we could have established a date/time axis style with these system variables before producing our previous display and the display shown in “[Displaying Date/Time Data on a Contour Display](#)” on page 351:

```

; Establishing an axis style.
!X.TICKFORMAT = ['LABEL_DATE', 'LABEL_DATE', 'LABEL_DATE']
!X.TICKUNITS = ['Time', 'Hour', 'Day']
!X.TICKINTERVAL = 5
!X.TICKLAYOUT = 2

; Displaying data.
PLOT, date_time, displacement, /XSTYLE, $
    TITLE = 'Measured Signal', $
    XTITLE = 'Time (seconds)', $
    YTITLE = 'Displacement (inches)', $
    POSITION = [0.2, 0.7, 0.9, 0.9]

CONTOUR, temperature, date_time, angle, /FILL, $
    LEVELS = BYTSCL(INDGEN(8)), /XSTYLE, /YSTYLE, $
    C_COLORS = BYTSCL(INDGEN(8)), /NOERASE, $
    TITLE = 'Measured Temperature (degrees Celsius)', $
    XTITLE = 'Angle (degrees)', $
    YTITLE = 'Time (seconds)', $
    POSITION = [0.2, 0.25, 0.9, 0.45]
CONTOUR, temperature, date_time, angle, /OVERPLOT, $
    LEVELS = BYTSCL(INDGEN(8))
!X.TICKLAYOUT = 0
!X.TICKINTERVAL = 0
!X.TICKUNITS = ''
!X.TICKFORMAT = ''

```

Notice these system variables are set to their default values after the two displays are shown. When using system variables instead of keywords, remember to reset the system variables back to their default values. The above example produces the following results.

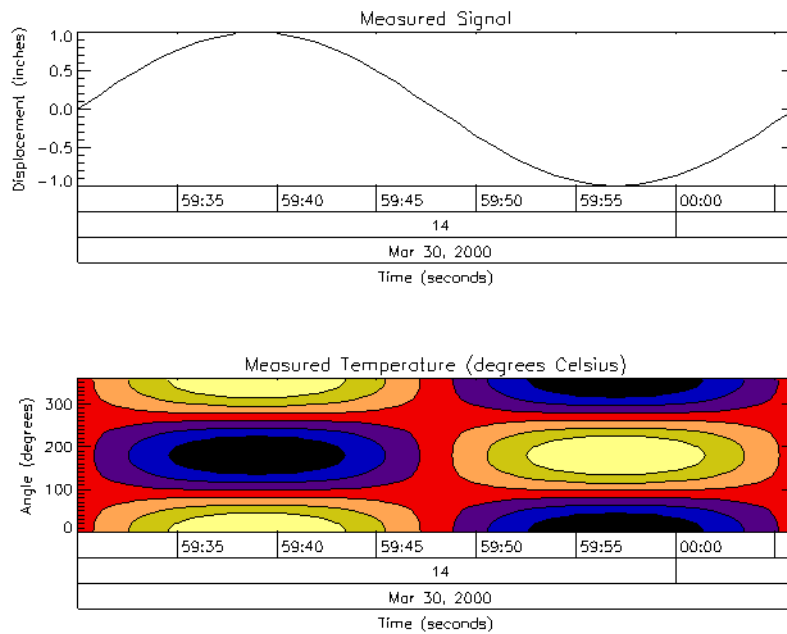

Figure 3-70: Date/Time Axis Style Established With System Variables

# LABEL\_REGION

The LABEL\_REGION function consecutively labels all of the regions, or blobs, of a bi-level image with a unique region index. This process is sometimes called “blob coloring”. A region is a set of non-zero pixels within a neighborhood around the pixel under examination.

The argument for LABEL\_REGION is an  $n$ -dimensional bi-level integer type array—only zero and non-zero values are considered.

Statistics on each of the regions may be easily calculated using the HISTOGRAM function as shown in the examples below.

## Syntax

*Result* = LABEL\_REGION( *Data* [, /ALL\_NEIGHBORS] [, /ULONG] )

## Return Value

The result of the function is an integer array of the same dimensions with each pixel containing its region index. A region index of zero indicates that the original pixel was zero and belongs to no region. Output values range from 0 to the number of regions.

## Arguments

### Data

A  $n$ -dimensional image to be labeled. *Data* is converted to integer type if necessary. Pixels at the edges of *Data* are considered to be zero.

## Keywords

### ALL\_NEIGHBORS

Set this keyword to indicate that all adjacent neighbors to a given pixel should be searched. (This is sometimes called 8-neighbor searching when the image is 2-dimensional). The default is to search only the neighbors that are exactly one unit in distance from the current pixel (sometimes called 4-neighbor searching when the image is 2-dimensional).

## ULONG

Set this keyword to specify that the output array should be an unsigned long integer.

## Examples

### Note

Also see [“Analyzing Image Shapes”](#) in Chapter 9 of the *Image Processing in IDL* manual.

### Example 1

This example counts the number of distinct regions within an image, and their population. Note that region 0 is the set of zero pixels that are not within a region:

```
image = DIST(40)

; Get blob indices:
b = LABEL_REGION(image)

; Get population of each blob:
h = HISTOGRAM(b)
FOR i=0, N_ELEMENTS(h)-1 DO PRINT, 'Region ', i, $
    ', Population = ', h[i]
```

### Example 2

This example also prints the average value and standard deviation of each region:

```
image = DIST(40)

; Get blob indices:
b = LABEL_REGION(image)

; Get population and members of each blob:
h = HISTOGRAM(b, REVERSE_INDICES=r)

; Each region
FOR i=0, N_ELEMENTS(h)-1 DO BEGIN
    ;Find subscripts of members of region i.
    p = r[r[i]:r[i+1]-1]

    ; Pixels of region i
    q = image[p]
    PRINT, 'Region ', i, $
        ', Population = ', h[i], $
        ', Standard Deviation = ', STDEV(q, mean), $
```

```
        ', Mean = ', mean  
    ENDFOR
```

# LADFIT

The LADFIT function fits the paired data  $\{x_i, y_i\}$  to the linear model,  $y = A + Bx$ , using a “robust” least absolute deviation method.

The figure below displays a two-dimensional distribution that is fitted to the model  $y = A + Bx$ , using a minimized Chi-square error criterion (left) and a “robust” least absolute deviation technique (right). The use of the Chi-square error statistic can result in a poor fit due to an undesired sensitivity to outlying data.

Figure 3-71: Comparison of Chi-square and Least Absolute Deviation

This routine is written in the IDL language. Its source code can be found in the file `ladfit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LADFIT( X, Y [, ABSDEV=variable] [, /DOUBLE] )
```

## Return Value

The result is a two-element vector containing the model parameters, A and B.

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector. Note that the  $X$  vector must be sorted into ascending order.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector. Note that the elements of the  $Y$  vector must be paired with the appropriate elements of  $X$ .

## Keywords

### ABSDEV

Set this keyword to a named variable that will contain the mean of the absolute deviation of the *Result* and  $Y$ .

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```

; Define two n-element vectors of paired data:
X = [-3.20, 4.49, -1.66, 0.64, -2.43, -0.89, -0.12, 1.41, $
      2.95, 2.18, 3.72, 5.26]
Y = [-7.14, -1.30, -4.26, -1.90, -6.19, -3.98, -2.87, -1.66, $
      -0.78, -2.61, 0.31, 1.74]

; Sort the X values into ascending order, and sort the Y values to
; match the new order of the elements in X:
XX = X[SORT(X)]
YY = Y[SORT(X)]

; Compute the model parameters, A and B:
PRINT, LADFIT(XX, YY)

```

IDL prints:

```
-3.15301      0.930440
```

# LAGUERRE

The LAGUERRE function returns the value of the associated Laguerre polynomial  $L_n^k(x)$ . The associated Laguerre polynomials are solutions to the differential equation:

$$xy'' + (k + 1 - x)y' + ny = 0$$

with orthogonality constraint:

$$\int_0^\infty e^{-x} x^{k+1} L_m^k(x) L_n^k(x) dx = \frac{(n+k)!}{n!} \delta_{mn}$$

Laguerre polynomials are used in quantum mechanics, for example, where the wave function for the hydrogen atom is given by the Laguerre differential equation.

This routine is written in the IDL language. Its source code can be found in the file `laguerre.pro` in the `lib` subdirectory of the IDL distribution.

This routine is written in the IDL language. Its source code can be found in the file `laguerre.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = LAGUERRE( *X*, *N* [, *K*] [, **COEFFICIENTS**=*variable*] [, **DOUBLE**] )

## Return Value

This function returns a scalar or array with the same dimensions as *X*. If *X* is double-precision or if the **DOUBLE** keyword is set, the result is double-precision complex, otherwise the result is single-precision complex.

## Arguments

### X

The value(s) at which  $L_n^k(x)$  is evaluated. *X* can be either a scalar or an array.

### N

A scalar integer,  $N \geq 0$ , specifying the order *n* of  $L_n^k(x)$ . If *N* is of type float, it will be truncated.

## K

A scalar,  $K \geq 0$ , specifying the order  $k$  of  $L_n^k(x)$ . If  $K$  is not specified, the default  $K = 0$  is used and the Laguerre polynomial,  $L_n(x)$ , is returned.

## Keywords

### COEFFICIENTS

Set this keyword to a named variable that will contain the polynomial coefficients in the expansion  $C[0] + C[1]x + C[2]x^2 + \dots$ .

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To compute the value of the Laguerre polynomial at the following  $X$  values:

```
;Define the parametric X values:
X = [0.0, 0.2, 0.4, 0.6, 0.8, 1.0]

;Compute the Laguerre polynomial of order N=2, K=1:
result = LAGUERRE(X, 2, 1)

;Print the result:
PRINT, result
```

IDL prints:

```
3.00000  2.42000  1.88000  1.38000  0.920000  0.500000
```

This is the exact solution vector to six-decimal accuracy.

# LEEFILT

The LEEFILT function performs the Lee filter algorithm on an image array using a box of size  $2N+1$ . This function can also be used on vectors. The Lee technique smooths additive image noise by generating statistics in a local neighborhood and comparing them to the expected values.

This routine is written in the IDL language. It is based upon the algorithm published by Lee (*Optical Engineering* 25(5), 636-646, May 1986). Its source code can be found in the file `leefilt.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LEEFILT( A [, N [, Sig]] [, /DOUBLE] [, /EXACT] )
```

## Return Value

This function returns an array with the same dimensions as *A*. If any of the inputs are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### A

The input image array or one-dimensional vector.

### N

The size of the filter box is  $2N+1$ . The default value is 5.

### Sig

Estimate of the standard deviation. The default is 5. If *Sig* is negative, IDL interactively prompts for a value of `sigma`, and displays the resulting image using `TVSCL` (for arrays) or `PLOT` (for vectors). To end this cycle, enter a value of 0 (zero) for `sigma`.

## Keywords

### DOUBLE

Set this keyword to force the computations to be done in double-precision arithmetic.

### EXACT

Set this keyword to apply a more accurate (but slower) implementation of the Lee filter.

## Examples

# LEGENDRE

The LEGENDRE function returns the value of the associated Legendre polynomial  $P_l^m(x)$ . The associated Legendre functions are solutions to the differential equation:

$$(1-x^2)y'' - 2xy' + \left[ l(l+1) - \frac{m^2}{(1-x^2)} \right] y = 0$$

with orthogonality constraints:

$$\int_{-1}^{+1} P_l^m(x) P_k^n(x) dx = \frac{2}{2l+1} \frac{(l+m)!}{(l-m)!} \delta_{lk} \delta_{mn}$$

The Legendre polynomials are the solutions to the Legendre equation with  $m = 0$ . For positive  $m$ , the associated Legendre functions can be written in terms of the Legendre polynomials as:

$$P_l^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_l(x)$$

Associated polynomials for negative  $m$  are related to positive  $m$  by:

$$P_l^{-m}(x) = (-1)^m \frac{(l-m)!}{(l+m)!} P_l^m(x)$$

LEGENDRE is based on the routine *plgndr* described in section 6.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = LEGENDRE( *X*, *L* [, *M*] [, /DOUBLE] )

## Return Value

If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of *X*, *L*, and *M*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments are arrays, the function uses the scalar value with each element

of the arrays, and returns an array with the same dimensions as the smallest input array.

If any of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

## Arguments

### X

The expression for which  $P_l^m(x)$  is evaluated. Values for  $X$  must be in the range  $-1 \leq X \leq 1$ .

### L

An integer scalar or array,  $L \geq 0$ , specifying the order  $l$  of  $P_l^m(x)$ . If  $L$  is of type float, it will be truncated.

### M

An integer scalar or array,  $-L \leq M \leq L$ , specifying the order  $m$  of  $P_l^m(x)$ . If  $M$  is not specified, then the default  $M = 0$  is used and the Legendre polynomial,  $P_l(x)$ , is returned. If  $M$  is of type float, it will be truncated.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

### Example 1

Compute the value of the Legendre polynomial at the following  $X$  values:

```
; Define the parametric X values:
X = [-0.75, -0.5, -0.25, 0.25, 0.5, 0.75]

; Compute the Legendre polynomial of order L=2:
result = LEGENDRE(X, 2)

; Print the result:
PRINT, result
```

The result of this is:

```
0.343750 -0.125000 -0.406250 -0.406250 -0.125000 0.343750
```

## Example 2

Compute the value of the associated Legendre polynomial at the same X values:

```
; Compute the associated Legendre polynomial of order L=2, M=1:
result = LEGENDRE(X, 2, 1)
; Print the result:
PRINT, result
```

IDL prints:

```
1.48824 1.29904 0.726184 -0.726184 -1.29904 -1.48824
```

This is the exact solution vector to six-decimal accuracy.

## Version History

# LINBCG

The LINBCG function is used in conjunction with SPRSIN to solve a set of  $n$  sparse linear equations with  $n$  unknowns using the iterative biconjugate gradient method.

LINBCG is based on the routine `linbcg` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

## Note

*Numerical Recipes* recommends using double-precision arithmetic to perform this computation.

---

## Syntax

```
Result = LINBCG( A, B, X [, /DOUBLE] [, ITOL={4 | 5 | 6 | 7}] [, TOL=value]
               [, ITER=variable] [, ITMAX=value] )
```

## Return Value

The result is an  $n$ -element vector.

## Arguments

### A

A row-indexed sparse array created by the SPRSIN function.

---

### Note

If LINBCG is complex then only the real part is used for the computation.

---

### B

An  $n$ -element vector containing the right-hand side of the linear system  $\mathbf{Ax}=\mathbf{b}$ .

### X

An  $n$ -element vector containing the initial solution of the linear system.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ITOL

Use this keyword to specify which convergence test should be used. Set ITOL to one of the following:

1. Iteration stops when  $|A \cdot x - b| / |b|$  is less than the value specified by TOL.
2. Iteration stops when  $|\tilde{A}^{-1} \cdot (A \cdot x - b)| / |\tilde{A}^{-1} \cdot b|$  (where  $\tilde{A}$  is a “preconditioning” matrix close to  $A$ ) is less than the value specified by TOL.
3. The routine uses its own estimate of error in  $x$ . Iteration stops when the magnitude of the error divided by the magnitude of  $x$  is less than the value specified by TOL. This is the default setting.
4. The same as 3, except that the routine uses the largest (in absolute value) component of the error and the largest component of  $x$  rather than the vector magnitudes.

### TOL

Use this keyword to specify the desired convergence tolerance. For single-precision calculations, the default value is  $1.0 \times 10^{-7}$ . For double-precision values, the default is  $1.0 \times 10^{-14}$ .

### ITER

Use this keyword to specify an output variable that will be set to the number of iterations performed.

### ITMAX

The maximum allowed number of iterations. The default is  $n^2$ .

## Examples

```

; Begin with an array A:
A = [[ 5.0,  0.0,  0.0,  1.0, -2.0], $
      [ 3.0, -2.0,  0.0,  1.0,  0.0], $
      [ 4.0, -1.0,  0.0,  2.0,  0.0], $
      [ 0.0,  3.0,  3.0,  1.0,  0.0], $

```

```

        [-2.0, 0.0, 0.0, -1.0, 2.0]]

; Define a right-hand side vector B:
B = [7.0, 1.0, 3.0, 3.0, -4.0]

; Start with an initial guess at the solution:
X = REPLICATE(1.0, N_ELEMENTS(B))

; Solve the linear system Ax=b:
result = LINBCG(SPRSIN(A), B, X)

; Print the result:
PRINT, result

```

IDL prints:

```

1.00000  1.00000  8.94134e-008  -2.37107e-007  -1.00000

```

The exact solution is [1, 1, 0, 0, -1].

# LINDGEN

The LINDGEN function creates a longword integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$Result = LINDGEN(D_1 [, \dots, D_8])$$

## Return Value

Returns a longword integer array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create L, a 10-element by 10-element longword array where each element is set to the value of its one-dimensional subscript, enter:

```
L = LINDGEN(10, 10)
```

## Version History

# LINFIT

The LINFIT function fits the paired data  $\{x_i, y_i\}$  to the linear model,  $y = A + Bx$ , by minimizing the chi-square error statistic.

This routine is written in the IDL language. Its source code can be found in the file `linfit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LINFIT( X, Y [, CHISQ=variable] [, COVAR=variable] [, /DOUBLE]
               [, MEASURE_ERRORS=vector] [, PROB=variable] [, SIGMA=variable]
               [, YFIT=variable] )
```

## Return Value

The result is a two-element vector containing the linear model parameters [A, B].

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector.

## Keywords

### CHISQ

Set this keyword to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

### COVAR

Set this keyword to a named variable that will contain the covariance matrix of the coefficients.

**Note**

The COVAR matrix depends only upon the independent variable  $X$  and (optionally) the MEASURE\_ERRORS. The values do not depend upon  $Y$ . See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

**DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

**MEASURE\_ERRORS**

Set this keyword to a vector containing standard measurement errors for each point  $Y[i]$ . This vector must be the same length as  $X$  and  $Y$ .

**Note**

For Gaussian errors (e.g., instrumental uncertainties), MEASURE\_ERRORS should be set to the standard deviations of each point in  $Y$ . For Poisson or statistical weighting, MEASURE\_ERRORS should be set to  $\text{SQRT}(\text{ABS}(Y))$ .

**PROB**

Set this keyword to a named variable that will contain the probability that the computed fit would have a value of CHISQ or greater. If PROB is greater than 0.1, the model parameters are “believable”. If PROB is less than 0.1, the accuracy of the model parameters is questionable.

**SIGMA**

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters

**Note**

If MEASURE\_ERRORS is omitted, then you are assuming that a straight line is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by  $\text{SQRT}(\text{CHISQ}/(N-M))$ , where  $N$  is the number of points in  $X$ , and  $M$  is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

## YFIT

Set this keyword equal to a named variable that will contain the vector of calculated  $Y$  values.

## Examples

```
; Define two n-element vectors of paired data:
X = [-3.20, 4.49, -1.66, 0.64, -2.43, -0.89, -0.12, 1.41, $
     2.95, 2.18, 3.72, 5.26]
Y = [-7.14, -1.30, -4.26, -1.90, -6.19, -3.98, -2.87, -1.66, $
     -0.78, -2.61, 0.31, 1.74]

; Define an n-element vector of Poisson measurement errors:
measure_errors = SQRT(ABS(Y))

; Compute the model parameters, A and B, and print the result:
result = LINFIT(X, Y, MEASURE_ERRORS=measure_errors)
PRINT, result
```

IDL prints:

```
-3.16574    0.829856
```

## Version History

4.0	Introduced
Pre 6.1	Deprecated the SDEV keyword.

For more information on deprecated features, see [Appendix J, “Obsolete Features”](#).

## See Also

# LINKIMAGE

The LINKIMAGE procedure merges routines written in other languages with IDL at runtime. Each call to LINKIMAGE defines a new system procedure or function by specifying the routine's name, the name of the file containing the code, and the entry point name. The name of your routine is added to IDL's internal system routine table, making it available in the same manner as any other IDL built-in routine.

LINKIMAGE can also be used to add graphics device drivers.

## Warning

---

Using LINKIMAGE requires intimate knowledge of the internals of IDL, and is not for use by the novice user. We recommend use of CALL\_EXTERNAL, which has a simpler interface, instead of LINKIMAGE unless your application specifically requires it. To use LINKIMAGE, you should be familiar with the material in the *IDL External Development Guide*.

---

LINKIMAGE uses the dynamic linking interface supported by the operating system to do its work. Programmers should be familiar with the services supported by their system in order to better understand LINKIMAGE:

- Under UNIX, LINKIMAGE uses the `dlopen()` interface to the dynamic linker in all cases except for HP-UX (which uses `shl_load()`) and AIX (which uses `load()`).
- Under Windows, LINKIMAGE uses `LoadLibrary()` to load a 32-bit, Win32 DLL.

## Note

---

Modules must be merged via LINKIMAGE before other procedures and functions that call them are compiled, or the compilation of those routines will fail. Note that because routines merged via LINKIMAGE are considered built-in routines by IDL, declaring the routine with the FORWARD\_FUNCTION statement will not eliminate this restriction.

---

## Syntax

```
LINKIMAGE, Name, Image [, Type [, Entry]] [, /DEVICE] [, /FUNCT]  
[, /KEYWORDS] [, MAX_ARGS=value] [, MIN_ARGS=value]
```

# Arguments

## Name

A string containing the IDL name of the function, procedure or device routine which is to be merged. When loading a device driver, *Name* contains the name of the global `DEVICE_DEF` structure in the driver. Upon successful loading of the routine, a new procedure or function with the given name will exist, or the new device driver will be loaded.

## Image

A string containing the full path specification of the dynamically loaded object file. See your system documentation on sharable libraries or DLLs for details.

## Type

An optional scalar integer parameter that contains 0 (zero) for a procedure, 1 (one) for a function, and 2 for a device driver. The keyword parameters `DEVICE` and `FUNCT` can also be used to indicate the type of routine being merged. The default value is 0, for procedure.

## Entry

An optional string that contains the name of the symbol which is the entry point of the procedure or function. With some compilers or operating systems, this name may require the addition of leading or trailing characters. For example, some UNIX C compilers add a leading underscore to the beginning of a function name, and some UNIX FORTRAN compilers add a trailing underscore.

If *Entry* is not supplied, `LINKIMAGE` will provide a default name by converting the value supplied for *Name* to lower case and adding any special characters (leading or trailing underscores) typical of the system.

**Warning**

---

Under Microsoft Windows operating systems, only `cdecl` functions can be used with `LINKIMAGE`. Attempting to use routines with other calling conventions will yield undefined results, including memory corruption or even IDL crashing.

The Windows operating system has two distinct system defined standards that govern how routines pass arguments: `stdcall`, which is used by much of the operating system as well as languages such as Visual Basic, and `cdecl`, which is used widely for programming in the C language. These standards differ in how and when arguments are pushed onto the system stack. The standard used by a given function is determined when the function is compiled, and can be controlled by the programmer. `LINKIMAGE` can only be used with `cdecl` functions. Unfortunately, there is no way for IDL to know which convention a given function uses, meaning that `LINKIMAGE` will quietly accept an entry point of the wrong type. The `LINKIMAGE` user is responsible for ensuring that Entry is a `cdecl` function.

---

## Keywords

### DEVICE

Set this keyword to indicate that the module being loaded contains a device driver.

### FUNCT

Set this keyword to indicate that the module being loaded contains a function.

### KEYWORDS

Set this keyword to indicate that the procedure or function being loaded accepts keyword parameters.

### MAX\_ARGS

Set this keyword equal to the maximum number of non-keyword arguments the procedure or function accepts. If this keyword is not present, the maximum number of parameters is not checked when the routine is called.

**Note**

---

It is a very good idea to specify a value for `MAX_ARGS`. Passing the wrong number of arguments to an external routine may cause unexpected results, including causing IDL to crash. By forcing IDL to check the number of arguments before passing them to the linked routine, you will avoid parameter mismatch problems.

---

**MIN\_ARGS**

Set this keyword equal to the minimum number of non-keyword arguments accepted by the procedure or function.

**Examples**

To add a procedure called `MY_PROC`, whose entry symbol is named `my_proc`, that is contained in the file `/home/smith/my_proc.so`:

```
LINKIMAGE, 'MY_PROC', '/home/smith/my_proc.so'
```

# LL\_ARC\_DISTANCE

The `LL_ARC_DISTANCE` function returns a two-element vector containing the longitude and latitude [lon, lat] of a point given arc distance ( $-\pi \leq \text{Arc\_Dist} \leq \pi$ ), and azimuth (*Az*), from a specified location *Lon\_lat0*. Values are in radians unless the keyword `DEGREES` is set.

This routine is written in the IDL language. Its source code can be found in the file `ll_arc_distance.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LL_ARC_DISTANCE( Lon_lat0, Arc_Dist, Az [, /DEGREES] )
```

## Return Value

Returns a two-element vector containing the point longitude and latitude.

## Arguments

### Lon\_lat0

A 2-element vector containing the longitude and latitude of the starting point. Values are assumed to be in radians unless the keyword `DEGREES` is set.

### Arc\_Dist

The arc distance from *Lon\_lat0*. The value must be between  $-\pi$  and  $+\pi$ . To express distances in arc units, divide by the radius of the globe expressed in the original units. For example, if the radius of the earth is 6371 km, divide the distance in km by 6371 to obtain the arc distance.

### Az

The azimuth from *Lon\_lat0*. The value is assumed to be in radians unless the keyword `DEGREES` is set.

## Keywords

### DEGREES

Set this keyword to express all measurements and results in degrees.

## Examples

```
; Initial point specified in radians:  
Lon_lat0 = [1.0, 2.0]  
  
; Arc distance in radians:  
Arc_Dist = 2.0  
  
; Azimuth in radians:  
Az = 1.0  
  
Result = LL_ARC_DISTANCE(Lon_lat0, Arc_Dist, Az)  
PRINT, Result
```

IDL prints:

```
2.91415   -0.622234
```

[MAP\\_SET](#)

# LMFIT

The LMFIT function does a non-linear least squares fit to a function with an arbitrary number of parameters. LMFIT uses the Levenberg-Marquardt algorithm, which combines the steepest descent and inverse-Hessian function fitting methods. The function may be any non-linear function.

Iterations are performed until three consecutive iterations fail to change the chi-square value by more than the specified tolerance amount, or until a maximum number of iterations have been performed. The LMFIT function returns a vector of values for the dependent variables, as fitted by the function fit.

The initial guess of the parameter values should be as close to the actual values as possible or the solution may not converge. Test the value of the variable specified by the CONVERGENCE keyword to determine whether the algorithm converged, failed to converge, or encountered a singular matrix.

This routine is written in the IDL language. Its source code can be found in the file `lmfit.pro` in the `lib` subdirectory of the IDL distribution. LMFIT is based on the routine `mrqmin` described in section 15.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = LMFIT( X, Y, A [, ALPHA=variable] [, CHISQ=variable]
  [, CONVERGENCE=variable] [, COVAR=variable] [, /DOUBLE]
  [, FITA=vector] [, FUNCTION_NAME=string] [, ITER=variable]
  [, ITMAX=value] [, ITMIN=value] [, MEASURE_ERRORS=vector]
  [, SIGMA=variable] [, TOL=value] )
```

## Return Value

Returns a vector of values for the dependent variable, resulting from the function fit.

## Arguments

### X

A row vector of independent variables. LMFIT does not manipulate or use values in *X*, it simply passes *X* to the user-written function.

**Y**

A row vector containing the dependent variables.

**A**

A vector that contains the initial estimate for each coefficient. Upon return, *A* will contain the final estimates for the coefficients.

## Keywords

**ALPHA**

Set this keyword equal to a named variable that will contain the value of the curvature matrix.

**CHISQ**

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

**CONVERGENCE**

Set this keyword equal to a named variable that will indicate whether the LMFIT algorithm converged. The possible returned values are:

- 1 = the algorithm converged.
- 0 = the algorithm did not converge.
- -1 = the algorithm encountered a singular matrix and did not converge.

**Tip**

---

If LMFIT fails to converge, try setting the `DOUBLE` keyword.

---

**COVAR**

Set this keyword equal to a named variable that will contain the value of the covariance matrix.

**Note**

---

The `COVAR` matrix depends only upon the independent variable *X* and (optionally) the `MEASURE_ERRORS`. The values do not depend upon *Y*. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

---

## DOUBLE

Set this keyword to force the computations to be performed in double precision.

## FITA

Set this keyword equal to a vector, with as many elements as  $A$ , which contains a zero for each fixed parameter, and a non-zero value for elements of  $A$  to fit. If FITA is not specified, all parameters are taken to be non-fixed.

## FUNCTION\_NAME

Use this keyword to specify the name of the function to fit. If this keyword is omitted, LMFIT assumes that the IDL routine LMFUNCT is to be used. If LMFUNCT is not already compiled, IDL compiles the function from the file `lmfunct.pro`, located in the `lib` subdirectory of the IDL distribution. LMFUNCT is designed to fit a quadratic equation.

The function to be fit must be written as an IDL function and compiled prior to calling LMFIT. The function must accept a vector  $X$  (the independent variables) and a vector  $A$  containing the fitted function's parameter values. It must return an  $N\_ELEMENTS(A)+1$ -element vector in which the first (zeroth) element is the evaluated function value and the remaining elements are the partial derivatives with respect to each parameter in  $A$ .

### Note

---

The returned value must be of the same data type as the input  $X$  value.

---

## ITER

Set this keyword equal to a named variable that will contain the actual number of iterations which were performed

## ITMAX

Set this keyword equal to the maximum number of iterations. The default is 50.

## ITMIN

Set this keyword equal to the minimum number of iterations. The default is 5.

## MEASURE\_ERRORS

Set this keyword to a vector containing standard measurement errors for each point  $Y[i]$ . This vector must be the same length as  $X$  and  $Y$ .

**Note**

---

For Gaussian errors (e.g., instrumental uncertainties), MEASURE\_ERRORS should be set to the standard deviations of each point in  $Y$ . For Poisson or statistical weighting, MEASURE\_ERRORS should be set to  $\text{SQRT}(\text{ABS}(Y))$ .

---

**SIGMA**

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters

**Note**

---

If MEASURE\_ERRORS is omitted, then you are assuming that your user-supplied model (or the default quadratic) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by  $\text{SQRT}(\text{CHISQ}/(N-M))$ , where  $N$  is the number of points in  $X$ , and  $M$  is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

---

**TOL**

Set this keyword to the convergence tolerance. The routine returns when the relative decrease in chi-squared is less than TOL in an iteration. The default is  $1.0 \times 10^{-6}$  for single-precision, and  $1.0 \times 10^{-12}$  for double-precision.

**Examples**

In this example, we fit a function of the form:

$$f(x) = a[0] * \exp(a[1]*x) + a[2] + a[3] * \sin(x)$$

```

; First, define a return function for LMFIT:
FUNCTION myfunct, X, A
    bx = A[0]*EXP(A[1]*X)
    RETURN, [ [bx+A[2]+A[3]*SIN(X)], [EXP(A[1]*X)], [bx*X], $
             [1.0] , [SIN(X)] ]
END

PRO lmfit_example

; Compute the fit to the function we have just defined. First,
; define the independent and dependent variables:
X = FINDGEN(40)/20.0
Y = 8.8 * EXP(-9.9 * X) + 11.11 + 4.9 * SIN(X)
measure_errors = 0.05 * Y

```

```

; Provide an initial guess for the function's parameters:
A = [10.0, -0.1, 2.0, 4.0]
fita = [1,1,1,1]

; Plot the initial data, with error bars:
PLOTERR, X, Y, measure_errors
coefs = LMFIT(X, Y, A, MEASURE_ERRORS=measure_errors, /DOUBLE, $
    FITA = fita, FUNCTION_NAME = 'myfunct')

; Overplot the fitted data:
OPLOT, X, coefs

END

```

# LMGR

The LMGR function tests whether a particular licensing mode is in effect. Different licensing modes are specified by keyword; see the “Keywords” section below for a description of each licensing mode.

The LMGR function can also force IDL into time demo mode or report the LMHostid number for the machine in use.

For more information on IDL’s licensing methods, consult the *IDL License Management Guide*, which is included in Adobe Acrobat Portable Document Format on your IDL CD-ROM.

## Syntax

```
Result = LMGR( [, /CLIENTSERVER | , /DEMO | , /EMBEDDED | , /RUNTIME | ,  
/STUDENT | , /TRIAL | , /VM] [, EXPIRE_DATE=variable] [, /FORCE_DEMO]  
[, INSTALL_NUM=variable] [, LMHOSTID=variable]  
[, SITE_NOTICE=variable])
```

## Return Value

The function returns True (1) if the mode specified is in effect, or False (0) otherwise.

## Arguments

None

## Keywords

### CLIENTSERVER

Set this keyword to test whether the current IDL session is using Client/Server licensing (as opposed to Desktop licensing).

### DEMO

Set this keyword to test whether the current IDL session is running in timed demo mode. Unlicensed copies of IDL and copies running directly from a CD-ROM run in timed demo mode. If the IDL session is running in timed demo mode, no license is used even if one is available.

## EMBEDDED

Set this keyword to test whether the current IDL session is running in embedded mode. Embedded-mode applications contain a built-in version of the IDL license. Examples of applications running in embedded mode are the IDL demo and the IDL registration program.

## EXPIRE\_DATE

Set this keyword to a named variable that will receive a string containing the expiration date of the current IDL session if the session is a trial session. This named variable will be undefined if the IDL session has a permanent license.

## FORCE\_DEMO

Set this keyword to force the current session into timed demo mode. Forcing an IDL session into demo mode can be useful if you are testing an application that will be run with an unlicensed copy of IDL. Note that you must exit IDL and restart to return to normal licensed mode after forcing IDL into demo mode.

## INSTALL\_NUM

Set this keyword to a named variable that will receive a string containing the installation number of the current IDL session. This named variable will be undefined if the IDL session is unlicensed.

## LMHOSTID

Set this keyword equal to a named variable that will contain a string value representing the LMHostid for the machine in use. The LMHostid is used when creating client/server IDL licenses. This keyword returns the string “0” on machines which do not have a unique LMHostid (some Windows machines that use Desktop licensing.)

## RUNTIME

Set this keyword to test whether the current IDL session is running in runtime mode. Runtime-mode applications do not provide access to the IDL Command Line. See [Chapter 24, “Distributing Runtime Mode Applications”](#) in the *Building IDL Applications* manual for additional details on runtime applications.

**Note**

The fact that the IDL session is running in runtime mode does not imply that a runtime license is in use. A session in runtime mode may be running in demo mode, Virtual Machine mode, or may have checked out either a runtime or a full IDL license.

**SITE\_NOTICE**

Set this keyword to a named variable that will receive a string containing the site notice of the current IDL session. This named variable will be undefined if the IDL session is unlicensed.

**STUDENT**

Set this keyword to test whether the current IDL session is running in student mode. The IDL Student version, which provides a subset of IDL's full functionality, is currently the only product that runs in student mode.

**TRIAL**

Set this keyword to test whether the current IDL session is running in trial mode. Trial mode licenses allow IDL to operate for a limited time period (generally 30 days) but do not otherwise restrict functionality.

**VM**

Set this keyword to test whether the current IDL session is running in IDL Virtual Machine mode. IDL Virtual Machine applications do not provide access to the IDL Command Line. See [Chapter 25, "Distributing Virtual Machine Applications"](#) in the *Building IDL Applications* manual for additional details on IDL Virtual Machine applications. If the IDL session is running in Virtual Machine mode, no license is used even if one is available.

**Examples**

Use the following commands to test whether the current IDL session is running in timed demo mode:

```
Result = LMGR(/DEMO)
IF (Result GT 0) THEN PRINT, "IDL is in Demo Mode"
```

Use the following commands to generate the LMHostid number for the machine in use:

```
Result = LMGR(LMHOSTID = myId)
PRINT, "LMHostid for this machine is: ", myId
```

## Version History

Pre 4.0	Introduced
6.0	Added VM keyword

# LNGAMMA

The LNGAMMA function returns the logarithm of the gamma function of  $Z$ .

## Syntax

*Result* = LNGAMMA( $Z$ )

## Return Value

For negative integers, LNGAMMA returns the correct value of Infinity. If  $Z$  is double-precision, the result is double-precision (either double or double complex), otherwise the result is single-precision (either float or complex).

---

### Note

For negative nonintegers, LNGAMMA will also return Infinity. To compute the actual LNGAMMA of a negative noninteger, you should convert your input to complex first.

---

## Arguments

### $Z$

The expression for which the logarithm of the gamma function will be evaluated.  $Z$  may be complex.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To find the logarithm of the gamma function of 0.5 and store the result in variable A, enter:

```
A = LNGAMMA(0.5)
```

## Version History

Pre 4.0	Introduced
5.6	Z argument accepts complex input

## See Also

[BETA](#), [GAMMA](#), [IBETA](#), [IGAMMA](#)

# LNP\_TEST

The LNP\_TEST function computes the Lomb Normalized Periodogram of two sample populations  $X$  and  $Y$  and tests the hypothesis that the populations represent a significant periodic signal against the hypothesis that they represent random noise.

LNP\_TEST is based on the routine `fasper` described in section 13.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = LNP_TEST( X, Y [, /DOUBLE] [, HIFAC=scale_factor]  
[, JMAX=variable] [, OFAC=value] [, WK1=variable] [, WK2=variable] )
```

## Return Value

The result is a two-element vector containing the maximum peak in the Lomb Normalized Periodogram and its significance. The significance is a value in the interval [0.0, 1.0]; a small value indicates that a significant periodic signal is present.

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector containing equally or unequally spaced time samples.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector containing amplitudes corresponding to  $X_i$ .

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## HIFAC

Use this keyword to specify the scale factor of the average Nyquist frequency. The default value is 1.

## JMAX

Use this keyword to specify a named variable that will contain the index of the maximum peak in the Lomb Normalized Periodogram.

## OFAC

Use this keyword to specify the oversampling factor. The default value is 4.

## WK1

Use this keyword to specify a named variable that will contain a vector of increasing linear frequencies.

## WK2

Use this keyword to specify a named variable that will contain a vector of values from the Lomb Normalized Periodogram corresponding to the frequencies in WK1.

## Examples

This example tests the hypothesis that two sample,  $n$ -element populations X and Y represent a significant periodic signal against the hypothesis that they represent random noise:

```
; Define two n-element sample populations:
X = [ 1.0,  2.0,  5.0,  7.0,  8.0,  9.0, $
      10.0, 11.0, 12.0, 13.0, 14.0, 15.0, $
      16.0, 17.0, 18.0, 19.0, 20.0, 22.0, $
      23.0, 24.0, 25.0, 26.0, 27.0, 28.0]
Y = [ 0.69502, -0.70425,  0.20632,  0.77206, -2.08339,  0.97806, $
      1.77324,  2.34086,  0.91354,  2.04189,  0.53560, -2.05348, $
      -0.76308, -0.84501, -0.06507, -0.12260,  1.83075,  1.41403, $
      -0.26438, -0.48142, -0.50929,  0.01942, -1.29268,  0.29697]

; Test the hypothesis that X and Y represent a significant periodic
; signal against the hypothesis that they represent random noise:
result = LNP_TEST(X, Y, WK1 = wk1, WK2 = wk2, JMAX = jmax)
PRINT, result
```

IDL prints:

```
4.69296    0.198157
```

The small value of the significance represents the possibility of a significant periodic signal. A larger number of samples for  $X$  and  $Y$  would produce a more conclusive result. WK1 and WK2 are both 48-element vectors containing linear frequencies and corresponding Lomb values, respectively. JMAX is the indexed location of the maximum Lomb value in WK2.

# LOADCT

The LOADCT procedure loads one of 41 predefined IDL color tables. These color tables are defined in the file `colors1.tbl`, located in the `\resource\colors` subdirectory of the main IDL directory, unless the FILE keyword is specified. The selected colortable is loaded into the COLORS common block as both the “current” and “original” colortable. If the current device has fewer than 256 colors, the color table data is interpolated to cover the number of colors in the device.

This routine is written in the IDL language. Its source code can be found in the file `loadct.pro` in the `lib` subdirectory of the IDL distribution.

## Obtaining the Color Tables

All of the IDL color-table procedures maintain the current color table in a common block called COLORS, defined as follows:

```
COMMON COLORS, R_orig, G_orig, B_orig, R_curr, G_curr, B_curr
```

The variables are integer vectors of length equal to the number of color indices. Your program can access these variables by defining the common block. The convention is that routines that modify the current color table should read it from `R_orig`, `G_orig`, and `B_orig`, then load the color table using TVLCT and leave the resulting color table in `R_curr`, `G_curr`, and `B_curr`.

## Syntax

```
LOADCT [, Table] [, BOTTOM=value] [, FILE=string] [, GET_NAMES=variable]
      [, NCOLORS=value] [, /SILENT]
```

## Arguments

### Table

The number of the pre-defined color table to load, from 0 to 40. If this value is omitted, a menu of the available tables is printed and the user is prompted to enter a table number.

## Keywords

### BOTTOM

The first color index to use. `LOADCT` will use color indices from `BOTTOM` to `BOTTOM+NCOLORS-1`. The default is `BOTTOM=0`.

### FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl`. See [MODIFYCT](#) to create and modify colortable files.

### GET\_NAMES

Set this keyword to a named variable in which the names of the color tables are returned as a string array. No changes are made to the color table.

### NCOLORS

The number of colors to use. The default is all available colors (this number is stored in the system variable `!D.TABLE_SIZE`).

### SILENT

If this keyword is set, the Color Table message is suppressed.

## Examples

The following example introduces using `LOADCT`.

### Tip

---

If you are running IDL on a TrueColor display, set `DEVICE, DECOMPOSED = 0` before your first color table related routine is used within an IDL session or program.

---

1. View a list of IDL's tables and their related indices by calling `LOADCT` without an argument:

```
LOADCT
```

The list of color tables appears in the Output Log:

When running `LOADCT` without an argument, it will prompt you to enter the number of one of the color tables at the IDL command line.

2. Enter in the number 5 at the Enter table number: prompt:

```
Enter table number: 5
```

The following text is displayed in the Output Log:

```
% LOADCT: Loading table STD GAMMA-II
```

If you already know the number of the pre-defined color table you want, you can load a color table by providing that number as the first input argument to LOADCT.

3. Load in color table number 13 (RAINBOW):

```
LOADCT, 13
```

The following text is displayed in the Output Log:

```
% LOADCT: Loading table RAINBOW
```

4. View the color table in a simple image display:

```
TV, DIST(300)
```

---

#### Note

To see the organization of the colors associated with each color table, use XLOADCT .

---

# LOCALE\_GET

The LOCALE\_GET function returns the current locale (string) of the operating platform.

## Syntax

*Result* = LOCALE\_GET()

## Return Value

Returns a string containing the current operating platform locale.

## Arguments

None

## Keywords

None

## Version History

5.2.1	Introduced
-------	------------

# LOGICAL\_AND

The LOGICAL\_AND function performs a logical AND operation on its arguments. It returns True (1) if both of its arguments are non-zero (non-NULL for strings and heap variables), or False (0) otherwise.

The LOGICAL\_AND function is similar to the AND operator, except that it performs a logical “and” rather than a bitwise “and” on its arguments.

---

**Note**

LOGICAL\_AND always returns either 0 or 1, unlike the AND operator, which performs a bitwise AND operation on integers, and returns one of the two arguments for other types.

---

Unlike the && operator, LOGICAL\_AND accepts multi-element arrays as its arguments. In addition, where the && operator *short-circuits* if it can determine the result by evaluating only the first argument, all arguments to a function are always evaluated.

## Syntax

$$Result = LOGICAL\_AND(Arg1, Arg2)$$

## Return Value

Integer zero (false) or one (true) if both arguments are scalars, or an array of zeroes and ones if either argument is an array.

## Arguments

### Arg1, Arg2

The expressions on which the logical AND operation is to be carried out. The arguments can be scalars or arrays of any type other than structure.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU

system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See Appendix D, “Thread Pool Keywords” for details.

## Example

At the IDL Command line, enter:

```
PRINT, LOGICAL_AND(2,4), LOGICAL_AND(2,0), LOGICAL_AND(0,4), $
      LOGICAL_AND(0,0)
```

IDL Prints:

```
1 0 0 0
```

## Version History

“[Logical Operators](#)” and “[Bitwise Operators](#)” in Chapter 12 of the *Building IDL Applications* manual, [LOGICAL\\_OR](#), [LOGICAL\\_TRUE](#)

# LOGICAL\_OR

The LOGICAL\_OR function performs a logical OR operation on its arguments. It returns True (1) if either of its arguments are non-zero (non-NULL for strings and heap variables), and False (0) otherwise.

The LOGICAL\_OR function is similar to the OR operator, except that it performs a logical “or” rather than a bitwise “or” on its arguments.

---

**Note**

LOGICAL\_OR always returns either 0 or 1, unlike the OR operator, which performs a bitwise OR operation on integers, and returns one of the two arguments for other types.

---

Unlike the || operator, LOGICAL\_OR accepts multi-element arrays as its arguments. In addition, where the || operator *short-circuits* if it can determine the result by evaluating only the first argument, all arguments to a function are always evaluated.

## Syntax

$$Result = LOGICAL\_OR(Arg1, Arg2)$$

## Return Value

Integer zero (false) or one (true) if both operands are scalars, or an array of zeroes and ones if either operand is an array.

## Arguments

### Arg1, Arg2

The expressions on which the logical OR operation is to be carried out. The arguments can be scalars or arrays of any type other than structure.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU

system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See Appendix D, “Thread Pool Keywords” for details.

## Example

At the IDL Command Line, enter:

```
PRINT, LOGICAL_OR(2,4), LOGICAL_OR(2,0), LOGICAL_OR(0,4), $
      LOGICAL_OR(0,0)
```

IDL Prints:

```
1 1 1 0
```

# LOGICAL\_TRUE

The LOGICAL\_TRUE function returns True (1) if its arguments are non-zero (non-NULL for strings and heap variables), and False (0) otherwise.

---

**Note**

For a given argument, the value returned by LOGICAL\_TRUE is the opposite of the value returned by the ~ operator.

---

## Syntax

*Result* = LOGICAL\_TRUE(*Arg*)

## Return Value

Integer zero (false) or one (true) if the argument is a scalar, or an array of zeroes and ones if the argument is an array.

## Arguments

### Arg

The expression on which the logical truth evaluation is to be carried out. The argument can be a scalar or an array of any type other than structure.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix D, "Thread Pool Keywords" for details.

## Example

At the IDL Command Line, enter:

```
PRINT, LOGICAL_TRUE(2), LOGICAL_TRUE(0)
```

IDL Prints:

```
1 0
```

# LON64ARR

The LON64ARR function returns a 64-bit integer vector or array.

## Syntax

$$\text{Result} = \text{LON64ARR}(D_1 [, \dots, D_8] [, /\text{NOZERO}] )$$

## Return Value

Returns a 64-bit array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### NOZERO

Normally, LON64ARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and LON64ARR executes faster.

## Examples

To create L, a 100-element, 64-bit vector with each element set to 0, enter:

```
L = LON64ARR(100)
```

## Version History

5.2	Introduced
-----	------------

# LONARR

The LONARR function returns a longword integer vector or array.

## Syntax

$$\text{Result} = \text{LONARR}(D_1 [, \dots, D_8] [, /\text{NOZERO}] )$$

## Return Value

Returns a long array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### NOZERO

Normally, LONARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and LONARR executes faster.

## Examples

To create L, a 100-element, longword vector with each element set to 0, enter:

```
L = LONARR(100)
```

## Version History

Original	Introduced
----------	------------

## See Also

# LONG

The LONG function returns a result equal to *Expression* converted to longword integer type.

## Syntax

$$\text{Result} = \text{LONG}(\text{Expression}[, \text{Offset} [, D_1 [, \dots, D_8]]])$$

## Return Value

Returns the conversion of the given scalar or array to a longword integer type.

## Arguments

### Expression

The expression to be converted to longword integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as longword integer data.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON\_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

# Keywords

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

If A contains the floating-point value 32000.0, it can be converted to a longword integer and stored in the variable B by entering:

```
B = LONG(A)
```

# LONG64

The LONG64 function returns a result equal to *Expression* converted to 64-bit integer type.

## Syntax

$$Result = \text{LONG64}( Expression[, Offset [, D_1 [, \dots, D_8]]])$$

## Return Value

Returns the conversion of the given scalar or array to a 64-bit integer type.

## Arguments

### Expression

The expression to be converted to 64-bit integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as 64-bit integer data.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON\_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

# LSODE

The LSODE function uses adaptive numerical methods to advance a solution to a system of ordinary differential equations one time-step  $H$ , given values for the variables  $Y$  and  $X$ .

## Syntax

```
Result = LSODE( Y, X, H, Derivs[, Status] [, ATOL=value] [, /QUIET]
               [, RTOL=value] )
```

## Return Value

Returns the solution in a vector with the same number of elements as  $Y$ .

## Arguments

### Y

A vector of values for  $Y$  at  $X$

### X

A scalar value for the initial condition.

### H

A scalar value giving interval length or step size.

### Derivs

A scalar string specifying the name of a user-supplied IDL function that calculates the values of the derivatives  $Dydx$  at  $X$ . This function must accept two arguments: A scalar floating value  $X$ , and an  $n$ -element vector  $Y$ . It must return an  $n$ -element vector result.

For example, suppose the values of the derivatives are defined by the following relations:

$$dy_0 / dx = -0.5y_0, \quad dy_1 / dx = 4.0 - 0.3y_1 - 0.1y_0$$

We can write a function called `differential` to express these relationships in the IDL language:

```
FUNCTION differential, X, Y
  RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END
```

## Status

An index used for input and output to specify the state of the calculation. This argument contains a positive value if the function was successfully completed. Negative values indicate different errors.

Input Value	Description
1	This is the first call for the problem; initializations will occur. This is the default value.
2	This is not the first call. The calculation is to continue normally.
3	This is not the first call. The calculation is to continue normally, but with a change in input parameters.

*Table 3-77: Input Values for Status*

### Note

A preliminary call with `tout = t` is not counted as a first call here, as no initialization or checking of input is done. (Such a call is sometimes useful for the purpose of outputting the initial condition *s*.) Thus, the first call for which `tout ≠ t` requires `STATUS = 1` on input.

Output Value	Description
1	Nothing occurred. (However, an internal counter was set to detect and prevent repeated calls of this type.)
2	The integration was performed successfully, and no roots were found.
3	The integration was successful, and one or more roots were found.

*Table 3-78: Output Values for Status*

Output Value	Description
-1	An excessive amount of work was done on this call, but the integration was otherwise successful. To continue, reset STATUS to a value greater than 1 and begin again (the excess work step counter will be reset to 0).
-2	The precision of the machine being used is insufficient for the requested amount of accuracy. Integration was successful. To continue, the tolerance parameters must be reset, and STATUS must be set to 3. (If this condition is detected before taking any steps, then an illegal input return (STATUS = -3) occurs instead.)
-3	Illegal input was detected, before processing any integration steps. If the solver detects an infinite loop of calls to the solver with illegal input, it will cause the run to stop.
-4	There were repeated error test failures on one attempted step, before completing the requested task, but the integration was successful. The problem may have a singularity, or the input may be inappropriate.
-5	There were repeated convergence test failures on one attempted step, before completing the requested task, but the integration was successful. This may be caused by an inaccurate jacobian matrix, if one is being used.
-6	ewt( <i>i</i> ) became zero for some <i>i</i> during the integration. Pure relative error control was requested on a variable which has now vanished. Integration was successful.

*Table 3-78: Output Values for Status (Continued)*

**Note**

Since the normal output value of STATUS is 2, it does not need to be reset for normal continuation. Also, since a negative input value of STATUS will be regarded as illegal, a negative output value requires the user to change it, and possibly other inputs, before calling the solver again.

## Keywords

### ATOL

A scalar or array value that specifies the absolute tolerance. The default value is 1.0e-7. Use  $ATOL = 0.0$  (or  $ATOL[i] = 0.0$ ) for pure relative error control, and use  $RTOL = 0.0$  for pure absolute error control. For an explanation of how to use ATOL and RTOL together, see RTOL below.

### QUIET

Set this keyword to suppress warning messages. By default, warning messages will be output to the screen.

### RTOL

A scalar value that specifies the relative tolerance. The default value is 1.0e-7. Use  $RTOL = 0.0$  for pure absolute error control, and use  $ATOL = 0.0$  (or  $ATOL[i] = 0.0$ ) for pure relative error control.

The estimated local error in the  $Y[i]$  argument will be controlled to be less than

```
ewt[i] = RTOL*abs(Y[i]) + ATOL      ; If ATOL is a scalar.
ewt[i] = RTOL*abs(Y[i]) + ATOL[i]  ; If ATOL is an array.
```

Thus, the local error test passes if, in each component, either the absolute error is less than ATOL (or  $ATOL[i]$ ), or if the relative error is less than RTOL.

### Warning

---

Actual, or global, errors might exceed these local tolerances, so choose values for ATOL and RTOL conservatively.

---

## Examples

To integrate the example system of differential equations for one time step, H:

```
PRO LSODETEST

    ; Define the step size:
    H = 0.5

    ; Define an initial X value:
    X = 0.0

    ; Define initial Y values:
    Y = [4.0, 6.0]
```

```

; Integrate over the interval (0, 0.5):
result = LSODE(Y, X, H, 'differential')

```

```

; Print the result:
PRINT, result

```

```
END
```

```

FUNCTION differential, X, Y
  RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END

```

IDL prints:

```
3.11523      6.85767
```

This is the exact solution vector to 5-decimal precision.

# LU\_COMPLEX

The `LU_COMPLEX` function solves an  $n$  by  $n$  complex linear system  $\mathbf{Az} = \mathbf{b}$  using LU decomposition. The result is an  $n$ -element complex vector  $z$ . Alternatively, `LU_COMPLEX` computes the generalized inverse of an  $n$  by  $n$  complex array.

This routine is written in the IDL language. Its source code can be found in the file `lu_complex.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = LU_COMPLEX( A, B [, /DOUBLE] [, /INVERSE] [, /SPARSE] )
```

## Return Value

The result is an  $n$  by  $n$  complex array.

## Arguments

### A

An  $n$  by  $n$  complex array.

### B

An  $n$ -element right-hand side vector (real or complex).

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### INVERSE

Set this keyword to compute the generalized inverse of  $A$ . If `INVERSE` is specified, the input argument  $B$  is ignored.

### SPARSE

Set this keyword to convert the input array to row-indexed sparse storage format. Computations are done using the iterative biconjugate gradient method. This

keyword is effective only when solving complex linear systems. This keyword has no effect when calculating the generalized inverse.

## Examples

```
; Define a complex array A and right-side vector B:
A = [[COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3,1)], $
      [COMPLEX(1,-2), COMPLEX(2, 2), COMPLEX(1, 0)], $
      [COMPLEX(1, 1), COMPLEX(0, 1), COMPLEX(1, 5)]]
B = [COMPLEX(1, 1), COMPLEX(3,-2), COMPLEX(1,-2)]

; Solve the complex linear system Az = b:
Z = LU_COMPLEX(A, B)
PRINT, 'Z:'
PRINT, Z

; Compute the inverse of the complex array A by supplying a scalar
; for B (in this example -1):
inv = LU_COMPLEX(A, B, /INVERSE)
PRINT, 'Inverse:'
PRINT, inv
```

IDL prints:

```
Z:
(   0.552267,   1.22818) (  -0.290371,  -0.600974)
(  -0.629824,  -0.340952)

Inverse:
(   0.261521,  -0.0303485) (   0.0138629,   0.329337)
(  -0.102660,  -0.168602) (   0.0340952,  -0.162982)
(   0.102660,   0.168602) (  -0.0666916,  -0.0438366)
(   0.125890,  -0.0633196) (   0.0108655,   0.0614462)
(  -0.0689397,  0.0108655) (  -0.0666916,  -0.0438366)
(   0.0614462,  -0.161858)
```

# LUDC

The LUDC procedure replaces an  $n$  by  $n$  array,  $A$ , with the LU decomposition of a row-wise permutation of itself.

LUDC is based on the routine `ludcmp` described in section 2.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the `LA_LUDC` procedure instead.

---

## Syntax

LUDC,  $A$ ,  $Index$  [, /COLUMN] [, /DOUBLE] [, INTERCHANGES=*variable*]

## Arguments

### A

An  $n$  by  $n$  array of any type except string. Upon output,  $A$  is replaced with its LU decomposition.

### Index

An output vector that records the row permutations which occurred as a result of partial pivoting.

## Keywords

### COLUMN

Set this keyword if the input array  $A$  is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## INTERCHANGES

An output variable that is set to positive 1 if the number of row interchanges was even, or to negative 1 if the number of interchanges was odd.

## Examples

See the description of [LUSOL](#) for an example using this procedure.

## Version History

# LUMPROVE

The LUMPROVE function uses LU decomposition to iteratively improve an approximate solution  $X$  of a set of  $n$  linear equations in  $n$  unknowns  $Ax = b$ .

LUMPROVE is based on the routine `mprove` described in section 2.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the `LA_LUMPROVE` function instead.

---

## Syntax

*Result* = LUMPROVE( *A*, *Alud*, *Index*, *B*, *X* [, /COLUMN] [, /DOUBLE] )

## Return Value

The result is a vector, whose type and length are identical to  $X$ , containing the improved solution.

## Arguments

### A

The  $n$  by  $n$  coefficient array of the linear system  $Ax = b$ .

### Alud

The  $n$  by  $n$  LU decomposition of  $A$  created by the LUDC procedure.

### Index

An input vector, created by the LUDC procedure, containing a record of the row permutations which occurred as a result of partial pivoting.

### B

An  $n$ -element vector containing the right-hand side of the linear system  $Ax = b$ .

**X**

An  $n$ -element vector containing the approximate solution of the linear system  $Ax = b$ .

**Keywords****COLUMN**

Set this keyword if the input array  $A$  is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

**DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

**Examples**

This example uses LUMPROVE to improve an approximate solution  $X$  to the linear system  $Ax = B$ :

```

; Create coefficient array A:
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]

; Create a duplicate of A:
alud = A
; Define the right-hand side vector B:
B = [3.0, -8.0, 10.0]

; Begin with an estimated solution X:
X = [.89, 1.78, -0.88]

; Decompose the duplicate of A:
LUDC, alud, INDEX

; Compute an improved solution:
result = LUMPROVE(A, alud, INDEX, B, X)

; Print the result:
PRINT, result

```

IDL prints:

```
1.00000 2.00000 -1.00000
```

This is the exact solution vector.

## Version History

# LUSOL

The LUSOL function is used in conjunction with the LUDC procedure to solve a set of  $n$  linear equations in  $n$  unknowns  $Ax = b$ . The parameter  $A$  is input not as the original array, but as its LU decomposition, created by the routine LUDC.

LUSOL is based on the routine `lubksb` described in section 2.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

## Note

If you are working with complex inputs, use the `LA_LUSOL` function instead.

---

## Syntax

*Result* = LUSOL(*A*, *Index*, *B* [, /COLUMN] [, /DOUBLE])

## Return Value

The result is an  $n$ -element vector whose type is identical to  $A$ .

## Arguments

### A

The  $n$  by  $n$  LU decomposition of an array created by the LUDC procedure.

---

### Note

If LUSOL is complex then only the real part is used for the computation.

---

### Index

An input vector, created by the LUDC procedure, containing a record of the row permutations which occurred as a result of partial pivoting.

### B

An  $n$ -element vector containing the right-hand side of the linear system  $Ax = b$ .

## Keywords

### COLUMN

Set this keyword if the input array  $A$  is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

This example solves the linear system  $Ax = b$  using LU decomposition and back substitution:

```

; Define array A:
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]

; Define right-hand side vector B:
B = [3.0, -8.0, 10.0]

; Decompose A:
LUDC, A, INDEX

; Compute the solution using back substitution:
result = LUSOL(A, INDEX, B)

; Print the result:
PRINT, result

```

IDL prints:

```
1.00000  2.00000  -1.00000
```

This is the exact solution vector.

# M\_CORRELATE

The M\_CORRELATE function computes the multiple correlation coefficient of a dependent variable and two or more independent variables.

This routine is written in the IDL language. Its source code can be found in the file `m_correlate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = M_CORRELATE( X, Y [, /DOUBLE] )
```

## Return Value

Returns the single or double-precision multiple correlation coefficient.

## Arguments

### X

An integer, single-, or double-precision floating-point array of  $m$ -columns and  $n$ -rows that specifies the independent variable data. The columns of this two dimensional array correspond to the  $n$ -element vectors of independent variable data.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector that specifies the dependent variable data.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Example

```
PRO M_CORRELATE_TEST

; Define the independent (X) and dependent (Y) data:
X = [[0.477121, 2.0, 13.0], $
     [0.477121, 5.0, 6.0], $
     [0.301030, 5.0, 9.0], $
```

```

# MACHAR

The MACHAR function determines and returns machine-specific parameters affecting floating-point arithmetic. Information is returned in the form of a structure with the fields listed in the “Return Value” section.

MACHAR is based on the routine `machar` described in section 20.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission. See that section for more details on and sample values of the various parameters returned.

## Syntax

*Result* = MACHAR( [, /DOUBLE] )

## Return Value

The following table lists the fields in the structure returned from the MACHAR function:

Field Name	Description
IBETA	The radix in which numbers are represented. A longword integer.
IT	The number of base-IBETA digits in the floating-point mantissa M. A longword integer.
IRND	A code in the range 0 – 5 giving information on what type of rounding is done and how underflow is handled. A longword integer.
NGRD	The number of “guard digits” used when truncating the product of two mantissas. A longword integer.
MACHEP	The exponent of the smallest power of IBETA that, added to 1.0, gives something different from 1.0. A longword integer.
NEGEP	The exponent of the smallest power of IBETA that, subtracted from 1.0, gives something different from 1.0. A longword integer.

Table 3-79: MACHAR Fields

Field Name	Description
IEXP	The number of bits in the exponent. A longword integer.
MINEXP	The smallest value of IBETA consistent with there being no leading zeros in the mantissa. A longword integer.
MAXEXP	The smallest positive value of IBETA that causes overflow. A longword integer.
EPS	The floating-point number $IBETA^{MACHEP}$ , loosely referred to as the “floating-point precision.”
EPSNEG	The floating-point number $IBETA^{NEGEP}$ , which is another way of determining floating-point precision.
XMIN	The floating-point number $IBETA^{MINEXP}$ , generally the magnitude of the smallest usable floating-point value.
XMAX	The largest usable floating-point value, defined as the number $(1-EPSNEG) \times IBETA^{MAXEXP}$ .

Table 3-79: MACHAR Fields

## Arguments

None

## Keywords

### DOUBLE

The information returned is normally for single-precision floating-point arithmetic. Specify DOUBLE to see double-precision information.

## Version History

4.0	Introduced
-----	------------

## See Also

# MAKE\_ARRAY

The MAKE\_ARRAY function enables you to dynamically create an array whose characteristics are not known until run time.

## Syntax

```
Result = MAKE_ARRAY ( [D1 [, ..., D8]] [, /BYTE | /COMPLEX | /DCOMPLEX
| /DOUBLE | /FLOAT | /INTEGER | /L64 | /LONG | /OBJ | /PTR |
/STRING | /UINT | /UL64 | /ULONG] [, DIMENSION=vector] [, /INDEX]
[, /NOZERO] [, SIZE=vector] [, TYPE=type_code] [, VALUE=value] )
```

## Return Value

Returns an array of the specified type, dimensions, and initialization.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

The  $D_i$  arguments are optional if the dimensions of the result are specified using the DIMENSION keyword. Note that you should supply either the  $D_i$  arguments or a value for the DIMENSION keyword, but not both.

## Keywords

### BYTE

Set this keyword to create a byte array.

### COMPLEX

Set this keyword to create a complex, single-precision, floating-point array.

## **DCOMPLEX**

Set this keyword to create a complex, double-precision, floating-point array.

## **DIMENSION**

An array of up to eight scalar elements, specifying the dimensions of the result. Note that you should supply either the  $D_i$  arguments or a value for the DIMENSION keyword, but not both.

## **DOUBLE**

Set this keyword to create a double-precision, floating-point array.

## **FLOAT**

Set this keyword to create a single-precision, floating-point array.

## **L64**

Set this keyword to create a 64-bit integer array.

## **INDEX**

Set this keyword to initialize the array with each element set to the value of its one-dimensional subscript.

## **INTEGER**

Set this keyword to create an integer array.

## **LONG**

Set this keyword to create a longword integer array.

## **NOZERO**

Set this keyword to prevent the initialization of the array. Normally, each element of the resulting array is set to zero.

## **OBJ**

Set this keyword to create an object reference array.

## **PTR**

Set this keyword to create a pointer array.

## SIZE

A size vector specifying the type and dimensions of the result. The format of a size vector is given in the description of the `SIZE` function.

## STRING

Set this keyword to create a string array.

## TYPE

The type code to set the type of the result. See the description of the `SIZE` function for a list of IDL type codes.

## UINT

Set this keyword to create an unsigned integer array.

## UL64

Set this keyword to create an unsigned 64-bit integer array.

## ULONG

Set this keyword to create an unsigned longword integer array.

## VALUE

The value to initialize each element of the resulting array. `VALUE` can be a scalar of any type including structure types. The result type is taken from `VALUE` unless one of the other keywords that specify a type is also set. In that case, `VALUE` is converted to the type specified by the other keyword prior to initializing the resulting array.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create a 3-element by 4-element integer array with each element set to the value 5, enter:

```
M = MAKE_ARRAY(3, 4, /INTEGER, VALUE = 5)
```

# MAKE\_DLL

The MAKE\_DLL procedure builds a sharable library from C language code which is suitable for use by IDL's dynamic linking features such as CALL\_EXTERNAL, LINKIMAGE, and dynamically loadable modules (DLMs). MAKE\_DLL reduces the complexity of building sharable libraries by providing a stable cross-platform method for the user to describe the desired library, and issuing the necessary operating system commands to build the library.

Although MAKE\_DLL is very convenient, it is not intended for use as a general purpose compiler. Instead, MAKE\_DLL is specifically targeted to solving the most common IDL dynamic linking problem: building a sharable library from C language source files that are usable by IDL. Because of this, the following requirements apply:

- You must have a C compiler installed on your system. It is easiest to use the compiler used to build IDL, because MAKE\_DLL already knows how to use that compiler without any additional configuring. To determine which compiler was used, query the !MAKE\_DLL system variable with a print statement such as the following:

```
PRINT, !MAKE_DLL.COMPILER_NAME
```

- MAKE\_DLL only compiles programs written in the C language; it does not understand Fortran, C++, or any other languages.
- MAKE\_DLL provides only the functionality necessary to build C code intended to be linked with IDL. Not every possible option supported by the C compiler or system linker is addressed, only those commonly needed by IDL-related C code.

MAKE\_DLL solves the most common IDL-centric problem of linking C code with IDL. To do more than this or to use a different language requires a system-specific building process (*e.g.* make files or projects).

## Syntax

```
MAKE_DLL, InputFiles [, OutputFile], ExportedRoutineNames [, CC=string]
  [, COMPILE_DIRECTORY=path] [, DLL_PATH=variable]
  [, EXPORTED_DATA=string] [, EXTRA_CFLAGS=string]
  [, EXTRA_LFLAGS=string] [, INPUT_DIRECTORY=path] [, LD=string]
  [, /NOCLEANUP] [, OUTPUT_DIRECTORY=path] [, /REUSE_EXISTING]
  [, /SHOW_ALL_OUTPUT] [, /VERBOSE]
```

## Arguments

### InputFiles

A string (scalar or array) giving the names of the input C program files to be compiled by `MAKE_DLL`. These names should not include any directory path information or the `.c` suffix, they are simply the base file names.

The input directory is specified using the `INPUT_DIRECTORY` keyword, and the `.c` file suffix is assumed.

### OutputFile

The base name of the resulting sharable library. This name should not include any directory path information or the sharable library suffix, which differs between platforms (for example: `.so`, `.a`, `.sl`, `.exe`, `.dll`).

The output directory can be specified using the `OUTPUT_DIRECTORY` keyword.

If the *OutputFile* argument is omitted, the first name given by *InputFile* is used as the base name of output file.

### ExportedRoutineNames

A string (scalar or array) specifying the names of the routines to be exported (i.e., that are visible for linking) from the resulting sharable library.

## Keywords

### CC

If present, a template string to use in generating the C compiler commands to compile *InputFiles*. If `CC` is not specified, the value given by the `!MAKE_DLL.CC` system variable is used by default. See the discussion of [!MAKE\\_DLL](#) for a description of how to write the format string for `CC`.

### COMPILE\_DIRECTORY

To build a sharable library, `MAKE_DLL` requires a place to create the necessary intermediate files and possibly the final library itself. If `COMPILE_DIRECTORY` is specified, the directory specified is used. If `COMPILE_DIRECTORY` is not specified, the directory given by the `!MAKE_DLL.COMPILE_DIRECTORY` system variable is used.

## DLL\_PATH

If present, the name of a variable to receive the complete file path for the newly created sharable library. The location of the resulting sharable library depends on the setting of the `OUTPUT_DIRECTORY` or `COMPILE_DIRECTORY` keywords as well as the `!MAKE_DLL.COMPILE_DIRECTORY` system variable, and different platforms use different file suffixes to indicate sharable libraries. Use of the `DLL_PATH` keyword makes it possible to determine the resulting file path in a simple and portable manner.

## EXPORTED\_DATA

A string (scalar or array) containing the names of variables to be exported (i.e., are visible for linking) from the resulting sharable library.

## EXTRA\_CFLAGS

If present, a string supplying extra options for the command used to execute the C compiler to compile the files given by *InputFiles*. This keyword is frequently used to specify header file include directories. This text is inserted in place of the `%X` format code in the compile string. See the discussion of the `CC` keyword and `!MAKE_DLL.CC` system variable for more information.

## EXTRA\_LFLAGS

If present, a string supplying extra options for the command used to execute the linker when combining the object files to produce the sharable library. This keyword is frequently used to specify libraries to be included in the link, and is inserted in place of the `%X` format code in the linker string. See the discussion of the `LD` keyword and `!MAKE_DLL.LD` system variable for more information.

## INPUT\_DIRECTORY

If present, the path to the directory containing the source C files listed in *InputFiles*. If `INPUT_DIRECTORY` is not specified, the directory given by `COMPILE_DIRECTORY` is assumed to contain the files.

## LD

If present, a template string to use when generating the linker command to generate the resulting sharable library. If `LD` is not specified, the value given by the `!MAKE_DLL.LD` system variable is used by default. See the discussion of `!MAKE_DLL` for a description of how to write the format string for `LD`.

## NOCLEANUP

To produce a sharable library, MAKE\_DLL produces several intermediate files:

1. A shell script (UNIX) or batch file (Windows) that is then executed via SPAWN to build the library.
2. A linker options file. This file is used to control the linker. MAKE\_DLL uses it to cause the routines given by the *ExportedRoutineNames* argument (and EXPORTED\_DATA keyword) to be exported from the resulting sharable library. The general platform terminology is shown below.

Platform	Linker Options File Terminology
UNIX	export file, or linker map file
Windows	a .DEF file

*Table 3-80: Platform Terminology for Linker Options File*

3. Object files, resulting from compiling the source C files given by the *InputFiles* argument.
4. A log file that captures the output from executing the script, and which can be used for debugging in case of error.

By default, MAKE\_DLL deletes all of these intermediate files once the sharable library has been successfully built. Setting the NOCLEANUP keyword prevents MAKE\_DLL from removing them.

### Note

Set the NOCLEANUP keyword (possibly in conjunction with VERBOSE) for troubleshooting, or to read the files for additional information on how MAKE\_DLL works.

## OUTPUT\_DIRECTORY

By default, MAKE\_DLL creates the resulting sharable library in the compile directory specified by the COMPILE\_DIRECTORY keyword or the !MAKE\_DLL.COMPILE\_DIRECTORY system variable. The OUTPUT\_DIRECTORY keyword can be used to override this and explicitly specify where the library file should go.

## REUSE\_EXISTING

If this keyword is set, and the sharable library file specified by *OutputFile* already exists, MAKE\_DLL returns without building the sharable library again. Use this keyword in situations where you wish to ensure that a library exists, but only want to build it if it does not. Combining the REUSE\_EXISTING and DLL\_PATH keywords allows you to get a path to the library in a platform independent manner, building the library only if necessary.

## SHOW\_ALL\_OUTPUT

MAKE\_DLL normally produces no output unless an error prevents successful building of the sharable library. Set SHOW\_ALL\_OUTPUT to see all output produced by the spawned process building the library.

## VERBOSE

If set, VERBOSE causes MAKE\_DLL to issue informational messages as it carries out the task of building the sharable library. These messages include information on the intermediate files created to build the library and how they are used.

## Examples

### Example 1: Testmodule DLM

The IDL distribution contains an example of a simple DLM (dynamically loadable module) in the `external/dlm` subdirectory. This example consists of a single C source file, and the desired sharable library exports a single function called `IDL_Load`. The following MAKE\_DLL statement builds this sharable library, leaving the resulting file in the directory given by

**!MAKE\_DLL.COMPILE\_DIRECTORY:**

```
; Locate the source file:
INDIR = FILEPATH('', SUBDIRECTORY=['external', 'dlm'])
; Build the sharable library:
MAKE_DLL, 'testmodule', 'IDL_Load', INPUT_DIRECTORY=INDIR
```

### Example 2: Using GCC

IDL is built with the standard vendor-supported C compiler in order to get maximum integration with the target system. MAKE\_DLL assumes that you have the same compiler installed on your system and its defaults are targeted to use it. To use other compilers, you tell MAKE\_DLL how to use them.

For example, many IDL users have the gcc compiler installed on their systems. This example (tested under 32-bit Solaris 7 using gcc 2.95.2) shows how to use gcc to build the testmodule sharable library from the previous example:

```

; We need the include directory for the IDL export.h header
; file. One way to get this is to extract it from the
; !MAKE_DLL system variable using the STREGEX function
INCLUDE=STREGEX(!MAKE_DLL.CC, '-I[^\ ]+', /EXTRACT)
; Locate the source file
INDIR = FILEPATH('', SUBDIRECTORY=['external', 'dlm'])
; Build the sharable library, using the CC keyword to specify gcc:
MAKE_DLL, 'testmodule', 'IDL_Load', INPUT_DIRECTORY=INDIR, $
      CC='gcc -c -fPIC '+ INCLUDE + '%C -o %O'

```

## Version History

5.4	Introduced
5.6	Added REUSE_EXISTING keyword
Pre 6.1	Deprecated VAX_FLOAT keyword

For information on deprecated keywords, see [Appendix J, “Obsolete Features”](#).

## See Also

[!MAKE\\_DLL](#)

# MAP\_2POINTS

The MAP\_2POINTS function returns parameters such as distance, azimuth, and path relating to the great circle or rhumb line connecting two points on a sphere.

This routine is written in the IDL language. Its source code can be found in the file `map_2points.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MAP_2POINTS( lon0, lat0, lon1, lat1 [, DPATH=value | , /METERS |  
, /MILES | , NPATH=integer{2 or greater} | , /PARAMETERS | , RADIANS=value]  
[, /RADIUS] [, /RHUMB] )
```

## Return Value

This function returns a two-element vector containing the distance and azimuth of the great circle or rhumb line connecting the two points, P0 to P1, in the specified angular units, unless one or more of the keywords NPATH, DPATH, METERS, MILES, PARAMETERS, or RADIUS is specified. See the keyword descriptions for the return value associated with each of these keywords.

If MILES, METERS, or RADIUS is not set, distances are angular distance, from 0 to 180 degrees (or 0 to !DPI if the RADIANS keyword is set). Azimuth is measured in degrees or radians, east of north.

## Arguments

### Lon0, Lat0

Longitude and latitude of the first point, P0.

### Lon1, Lat1

Longitude and latitude of the second point, P1.

## Keywords

### DPATH

Set this keyword to a value specifying the maximum angular distance between the points on the path in the prevalent units, degrees or radians.

## METERS

Set this keyword to return the distance between the two points in meters, calculated using the Clarke 1866 equatorial radius of the earth.

## MILES

Set this keyword to return the distance between the two points in miles, calculated using the Clarke 1866 equatorial radius of the earth.

## NPATH

Set this keyword to a value specifying the number of points to return. If this keyword is set, the function returns a (2, NPATH) array containing the longitude/latitude of the points on the great circle or rhumb line connecting P0 and P1. For a great circle, the points will be evenly spaced in distance, while for a rhumb line, the points will be evenly spaced in longitude.

### Note

---

This keyword must be set to an integer of 2 or greater.

---

## PARAMETERS

Set this keyword to return the parameters determining the great circle connecting the two points,  $[\sin(c), \cos(c), \sin(az), \cos(az)]$ , where  $c$  is the great circle angular distance, and  $az$  is the azimuth of the great circle at P0, in degrees east of north.

## RADIANS

Set this keyword if inputs and angular outputs are to be specified in radians. The default is degrees.

## RADIUS

Set this keyword to a value specifying the radius of the sphere to be used to calculate the distance between the two points. If this keyword is specified, the function returns the distance between the two points calculated using the given radius.

## RHUMB

Set this keyword to return the distance and azimuth of the rhumb line connecting the two points, P0 to P1. The default is to return the distance and azimuth of the great circle connecting the two points. A rhumb line is the line of constant direction connecting two points.

## Examples

The following examples use the geocoordinates of two points, Boulder and London:

```
B = [ -105.19, 40.02] ;Longitude, latitude in degrees.
L = [ -0.07, 51.30]
```

### Example 1

Print the angular distance and azimuth, from B, of the great circle connecting the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1])
```

IDL prints 67.854333 40.667833

### Example 2

Print the angular distance and course (azimuth), connecting the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1], /RHUMB)
```

IDL prints 73.966283 81.228057

### Example 3

Print the distance in miles between the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1], /MILES)
```

IDL prints 4693.5845

### Example 4

Print the distance in miles along the rhumb line connecting the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1], /MILES, /RHUMB)
```

IDL prints 5116.3571

### Example 5

Display a map containing the two points, and annotate the map with both the great circle and the rhumb line path between the points, drawn at one degree increments:

```
MAP_SET, /MOLLWEIDE, 40, -50, /GRID, SCALE=75e6, /CONTINENTS
PLOTS, MAP_2POINTS(B[0], B[1], L[0], L[1], /RHUMB, DPATH=1)
PLOTS, MAP_2POINTS(B[0], B[1], L[0], L[1], DPATH=1)
```

This displays the following map:

*Figure 3-72: Map annotated with great circle and rhumb line path between Boulder and London, drawn at one degree increments.*

## Version History

5.4	Introduced
-----	------------

[MAP\\_SET](#)

# MAP\_CONTINENTS

The MAP\_CONTINENTS procedure draws continental boundaries, filled continents, political boundaries, coastlines, and/or rivers, over a map projection. Outlines can be drawn in low or high-resolution (if the optional high-resolution CIA World Map database is installed). If MAP\_CONTINENTS is called without any keywords, it draws low-resolution, unfilled continent outlines.

The MAP\_STRUCTURE keyword can be used to draw directly to UV (Cartesian) coordinates. Otherwise, MAP\_SET must be called before MAP\_CONTINENTS to establish the projection type, the center of the projection, polar rotation and geographic limits.

## Syntax

```
MAP_CONTINENTS [, /COASTS] [, COLOR=index] [, /CONTINENTS]
  [, /COUNTRIES] [, ,FILL_CONTINENTS={1 | 2}[, ORIENTATION=value]]
  [, /HIRES] [, LIMIT=vector] [, MAP_STRUCTURE=structure]
  [, MLINestyle={0 | 1 | 2 | 3 | 4 | 5}] [, MLINETHICK=value] [, /RIVERS]
  [, SPACING=centimeters] [, /USA]
```

**Graphics Keywords:** [, /T3D] [, ZVALUE=*value*{0 to 1}]

## Keywords

### COASTS

Set this keyword to draw coastlines, islands, and lakes instead of the default continent outlines. Note that if you are using the low-resolution map database (if the HIRES keyword is *not* set), many islands are drawn even when COASTS is not set. If you are using the high-resolution map database (if the HIRES keyword *is* set), no islands are drawn unless COASTS is set.

### COLOR

Set this keyword to the color index of the lines being drawn.

### CONTINENTS

Set this keyword to plot the continental boundaries. This is the default, unless COASTS, COUNTRIES, RIVERS and/or USA is set.

---

**Note**

If you are using the low-resolution map database (if the `HIRES` keyword is *not* set), outlines for continents, islands, and lakes are drawn when the `CONTINENTS` keyword is set. If you are using the high-resolution map database (if the `HIRES` keyword *is* set), only continental outlines are drawn when the `CONTINENTS` keyword is set. To draw islands and lakes when using the high-resolution map database, use the `COASTS` keyword.

---

**Note**

If you are using the `USA` and `CONTINENTS` keywords in conjunction to map the outline of each state in the United States onto an existing outline of the continent, you may see discrepancies in the coastline. This is due to the fact that the two outlines are derived from different databases (the `USA` keyword uses a geographical database, and the `CONTINENTS` keyword uses a geological database).

---

## COUNTRIES

Set this keyword to draw political boundaries as of 1993.

## FILL\_CONTINENTS

Set this keyword to 1 to fill continent boundaries with a solid color. The color is set by the `COLOR` keyword. Set this keyword to 2 to fill continent boundaries with a line fill. For line filling, the `COLOR`, `MLINESTYLE`, `MLINETHICK`, `ORIENTATION`, and `SPACING` keywords can be used to control the type of line fill.

---

**Note**

When using this keyword in conjunction with the `HIRES` keyword, lakes on continents will be filled and islands will not be filled.

---

## HIRES

Set this keyword to use high-resolution map data instead of the default low-resolution data. This option is only available if you have installed the optional high-resolution map datasets. If the high-resolution data is not available, a warning is printed and the low-resolution data is used instead.

This keyword can be used in conjunction with the `COASTS`, `COUNTRIES`, `FILL_CONTINENTS`, and `RIVERS` keywords.

## LIMIT

Set this keyword to a four-element vector [ $Lat_{min}$ ,  $Lon_{min}$ ,  $Lat_{max}$ ,  $Lon_{max}$ ] to only plot continents that pass through the LIMIT rectangle. The points ( $Lat_{min}$ ,  $Lon_{min}$ ) and ( $Lat_{max}$ ,  $Lon_{max}$ ) are the latitudes and longitudes of two points diagonal from each other on the region's boundary. The default is to use the limits from the current map projection.

### Note

---

Line segments for continents which extend outside of the LIMIT rectangle will still be plotted.

---

## MAP\_STRUCTURE

Set this keyword to a !MAP structure, as returned from [MAP\\_PROJ\\_INIT](#). If this keyword is set, the !MAP system variable is ignored, and the polygons and polylines are drawn using UV (Cartesian) coordinates.

## MLINESTYLE

The line style of the boundaries being drawn. The default is solid lines. Valid linestyle are shown in the table below:

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

*Table 3-81: IDL Linestyles*

## MLINETHICK

The thickness of the boundary or fill lines. The default thickness is 1.

## ORIENTATION

Set this keyword to the counterclockwise angle in degrees from horizontal that the line fill should be drawn. The default is 0. This keyword only has effect if the FILL\_CONTINENTS keyword is set to 2.

## RIVERS

Set this keyword to draw rivers.

## SPACING

Set this keyword to the spacing, in centimeters, for a line fill. This keyword only has effect if the FILL\_CONTINENTS keyword is set to 2. The default is 0.5 centimeters.

## USA

Set this keyword to draw borders for each state in the United States in addition to continental boundaries.

### Note

---

If you are using the USA and CONTINENTS keywords in conjunction to map the outline of each state in the United States onto an existing outline of the continent, you may see discrepancies in the coastline. This is due to the fact that the two outlines are derived from different databases (the USA keyword uses a geographical database, and the CONTINENTS keyword uses a geological database).

---

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[T3D](#), [ZVALUE](#)

## Examples

The following example demonstrates the use of map outlines to embellish a map projection:

```
; Handle TrueColor displays:
DEVICE, DECOMPOSED=0

; Load discrete color table:
tek_color
```

```

; Match color indices to colors we want to use:
black=0 & white=1 & red=2
green=3 & dk_blue=4 & lt_blue=5

; Set up an orthographic projection centered over the north
; Atlantic. Fill the hemisphere with dark blue. Specify black
; gridlines:
MAP_SET, /ORTHO, 40, -30, 23, /ISOTROPIC, $
        /HORIZON, E_HORIZON={FILL:1, COLOR:dk_blue}, $
        /GRID, COLOR=black

; Fill the continent boundaries with solid white:
MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=white

; Overplot coastline data:
MAP_CONTINENTS, /COASTS, COLOR=black

; Add rivers, in light blue:
MAP_CONTINENTS, /RIVERS, COLOR=lt_blue

; Show national borders:
MAP_CONTINENTS, /COUNTRIES, COLOR=red, MLINEWIDTH=2

```

The following example uses the `MAP_STRUCTURE` keyword to map the continents in UV (Cartesian) coordinates, without having to set up a `!MAP` transform using `MAP_SET`.

```

; GCTP Polar stereographic projection
mapStruct = MAP_PROJ_INIT(106, LIMIT=[0, -180, 90, 180], $
        CENTER_LATITUDE=90)

; Create a plot window using the UV Cartesian range.
PLOT, mapStruct.uv_box[[0,2]], mapStruct.uv_box[[1,3]], $
        /NODATA, /ISOTROPIC, XSTYLE=1, YSTYLE=1

MAP_CONTINENTS, MAP_STRUCTURE=mapStruct
MAP_GRID, MAP_STRUCTURE=mapStruct

```

## Version History

Pre 4.0	Introduced
6.1	Added <code>MAP_STRUCTURE</code> keyword

## See Also

# MAP\_GRID

The MAP\_GRID procedure draws the graticule of parallels and meridians (grid lines) over a map projection.

The MAP\_STRUCTURE keyword may be used to draw directly to UV (Cartesian) coordinates. Otherwise, MAP\_SET must be called before MAP\_GRID to establish the projection type, the center of the projection, polar rotation and geographical limits.

## Syntax

```
MAP_GRID [, /BOX_AXES | [, CLIP_TEXT=0] [, LATALIGN=value{0.0 to 1.0}]
  [, LONALIGN=value{0.0 to 1.0}] [, LATLAB=longitude] [, LONLAB=latitude]
  [, ORIENTATION=clockwise_degrees_from_horiz]]
  [, CHARSIZE=value] [, COLOR=index] [, /FILL_HORIZON]
  [, GLINESTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, GLINETHICK=value] [, /HORIZON]
  [, INCREMENT=value] [, LABEL=n{label_every_nth_gridline}]
  [, LATDEL=degrees] [, LATNAMES=array, LATS=vector]
  [, LONDEL=degrees] [, LONNAMES=array, LONS=vector]
  [, MAP_STRUCTURE=structure] [, /NO_GRID]
```

**Graphics Keywords:** [, /T3D] [, ZVALUE=value{0 to 1}]

## Keywords

### BOX\_AXES

Set this keyword to create box-style axes for map plots where the parallels intersect the sides, and the meridians intersect the bottom and top edges of the box.

#### Warning

---

If a device (or hardware) font is in use, the labels generated by this keyword may appear incorrectly. Consider using TrueType or vector fonts instead.

---

### CHARSIZE

Set this keyword to the size of the characters used for the labels. The default is 1.

**Warning**

---

If a device (or hardware) font is in use, this keyword will have no effect. Use the `FONTSIZE` keyword to the `DEVICE` procedure to specify character size when using hardware fonts.

---

**CLIP\_TEXT**

Set this keyword to a zero value to turn off clipping of text labels. By default, text labels are clipped. This keyword is ignored if the `BOX_AXES` keyword is set.

**COLOR**

Set this keyword to the color index for the grid lines.

**FILL\_HORIZON**

Set this keyword to fill the current `map_horizon`.

**GLINESTYLE**

If set, the line style used to draw the grid of parallels and meridians. See [“LINESTYLE”](#) on page 4782 for a list of available linestyles. The default index is 1, drawing a dotted line.

**GLINETHICK**

Set this keyword to the thickness of the grid lines. Default is 1.

**HORIZON**

Set this keyword to draw the current `map_horizon`.

**INCREMENT**

Set this keyword to the spacing between graticule points.

**LABEL**

Set this keyword to label the parallels and meridians with their corresponding latitudes and longitudes. Setting this keyword to an integer will cause every `LABEL` gridline to be labeled (that is, if `LABEL=3` then every third gridline will be labeled). The starting point for determining which gridlines are labeled is the minimum latitude or longitude (-180 to 180), unless the `LATS` or `LONS` keyword is set to a single value. In this case, the starting point is the value of `LATS` or `LONS`.

## LATALIGN

This keyword controls the alignment of the text baseline for latitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it. This keyword is ignored if the BOX\_AXES keyword is set.

## LATDEL

Set this keyword equal to the spacing (in degrees) between parallels of latitude in the grid. If this keyword is not set, a suitable value is determined from the current map projection.

## LATLAB

The longitude at which to place latitude labels. The default is the center longitude on the map. This keyword is ignored if the BOX\_AXES keyword is set.

## LATNAMES

Set this keyword equal to an array specifying the names to be used for the latitude labels. By default, this array is automatically generated in units of degrees. The LATNAMES array can be either type string or any single numeric type, but should not be of mixed type.

When LATNAMES is specified, the LATS keyword must also be specified. The number of elements in the two arrays need not be equal. If there are more elements in the LATNAMES array than in the LATS array, the extra LATNAMES are ignored. If there are more elements in the LATS array than in the LATNAMES array, labels in degrees will be automatically provided for the missing latitude labels.

The LATNAMES keyword can be also used when the LATS keyword is set to a single value. In this case, the first label supplied will be used at the specified latitude; subsequent names will be placed at the next latitude line to the north, wrapping around the globe if appropriate. Caution should be used when using LATNAMES in conjunction with a single LATS value, since the number of visible latitude gridlines is dependent on many factors.

## LATS

Set this keyword equal to a one or more element vector of latitudes for which lines will be drawn (and optionally labeled). If LATS is omitted, appropriate latitudes will be generated based on the value of the (optional) LATDEL keyword. If LATS is set

to a single value, that latitude and a series of automatically generated latitudes will be drawn (and optionally labeled). Automatically generated latitudes have the values:

```
[ . . . , LATS - LATDEL , LATS , LATS + LATDEL , . . . ]
```

over the extent of the map. If LATS is a single value, that value is taken to be the starting point for labelling (See the LABEL keyword).

## LONALIGN

This keyword controls the alignment of the text baseline for longitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it. This keyword is ignored if the BOX\_AXES keyword is set.

## LONDEL

Set this keyword equal to the spacing (in degrees) between meridians of longitude in the grid. If this keyword is not set, a suitable value is determined from the current map projection.

## LONLAB

The latitude at which to place longitude labels. The default is the center latitude on the map. This keyword is ignored if the BOX\_AXES keyword is set.

## LONNAMES

Set this keyword equal to an array specifying the names to be used for the longitude labels. By default, this array is automatically generated in units of degrees. The LONNAMES array can be either type string or any single numeric type, but should not be of mixed type.

When LONNAMES is specified, the LONS keyword must also be specified. The number of elements in the two arrays need not be equal. If there are more elements in the LONNAMES array than in the LONS array, the extra LONNAMES are ignored. If there are more elements in the LONS array than in the LONNAMES array, labels in degrees will be automatically provided for the missing longitude labels.

The LONNAMES keyword can be also used when the LONS keyword is set to a single value. In this case, the first label supplied will be used at the specified longitude; subsequent names will be placed at the next longitude line to the east, wrapping around the globe if appropriate. Caution should be used when using LONNAMES in conjunction with a single LONS value, since the number of visible longitude gridlines is dependent on many factors.

## LONS

Set this keyword equal to a one or more element vector of longitudes for which lines will be drawn (and optionally labeled). If LONS is omitted, appropriate longitudes will be generated based on the value of the (optional) LONDEL keyword. If LONS is set to a single value, that longitudes and a series of automatically generated longitudes will be drawn (and optionally labeled). Automatically generated longitudes have the values:

```
[ . . . , LONS - LONDEL , LONS , LONS + LONDEL , . . . ]
```

over the extent of the map. If LONS is a single value, that value is taken to be the starting point for labelling (See the LABEL keyword).

## MAP\_STRUCTURE

Set this keyword to a !MAP structure, as returned from [MAP\\_PROJ\\_INIT](#). If this keyword is set, the !MAP system variable is ignored, and the grid lines are drawn using UV (Cartesian) coordinates.

## NO\_GRID

Set this keyword if you only want labels but not gridlines.

## ORIENTATION

Set this keyword equal to an angle in degrees from horizontal (in the clockwise direction) to rotate the labels. This keyword is ignored if the BOX\_AXES keyword is set.

### Warning

---

If a device (or hardware) font is in use, this keyword will have no effect.

---

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[T3D](#), [ZVALUE](#)

## Examples

The following example creates an orthographic projection, defines which latitudes to label, and provides text labels. Note that the text labels are rotated to match the orientation of the map projection.

```

; Set up an orthographic projection:
MAP_SET, /ORTHO, 10, 20, 30, /ISOTROPIC, /CONTINENTS, /HORIZON
; Define latitudes of interest:
lats = [ -80, -45, -30, -20, 0, 15, 27, 35, 45, 55, 75]
; Create string equivalents of latitudes:
latnames = strtrim(lats, 2)
; Label the equator:
latnames(where(lats eq 0)) = 'Equator'
; Draw the grid:
MAP_GRID, LABEL=2, LATS=lats, LATNAMES=latnames, LATLAB=7, $
    LONLAB=-2.5, LONDEL=20, LONS=-15, ORIENTATION=-30

```

The following example uses the `MAP_STRUCTURE` keyword to map the grid lines in UV (Cartesian) coordinates, without having to set up a `!MAP` transform using `MAP_SET`.

```

; GCTP Polar stereographic projection
mapStruct = MAP_PROJ_INIT(106, LIMIT=[0, -180, 90, 180], $
    CENTER_LATITUDE=90)

; Create a plot window using the UV Cartesian range.
PLOT, mapStruct.uv_box[[0,2]], mapStruct.uv_box[[1,3]], $
    /NODATA, /ISOTROPIC, XSTYLE=1, YSTYLE=1

MAP_CONTINENTS, MAP_STRUCTURE=mapStruct
MAP_GRID, MAP_STRUCTURE=mapStruct

```

## Version History

6.1	Added <code>MAP_STRUCTURE</code> keyword

## See Also

[MAP\\_CONTINENTS](#), [MAP\\_IMAGE](#), [MAP\\_PATCH](#), [MAP\\_PROJ\\_INIT](#), [MAP\\_SET](#)

# MAP\_IMAGE

The MAP\_IMAGE function warps an image (or other dataset) to a map projection. This function provides an easy method for displaying geographical data as an image on a map. The MAP\_SET or MAP\_PROJ\_INIT procedures should be called prior to calling MAP\_IMAGE.

MAP\_IMAGE works in image (graphic) space. For each destination pixel (when COMPRESS is set to one) MAP\_IMAGE calculates the latitude and longitude by applying the inverse map projection. This latitude and longitude are then used to index and interpolate the *Image* argument, obtaining an interpolated value for the destination pixel. The time required by MAP\_IMAGE depends mainly on the number of pixels in the destination and the setting of the COMPRESS parameter.

---

## Note

MAP\_IMAGE is more efficient than MAP\_PATCH when the input data set is large compared to the destination area. If the converse is true, MAP\_PATCH is more efficient.

---

## Syntax

```
Result = MAP_IMAGE( Image [, Startx, Starty [, Xsize, Ysize]]
  [, LATMIN=degrees{-90 to 90}] [, LATMAX=degrees{-90 to 90}]
  [, LONMIN=degrees{-180 to 180}] [, LONMAX=degrees{-180 to 180}]
  [, /BILINEAR] [, COMPRESS=value] [, SCALE=value]
  [, MAP_STRUCTURE=structure] [, MASK=variable]
  [, MAX_VALUE=value] [, MIN_VALUE=value] [, MISSING=value] )
```

## Return Value

Returns the image or dataset warped to the current map projection.

## Arguments

### Image

A two-dimensional array containing the image to be overlaid on the map.

## Startx

A named variable that, upon return, contains the X coordinate position where the left edge of the image should be placed on the screen.

## Starty

A named variable that, upon return, contains the Y coordinate position where the left edge of the image should be placed on the screen.

## Xsize

A named variable that, upon return, contains the width of the image expressed in graphic coordinate units. If the current graphics device uses scalable pixels (PostScript, for example), the values of *Xsize* and *Ysize* should be passed to the TV procedure.

## Ysize

A named variable that, upon return, contains the height of the image expressed in graphic coordinate units. If the current graphics device uses scalable pixels (PostScript, for example), the values of *Xsize* and *Ysize* should be passed to the TV procedure.

## Keywords

### LATMIN

The latitude corresponding to the first row of *Image*. The default is -90 degrees. Note also that  $-90^\circ \leq \text{LATMIN} < \text{LATMAX} \leq 90^\circ$ .

### LATMAX

The latitude corresponding to the last row of *Image*. The default value is 90 degrees. Note also that  $-90^\circ \leq \text{LATMIN} < \text{LATMAX} \leq 90^\circ$ .

### LONMIN

The longitude corresponding to the first (leftmost) column of the *Image* argument. Select LONMIN so that  $-180^\circ \leq \text{LONMIN} \leq 180^\circ$ . The default value is -180.

### LONMAX

The longitude corresponding to the last (rightmost) column of the *Image* argument. Select LONMAX so that it is larger than LONMIN. If the longitude of the last

column is equal to  $(\text{LONMIN} - (360. / N_x)) \text{ MODULO } 360$ , it is assumed that the image covers all longitudes ( $N_x$  being the total number of columns in the *Image* argument).

## BILINEAR

Set this flag to use bilinear interpolation to soften edges in the returned image, otherwise, nearest neighbor sampling is used.

## COMPRESS

This keyword, the interpolation compression flag, controls the accuracy of the results from `MAP_IMAGE`. The default is 4 for output devices with fixed pixel sizes. The inverse projection transformation is applied to each *i*th row and column. Setting this keyword to a higher number saves time while lower numbers produce more accurate results. Setting this keyword to 1 solves the inverse map transformation for every pixel of the output image.

## SCALE

Set this keyword to the pixel/graphics scale factor for devices with scalable pixels (e.g., PostScript). The default is 0.02 pixels/graphic coordinate. This setting yields an approximate output image size of 350 x 250. Make this number larger for more resolution (and larger PostScript files and images), or smaller for faster, smaller, and less accurate images.

## MAP\_STRUCTURE

Set this keyword to a !MAP structure as returned from `MAP_PROJ_INIT`, to be used instead of the default !MAP projection. This keyword is useful if you want to display the image in a UV (Cartesian) coordinate system, instead of the !MAP coordinate system.

## MASK

Set this keyword equal to a named variable that will contain a byte array of the same dimensions as the *Result*, containing a mask of the good values. Values in the *Result* that were set to MISSING (that is, values were either off the map or outside the range specified by the `MIN_VALUE` and `MAX_VALUE` keywords) will have a mask value of zero, while all other mask values will be one.

**Tip**

The MASK array allows you to distinguish values in the *Result* that were explicitly set to MISSING versus those that happen to have the same value. The array may also be useful in defining an alpha (transparency) channel for an object graphics image.

**MAX\_VALUE**

Data points with values equal to or greater than this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

**MIN\_VALUE**

Data points with values equal to or less than this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

**MISSING**

The pixel value to set areas outside the valid map coordinates. If this keyword is omitted, areas outside the map are set to 255 (white) if the current graphics device is PostScript, otherwise they are set to 0.

**Examples**

The following lines of code set up an orthographic map projection and warp a simple image to it.

```

; Create a simple image to be warped:
image = BYTSC(SIN(DIST(400)/10))

; Display the image so we can see what it looks like before
; warping:
TV, image
latmin = -65
latmax = 65

; Left edge is 160 East:
lonmin = 160

; Right edge is 70 West = +360:
lonmax = -70 + 360
MAP_SET, 0, -140, /ORTHOGRAPHIC, /ISOTROPIC, $
LIMIT=[latmin, lonmin, latmax, lonmax]

```

```
result = MAP_IMAGE(image, Startx, Starty, COMPRESS=1, $
    LATMIN=latmin, LONMIN=lonmin, $
    LATMAX=latmax, LONMAX=lonmax)

; Display the warped image on the map at the proper position:
TV, result, Startx, Starty

; Draw gridlines over the map and image:
MAP_GRID, latdel=10, londel=10, /LABEL, /HORIZON

; Draw continent outlines:
MAP_CONTINENTS, /coasts
```

## Version History

Pre 4.0	Introduced
6.1	Added MAP_STRUCTURE keyword

## See Also

[MAP\\_CONTINENTS](#), [MAP\\_GRID](#), [MAP\\_PATCH](#), [MAP\\_PROJ\\_IMAGE](#),  
[MAP\\_PROJ\\_INIT](#), [MAP\\_SET](#)

# MAP\_PATCH

The `MAP_PATCH` function warps an image (or other dataset) to the current map projection. Mapping coordinates should be setup via a call to `MAP_SET` before using `MAP_PATCH`.

`MAP_PATCH` works in object (data) space. It divides the input data set, *Image\_Orig*, into triangular patches, either directly from the implicit rectangular grid, or by triangulating the data points on the surface of the sphere using the `TRIANGULATE` procedure. These triangular patches are then projected to the map plane in the image space of the destination array and then interpolated. The time required by `MAP_PATCH` depends mainly on the number of elements in the input array.

## Note

---

`MAP_PATCH` is more efficient than `MAP_IMAGE` when the destination area is large compared to the input data set. If the converse is true, `MAP_IMAGE` is more efficient.

---

This routine is written in the IDL language. Its source code can be found in the file `map_patch.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MAP_PATCH( Image_Orig [, Lons, Lats] [, LAT0=value] [, LAT1=value]
  [, LON0=value] [, LON1=value] [, MAX_VALUE=value] [, MISSING=value]
  [, /TRIANGULATE] [, XSIZE=variable] [, XSTART=variable]
  [, YSIZE=variable] [, YSTART=variable] )
```

## Return Value

Returns the image or dataset warped to the current map projection.

## Arguments

### Image\_Orig

A one- or two-dimensional array that contains the data to be overlaid on the map. If the `TRIANGULATE` keyword is not set, *Image\_Orig* must be a two-dimensional array. Rows and columns must be arranged in increasing longitude and latitude order. Also, the corner points of each cell must be contiguous. This means that the seam of a map must lie on a cell boundary, not in its interior, splitting the cell.

## Lons

An optional vector that contains the longitude value for each column in *Image\_Orig*. If *Lons* is a one-dimensional vector, longitude ( $Image\_Orig[i,j] = Lons[i]$ ); if *Lons* is a two-dimensional vector, longitude ( $Image\_Orig[i,j] = Lons[i,j]$ ).

This argument can be omitted if the longitudes are equally-spaced and the beginning and ending longitudes are specified with the LON0 and LON1 keywords.

## Lats

An optional vector that contains the latitude value for each row in *Image\_Orig*. If *Lats* is a one-dimensional vector, latitude ( $Image\_Orig[i,j] = Lats[i]$ ); if *Lats* is a two-dimensional vector, latitude ( $Image\_Orig[i,j] = Lats[i,j]$ ).

This argument can be omitted if the latitudes are equally-spaced and the beginning and ending latitudes are specified with the LAT0 and LAT1 keywords.

## Keywords

### LAT0

The latitude of the first row of data. The default is -90.

### LAT1

The latitude of the last row of data. The default is +90.

### LON0

The longitude of the first column of data. The default is -180.

### LON1

The longitude of the last column of data. The default is  $180 - (360/\text{number of rows})$

### MAX\_VALUE

The largest data value to be warped. Values in *Image\_Orig* greater than this value are considered missing. Pixels in the output image that correspond to these missing values are set to the value specified by the MISSING keyword.

## MISSING

Set this keyword to a value to be used for areas outside the valid map coordinates (i.e., the “background color”). If the current plotting device is PostScript, the default is 255 (white). Otherwise, the default is 0 (usually black).

## TRIANGULATE

Set this keyword to convert the input data to device space and triangulate them. This keyword must be specified if the connectivity of the data points is not rectangular and monotonic in device space.

## XSIZE

Set this keyword to a named variable in which the width of the output image is returned, in graphic coordinate units. If the current graphics device has scalable pixels (PostScript, for example), the values returned by XSIZE and YSIZE should be passed to the TV procedure.

## XSTART

Set this keyword to a named variable in which the X coordinate where the left edge of the image should be placed on the screen is returned.

## YSIZE

Set this keyword to a named variable in which the height of the output image is returned, in graphic coordinate units. If the current graphics device has scalable pixels (PostScript, for example), the values returned by XSIZE and YSIZE should be passed to the TV procedure.

## YSTART

Set this keyword to a named variable in which the Y coordinate where the bottom edge of the image should be placed on the screen is returned.

## Examples

```
; Form a 24 x 24 dataset on a sphere:
n = 24

; Specify equally gridded latitudes:
lat = replicate(180./(n-1),n) # findgen(n) - 90
```

```

; Specify equally gridded longitudes:
lon = findgen(n) # replicate(360./(n-1), n)

; Convert to Cartesian coordinates:
x = cos(lon * !dtor) * cos(lat * !dtor)
y = sin(lon * !dtor) * cos(lat * !dtor)
z = sin(lat * !dtor)

; Set interpolation function to scaled distance squared
; from (1,1,0):
f = BYTSCL((x-1)^2 + (y-1)^2 + z^2)

; Set up projection:
MAP_SET, 90, 0, /STEREO, /ISOTROPIC, /HORIZ

; Grid and display the data:
TV, MAP_PATCH(f, XSTART=x0, YSTART=y0), x0, y0

; Draw gridlines over the map and image:
MAP_GRID

; Draw continent outlines:
MAP_CONTINENTS

; Draw a horizon line:
MAP_HORIZON

```

## Version History

4.0	Introduced
-----	------------

## See Also

[MAP\\_CONTINENTS](#), [MAP\\_GRID](#), [MAP\\_IMAGE](#), [MAP\\_SET](#)

# MAP\_PROJ\_FORWARD

The `MAP_PROJ_FORWARD` function transforms map coordinates from longitude and latitude to Cartesian (x, y) coordinates, using either the `!MAP` system variable or a supplied map projection structure created by `MAP_PROJ_INIT`.

## Syntax

```
Result = MAP_PROJ_FORWARD(Longitude [, Latitude]
  [, CONNECTIVITY=vector] [, /FILL] [, MAP_STRUCTURE=value]
  [, POLYGONS=variable] [, POLYLINES=variable] [, /RADIANS] )
```

## Return Value

The result is a (2, n) array containing the Cartesian (x, y) coordinates.

### Note

If the `POLYGONS` or `POLYLINES` keyword is present, the number of points in the result may be different than the number of input points, depending upon whether clipping and splitting occurs.

## Arguments

### Longitude

An *n*-element vector containing the longitude values. If the *Latitude* argument is omitted, *Longitude* must be a (2, *n*) array of longitude and latitude pairs.

### Latitude

An *n*-element vector containing latitude values. If this argument is omitted, *Longitude* must be a (2, *n*) array of longitude and latitude pairs.

## Keywords

### CONNECTIVITY

Set this keyword to a vector containing an input connectivity list for polygons or polylines. The `CONNECTIVITY` keyword allows you to specify multiple polygons or polylines using a single array.

The CONNECTIVITY list is a one-dimensional integer array of the form:

$$\left[ m_1, i_0, i_1, \dots, i_{m_1-1}, m_2, i_0, i_1, \dots, i_{m_2-1}, \dots, m_n, i_0, i_1, \dots, i_{m_n-1} \right]$$

where each  $m_j$  is an integer specifying the number of vertices that define the polyline or polygon (the *vertex count*), and each associated set of  $i_0 \dots i_{m-1}$  are indices into the arrays of vertices specified by the *Longitude* and *Latitude* arguments.

For example, to draw polylines between the first, third, and sixth longitude and latitude values and the fourth, sixth, ninth, and tenth longitude and latitude values, set the CONNECTIVITY array equal to `[3, 0, 2, 5, 4, 3, 5, 8, 9]`.

To ignore a set of entries in the CONNECTIVITY array, set the vertex count,  $m_j$ , equal to zero. (Note that if you set an  $m$  equal to zero, you must remove the associated set of  $i_0 \dots i_{m-1}$  values as well.) To ignore the remaining entries in the CONNECTIVITY array, set the vertex count,  $m_j$ , equal to -1.

This keyword is ignored if neither POLYGONS nor POLYLINES is present.

## FILL

Set this keyword, along with the POLYGONS keyword, to perform a tessellation on the returned polygons after any clipping or splitting has been completed. This keyword is ignored if POLYGONS is not set.

### Tip

---

The use of the FILL keyword avoids having to first pass your data through MAP\_PROJ\_FORWARD, and then again through the IDLgrTessellator object. Since IDLgrPolygon can only draw convex polygons correctly, you should use the FILL keyword when your input polygon is either complex (that is, if the polygon crosses itself) or concave. Tessellation is also useful if your data contains one polygon within another, such as an island within a lake within a country. In this case the CONNECTIVITY array could be used to pass all three polygons in to MAP\_PROJ\_FORWARD, and the FILL keyword would automatically perform the correct tessellation.

---

## MAP\_STRUCTURE

Set this keyword to a !MAP structure variable containing the projection parameters, as constructed by the [MAP\\_PROJ\\_INIT](#). If this keyword is omitted, the !MAP system variable is used.

## POLYGONS

Set this keyword to a named variable that will contain a connectivity array of the form described above in the CONNECTIVITY keyword.

If this keyword is present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be the vertices of a closed polygon. In this case, polygon clipping and splitting is performed in addition to the map transform, and the connectivity array is returned in the specified variable.

If this keyword is not present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be independent points and no clipping or splitting is performed.

## POLYLINES

Set this keyword to a named variable that will contain a connectivity array of the form described above in the CONNECTIVITY keyword.

If this keyword is present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be the vertices of a polyline. In this case, polyline clipping and splitting is performed in addition to the map transform, and the connectivity array is returned in the specified variable.

If this keyword is not present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be independent points and no clipping or splitting is performed.

## RADIANS

Set this keyword to indicate that the input longitude and latitude coordinates are in radians. By default, coordinates are assumed to be in degrees.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

**Note**

Threading is only used when individual points are being transformed, and has no effect if either the **POLYGONS** or **POLYLINES** keyword is specified.

**Example**

The following example creates a latitude and longitude grid with labels for the Goodes Homolosine map projection.

```

; Helper function. Constructs the polyline objects.
PRO Ex_Map_AddPolyline, label, $
    gridLon, gridLat, sMap, oModel, oContainer, oFont, $
    LONGITUDE = longitude

longitude = KEYWORD_SET(longitude)

; Transform from lat/lon to X/Y cartesian.
gridUV = MAP_PROJ_FORWARD(gridLon, gridLat, $
    MAP=sMap, POLYLINES = gridPoly)
IF (N_ELEMENTS(gridUV) LT 2) THEN $
    RETURN

; Construct label object if desired.
IF (label NE '') THEN BEGIN
    oLabel = OBJ_NEW('IDLgrText', label, $
        ALIGN = longitude ? 0.5 : 1, $
        FONT = oFont, VERTICAL_ALIGN=0.5)
    oContainer->Add, oLabel
ENDIF

; Create the polyline object.
oModel->Add, OBJ_NEW('IDLgrPolyline', gridUV, $
    LABEL_OBJ = oLabel, $
    LABEL_OFFSET = longitude ? 0.35 : 0, $
    /USE_LABEL_ORIENTATION, /USE_TEXT_ALIGN, $
    POLYLINE = gridPoly)

END

; Main function. Creates a grid over a map projection.
PRO Ex_Map_Proj_Forward

; Construct !MAP structure containing the projection.
sMap = MAP_PROJ_INIT('Goodes Homolosine')

; Create a graphics model to hold the visualizations.
oModel = OBJ_NEW('IDLgrModel')

```

```

oContainer = OBJ_NEW('IDL_Container')
oFont = OBJ_NEW('IDLgrFont', SIZE = 4)
oContainer->Add, oFont
deg = STRING(176b) ; degrees symbol in Truetype

; Latitude lines.
gridLon = DINDGEN(361) - 180
latitude = 15*(INDGEN(11) - 5)

FOR i = 0, (N_ELEMENTS(latitude) - 1) DO BEGIN
  lat = latitude[i]
  gridLat = REPLICATE(lat, 361)

  ; Create the latitude label.
  label = (lat EQ 0) ? 'Equ' : $
    STRTRIM(ABS(lat), 2) + deg + (['N', 'S'])[lat LT 0]
  Ex_Map_Addpolyline, label, gridLon, gridLat, $
    sMap, oModel, oContainer, oFont
ENDFOR

; Longitude lines.
gridLat = DINDGEN(181) - 90

; Add in some extra lines for the Goode projections.
longitude = [20*(DINDGEN(18) - 9), $
  -179.999d, -20.001d, -100.001d, -40.001d, 80.001d]

FOR i = 0, N_ELEMENTS(longitude) - 1 DO BEGIN
  lon = longitude[i]
  gridLon = REPLICATE(lon, 181)

  ; Create the longitude label.
  label = STRTRIM(ROUND(ABS(lon)), 2) + deg
  IF ((lon mod 180) NE 0) THEN $
    label = label + (['E', 'W'])[lon LT 0]
  IF (lon NE FIX(lon)) THEN label = ''

  Ex_Map_Addpolyline, label, gridLon, gridLat, $
    sMap, oModel, oContainer, oFont, /LONGITUDE
ENDFOR

; Visualize our map projection.
XOBJVIEW, oModel, SCALE = 0.9, /BLOCK

; Clean up our objects.
OBJ_DESTROY, [oModel, oContainer]

END

```

# MAP\_PROJ\_IMAGE

The MAP\_PROJ\_IMAGE function warps an image (or other 2-dimensional dataset) from geographic coordinates (longitude and latitude) to a specified map projection.

## Note

Use [MAP\\_SET](#) or pass in the result from [MAP\\_PROJ\\_INIT](#) using this function's [MAP\\_STRUCTURE](#) keyword to set up the desired map projection.

Optionally, the MAP\_PROJ\_IMAGE function can be used to warp an image in Cartesian (UV) coordinates from one map projection to another.

## Syntax

```
Result = MAP_PROJ_IMAGE(Image [, Range] [, /BILINEAR]
  [, DIMENSIONS=vector] [, IMAGE_STRUCTURE=structure]
  [, MAP_STRUCTURE=structure] [, MASK=variable] [, MAX_VALUE=value]
  [, MIN_VALUE=value] [, MISSING=value] [, UVRANGE=variable]
  [, XINDEX=variable] [, YINDEX=variable] )
```

## Return Value

This routine returns a two-dimensional array containing the warped image. The returned array has the same type as the input image.

## Arguments

### Image

A two-dimensional array containing the image to warp.

### Range

If you are warping *Image* from geographic coordinates to a map projection, *Range* is a four-element array specifying the longitude/latitude range (in degrees) of *Image*. *Range* has the format [*Lonmin*, *Latmin*, *Lonmax*, *Latmax*]. If *Range* is not supplied, the routine uses a default range of [-180, -90, 180, 90].

If you are warping *Image* from one map projection to another (that is, if you provide a value for the IMAGE\_STRUCTURE keyword), then *Range* is a four-element array specifying the Cartesian (UV) range. In this case, *Range* must be provided and has the format [*Umin*, *Vmin*, *Umax*, *Vmax*].

**Tip**

Use the `UVRANGE` keyword to retrieve the range in Cartesian (UV) coordinates of *Result*.

---

## Keywords

### BILINEAR

Set this keyword to use bilinear interpolation when warping *Image*. By default, the routine will use nearest neighbor sampling. Bilinear interpolation will produce smoother results but may be slower.

### DIMENSIONS

Set this keyword equal to a two-element vector specifying the width and height of the desired *Result*, in pixels. If this keyword is not specified, then the *Result* has the same dimensions as the input *Image*.

### IMAGE\_STRUCTURE

If the input *Image* is already in a certain projection, set this keyword equal to the !MAP structure associated with the input image. If `IMAGE_STRUCTURE` is supplied, the *Range* argument *must* be provided. In this case, *Image* will be warped from the projection specified by `IMAGE_STRUCTURE` to the projection specified by `MAP_STRUCTURE`.

### MAP\_STRUCTURE

Set this keyword equal to a !MAP structure (as returned from the `MAP_PROJ_INIT` function) to be used instead of the default !MAP projection. If this keyword is not specified, the value of the !MAP system variable must have been previously set by a call to the `MAP_SET` procedure.

### MASK

Set this keyword equal to a named variable that will contain a byte array of the same dimensions as the *Result*, containing a mask of the “good” values. Values in *Result* that were set to `MISSING` (that is, the values were either off the map or outside the range specified by the `MIN_VALUE` and `MAX_VALUE` keywords) will have a mask value of 0 (zero), while all other mask values will be 1 (one).

**Tip**

The MASK array allows you to distinguish values in the *Result* that were explicitly set to MISSING versus those that happen to have a value equal to the MISSING value.

**MAX\_VALUE**

Set this keyword equal to an integer that represents the maximum value an element of the *Result* array should be allowed to have. Data points with values greater than or equal to this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

**MIN\_VALUE**

Set this keyword equal to an integer that represents the minimum value an element of the *Result* array should be allowed to have. Data points with values less than or equal to this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

**MISSING**

Set this keyword equal to an integer value to be used for pixels that fall outside of the valid map coordinates or whose data values are outside of the range specified by the MIN\_VALUE and MAX\_VALUE keywords. The default value is 0.

**UVRANGE**

Set this keyword equal to a named variable that will contain the range of the UV coordinates of the *Result* in a four-element array of the form [*U min*, *V min*, *U max*, *V max*].

**XINDEX**

Set this keyword equal to a named variable that will contain the *x* index used to warp the image. Use this keyword (with [YINDEX](#)) when warping multiple images (or image channels) that have the same dimensions and map projection. For the first call to MAP\_PROJ\_IMAGE, XINDEX and YINDEX should be set to named variables that are either undefined or contain scalar values. Upon return, XINDEX and YINDEX contain the indices that were used for warping the image. For subsequent images, the XINDEX and YINDEX variables should be passed in unmodified. In this case, IDL bypasses the map projection and uses the indices to warp the image.

## YINDEX

Set this keyword equal to a named variable that will contain the y index used to warp the image. Use this keyword (with [XINDEX](#)) when warping multiple images (or image channels) that have the same dimensions and map projection. For the first call to `MAP_PROJ_IMAGE`, `XINDEX` and `YINDEX` should be set to named variables that are either undefined or contain scalar values. Upon return, `XINDEX` and `YINDEX` contain the indices that were used for warping the image. For subsequent images, the `XINDEX` and `YINDEX` variables should be passed in unmodified. In this case, IDL bypasses the map projection and uses the indices to warp the image.

---

### Note

If the `XINDEX` and `YINDEX` keywords are present, IDL ignores the *Range* argument and the [IMAGE\\_STRUCTURE](#), [MAP\\_STRUCTURE](#), and [UVRANGE](#) keywords. If you specified the [BILINEAR](#), [DIMENSIONS](#), [MAX\\_VALUE](#), [MIN\\_VALUE](#), or [MISSING](#) keywords on the first call to `MAP_PROJ_IMAGE`, you should supply the same keywords with the same values on subsequent calls.

---

## Example

The following example warps a global map from longitude/latitude (geographic) coordinates into the Interrupted Goode projection:

```
; Load an image in longitude/latitude (geographic) coordinates
file = FILEPATH( 'avhrr.png', SUBDIRECTORY=['examples','data'] )
data = READ_PNG( file, r, g, b )

; Resize the image data
red0 = REBIN( r[data], 360, 180 )
green0 = REBIN( g[data], 360, 180 )
blue0 = REBIN( b[data], 360, 180 )

iImage, RED=red0, GREEN=green0, BLUE=blue0, $
      DIMENSIONS=[500,600], VIEW_GRID=[1,3]

; First map projection
sMap = MAP_PROJ_INIT('Interrupted Goode')

; Warp each channel to the map projection. For the first
; channel also compute the MASK and the UVRANGE.
; Use XINDEX and YINDEX to speed up green and blue channels.
red1 = MAP_PROJ_IMAGE( red0, MAP_STRUCTURE=sMap, MASK=mask, $
      UVRANGE=uvrange, XINDEX=xindex, YINDEX=yindex )
green1 = MAP_PROJ_IMAGE( green0, XINDEX=xindex, YINDEX=yindex )
blue1 = MAP_PROJ_IMAGE( blue0, XINDEX=xindex, YINDEX=yindex )
```

```
IIMAGE, RED=red1, GREEN=green1, BLUE=blue1, ALPHA=mask*255b, $
/VIEW_NEXT
```

Now warp the image from the Interrupted Goode projection to a new projection:

```
; New map projection
mapStruct = MAP_PROJ_INIT( 'Mollweide', /GCTP )

; Now use the IMAGE_STRUCTURE keyword to warp each channel
; from the Interrupted Goode projection to Mollweide.
; We also need to input the UVRANGE of the input image.
; Use XINDEX and YINDEX to speed up green and blue channels,
; but use a new variable since we already have xindex/yindex.
red2 = MAP_PROJ_IMAGE( red1, uvrange, IMAGE_STRUCTURE=sMap, $
    MAP_STRUCTURE=mapStruct, MASK=mask, $
    XINDEX=xindex2, YINDEX=yindex2 )
green2 = MAP_PROJ_IMAGE( green1, XINDEX=xindex2, YINDEX=yindex2 )
blue2 = MAP_PROJ_IMAGE( blue1, XINDEX=xindex2, YINDEX=yindex2 )

IIMAGE, RED=red2, GREEN=green2, BLUE=blue2, ALPHA=mask*255b, $
/VIEW_NEXT
```

The resulting iImage tool display is shown in the following figure.

[IMAP](#), [MAP\\_IMAGE](#), [MAP\\_PROJ\\_INIT](#), [MAP\\_SET](#)

# MAP\_PROJ\_INFO

The MAP\_PROJ\_INFO procedure returns information about the current map and/or the available projections.

---

## Note

The MAP\_PROJ\_INFO procedure is compiled along with the MAP\_SET procedure. You *must* call the [MAP\\_SET](#) procedure to set up mapping parameters before calling MAP\_PROJ\_INFO.

---

This routine is written in the IDL language. Its source code can be found in `map_set.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
MAP_PROJ_INFO [, iproj] [, AZIMUTHAL=variable] [, CIRCLE=variable]
  [, CYLINDRICAL=variable] [, /CURRENT] [, LL\_LIMITS=variable]
  [, NAME=variable] [, PROJ\_NAMES=variable] [, UV\_LIMITS=variable]
  [, UV\_RANGE=variable]
```

## Arguments

### **iproj**

The projection index. If the CURRENT keyword is set, then the index of the current map projection is returned in *iproj*.

## Keywords

### **AZIMUTHAL**

Set this keyword to a named variable that, upon return, will be set to 1 if the projection is azimuthal and 0 otherwise.

### **CIRCLE**

Set this keyword to a named variable that, upon return, will be set to 1 if the projection is circular or elliptical and 0 otherwise.

### **CURRENT**

Set this keyword to use the current projection index and return that index in *iproj*.

## CYLINDRICAL

Set this keyword to a named variable that, upon return, will be set to 1 if the projection is cylindrical and 0 otherwise.

## LL\_LIMITS

Set this keyword to a named variable that will contain the geocoordinate rectangle of the current map in degrees, [Latmin, Lonmin, Latmax, Lonmax]. This range may not always be available, especially if the LIMIT keyword was not specified in the call to MAP\_SET. If either or both the longitude and latitude range are not available, the minimum and maximum values will be set to zero.

## NAME

Set this keyword to a named variable that will contain the name of the projection.

## PROJ\_NAMES

Set this keyword to a named variable that will contain a string array containing the names of the available projections, ordered by their indices. The first projection name is stored in element one.

## UV\_LIMITS

Set this keyword to a named variable that will contain the UV bounding box of the current map, [Umin, Vmin, Umax, Vmax].

## UV\_RANGE

Set this keyword to a named variable that will contain the UV coordinate limits of the selected map projection, [Umin, Vmin, Umax, Vmax]. UV coordinates are mapped to normalized coordinates using the system variables !X.S and !Y.S. These limits are dependent upon the selected projection, but independent of the current map.

## Examples

```
; Establish a projection
MAP_SET, /MERCATOR

; Obtain projection characteristics
MAP_PROJ_INFO, /CURRENT, NAME=name, AZIMUTHAL=az, $
CYLINDRICAL=cyl, CIRCLE=cir
```

On return, the variables will be set as follows:

```
AZIM      INT = 0
CIRC      INT = 0
CYL       INT = 1
NAME      STRING 'Mercator'
```

## Version History

[MAP\\_SET](#)

# MAP\_PROJ\_INIT

The MAP\_PROJ\_INIT function initializes a mapping projection (establishes the coordinate conversion mechanism for mapping points on a globe's surface to points on a plane), using either IDL's own map projections or map projections from the U.S. Geological Survey's General Cartographic Transformation Package (GCTP). GCTP version 2.0 is included with IDL.

## Note

The !MAP system variable is unaffected by MAP\_PROJ\_INIT. To use the map projection returned by MAP\_PROJ\_INIT for direct or object graphics, use the [MAP\\_PROJ\\_FORWARD](#) and [MAP\\_PROJ\\_INVERSE](#) functions to convert longitude/latitude values into Cartesian (x, y) coordinates before visualization.

This routine is written in the IDL language. Its source code can be found in `map_proj_init.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MAP_PROJ_INIT( Projection [, DATUM=value] [, /GCTP]
    [, LIMIT=vector] [, /RADIANS] [, /RELAXED] )
```

**Keywords—Projection Parameters:** [, CENTER\_AZIMUTH=value]

 [, STANDARD\_PARALLEL=value] [, STANDARD\_PAR1=value]  
 [, STANDARD\_PAR2=value] [, SAT\_TILT=value]  
 [, TRUE\_SCALE\_LATITUDE=value] [, ZONE=value]

## Return Value

The result is a !MAP structure containing the map parameters, which can be used as input to the map transformation functions MAP\_PROJ\_FORWARD and MAP\_PROJ\_INVERSE.

## Arguments

### Projection

Set this argument to either a projection index or a scalar string containing the name of the map projection, as described in following tables:

#	Projection Name	Available Spheroids	Allowed Keyword Parameters
1	Stereographic	Sphere	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION
2	Orthographic	Sphere	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION

## Keywords

### Note

The following keywords apply to all projections.

## DATUM

Set this keyword to either an integer code or a scalar string containing the name of the datum to use for the ellipsoid. The default value depends upon the projection selected, but is either the Clarke 1866 ellipsoid (datum 0), or a sphere of radius 6370.997 km (datum 19).

The following datums (or spheroids) are available for use with the DATUM keyword:

Index	Name	Semimajor axis (m)	Semiminor axis (m)
0	Clarke 1866	6378206.4	6356583.8
1	Clarke 1880	6378249.145	6356514.86955
2	Bessel	6377397.155	6356078.96284
3	International 1967	6378157.5	6356772.2
4	International 1909	6378388.0	6356911.94613
5	WGS 72	6378135.0	6356750.519915
6	Everest	6377276.3452	6356075.4133
7	WGS 66	6378145.0	6356759.769356
8	GRS 1980/WGS 84	6378137.0	6356752.31414
9	Airy	6377563.396	6356256.91
10	Modified Everest	6377304.063	6356103.039
11	Modified Airy	6377340.189	6356034.448
12	Walbeck	6378137.0	6356752.314245
13	Southeast Asia	6378155.0	6356773.3205
14	Australian National	6378160.0	6356774.719
15	Krassovsky	6378245.0	6356863.0188
16	Hough	6378270.0	6356794.343479
17	Mercury 1960	6378166.0	6356784.283666

Table 3-84: Datums Available for Use by MAP\_PROJ\_INIT

Index	Name	Semimajor axis (m)	Semiminor axis (m)
18	Modified Mercury 1968	6378150.0	6356768.337303
19	Sphere	6370997.0	6370997.0

Table 3-84: Datums Available for Use by MAP\_PROJ\_INIT (Continued)

---

### Note

For many projections, you can specify your own datum by using either the SEMIMAJOR\_AXIS and SEMIMINOR\_AXIS or the SPHERE\_RADIUS keywords.

---

## GCTP

Set this keyword to indicate that the GCTP library should be used for the projection. By default, MAP\_PROJ\_INIT uses the IDL projection library. This keyword is ignored if the projection exists only in one system (GCTP or IDL), or if the *Projection* argument is specified as an index.

## LIMIT

Set this keyword to a four-element vector of the form

```
[Latmin, Lonmin, Latmax, Lonmax]
```

that specifies the boundaries of the region to be mapped. (*Lonmin*, *Latmin*) and (*Lonmax*, *Latmax*) are the longitudes and latitudes of two points diagonal from each other on the region's boundary.

---

### Note

If the longitude range in LIMIT is less than or equal to 180 degrees, map clipping is performed in lat/lon coordinates *before* the transform. If the longitude range is greater than 180 degrees, map clipping is done in Cartesian coordinates *after* the transform. For non-cylindrical projections, clipping *after* the transformation to Cartesian coordinates means that some lat/lon points that fall outside the bounds specified by LIMIT may not be clipped. This occurs when the *transformed* lat/lon points fall inside the cartesian clipping rectangle.

---

## RADIANS

Set this keyword to indicate that all parameters that represent angles are specified in radians rather than degrees.

## RELAXED

If this keyword is set, any projection parameters which do not apply to the specified projection will be quietly ignored. By default, MAP\_PROJ\_INIT will issue errors for parameters that do not apply to the specified projection.

## Projection Keywords

The following keywords apply only to some projections. Consult the list under [“Projection”](#) on page 1430 to determine which keywords apply to the projection you have selected.

---

**Note**

Unless the RADIANS keyword is set, all angles are measured in degrees, specified as a floating-point value.

---

## CENTER\_AZIMUTH

Set this keyword to the angle of the central azimuth, in degrees east of North. The default is 0 degrees. The pole is placed at an azimuth of CENTRAL\_AZIMUTH degrees counterclockwise of North, as specified by the ROTATION keyword.

## CENTER\_LATITUDE

Set this keyword to the latitude of the point on the earth’s surface to be mapped to the center of the projection plane. Latitude is measured in degrees North of the equator and must be in the range: -90 to +90. The default value is zero.

---

**Note**

For the Hotine Oblique Mercator projection, the center latitude should not be set to 0, +90, or -90

---

## CENTER\_LONGITUDE

Set this keyword to the longitude of the point on the earth’s surface to be mapped to the center of the map projection. Longitude is measured in degrees east of the Greenwich meridian and must be in the range: -360 to +360. The default value is zero.

## FALSE\_EASTING

Set this keyword to the false easting value (in meters) to be added to each x coordinate for the forward transform, or subtracted from each x coordinate for the inverse transform.

## FALSE\_NORTHING

Set this keyword to the false northing value (in meters) to be added to each y coordinate for the forward transform, or subtracted from each y coordinate for the inverse transform.

## HEIGHT

Set this keyword to the height (in meters) above the earth's surface for satellite projections.

## HOM\_AZIM\_LONGITUDE

Set this keyword to the longitude in degrees of the central meridian point where the azimuth occurs.

## HOM\_AZIM\_ANGLE

Set this keyword to the azimuth angle, measured in degrees, east of a north-south line that intersects the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

## HOM\_LATITUDE1

Set this keyword to the latitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

---

**Note**

HOM\_LATITUDE1 cannot be equal to HOM\_LATITUDE2.

---

## HOM\_LATITUDE2

Set this keyword to the latitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

**Note**

---

HOM\_LATITUDE1 cannot be equal to HOM\_LATITUDE2.

---

**HOM\_LONGITUDE1**

Set this keyword to the longitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

**HOM\_LONGITUDE2**

Set this keyword to the longitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

**IS\_ZONES**

Set this keyword to the number of longitudinal zones to include in the projection.

**IS\_JUSTIFY**

Set this keyword to a flag indicating what to do with rows with an odd number of columns. The possible values are:

0	Indicates the extra column is on the right of the projection Y axis
1	Indicates the extra column is on the left of the projection Y axis
2	Calculate an even number of columns

**MERCATOR\_SCALE**

Set this keyword to the scale factor at the central meridian (Transverse Mercator projection) or the center of the projection (Hotine Oblique Mercator projection). For the Transverse Mercator projection, the default scale is 0.9996.

**OEA\_ANGLE**

Set this keyword to the Oblated Equal Area oval rotation angle in degrees.

## OEA\_SHAPEM

Set this keyword to the Oblated Equal Area shape parameter  $m$ . The value of OEA\_SHAPEM determines the horizontal flatness of the oblong region, and is usually set to a value between one and three.

## OEA\_SHAPEN

Set this keyword to the Oblated Equal Area oval shape parameter  $n$ . The value of OEA\_SHAPEN determines the vertical flatness of the oblong region, and is usually set to a value between one and three.

### Note

---

Setting both OEA\_SHAPEM and OEA\_SHAPEN equal to two is equivalent to using the Lambert Azimuthal projection.

---

## ROTATION

Set this keyword to the angle through which the North direction should be rotated around the line between the earth's center and the point (CENTER\_LONGITUDE, CENTER\_LATITUDE). ROTATION is measured in degrees with the positive direction being clockwise rotation around the line. Values should be in the range -180 to +180. The default value is zero.

### Note

---

If the center of the map is at the North pole, North is in the direction CENTER\_LONGITUDE + 180. If the origin is at the South pole, North is in the direction CENTER\_LONGITUDE.

---

## SEMIMAJOR\_AXIS

Set this keyword to the length (in meters) of the semimajor axis of the reference ellipsoid. The default is either the Clarke 1866 datum (6378206.4 m) or the Sphere radius (6370997 m), depending upon the projection.

## SEMIMINOR\_AXIS

Set this keyword to the length (in meters) of the semiminor axis of the reference ellipsoid. The default is either the Clarke 1866 datum (6356583.8 m) or the Sphere radius (6370997 m), depending upon the projection.

## **SOM\_INCLINATION**

Set this keyword to the orbit inclination angle in degrees of the ascending node, counter-clockwise from equator.

## **SOM\_LONGITUDE**

Set this keyword to the longitude in degrees of the ascending orbit at the equator.

## **SOM\_PERIOD**

Set this keyword to the period in minutes of the satellite revolution.

## **SOM\_RATIO**

Set this keyword to the Landsat ratio to compensate for confusion at the northern end of orbit. A typical value is 0.5201613.

## **SOM\_FLAG**

Set this keyword to the end of path flag for Landsat, where 0 is the start and 1 is the end.

## **SOM\_LANDSAT\_NUMBER**

Set this keyword to the Landsat satellite number.

## **SOM\_LANDSAT\_PATH**

Set this keyword to the Landsat path number (use 1 for Landsat 1, 2 and 3; use 2 for Landsat 4, 5 and 6).

## **SPHERE\_RADIUS**

Set this keyword to the radius (in meters) of the reference sphere. The default is 6370997 m.

## **STANDARD\_PARALLEL**

Set this keyword to the latitude in degrees of the standard parallel along which the scale is true.

## **STANDARD\_PAR1**

Set this keyword to the latitude in degrees of the first standard parallel along which the scale is true.

**Note**

---

For Albers Equal Area and Lambert Conformal Conic projections, STANDARD\_PAR1 and STANDARD\_PAR2 should not be set to values that are equal and opposite.

---

**STANDARD\_PAR2**

Set this keyword to the latitude in degrees of the second standard parallel along which the scale is true.

**Note**

---

For Albers Equal Area and Lambert Conformal Conic projections, STANDARD\_PAR1 and STANDARD\_PAR2 should not be set to values that are equal and opposite.

---

**SAT\_TILT**

Set this keyword to the downward tilt in degrees of the camera, in degrees from the projection horizontal.

**TRUE\_SCALE\_LATITUDE**

Set this keyword to the latitude in degrees of true scale.

**ZONE**

Set this keyword to an integer giving the zone for the GCTP UTM projection or GCTP State Plane projection.

**Note**

---

For the UTM projection, you may also use the CENTER\_LONGITUDE and CENTER\_LATITUDE keywords to set the zone. Internally, the ZONE value will be computed from the longitude and latitude.

---

**Note**

---

For UTM, the range is -60 to -1 and 1 to 60, where negative numbers indicate the southern hemisphere.

---

**Note**

---

For UTM, the zone number should be in the range -60 to -1 (Southern Hemisphere) or 1 to 60 (Northern Hemisphere).

---

The following table lists the allowed zones for the State Plane projection:

<b>State</b>	<b>Jurisdiction Zone</b>	<b>NAD27 Zone Code</b>	<b>NAD83 Zone Code</b>
Alabama	East	0101	0101
	West	0102	0102
Alaska	01 through 10	5001 ... 5010	5001 ... 5010

## Example

See [MAP\\_PROJ\\_FORWARD](#) for an example of using this function.

## Version History

5.6	Introduced
-----	------------

## See Also

[MAP\\_PROJ\\_FORWARD](#), [MAP\\_PROJ\\_INVERSE](#), [MAP\\_SET](#)

# MAP\_PROJ\_INVERSE

The MAP\_PROJ\_INVERSE function transforms map coordinates from Cartesian (x, y) coordinates to longitude and latitude, using either the !MAP system variable or a supplied map projection variable created by [MAP\\_PROJ\\_INIT](#).

## Syntax

```
Result = MAP_PROJ_INVERSE (X [, Y] [, MAP_STRUCTURE=value]  
[, /RADIANS] )
```

## Return Value

The result is a (2, *n*) array containing the longitude/latitude coordinates.

## Arguments

### X

An *n*-element vector containing the x values. If the *Y* argument is omitted, *X* must be a (2, *n*) array of X and Y pairs.

### Y

An *n*-element vector containing y values. If this argument is omitted, *X* must be a (2, *n*) array of X and Y pairs.

## Keywords

### MAP\_STRUCTURE

Set this keyword to a !MAP structure variable containing the projection parameters, as constructed by the [MAP\\_PROJ\\_INIT](#). If this keyword is omitted, the !MAP system variable is used.

### RADIANS

Set this keyword to indicate that the returned longitude and latitude coordinates should be expressed in radians. By default, returned coordinates are expressed in degrees.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Version History

5.6	Introduced
6.2	Thread pool keywords added

# MAP\_SET

The MAP\_SET procedure establishes the axis type and coordinate conversion mechanism for mapping points on the earth's surface, expressed in latitude and longitude, to points on a plane, according to one of several possible map projections. This procedure also sets up the clipping parameters of the region to be mapped, the center of the map, and the polar rotation. Mapping transformation values are stored in the !MAP system variable.

You can select the type of map projection, the map center, polar rotation and geographical limits can all be customized. The system variable !MAP retains the information needed to effect coordinate conversions to the plane and, inversely, from the projection plane to points on the earth in latitude and longitude. Users should not change the values of the fields in !MAP directly.

MAP\_SET can also be made to plot the graticule (the grid of latitude and longitude lines) and continental boundaries by setting the keywords GRID and CONTINENTS. Many other types of boundaries can be overplotted on maps using the MAP\_CONTINENTS procedure.

---

## Note

Using MAP\_SET changes the !X.TYPE system variable.

---

---

## Note

If the graphics device is changed, MAP\_SET (and all other mapping calls) must be re-called for the projection to be set up properly for the new device.

---

This routine is written in the IDL language. Its source code can be found in `map_set.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

MAP\_SET [, P<sub>olat</sub>, P<sub>olon</sub>, Rot]

**Keywords—Projection Types:** [ [, /AITOFF | , /ALBERS | , /AZIMUTHAL | , /CONIC | , /CYLINDRICAL | , /GNOMIC | , /GOODESHOMOLOSINE | , /HAMMER | , /LAMBERT | , /MERCATOR | , /MILLER\_CYLINDRICAL | , /MOLLWEIDE | , /ORTHOGRAPHIC | , /ROBINSON | , /SATELLITE | , /SINUSOIDAL | , /STEREOGRAPHIC | , /TRANSVERSE\_MERCATOR ] | [, NAME=*string*] ]

**Keywords—Map Characteristics:** [ [, /ADVANCE] [ , CHARSIZE=*value*] [ , /CLIP] [ , COLOR=*index*] [ , /CONTINENTS [ , CON\_COLOR=*index*] [ , /HIRES]] ]

```
[, E_CONTINENTS=structure] [, E_GRID=structure]
[, E_HORIZON=structure] [, GLINESTYLE={0 | 1 | 2 | 3 | 4 | 5}]
[, GLINETHICK=value] [, /GRID] [, /HORIZON]
[, LABEL=n{label every nth gridline}] [, LATALIGN=value{0.0 to 1.0}]

[, YMARGIN=value]
```

### Keywords—Projection Parameters:

```
[, CENTRAL_AZIMUTH=degrees_east_of_north] [, ELLIPSOID=array]
[, /ISOTROPIC] [, LIMIT=vector] [, SAT_P=vector] [, SCALE=value]
[, STANDARD_PARALLELS=array]
```

**Graphics Keywords:** [, POSITION=[ $X_0$ ,  $Y_0$ ,  $X_1$ ,  $Y_1$ ]] [, /T3D] [, ZVALUE=value{0 to 1}]

## Arguments

### $P_{0lat}$

The latitude of the point on the earth's surface to be mapped to the center of the projection plane. Latitude is measured in degrees North of the equator and  $P_{0lat}$  must be in the range:  $-90^\circ \leq P_{0lat} \leq 90^\circ$ .

If  $P_{0lat}$  is not set, the default value is zero.

### Note

---

If the longitude and latitude limits (specified via the **LIMIT** keyword) do not include the point (0,0), you might want to specify the  $P_{0lon}$  and  $P_{0lat}$  arguments explicitly, to avoid unexpected results.

---

### $P_{0lon}$

The longitude of the point on the earth's surface to be mapped to the center of the map projection. Longitude is measured in degrees east of the Greenwich meridian and  $P_{0lon}$  must be in the range:  $-180^\circ \leq P_{0lon} \leq 180^\circ$ .

If  $P_{0lon}$  is not set, the default value is zero.

**Note**

---

If the longitude and latitude limits (specified via the **LIMIT** keyword) do not include the point (0,0), you might want to specify the  $P_{0lon}$  and  $P_{0lat}$  arguments explicitly, to avoid unexpected results.

---

**Rot**

*Rot* is the angle through which the North direction should be rotated around the line  $L$  between the earth's center and the point  $(P_{0lat}, P_{0lon})$ . *Rot* is measured in degrees with the positive direction being clockwise rotation around line  $L$ . *Rot* can have values from  $-180^\circ$  to  $180^\circ$ .

If the center of the map is at the North pole, North is in the direction  $P_{0lon} + 180^\circ$ . If the origin is at the South pole, North is in the direction  $P_{0lon}$ .

The default value of *Rot* is 0 degrees.

**Keywords****Projection Type Keywords:****AITOFF**

Set this keyword to select the Aitoff projection.

An Aitoff projection centered on the international dateline can be produced by the command:

```
MAP_SET, 0, 180, /AITOFF, /GRID, /CONTINENTS, /ISOTROPIC, $
      TITLE= 'Aitoff Projection'
```

**ALBERS**

Set this keyword to select the Albers equal-area conic projection. To specify the latitude of the standard parallels, see “[STANDARD\\_PARALLELS](#)” on page 1467.

**AZIMUTHAL**

Set this keyword to select the azimuthal equidistant projection.

If the keyword **LIMIT** is not set, the whole globe is mapped to the  $UV$  plane.

```
MAP_SET, /AZIMUTHAL, /ISOTROPIC, -90, $
      /GRID, LONDEL=20, LATDEL=20, /CONTINENT, $
      /HORIZON, TITLE = 'Polar Azimuthal'
```

This produces a projection centered at the South Pole and shows the entire globe.

**Note**

With azimuthal projections, the *UV* plane is tangent to the globe. The point of tangency is projected onto the center of the plane and its latitude and longitude are *P0lat* and *P0lon*, respectively. *Rot* is the angle between North and the v-axis.

**CONIC**

Set this keyword to select Lambert's conformal conic projection with one or two standard parallels. The `STANDARD_PARALLELS` keyword specifies the latitudes of one or two standard parallels., see "[STANDARD\\_PARALLELS](#)" on page 1467. This keyword can be used with the `ELLIPSOID` keyword.

The following statement produces the map shown in the accompanying figure, which features North America with standard parallels at 20 degrees and 60 degrees:

```
MAP_SET, /CONIC, 40, -80, STANDARD_PARALLELS=[20,60], $
      /ISOTROPIC, LIMIT=[0, -260, 90, 100], $
      /GRID, LATDEL=15, LONDEL=20, /CONTINENT, $
      TITLE= 'Lambert's Conic'
```

**CYLINDRICAL**

Set this keyword to select the cylindrical equidistant projection. Cylindrical is the default map projection.

The following code is used to produce a simple cylindrical equidistant projection and an oblique cylindrical equidistant projection:

```
MAP_SET, /CYLINDRICAL, 0, 0, /GRID, /CONTINENTS, $
      TITLE = 'Simple Cylindrical Equidistant'
```

Now rotate the projection by 45°:

```
MAP_SET, /CYLINDRICAL, 0, 0, 45, $
      /GRID, /CONTINENT, /HORIZON, $
      TITLE='Oblique Cylindrical Equidistant'
```

**GOODESHOMOLOSINE**

Set this keyword to select the Goode's Homolosine Projection. The central latitude for this projection is fixed on the equator, 0 degrees latitude. This projection is interrupted, as the inventor originally intended, and is best viewed with the central longitude set to 0.

The following statement produced the example of Goode's Homolosine projection:

```
MAP_SET, /GOODESHOMOLOSINE, 0, 0, /ISOTROPIC, /GRID, $
      LATDEL=15, LONDEL=20, /HORIZON, E_CONTINENTS={FILL:1}, $
```

```
TITLE='Goode Homolosine'
```

## GNOMIC

Set this keyword to select the gnomonic projection. If default clipping is enabled, this projection will display a maximum of  $\pm 60^\circ$  from the center of the projection area when the center is at either the equator or one of the poles.

```
MAP_SET, /GNOMIC, 40, -105, LIMIT = [20, -130, 70, -70], $
  /ISOTROPIC, /GRID, /CONTINENT, $
  TITLE = 'Oblique Gnomonic'
```

This projection is centered around the point at latitude 40 degrees and longitude  $-105$  degrees. The region on the globe that is mapped lies between 20 degrees and 70 degrees of latitude and  $-130$  degrees and  $-70$  degrees of longitude.

## HAMMER

Set this keyword to select the Hammer-Aitoff equal area projection.

A Hammer-Aitoff projection centered on the international dateline can be produced by the command:

```
MAP_SET, 0, 180, /HAMMER, /GRID, /CONTINENTS, /ISOTROPIC, $
  /HORIZON, TITLE= 'Hammer-Aitoff Projection'
```

## LAMBERT

Set this keyword to select Lambert's azimuthal equal area projection.

The following statements create a projection that shows the Northern Hemisphere rotated counterclockwise 105 degrees, and the continents are filled with a solid color.

```
MAP_SET, /LAMBERT, 90, 0, -105, /ISOTROPIC, $
  /GRID, LATDEL=20, LONDEL=20, $
  /CONTINENTS, E_CONTINENTS={FILL:1}, /HORIZON, $
  TITLE = 'Polar Lambert'
```

## MERCATOR

Set this keyword to select the Mercator projection. Note that this projection will not display regions within  $\pm 10^\circ$  of the poles of projection.

By default, the keyword LIMIT is set to  $[-80, -180, 80, 180]$  because of the great distortions around the poles when the equator is selected. The following statement produces a simple Mercator projection:

```
MAP_SET, /MERCATOR, 0, 0, /ISOTROPIC, $
  /GRID, /CONTINENTS, $
  TITLE = 'Simple Mercator'
```

When the eccentricity of the Earth is not important, global scale Transverse Mercator projections (see “[TRANSVERSE\\_MERCATOR](#)” on page 1460) can be easily created using the Mercator projection with the `CENTRAL_AZIMUTH` keyword set to 90 degrees, and setting *Rot* to rotate the map 90 degrees. For example, to create the Transverse Mercator map showing North and South America, with a central meridian of -90 degrees West and centered on the Equator, use the following statement:

```
MAP_SET, /MERCATOR, 0, -75, 90, CENTRAL_AZIMUTH=90, $
      /ISOTROPIC, LIMIT= [32,-130, 70,-86, -5,-34, -58, -67], $
      /GRID, LATDEL=15, LONDEL=15, /CONTINENTS, $
      TITLE = 'Transverse Mercator'
```

## MILLER\_CYLINDRICAL

Set this keyword to select the Miller Cylindrical projection.

## MOLLWEIDE

Set this keyword to select the Mollweide projection.

If the keyword `LIMIT` is not set, the whole globe will be mapped to the plane. The following statement produces a Mollweide projection in oblique form:

```
MAP_SET, /MOLLWEIDE, 45, 0, /ISOTROPIC, $
      /GRID, LATDEL=20, LONDEL=20, $
      /HORIZON, E_CONTINENTS={FILL:1}, $
      TITLE='Oblique Mollweide'
```

Since the center of the projection is not on the equator, parallels of latitude are not straight lines, just as they are not straight lines with an oblique Mercator or cylindrical equidistant projection.

## NAME

Set this keyword to a string indicating the projection that you wish to use. A list of available projections can be found using `MAP_PROJ_INFO`, `PROJ_NAMES=names`. This keyword will override any of the individual projection keywords.

## ORTHOGRAPHIC

Set this keyword to select the orthographic projection. Note that this projection will display a maximum of  $\pm 90^\circ$  from the center of the projection area.

The following statements are used to produce an orthographic projection centered over Eastern Spain at a scale of 70 million to 1:

```
MAP_SET, /ORTHOGRAPHIC, 40, 0, SCALE=70e6, /CONTINENTS, $
      /GRID, LONDEL=15, LATDEL=15, $
```

```
TITLE = 'Oblique Orthographic'
```

## ROBINSON

Set this keyword to select the Robinson pseudo-cylindrical projection.

### Note

---

The central meridian should always be 0 degrees longitude to retain the correct balance of shapes, sizes, and relative positions.

---

The next statement produces a Robinson projection.

```
MAP_SET, /ROBINSON, 0, 0, /ISOTROPIC, /GRID, $
        /HORIZON, E_CONTINENTS={FILL:1}, TITLE='Robinson'
```

## SATELLITE

Set this keyword to select the satellite projection. For the satellite projection,  $P_{OLat}$  and  $P_{OLon}$  represent the latitude and longitude of the sub-satellite point. Three additional parameters,  $P$ ,  $\Omega$ , and  $\Gamma$  (supplied as a three-element vector argument to the SAT\_P keyword), are required where:

- $P$  is the distance of the point of perspective (camera) from the center of the globe, expressed in units of the radius of the globe.
- $\Omega$  is the downward tilt of the camera, in degrees from the new horizontal. If both  $\Gamma$  and  $\Omega$  are 0, a Vertical Perspective projection results.
- $\Gamma$  is the angle, expressed in degrees clockwise from north, of the rotation of the projection plane. This parameter is equivalent to the *Rot* argument to the MAP\_SET procedure.

### Note

---

Since all meridians and parallels are oblique lines or arcs, the LIMIT keyword must be supplied as an eight-element vector representing four points that delineate the limits of the map. The extent of the map limits, when expressed in latitude/longitude is a complicated polygon, rather than a simple quadrilateral.

---

See [“Labeling and Drawing Projections”](#) on page 1467 for an example.

## SINUSOIDAL

Set this keyword to select the sinusoidal projection.

The parameters  $P_{OLat}$  and *Rot* of the MAP\_SET procedure must be zero. If they are not, an error message results and the procedure MAP\_SET will reset both of these

parameters to zero and continue. By default,  $P_{0Lon}$  (the central longitude) is zero, but the user can set it to any other value between  $-180$  and  $180$ . If the keyword `LIMIT` is undefined, the entire globe is the region selected for mapping.

The following statements produces the sinusoidal map of the whole globe centered at longitude 0 degrees and latitude 0 degrees:

```
MAP_SET, /SINUSOIDAL, /ISOTROPIC, $
        /CONTINENTS, TITLE='Sinusoidal'
MAP_GRID, LONDEL=20, /HORIZON
```

## STEREOGRAPHIC

Set this keyword to select the stereographic projection. Note that if default clipping is enabled, this projection will display a maximum of  $\pm 90^\circ$  from the center of the projection area.

The following statement uses the stereographic projection to draw the hemisphere centered on the equator at longitude  $-105$  degrees and produces an equatorial stereographic map:

```
MAP_SET, /STEREOGRAPHIC, 0, -105, /ISOTROPIC, $
        /GRID, LATDEL = 20, LONDEL = 20, /HORIZON, /CONTINENT, $
        TITLE = 'Equatorial Stereographic'
```

Since the `LATDEL` and `LONDEL` keywords are set to 20, parallels and meridians are spaced 20 degrees apart. The `GRID` and `CONTINENT` keywords signal that the grid and continents should be drawn.

## TRANSVERSE\_MERCATOR

Set this keyword to select the Transverse Mercator projection, also called the UTM or Gauss-Krueger projection. This projection works well with the ellipsoid form. The default ellipsoid is the Clarke 1866 ellipsoid. To change the default ellipsoid characteristics, see “[ELLIPSOID](#)” on page 1465.

To create a UTM map, centered near London, with a scale of 10 million to one, type the following:

```
MAP_SET, /TRANSVERSE_MERCATOR, 51, 0, SCALE=10e6, $
        /GRID, LATDEL=2.5, LONDEL=2.5, /LABEL, LONLAB=48, $
        /CONTINENTS, E_CONT={COUNTRIES:1, COASTS:1}, $
        TITLE='UTM Projection'
```

## Map Characteristic Keywords:

### ADVANCE

If this keyword is set, and the screen is set to display multiple plots (using !P.MULTI), IDL will automatically advance to the next plot position. If there are no plot positions remaining, IDL will erase the screen and use the first plot position. If this keyword is not set, and [NOERASE](#) is also not set, IDL always erases the screen.

### CHARSIZE

The size of the characters used for the labels. The default is 1.

### CLIP

Set this keyword to clip the map using the map-specific graphics technique. The default is to perform map-specific clipping. Set CLIP=0 to disable clipping.

#### Note

---

Clipping controlled by the CLIP keyword applies only to the map itself. In order to disable general clipping within the plot window, you must set the system variable !P.NOCLIP=1. For more information, see [“NOCLIP”](#) on page 4782.

---

### COLOR

The color index of the map border in the plotting window.

### CONTINENTS

Set this keyword to plot the continental boundaries. Note that if you are using the low-resolution map database (if the HIRES keyword is *not* set), outlines for continents, islands, and lakes are drawn when the CONTINENTS keyword is set. If you are using the high-resolution map database (if the HIRES keyword *is* set), only continental outlines are drawn when the CONTINENTS keyword is set. To draw islands and lakes when using the high-resolution map database, use the COASTS keyword to the MAP\_CONTINENTS procedure.

### CON\_COLOR

The color index for continent outlines if CONTINENTS is set.

## E\_CONTINENTS

Set this keyword to a structure containing extra keywords to be passed to MAP\_CONTINENTS. For example, to fill continents, the FILL keyword of MAP\_CONTINENTS is set to 1. To fill the continents with MAP\_SET, specify E\_CONTINENTS={FILL:1}.

## E\_GRID

Set this keyword to a structure containing extra keywords to be passed to MAP\_GRID. For example, to label every other gridline on a grid of parallels and meridians, the LABEL keyword of MAP\_GRID is set to 2. To do the same with MAP\_SET, specify E\_GRID={LABEL:2}.

## E\_HORIZON

Set this keyword to a structure containing extra keywords to be set as modifiers to the HORIZON keyword.

### Example

To draw a Stereographic map, with the sphere filled in color index 3, enter:

```
MAP_SET, 0, 0, /STEREO, /HORIZON, /ISOTROPIC, $
      E_HORIZON={FILL:1, COLOR:3}
```

## GLINESTYLE

Set this keyword to a line style index used to draw the grid of parallels and meridians. See [MLINESTYLE](#) for a list of available linestyles. The default is 1, drawing a grid of dotted lines.

## GLINETHICK

Set this keyword to the thickness of the gridlines drawn if the GRID keyword is set. The default is 1.

## GRID

Set this keyword to draw the grid of parallels and meridians.

## HIRES

Set this keyword to use the high-resolution continent outlines when drawing continents. This keyword only has effect if the CONTINENTS keyword is also set.

## HORIZON

Set this keyword to draw a horizon line, when the projection in use permits. The horizon delineates the boundary of the sphere. See [E\\_HORIZON](#) for more options.

## LABEL

Set this keyword to label the parallels and meridians with their corresponding latitudes and longitudes. Setting this keyword to an integer will cause every LABEL gridline to be labeled (that is, if LABEL=3 then every third gridline will be labeled). The starting point for determining which gridlines are labeled is the minimum latitude or longitude (-180 to 180).

## LATALIGN

The alignment of the text baseline for latitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it.

## LATLAB

The longitude at which to place latitude labels. The default is the center longitude of the map.

## LATDEL

Set this keyword equal to the spacing (in degrees) between parallels of latitude drawn by the MAP\_GRID procedure. If this keyword is not set, a suitable value is determined from the current map projection.

## LONALIGN

The alignment of the text baseline for longitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it.

## LONDEL

Set this keyword equal to the spacing (in degrees) between meridians of longitude drawn by the MAP\_GRID procedure. If this keyword is not set, a suitable value is determined from the current map projection.

## LONLAB

The latitude at which to place longitude labels. The default is the center latitude of the map.

## MLINESTYLE

The line style index used for continental boundaries. Linestyles are described in the table below. The default is 0 for solid.

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

*Table 3-86: IDL Linestyles*

## MLINETHICK

The line thickness used for continental boundaries. The default is 2.

## NOBORDER

Set this keyword to not draw a border around the map. The map will fill the extent of the plotting region. If **NOBORDER** is *not* specified, a margin equalling 1% of the plotting region will be placed between the map and the border.

## NOERASE

If this keyword is set, IDL does not erase the screen before setting up the map projection. The default behavior is to erase the screen. This keyword is ignored if **ADVANCE** is set.

## REVERSE

Set this keyword to one of the following values to reverse the X and/or Y axes:

- 0 = no reversal (the default)
- 1 = reverse X
- 2 = reverse Y
- 3 = reverse both.

## TITLE

A string containing the main title for the map. The title appears centered above the map window.

## USA

Set this keyword to draw borders for each state in the United States.

## XMARGIN

A scalar or two-element vector that specifies the vertical margin between the map and screen border in character units. If a scalar is specified, the same margin will be used on both sides of the map.

## YMARGIN

A scalar or two-element vector that specifies in the horizontal margin between the map and screen border in character units. If a scalar is specified, the same margin will be used on the top and bottom of the map.

## Projection Parameter Keywords:

### CENTRAL\_AZIMUTH

Set this keyword to the angle of the central azimuth, in degrees east of North. This keyword can be used with the following projections: Cylindrical, Mercator, Miller, Mollweide, and Sinusoidal. The default is 0 degrees. The pole is placed at an azimuth of CENTRAL\_AZIMUTH degrees CCW of North, as specified by the *Rot* argument.

### ELLIPSOID

Set this keyword to a 3-element array,  $[a, e^2, k_0]$ , defining the ellipsoid for the Transverse Mercator or Lambert Conic projections.

- $a$ : equatorial radius, in meters ( $a$  must be greater than zero)
- $e^2$ : eccentricity squared.  $e^2 = 2 * f - f^2$ , where  $f = 1 - b/a$  ( $a$ : equatorial radius,  $b$ : polar radius; in meters).  $e^2$  must be nonnegative and less than 1.
- $k_0$ : scale on the central meridian

The default is the Clarke 1866 ellipsoid,  $[6378206.4, 0.00676866, 0.9996]$ .

This keyword can be used with the CONIC or TRANSVERSE\_MERCATOR keywords. For CONIC if ELLIPSOID is not supplied, a sphere of normalized radius

1.0 is used. For TRANSVERSE\_MERCATOR if ELLIPSOID is not supplied, the default is the Clarke 1866 ellipsoid, [6378206.4, 0.00676866, 0.9996].

## ISOTROPIC

Set this keyword to produce a map that has the same scale in the X and Y directions.

### Note

---

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See “POSITION” on page 4784 for more information.

---

## LIMIT

A four- or eight-element vector that specifies the limits of the map.

As a four-element vector, LIMIT has the form  $[Lat_{min}, Lon_{min}, Lat_{max}, Lon_{max}]$  that specifies the boundaries of the region to be mapped.  $(Lat_{min}, Lon_{min})$  and  $(Lat_{max}, Lon_{max})$  are the latitudes and longitudes of two points diagonal from each other on the region's boundary.

For more complex regions or projections, the eight-element vector, LIMIT has the form:  $[Lat_0, Lon_0, Lat_1, Lon_1, Lat_2, Lon_2, Lat_3, Lon_3]$ . These four latitude/longitude pairs describe, respectively, four points on the left, top, right, and bottom edges of the map extent.

### Note

---

If the longitude range in LIMIT is less than or equal to 180 degrees, map clipping is performed in lat/lon coordinates before the transform. If the longitude range is greater than 180 degrees, map clipping is done in Cartesian coordinates after the transform. For non-cylindrical projections, clipping after the transformation to Cartesian coordinates means that some lat/lon points that fall outside the bounds specified by LIMIT may not be clipped. This occurs when the transformed lat/lon points fall inside the cartesian clipping rectangle.

---

## SAT\_P

A three-element vector containing three parameters,  $P$ ,  $\Omega$ , and  $\Gamma$ , that must be supplied when using the SATELLITE projection where:

- $P$  is the distance of the point of perspective (camera) from the center of the globe, expressed in units of the radius of the globe.

- *Omega* is the downward tilt of the camera, in degrees from the new horizontal. If both *Gamma* and *Omega* are 0, a Vertical Perspective projection results.
- *Gamma* is the angle, expressed in degrees clockwise from north, of the Earth's rotation. This parameter is equivalent to the *Rot* argument.

## SCALE

Set this keyword to construct an isotropic map with the given scale, set to the ratio of 1:*scale*. If **SCALE** is not specified, the map is fit to the window. The typical scale for global maps is in the ratio of between 1:100 million and 1:200 million. For continents, the typical scale is in the ratio of approximately 1:50 million. For example, **SCALE=100E6** sets the scale at the center of the map to 1:100 million, which is in the same ratio as 1 inch to 1578 miles (1 cm to 1000 km).

## STANDARD\_PARALLELS

Set this keyword to a one- or two-element array defining, respectively, one or two standard parallels for conic projections.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[POSITION](#), [T3D](#), [ZVALUE](#)

## Examples

To draw a Stereographic map, with the sphere filled in color index 3:

```
MAP_SET, 0, 0, /STEREO, /HORIZON, /ISOTROPIC, E_HORIZON={FILL:1,
COLOR:3}
```

## Labeling and Drawing Projections

Labeling and drawing a vector on a satellite projection.

```
MAP_SET, /SATELLITE, SAT_P=[1.0251, 55, 150], 41.5, -74., $
  /ISOTROPIC, /HORIZON, $
  LIMIT=[39, -74, 33, -80, 40, -77, 41, -74], $
  /CONTINENTS, TITLE='Satellite / Tilted Perspective'
; Set up the satellite projection:
MAP_GRID, /LABEL, LATLAB=-75, LONLAB=39, LATDEL=1, LONDEL=1
; Get North vector:
p = convert_coord(-74.5, [40.2, 40.5], /TO_NORM)
; Draw North arrow:
```

```
ARROW, p(0,0), p(1,0), p(0,1), p(1,1), /NORMAL
XYOUTS, -74.5, 40.1, 'North', ALIGNMENT=0.5
```

The map in the accompanying figure, which shows the eastern seaboard of the United States from an altitude of about 160km, above Newburgh, NY, was produced with the previous code.

Figure 3-74: Satellite Projection

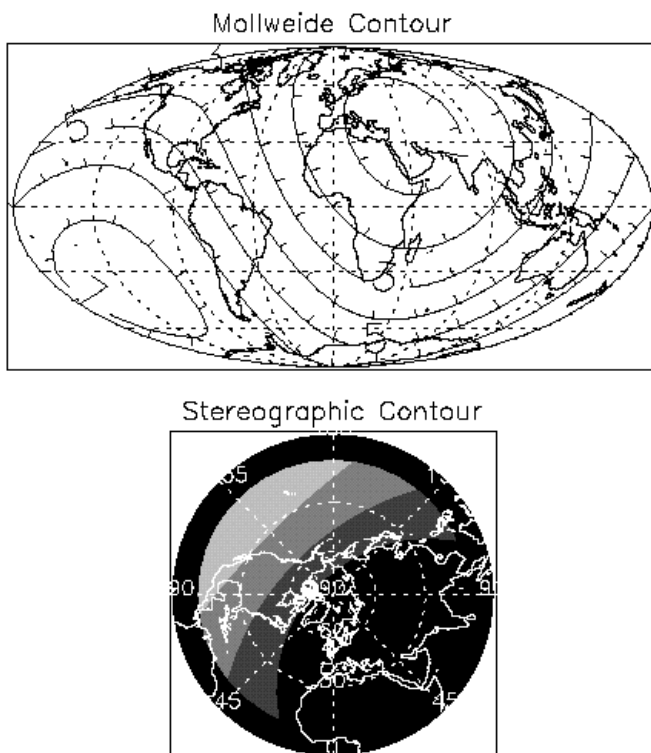

The parameters for this satellite projection are:

- Center of projection = 41.5N latitude, -74W longitude
- $P$  (altitude) = 1.025 =  $(1.0 + 160 / 6371\text{km})$
- $\Gamma$  (rotation of projection plane) = 150 degrees
- $\Omega$  (tilt of projection plane) = 55 degrees
- The eight element LIMIT keyword array specifies the latitude/longitude locations of points at the bottom, left, top, and right of the map respectively.
- The HORIZON keyword draws a horizon line.

## Putting Data on Maps — Using CONTOUR with MAP\_SET

The procedures PLOT, OPLOT, PLOTS, XYOUTS, and CONTOUR can be used to display and annotate geographical data on maps created by the routines MAP\_SET, MAP\_GRID, and MAP\_CONTINENTS. The MAP\_IMAGE procedure can be used to warp regularly-gridded images to map projections.

The following simple example creates a CONTOUR plot over a Mollweide map projection and then over a polar stereographic projection. The resulting map is shown below.

*Figure 3-75: Combining CONTOUR with MAP\_SET*

```
; Make a 10 degree latitude/longitude grid covering the Earth:
lat = REPLICATE(10., 37) # FINDGEN(19) - 90.
lon = FINDGEN(37) # REPLICATE(10, 19)
; Convert lat and lon to Cartesian coordinates:
```

```

X = COS(!DTOR * lon) * COS(!DTOR * lat)
Y = SIN(!DTOR * lon) * COS(!DTOR * lat)
Z = SIN(!DTOR * lat)
; Create the function to be plotted, set it equal
; to the distance squared from (1,1,1):
F = (X-1.)^2 + (Y-1.)^2 + (Z-1.)^2
MAP_SET, /MOLLWEIDE, 0, 0, /ISOTROPIC, $
      /HORIZON, /GRID, /CONTINENTS, $
      TITLE='Mollweide Contour'
CONTOUR, F, lon, lat, NLEVELS=7, $
      /OVERPLOT, /DOWNHILL, /FOLLOW
; Fill the contours over the northern hemisphere and
; display in a polar stereographic projection:
MAP_SET, /STEREO, 90, 0, $
      /ISOTROPIC, /HORIZON, E_HORIZON={FILL:1}, $
      TITLE='Stereographic Contour'
; Display points in the northern hemisphere only:
CONTOUR, F(*,10:*), lon(*,10:*), lat(*,10:*), $
      /OVERPLOT, /FILL, NLEVELS=5
MAP_GRID, /LABEL, COLOR=255
MAP_CONTINENTS, COLOR=255

```

## Limitations

Filling contours or polygons over maps that cover more than a hemisphere will produce incorrect results. This is because of the ambiguity between polygons that enclose an area, and those that enclose the entire surface of the sphere outside the area; and because of the ambiguity of determining the clockwise-ness of polygons on a sphere that cover more than a hemisphere.

# MATRIX\_MULTIPLY

The `MATRIX_MULTIPLY` function calculates the IDL `#` operator of two (possibly transposed) arrays. The transpose operation (if desired) is done simultaneously with the multiplication, thus conserving memory and increasing the speed of the operation. If the arrays are not transposed, then `MATRIX_MULTIPLY` is equivalent to using the `#` operator.

## The # Operator vs. MATRIX\_MULTIPLY

The following table illustrates how various operations are performed using the `#` operator versus the `MATRIX_MULTIPLY` function:

# Operator	Function
<code>A # B</code>	<code>MATRIX_MULTIPLY(A, B)</code>
<code>transpose(A) # B</code>	<code>MATRIX_MULTIPLY(A, B, /ATRANSPOSE)</code>
<code>A # transpose(B)</code>	<code>MATRIX_MULTIPLY(A, B, /BTRANSPOSE)</code>
<code>transpose(A) # transpose(B)</code>	<code>MATRIX_MULTIPLY(A, B, /ATRANSPOSE, /BTRANSPOSE)</code>

Table 3-87: The # Operator vs. `MATRIX_MULTIPLY`

### Note

`MATRIX_MULTIPLY` can also be used in place of the `##` operator. For example, `A ## B` is equivalent to `MATRIX_MULTIPLY(B, A)`, and `A ## TRANSPOSE(B)` is equivalent to `MATRIX_MULTIPLY(B, A, /ATRANSPOSE)`.

## Syntax

*Result* = `MATRIX_MULTIPLY( A, B [, /ATRANSPOSE] [, /BTRANSPOSE] )`

## Return Value

The type for the result depends upon the input type. For byte or integer arrays, the result has the type of the next-larger integer type that could contain the result (for example, byte, integer, or long input returns type long integer). For floating-point, the result has the same type as the input.

For the case of no transpose, the resulting array has the same number of columns as the first array and the same number of rows as the second array. The second array must have the same number of columns as the first array has rows.

---

**Note**

If  $A$  and  $B$  arguments are vectors, then  $C = \text{MATRIX\_MULTIPLY}(A, B)$  is a matrix with  $C_{ij} = A_i B_j$ . Mathematically, this is equivalent to the outer product, usually denoted by  $A \otimes B$ .

---

## Arguments

### A

The left operand for the matrix multiplication. Dimensions higher than two are ignored.

### B

The right operand for the matrix multiplication. Dimensions higher than two are ignored.

## Keywords

### ATRANSPOSE

Set this keyword to multiply using the transpose of  $A$ .

### BTRANSPOSE

Set this keyword to multiply using the transpose of  $B$ .

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Version History

[MATRIX\\_POWER](#), “Multiplying Arrays” in Chapter 15 of the *Building IDL Applications* manual

# MATRIX\_POWER

The `MATRIX_POWER` function computes the product of a matrix with itself. For example, the fifth power of array *A* is *A* # *A* # *A* # *A* # *A*. Negative powers are computed using the matrix inverse of the positive power.

## Syntax

*Result* = `MATRIX_POWER(Array, N [, /DOUBLE] [, STATUS=value])`

## Return Value

The result is a square array containing the value of the matrix raised to the specified power. A power of zero returns the identity matrix.

## Arguments

### Array

A square, two-dimensional array of any numeric type.

### N

An integer representing the power. *N* may be positive or negative.

## Keywords

### DOUBLE

Set this keyword to return a double-precision result. Explicitly set this keyword equal to zero to return a single-precision result. The default return type depends upon the precision of *Array*.

### Note

---

Computations are always performed using double-precision arithmetic.

---

## STATUS

Set this keyword equal to a named variable that will contain the status of the matrix inverse for negative powers. Possible values are:

Value	Description
0	Successful completion.
1	Singular array (which indicates that the inversion is invalid).
2	Warning that a small pivot element was used and that significant accuracy was probably lost.

Table 3-88: STATUS Keyword Values

For non-negative powers, STATUS is always set to 0.

## Example

Print an array to the one millionth power:

```
array = [ [0.401d, 0.600d], $
          [0.525d, 0.475d] ]
PRINT, MATRIX_POWER(array, 1e6)
```

IDL prints:

```
2.4487434e+202  2.7960773e+202
2.4465677e+202  2.7935929e+202
```

## Version History

5.6	Introduced

## See Also

[MATRIX\\_MULTIPLY](#), “[Multiplying Arrays](#)” in Chapter 15 of the *Building IDL Applications* manual

# MAX

The MAX function returns the value of the largest element of *Array*.

## Syntax

```
Result = MAX( Array [, Max_Subscript] [, /ABSOLUTE] [, DIMENSION=value]  
            [, MIN=variable] [, /NAN] [, SUBSCRIPT_MIN=variable])
```

## Return Value

Return the largest array element value. The type of the result is the same as the type of *Array*.

## Arguments

### Array

The array to be searched.

### Max\_Subscript

A named variable that, if supplied, is converted to a long integer containing the one-dimensional subscript of the maximum element. Otherwise, the system variable !C is set to the one-dimensional subscript of the maximum element.

## Keywords

### ABSOLUTE

If this keyword is set, then the absolute value of each element is used when determining the maximum values. This keyword has no effect for arrays of type byte or unsigned integer.

### Note

---

If ABSOLUTE is set then the sign of each value is ignored when searching for the maximum. However, the return value retains the negative sign if the value was indeed negative.

---

**Tip**

For complex input, `MAX` by default only compares the real component of each value. Use the `ABSOLUTE` keyword to force `MAX` to compare the absolute value of each value, and to return the complex value corresponding to the maximum absolute value.

**DIMENSION**

Set this keyword to the dimension over which to find the maximum values of an array. If this keyword is not present or is zero, the maximum is found over the entire array and is returned as a scalar value. If this keyword is present and nonzero, the result is the “slice” of the input array that contains the maximum value element, and the return values for `Result`, `Max_Subscript`, `MIN`, and `SUBSCRIPT_MIN` will all be arrays of one dimension less than the input array. That is, if the dimensions of `Array` are  $N1$ ,  $N2$ ,  $N3$ , and `DIMENSION=2`, the dimensions of the result are  $(N1, N3)$ , and element  $(i,j)$  of the result contains the maximum value of `Array[i, *, j]`.

For example:

```
arr = FINDGEN(2,3,2)
PRINT, arr
```

IDL prints:

```
0.00000    1.00000
2.00000    3.00000
4.00000    5.00000
```

```
6.00000    7.00000
8.00000    9.00000
10.00000   11.00000
```

```
PRINT, MAX(arr, DIMENSION=2)
```

IDL prints:

```
4.00000    5.00000
10.00000   11.00000
```

```
PRINT, MAX(arr, DIMENSION=1)
```

IDL prints:

```
1.00000    3.00000    5.00000
7.00000    9.00000    11.00000
```

## MIN

A named variable to receive the value of the minimum array element. If you need to find both the minimum and maximum array values, use this keyword to avoid scanning the array twice with separate calls to MAX and MIN.

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

### Note

---

If the MAX function is run on an array containing NaN values and the NAN keyword is not set, an invalid result will occur.

---

## SUBSCRIPT\_MIN

Set this keyword equal to a named variable that will contain the one-dimensional subscript of the minimum element, the value of which is available via the MIN keyword.

## Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

### Example 1

This example prints the maximum value in an array, and the subscript of that value:

```
; Create a simple two-dimensional array:
D = DIST(100)
```

```

; Print the maximum value in array D and its linear subscript:
PRINT, 'Maximum value in array D is:', MAX(D, I)
PRINT, 'The subscript of the maximum value is', I

```

### IDL Output

```

Maximum value in array D is:          70.7107
The subscript of the maximum value is          5050

```

## Example 2

To convert I to a two-dimensional subscript, use the commands:

```

IX = I MOD 100
IY = I/100
PRINT, 'The maximum value of D is at location ('+ STRTRIM(IX, 1) $
      + ', ' + STRTRIM(IY, 1) + ')'

```

### IDL Output

```

The maximum value of D is at location (50, 50)

```

## Version History

# MD\_TEST

The MD\_TEST function tests the hypothesis that a sample population is random against the hypothesis that it is not random. This two-tailed function is an extension of the “Runs Test for Randomness” and is often referred to as the Median Delta Test.

This routine is written in the IDL language. Its source code can be found in the file `md_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MD_TEST( X [, ABOVE=variable] [, BELOW=variable]  
                [, MDC=variable] )
```

## Return Value

The result is a two-element vector containing the nearly-normal test statistic  $Z$  and its associated probability.

## Arguments

### X

An  $n$ -element integer, single- or double-precision floating-point vector.

## Keywords

### ABOVE

Use this keyword to specify a named variable that will contain the number of sample population values greater than the median of  $X$ .

### BELOW

Use this keyword to specify a named variable that will contain the number of sample population values less than the median of  $X$ .

### MDC

Use this keyword to specify a named variable that will contain the number of Median Delta Clusters (sequential values of  $X$  above and below the median).

## Examples

This example tests the hypothesis that  $X$  represents a random population against the hypothesis that it does not represent a random population at the 0.05 significance level:

```
; Define a sample population:
X = [ 2.00,  0.90, -1.44, -0.88, -0.24,  0.83, -0.84, -0.74, $
      0.99, -0.82, -0.59, -1.88, -1.96,  0.77, -1.89, -0.56, $
      -0.62, -0.36, -1.01, -1.36]

; Test the hypothesis that X represents a random population against
; the hypothesis that it does not represent a random population at
; the 0.05 significance level:
result = MD_TEST(X, MDC = mdc)
PRINT, result
```

IDL prints:

```
0.459468      0.322949
```

The computed probability (0.322949) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that  $X$  represents a random population.

# MEAN

The MEAN function computes the mean of a numeric vector. MEAN calls the IDL function MOMENT.

## Syntax

```
Result = MEAN( X [, /DOUBLE] [, /NAN] )
```

## Return Value

Returns the average value of a set of numbers.

## Arguments

### X

An  $n$ -element, integer, double-precision or floating-point vector.

## Keywords

### DOUBLE

If this keyword is set, computations are done in double precision arithmetic.

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]

; Compute the average:
result = MEAN(x)

; Print the result:
PRINT, result
```

IDL prints:

66.7333

# MEANABSDEV

The MEANABSDEV function computes the mean absolute deviation of an  $n$ -element vector or array.

This routine is written in the IDL language. Its source code can be found in the file `meanabsdev.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MEANABSDEV( X [, /DOUBLE] [, /MEDIAN] [, /NAN] )
```

## Return Value

Returns the average deviation.

## Arguments

**X**

An  $n$ -element vector or array of any numeric type.

## Keywords

### DOUBLE

Set this keyword to force computations to be done in double precision arithmetic and to return a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results). This has no effect if the MEDIAN keyword is set.

### MEDIAN

Set this keyword to return the average deviation from the median. By default, if MEDIAN is not set, MEANABSDEV will return the average deviation from the mean.

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity*

are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define an n-element vector:  
x = [1, 1, 1, 2, 5]  
  
; Compute average deviation from the mean:  
result = MEANABSDEV(x)  
  
; Print the result:  
PRINT, result
```

IDL prints:

```
1.20000
```

# MEDIAN

The MEDIAN function computes the median value. In an ordered set of values, the median is a value with an equal number of values above and below it. Median smoothing replaces each point with the median of the one- or two-dimensional neighborhood of a given width. It is similar to smoothing with a boxcar or average filter but does not blur edges larger than the neighborhood.

In addition, median filtering is effective in removing salt and pepper noise, (isolated high or low values). The scalar median is simply the middle value, which should not be confused with the average value (e.g., the median of the array [1,10,4] is 4, while the average is 5.)

---

**Note**

The MEDIAN function treats NaN values as missing data.

---

## Syntax

```
Result = MEDIAN ( Array [, Width] [, /DOUBLE] [, DIMENSION=value]
                [, /EVEN] )
```

## Return Value

Returns the median value of *Array* if one parameter is present, or applies a one- or two-dimensional median filter of the specified width to *Array* and returns the result.

## Arguments

### Array

The array to be processed. If *Width* is also supplied, and *Array* is of byte type, the result is of byte type. If *Array* is double precision or double complex, the computation is done using double precision and the result is double-precision. All other types are converted to single-precision floating-point, and the result is floating-point, unless the DOUBLE keyword is set. *Array* can have only one or two dimensions.

If *Width* is not given, *Array* can have any valid number of dimensions. The array is converted to single-precision floating-point, and the median value is returned as a floating-point value.

## Width

The size of the one or two-dimensional neighborhood to be used for the median filter. The neighborhood has the same number of dimensions as *Array*.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic and to return a double-precision result.

### DIMENSION

Set this keyword to the dimension over which to find the median values of an array. If this keyword is not present or is zero, the median is found over the entire array and is returned as a scalar value. If this keyword is present and nonzero, the result is a “slice” of the input array that contains the median value elements, and the return value will be an array of one dimension less than the input array.

For example, if the dimensions of *Array* are  $N_1, N_2, N_3$ , and  $DIMENSION = 2$ , the dimensions of the result are  $(N_1, N_3)$ , and element  $(i, j)$  of the result contains the median value of  $Array[i, *, j]$ . This keyword is ignored if the *Width* argument is present.

### EVEN

If the **EVEN** keyword is set when *Array* contains an even number of points (i.e. there is no middle number), **MEDIAN** returns the average of the two middle numbers. The returned value may not be an element of *Array*. If *Array* contains an odd number of points, **MEDIAN** returns the median value. The returned value will always be an element of *Array*—even if the **EVEN** keyword is set—since an odd number of points will always have a single middle value.

## Examples

```
; Create a simple image and display it:
D = SIN(DIST(200)^0.8) & TVSCL, D

; Display D median-filtered with a width of 9:
TVSCL, MEDIAN(D, 9)

; Print the median of a four-element array, with and without
; the EVEN keyword:
PRINT, MEDIAN([1, 2, 3, 4], /EVEN)
```

```
PRINT, MEDIAN([1, 2, 3, 4])
```

IDL prints:

```
2.50000  
3.00000
```

---

**Note**

Also see [“Smoothing an Image”](#) in Chapter 8 of the *Image Processing in IDL* manual.

# MEMORY

The MEMORY function returns information on the amount of dynamic memory currently in use by the IDL session if no keywords are set. If a keyword is set, MEMORY returns the specified quantity.

## Syntax

```
Result = MEMORY( [ , /CURRENT | , /HIGHWATER | , /NUM_ALLOC |
  , /NUM_FREE | , /STRUCTURE ] [ , /L64 ] )
```

## Return Value

The return value is a vector that is always of integer type. The following table describes the information returned if no keywords are set:

Element	Contents
<i>Result</i> [0]	Amount of dynamic memory (in bytes) currently in use by the IDL session.
<i>Result</i> [1]	The number of times IDL has made a memory allocation request from the underlying system.
<i>Result</i> [2]	The number of times IDL has made a request to free memory from the underlying system.
<i>Result</i> [3]	High water mark: The maximum amount of dynamic memory used since the last time the MEMORY function or HELP, /MEMORY procedure was called.

Table 3-89: MEMORY Function Return Values

## Arguments

None.

## Keywords

---

**Note**

The following keywords determine the return value of the MEMORY function. Except for L64, all of the keywords are mutually exclusive — specify at most one of the following.

---

### CURRENT

Set this keyword to return the amount of dynamic memory (in bytes) currently in use by the IDL session.

### HIGHWATER

Set this keyword to return the maximum amount of dynamic memory used since the last time the MEMORY function or HELP/MEMORY procedure was called. This can be used to determine maximum memory use of a code sequence as shown in the example below.

### L64

By default, the result of MEMORY is 32-bit integer when possible, and 64-bit integer if the size of the returned values requires it. Set L64 to force 64-bit integers to be returned in all cases.

---

**Note**

Only 64-bit versions of IDL are capable of using enough memory to require 64-bit MEMORY output. Check the value of !VERSION.MEMORY\_BITS to see if your IDL is 64-bit or not.

---

### NUM\_ALLOC

Returns the number of times IDL has requested dynamic memory from the underlying system.

### NUM\_FREE

Returns the number of times IDL has returned dynamic memory to the underlying system.

## STRUCTURE

Set this keyword to return all available information about Expression in a structure. The result will be an IDL\_MEMORY (32-bit) structure when possible, and an IDL\_MEMORY64 structure otherwise. Set L64 to force an IDL\_MEMORY64 structure to be returned in all cases.

The following are descriptions of the fields in the returned structure:

Field	Description
CURRENT	Current dynamic memory in use.
NUM_ALLOC	Number of calls to allocate memory.
NUM_FREE	Number of calls to free memory.
HIGHWATER	Maximum dynamic memory used since last call for this information.

Table 3-90: STRUCTURE Field Descriptions

## Examples

To determine how much dynamic memory is required to execute a sequence of IDL code:

```
; Get current allocation and reset the high water mark:
start_mem = MEMORY(/CURRENT)

; Arbitrary code goes here.

PRINT, 'Memory required: ', MEMORY(/HIGHWATER) - start_mem
```

The MEMORY function can also be used in conjunction with DIALOG\_MESSAGE as follows:

```
; Get current dynamic memory in use:
mem = MEMORY(/CURRENT)
; Prepare dialog message:
message = 'Current amount of dynamic memory used is '
sentence = message + STRTRIM(mem,2)+' bytes.'
; Display the dialog message containing memory usage statement:
status = DIALOG_MESSAGE (sentence, /INFORMATION)
```

# MESH\_CLIP

The MESH\_CLIP function clips a polygonal mesh to an arbitrary plane in space and returns a polygonal mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex. The portion of the mesh below the plane, satisfying  $ax+by+cz+d<0$ , remains after the clipping operation.

## Syntax

```
Result = MESH_CLIP (Plane, Vertsin, Connin, Vertsout, Connout  
[, AUXDATA_IN=array, AUXDATA_OUT=variable]  
[, CUT_VERTS=variable] )
```

## Return Value

The return value is the number of triangles in the returned mesh.

## Arguments

### Plane

Input four element array describing the equation of the plane to be clipped to. The elements are the coefficients  $(a,b,c,d)$  of the equation  $ax+by+cz+d=0$ .

### Vertsin

Input array of polygonal vertices  $[3, n]$ .

### Connin

Input polygonal mesh connectivity array.

### Vertsout

Output array of polygonal vertices.

### Connout

Output polygonal mesh connectivity array.

## Keywords

### AUXDATA\_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA\_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

### AUXDATA\_OUT

Set this keyword to a named variable that will contain an output array of interpolated auxiliary data.

### CUT\_VERTS

Set this keyword to a named variable that will contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be “on” the clipped surface.

## Example

This example clips an octahedral mesh (an eight-sided, three-dimensional shape similar to a cut diamond). The original mesh contains one rectangle and eight triangles. The connectivity list is formed with the rectangle listed first followed by the triangles. The mesh is placed in a polygon object, which is added to a model. The model is displayed in the XOBJVIEW utility, which allows you to click-and-drag the polygon object to rotate and translate it. See “[XOBJVIEW](#)” in the *IDL Reference Guide* manual for more information on this utility.

When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear. This display shows the mesh clipped with an oblique plane. The final XOBJVIEW display shows the results of using the TRIANGULATE routine to cover the clipped area. See “[TRIANGULATE](#)” in the *IDL Reference Guide* manual for more information in this routine.

```
PRO ClippingAMesh

; Create a mesh of an octahedron.
vertices = [[0, -1, 0], [1, 0, 0], [0, 1, 0], $
           [-1, 0, 0], [0, 0, 1], [0, 0, -1]]
connectivity = [4, 0, 1, 2, 3, 3, 0, 1, 4, 3, 1, 2, 4, $
              3, 2, 3, 4, 3, 3, 0, 4, 3, 1, 0, 5, 3, 2, 1, 5, $
              3, 3, 2, 5, 3, 0, 3, 5]
```

# MESH\_DECIMATE

The MESH\_DECIMATE simplifies a polygonal mesh by combining neighboring polygons in the mesh in such a way that the shape of the original mesh is maintained as closely as possible. The decimation process is accomplished by locating the two most coplanar polygons, combining them by removing the edge between them, and then retriangulating the combined area. The process is repeated until the mesh contains the requested number of vertices or polygons. The resulting mesh approximates the original mesh with fewer vertices and polygons.

MESH\_DECIMATE uses the algorithm described in the paper, "Surface Simplification Using Quadric Error Metrics" by Garland and Heckbert.

---

## Note

Decimation is a memory- and CPU-intensive process. Expect the decimation of large models to require large amounts of memory and time.

---

MESH\_DECIMATE converts the original mesh to a triangular mesh before performing decimation. The resulting mesh returned by MESH\_DECIMATE is always a triangular mesh. For best results, all the polygons in the original mesh should be convex.

If the original mesh is not a triangular mesh, the mesh returned by MESH\_DECIMATE might contain more triangles than the number of polygons in the original mesh, due to the conversion of the polygonal mesh to a triangular mesh. MESH\_DECIMATE applies the PERCENT\_POLYGONS keyword value to the number of triangles in the mesh after it is converted to a triangular mesh in order to perform the same amount of decimation.

MESH\_DECIMATE uses fourth-order polynomials to locate the polygons it combines. Despite using double-precision in these calculations, mesh coordinate data that varies greatly in magnitude can cause MESH\_DECIMATE to produce unacceptable results. For example, a 200x200 height field might have X and Y vertex coordinate data in the range [0-199] and Z data with a magnitude of about  $10^{20}$ . In cases like these, the data should be offset or scaled so that all dimensions of the vertex data are of similar magnitude.

## Syntax

```
Result = MESH_DECIMATE (Verts, Conn, Connout [, VERTICES=variable]
    [, PERCENT_VERTICES=percent | , PERCENT_POLYGONS=percent]
    [, PROGRESS_CALLBACK=string] [, PROGRESS_METHOD=string]
```

```
[, PROGRESS_OBJECT=objref] [, PROGRESS_PERCENT=percent{0 to 100}]  
[, PROGRESS_USERDATA=value] )
```

## Return Value

The return value is the number of triangles in the output connectivity array.

## Arguments

### Verts

Input array of polygonal vertices [3, *n*].

### Conn

Input polygonal mesh connectivity array.

### Connout

Output polygonal mesh connectivity array.

#### Note

---

Some of the vertices in the Verts array may not be referenced by the Connout array.

---

## Keywords

### PERCENT\_VERTICES

Set this keyword to the percent of the original vertices to be returned in the Connout array. It specifies the amount of decimation to perform.

### PERCENT\_POLYGONS

Set this keyword to the percent of the original polygons to be returned in the Connout array. It specifies the amount of decimation to perform.

#### Note

---

PERCENT\_VERTICES and PERCENT\_POLYGONS are mutually exclusive keywords. If neither keyword is supplied, MESH\_DECIMATE performs no decimation and returns the original mesh after converting it to a triangular mesh.

---

## PROGRESS\_CALLBACK

Set this keyword to a scalar string containing the name of the IDL function that MESH\_DECIMATE calls at PROGRESS\_PERCENT intervals as it decimates the polygonal mesh.

The PROGRESS\_CALLBACK function returns a zero to signal MESH\_DECIMATE to stop decimating, which causes MESH\_DECIMATE to return the partially decimated mesh. If the callback function returns a non-zero, MESH\_DECIMATE continues to decimate the mesh.

The PROGRESS\_CALLBACK function must specify a single argument, *Percent*, which MESH\_DECIMATE sets to an integer between 0 and 100, inclusive.

The PROGRESS\_CALLBACK function may specify an optional USERDATA keyword, which MESH\_DECIMATE sets to the variable provided in the PROGRESS\_USERDATA keyword.

The following code show an example of a progress callback function:

```
FUNCTION myProgressCallback, percent,$    USERDATA = myStruct

oProgressBar = myStruct.oProgressBar

; This method updates the progress bar
; graphic and returns TRUE if the user has
; NOT pressed the cancel button.
keepGoing = oProgressBar->$
    UpdateProgressValue(percent)

RETURN, keepGoing

END
```

## PROGRESS\_METHOD

Set this keyword to a scalar string containing the name of a function method that MESH\_DECIMATE calls at PROGRESS\_PERCENT intervals as it decimates the mesh. If this keyword is set, then the PROGRESS\_OBJECT keyword must be set to an object reference that is an instance of a class that defines the specified method.

The PROGRESS\_METHOD function method callback has the same specification as the callback described in the PROGRESS\_CALLBACK keyword, except that it is defined as an object class method:

```
FUNCTION myClass::myProgressCallback, $
    percent, USERDATA = myStruct
```

## PROGRESS\_OBJECT

Set this keyword to an object reference that is an instance of a class that defines the method specified with the `PROGRESS_METHOD` keyword. If this keyword is set, then the `PROGRESS_METHOD` keyword must also be set.

## PROGRESS\_PERCENT

Set this keyword to a scalar in the range [1, 100] to specify the interval between invocations of the callback function. The default value is 5 and IDL silently clamps other values to the range [1, 100].

For example, a value of 5 (the default) specifies `MESH_DECIMATE` will call the callback function when the decimation is 0% complete, 5% complete, 10% complete, ..., 95% complete, and 100% complete.

## PROGRESS\_USERDATA

Set this property to any IDL variable that `MESH_DECIMATE` passes to the callback function in the callback function's `USERDATA` keyword parameter. If this keyword is specified, then the callback function must be able to accept keyword parameters.

## VERTICES

Set this keyword to a named variable that will contain an output array of the vertices generated by the `MESH_DECIMATE` function. If this keyword is specified, the function is not restricted to using the original set of vertices specified in the *Verts* parameter when generating the decimated mesh, allowing it to generate a more optimal mesh by determining its own placement of vertices. If this keyword is specified, the *Connout* argument will consist of a polygon connectivity list whose indices refer to the vertex list stored in the named variable specified with this keyword. Otherwise, the *Connout* argument will consist of a polygon connectivity list that refers to the original vertex list *Verts*.

## Examples

This example decimates a DEM (digital elevation model) mesh. The DEM in this example comes from the `elevbin.dat` file found in the `examples/data` directory. The DEM is converted into a mesh with the `MESH_OBJ` procedure. The results of this routine are placed in a polygon object, which is added to a model. The models are displayed in the `XOBJVIEW` utility. The `XOBJVIEW` utility allows you to click-and-drag the polygon object to rotate and translate it. See “[XOBJVIEW](#)” in the *IDL Reference Guide* manual for more information on this utility.

The first display contains a wire outline of the DEM as a mesh. When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear showing a filled mesh. The colors correspond to the change in elevation. The third display is the result of decimating the mesh down to 20 percent of the original number of vertices. The final display is the resulting mesh filled with the elevation colors.

```

PRO DecimatingAMesh

; Determine path to data file.
elevbinFile = FILEPATH('elevbin.dat', $
    SUBDIRECTORY = ['examples', 'data'])

; Initialize data parameters.
elevbinSize = [64, 64]
elevbinData = BYTARR(elevbinSize[0], elevbinSize[1])

[MESH\\_VOLUME](#)

# MESH\_ISSOLID

The MESH\_ISSOLID function computes various mesh properties and enables IDL to determine if a mesh encloses space (is a solid). If the mesh can be considered a solid, routines can compute the volume of the mesh.

## Syntax

*Result* = MESH\_ISSOLID (*Conn*)

## Return Value

Returns 1 if the input mesh fully encloses space (assuming no polygonal interpenetration) or 0 otherwise. A mesh is defined to fully enclose space if each edge in the input mesh appears an even number of times in the mesh.

### Note

---

The input polygonal mesh is assumed to contain only planar, convex polygons.

---

## Arguments

### Conn

This is an integer or longword array that represents a series of polygon descriptions. Each polygon description takes the form  $[n, i_0, i_1, \dots, i_{n-1}]$ , where  $n$  is the number of vertices that define the polygon, and  $i_0 \dots i_{n-1}$  are indices into the vertex array.

## Keywords

None.

## Version History

5.5	Introduced
-----	------------

# MESH\_MERGE

The MESH\_MERGE function merges two polygonal meshes.

## Syntax

```
Result = MESH_MERGE (Verts, Conn, Verts1, Conn1 [, /COMBINE_VERTICES]  
[, TOLERANCE=value] )
```

## Return Value

The function return value is the number of triangles in the modified polygonal mesh connectivity array.

## Arguments

### Verts

Input/Output array of polygonal vertices [3, *n*]. These are potentially modified and returned to the user.

### Conn

Input/Output polygonal mesh connectivity array. This array is modified and returned to the user.

### Verts1

Additional input polygonal vertex array [3, *n*].

### Conn1

Additional input polygonal mesh connectivity array.

## Keywords

### COMBINE\_VERTICES

If this keyword is set, the routine will attempt to collapse vertices which are at the same location in space into single vertices. If the expression

$$\max(|x_i - x_{i+1}|, |y_i - y_{i+1}|, |z_i - z_{i+1}|) < tolerance$$

is true, the points ( $i$ ) and ( $i+1$ ) can be collapsed into a single vertex. The result is returned as a modification of the *Verts* argument.

### TOLERANCE

This keyword is used to specify the tolerance value used with the COMBINE\_VERTICES keyword. The default value is 0.0.

## Examples

This example merges two simple meshes: a single square and a single right triangle. The right side of the square is in the same location as the left side of the triangle. Each mesh is originally its own polygon object. These objects are then added to a model object. The model is displayed in the XOBJVIEW utility. The XOBJVIEW utility allows you to click-and-drag the polygon object to rotate and translate it. See “[XOBJVIEW](#)” in the *IDL Reference Guide* manual for more information on this utility.

When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear. The meshes are merged into a single polygon object. After you quit out of the second display, the final display shows the results of decimating the merged mesh to obtain the least number connections for these vertices. Decimation can often be used to refine the results of merging.

```
PRO MergingMeshes

; Create a mesh of a single square (4 vertices
; connected counter-clockwise from the lower left
; corner of the mesh.
vertices = [[-2., -1., 0.], [0., -1., 0.], $
           [0., 1., 0.], [-2., 1., 0.]]
connectivity = [4, 0, 1, 2, 3]
```

```

; Create a separate mesh of a single triangle (3
; vertices connected counter-clockwise from the lower
; left corner of the mesh.
triangleVertices = [[0., -1., 0.], [2., -1., 0.], $
    [0., 1., 0.]]
triangleConnectivity = [3, 0, 1, 2]

; Initialize model for display.
oModel = OBJ_NEW('IDLgrModel')

# MESH\_OBJ

The MESH\_OBJ procedure generates a polygon mesh (vertex list and polygon list) that represent the desired primitive object. The available primitive objects are: triangulated surface, rectangular surface, polar surface, cylindrical surface, spherical surface, surface of extrusion, surface of revolution, and ruled surface.

This routine is written in the IDL language. Its source code can be found in the file `mesh_obj.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
MESH_OBJ, Type, Vertex_List, Polygon_List, Array1 [, Array2] [, /CLOSED]
      [, /DEGREES] [, P1, P2, P3, P4, P5=value]
```

## Arguments

### Type

An integer that specifies what type of object to create. The various surface types are described in the table below.

Type	Surface Type
0	Triangulated
1	Rectangular
2	Polar
3	Cylindrical
4	Spherical
5	Extrusion
6	Revolution
7	Ruled
Other values	None

Table 3-91: Surface Types

## Vertex\_List

A named variable that will contain the mesh vertices. *Vertex\_List* has the same format as the lists returned by the SHADE\_VOLUME procedure.

## Polygon\_List

A named variable that will contain the mesh indexes. *Polygon\_List* has the same format as the lists returned by the SHADE\_VOLUME procedure.

## Array1

An array whose use depends on the type of object being created. The following table describes the differences.

Surface Type	Array1 Type
Triangulated	A (3, $n$ ) array containing random $[x, y, z]$ points to build a triangulated surface from. The resulting polygon mesh will have $n$ vertices. When shading a triangulated mesh, the shading array should have ( $n$ ) elements.
Rectangular	A two dimensional ( $n, m$ ) array containing $z$ values. The resulting polygon mesh will have $n \times m$ vertices. When shading a rectangular mesh, the shading array should have ( $n, m$ ) elements.
Polar	A two dimensional ( $n, m$ ) array containing $z$ values. The resulting polygon mesh will have $n \times m$ vertices. The $n$ dimension of the array is mapped to the polar angle, and the $m$ dimension is mapped to the polar radius. When shading a polar mesh, the shading array should have ( $n, m$ ) elements.
Cylindrical	A two dimensional ( $n, m$ ) array containing radius values. The resulting polygon mesh will have $n \times m$ vertices. The $n$ dimension of the array is mapped to the polar angle, and the $m$ dimension is mapped to the Z axis. When shading a cylindrical mesh, the shading array should have ( $n, m$ ) elements.

Table 3-92: Array 1 Type

Surface Type	Array1 Type
Spherical	A two dimensional ( $n, m$ ) array containing radius values. The resulting polygon mesh will have $n \times m$ vertices. The $n$ dimension of the array is mapped to the longitude (0.0 to 360.0 degrees), and the $m$ dimension is mapped to the latitude (-90.0 to +90.0 degrees). When shading a spherical mesh, the shading array should have ( $n, m$ ) elements.
Extrusion	A ( $3, n$ ) array of connected 3D points which define the shape to extrude. The resulting polygon mesh will have $n \times (\text{steps}+1)$ vertices (where steps is the number of “segments” in the extrusion). (See the P1 keyword). If the order of the elements in <i>Array1</i> is reversed, then the polygon facing is reversed. When shading an extrusion mesh, the shading array should have ( $n, \text{steps}+1$ ) elements.
Revolution	A ( $3, n$ ) array of connected 3D points which define the shape to revolve. The resulting polygon mesh will have $n \times ((\text{steps}>3)+1)$ vertices (where steps is the number of “steps” in the revolution). (See the P1 keyword). If the order of the elements in <i>Array1</i> is reversed, then the polygon facing is reversed. When shading a revolution mesh, the shading array should have ( $n, (\text{steps}>3)+1$ ) elements.
Ruled	A ( $3, n$ ) array of connected 3D points which define the shape of the first ruled vector. The optional ( $3, m$ ) <i>Array2</i> parameter defines the shape of the second ruled vector. The resulting polygon mesh will have $(n > m) \times (\text{steps}+1)$ vertices (where steps is the number of intermediate “steps”). (See the P1 keyword). When shading a ruled mesh, the shading array should have ( $n > m, \text{steps}+1$ ) elements.

Table 3-92: Array 1 Type (Continued)

## Array2

If the object type is 7 (Ruled Surface) then *Array2* is a ( $3, m$ ) array containing the 3D points which define the second ruled vector. If *Array2* has fewer elements than *Array1* then *Array2* is processed with CONGRID to give it the same number of elements as *Array1*. If *Array1* has fewer elements than *Array2* then *Array1* is processed with CONGRID to give it the same number of elements as *Array2*. *Array2* must be supplied if the object type is 7. Otherwise, *Array2* is ignored.

## Keywords

### CLOSED

Set this keyword to “close” the polygonal mesh topologically by using the first vertex in a given row for both the first and last polygons in that row. This keyword is only applicable to the CYLINDRICAL, SPHERICAL, REVOLUTION, and EXTRUSION surface types. Setting the CLOSED keyword removes the discontinuity when the mesh wraps back around on itself, which can improve the mesh’s appearance when viewing it as a shaded object. For the EXTRUSION surface type, this procedure handles input polygons that form a closed loop with the last vertex being a copy of the first vertex, as well as those that do not.

### DEGREES

If set, then the input parameters are in degrees (where applicable). Otherwise, the angles are in radians.

### P1

### P2

### P3

### P4

### P5

The meaning of the keywords P1 through P5 vary depending upon the object type. The table below describes the differences.

Surface Type	Keywords
Triangulated	P1 through P5 are ignored.

*Table 3-93: P1-P5 Keywords*

Surface Type	Keywords
Rectangular	If <i>Array1</i> is an ( $n$ , $m$ ) array, and if P1 has $n$ elements, then the values contained in P1 are the X coordinates for each column of vertices. Otherwise, FINDGEN( $n$ ) is used for the X coordinates. If P2 has $m$ elements, then the values contained in P2 are the Y coordinates for each row of vertices. Otherwise, FINDGEN( $m$ ) is used for the Y coordinates. The polygon facing is reversed if the order of either P1 or P2 (but not both) is reversed. P3, P4, and P5 are ignored.
Polar	P1 specifies the polar angle of the first column of <i>Array1</i> (the default is 0). P2 specifies the polar angle of the last column of <i>Array1</i> (the default is $2*\text{PI}$ ). If P2 is less than P1 then the polygon facing is reversed. P3 specifies the radius of the first row of <i>Array1</i> (the default is 0). P4 specifies the radius of the last row of <i>Array1</i> (the default is $m-1$ ). If P4 is less than P3 then the polygon facing is reversed. P5 is ignored.
Cylindrical	P1 specifies the polar angle of the first column of <i>Array1</i> (the default is 0). P2 specifies the polar angle of the last column of <i>Array1</i> (the default is $2*\text{PI}$ ). If P2 is less than P1 then the polygon facing is reversed. P3 specifies the Z coordinate of the first row of <i>Array1</i> (the default is 0). P4 specifies the Z coordinate of the last row of <i>Array1</i> (the default is $m-1$ ). If P4 is less than P3 then the polygon facing is reversed. P5 is ignored.
Spherical	P1 specifies the longitude of the first column of <i>Array1</i> (the default is 0). P2 specifies the longitude of the last column of <i>Array1</i> (the default is $2*\text{PI}$ ). If P2 is less than P1 then the polygon facing is reversed. P3 specifies the latitude of the first row of <i>Array1</i> (the default is $-\text{PI}/2$ ). P4 specifies the latitude of the last row of <i>Array1</i> (the default is $+\text{PI}/2$ ). If P4 is less than P3 then the polygon facing is reversed. P5 is ignored.
Extrusion	P1 specifies the number of steps in the extrusion (the default is 1). P2 is a three element vector specifying the direction (and length) of the extrusion (the default is $[0, 0, 1]$ ). P3, P4, and P5 are ignored.

Table 3-93: P1-P5 Keywords (Continued)

Surface Type	Keywords
Revolution	P1 specifies the number of “facets” in the revolution (the default is 3). If P1 is less than 3 then 3 is used. P2 is a three element vector specifying a point that the rotation vector passes through (the default is [0, 0, 0]). P3 is a three element vector specifying the direction of the rotation vector (the default is [0, 0, 1]). P4 specifies the starting angle for the revolution (the default is 0). P5 specifies the ending angle for the revolution (the default is 2*PI). If P5 is less than P4 then the polygon facing is reversed.
Ruled	P1 specifies the number of “steps” in the ruling (the default is 1). P2, P3, P4, and P5 are ignored.

*Table 3-93: P1-P5 Keywords (Continued)*

# MESH\_SMOOTH

The MESH\_SMOOTH function performs spatial smoothing on a polygon mesh. This function smooths a mesh by applying Laplacian smoothing to each vertex, as described by the following formula:

$$\vec{x}_{i_{(n+1)}} = \vec{x}_{i_n} + \frac{\lambda}{M} \sum_{j=0}^M (\vec{x}_{j_n} - \vec{x}_{i_n})$$

where:

$\vec{x}_{i_n}$  is vertex  $i$  for iteration  $n$

$\lambda$  is the smoothing factor

$M$  is the number of vertices that share a common edge with  $x_{i_n}$ .

## Syntax

```
Result = MESH_SMOOTH (Verts, Conn [, ITERATIONS=value]
  [, FIXED_VERTICES=array] [, /FIXED_EDGE_VERTICES]
  [, LAMBDA=value])
```

## Return Value

The output of this function is resulting  $[3, n]$  array of modified vertices.

## Arguments

### Verts

Input array of polygonal vertices  $[3, n]$ .

### Conn

Input polygonal mesh connectivity array.

## Keywords

### ITERATIONS

Number of iterations to smooth. The default value is 50.

### FIXED\_VERTICES

Set this keyword to an array of vertex indices which are not to be modified by the smoothing.

### FIXED\_EDGE\_VERTICES

Set this keyword to specify that mesh outer edge vertices are not to be modified by the smoothing.

### LAMBDA

Smoothing factor. The default value is 0.05.

## Examples

This example smooths a rectangular mesh containing a spike. First, we create a rectangular mesh made up 10 columns and 5 rows of vertices. The vertices are connected with right triangles. The mesh is placed in a polygon object, which is added to a model object. The model is displayed in the XOBJVIEW utility. The XOBJVIEW utility allows you to click-and-drag the polygon object to rotate and translate it. See “[XOBJVIEW](#)” in the *IDL Reference Guide* manual for more information on this utility.

When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear. The center vertex of the top row is displaced in the y-direction. This displacement causes the center of the top to spike out away from the mesh. After you quit out of the second display, the third display shows the result of smoothing the entire mesh. The final display shows the results of smoothing the spike with all the other vertices fixed.

```
PRO SmoothingMeshes

; Initialize mesh size parameters.

# MESH\_SURFACEAREA

The MESH\_SURFACEAREA function computes various mesh properties to determine the mesh surface area, including integration of other properties interpolated on the surface of the mesh.

## Syntax

```
Result = MESH_SURFACEAREA ( Verts, Conn [, AUXDATA=array]  
[, MOMENT=variable] )
```

## Return Value

Returns the cumulative (weighted) surface area of the polygons in the mesh.

### Note

---

The input polygonal mesh is assumed to contain only planar, convex polygons.

---

## Arguments

### Verts

Array of polygonal vertices [3, *n*].

### Conn

Polygonal mesh connectivity array.

## Keywords

### AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex for the purpose of the area computation. The surface area integral will linearly interpolate these values over the surface of each triangle. The default weight is 1.0 which results in the basic polygon area.

## MOMENT

If this keyword is present, it will return a three element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} = \sum_{ntris} a_i \vec{c}_i$$

where  $a$  is the (weighted) area of the triangle and  $c$  is the centroid of the triangle, thus

$$\vec{m}/sarea$$

yields the (weighted) centroid of the polygon mesh.

[MESH\\_VOLUME](#)

# MESH\_VALIDATE

The MESH\_VALIDATE function checks for NaN values in vertices, removes unused vertices, and combines close vertices.

## Syntax

```
Result = MESH_VALIDATE ( Verts, Conn [, /REMOVE_NAN]
                        [, /PACK_VERTICES] [, /COMBINE_VERTICES] [, TOLERANCE=value] )
```

## Return Value

The function return value is the number of triangles in the modified polygonal mesh connectivity array.

## Arguments

### Verts

Input/Output array of polygonal vertices [3, *n*]. These are potentially modified and returned to the user.

### Conn

Input/Output polygonal mesh connectivity array. This array is modified and returned to the user.

## Keywords

### COMBINE\_VERTICES

If this keyword is set, the routine will attempt to collapse vertices which are at the same location in space into single vertices. If the expression

$$\max(|x_i - x_{i+1}|, |y_i - y_{i+1}|, |z_i - z_{i+1}|) < tolerance$$

is true, the points (*i*) and (*i*+1) can be collapsed into a single vertex. The result is returned as a modification of the *Verts* argument.

## PACK\_VERTICES

If this keyword is set, the Verts input array will be packed to exclude any non-referenced vertices. The result is returned in the Verts argument.

## REMOVE\_NAN

If this keyword is set, the function will remove any polygons from CONN which reference vertices containing NaN values.

## TOLERANCE

This keyword is used to specify the tolerance value used with the COMBINE\_VERTS keyword. The default value is 0.0.

## Version History

[MESH\\_SURFACEAREA](#), [MESH\\_VOLUME](#)

# MESH\_VOLUME

The MESH\_VOLUME function computes the volume that the mesh encloses. A region that a mesh encloses has a positive value for its volume when it is enclosed by mesh polygons that face outward from the enclosed region. Outward-facing polygons follow the convention of their vertices being ordered in a counter-clockwise direction while observing the polygon from the outside of the enclosed region. Likewise, a region has a negative value for its volume when it is enclosed by polygons that face inward to the enclosed region.

A single mesh may contain regions that have positive and negative volume values. This function adds these signed values together to produce a single volume value that takes into account the total of all positive regions minus any "holes" or subtractions specified by the negative regions.

If the SIGNED keyword is not specified, IDL returns the absolute value of the volume, which may be useful in situations where the polygon vertex ordering convention is unknown or opposite of the convention described above.

## Syntax

*Result* = MESH\_VOLUME ( *Verts*, *Conn* [, /SIGNED] )

## Return Value

Returns the volume that the mesh encloses. If the mesh does not enclose space (i.e. MESH\_ISSOLID( ) would return 0), this function returns 0.0.

### Note

---

The input polygonal mesh is assumed to contain only planar, convex polygons.

---

## Arguments

### Verts

Array of polygonal vertices [3, *n*].

### Conn

Polygonal mesh connectivity array.

## Keywords

### SIGNED

Set this keyword to compute the signed volume. The sign will be negative for a mesh consisting of inward facing polygons.

# MESSAGE

The MESSAGE procedure issues error and informational messages using the same mechanism employed by built-in IDL routines. By default, the message is issued as an error, the message is output, and IDL performs the required error-handling actions (which can be controlled via the CATCH, ON\_ERROR, and ON\_IOERROR procedures). As a side-effect of issuing the error, the system variable !ERROR\_STATE is set and the text of the error message is placed in !ERROR\_STATE.MSG. (If there is an operating system component to the error message, !ERROR\_STATE.SYS\_MSG is updated as well).

The MESSAGE procedure supports the following uses:

1. To issue a simple error message containing user-specified text.
2. To issue a specific error from a *message block* by name, with optional arguments. The NAME keyword is required in this case; if the error is not defined in the default IDL message block, the BLOCK keyword is also required. See [DEFINE\\_MSGBLK](#) and [DEFINE\\_MSGBLK\\_FROM\\_FILE](#) for examples of this usage.
3. To reissue the most recent error encountered by IDL. If the CATCH procedure is used to trap errors, the REISSUE\_LAST keyword to MESSAGE can be used within the CATCH block to pass the error up to its caller.

If the call to the MESSAGE procedure causes execution to halt, traceback information is displayed automatically.

## Syntax

*To issue a simple error message:*

```
MESSAGE, [Text] [, /CONTINUE] [, LEVEL=CallLevel] [, /INFORMATIONAL]
      [, /IOERROR] [, /NONAME] [, /NOPREFIX] [, /NOPRINT] [, /RESET]
```

*To issue a named message from a message block:*

```
MESSAGE, [Arg1, ... ArgN] NAME=ErrorName [, BLOCK=BlockName]
      [, /CONTINUE] [, LEVEL=CallLevel] [, /INFORMATIONAL] [, /IOERROR]
      [, /NONAME] [, /NOPREFIX] [, /NOPRINT] [, /RESET]
```

*To reissue the most recent error:*

```
MESSAGE, /REISSUE_LAST
```

# Arguments

## Text

A string value specifying the text to be displayed in a simple error message.

### Note

---

The *Text* argument is only used when MESSAGE is issuing a simple error message; that is, if neither the NAME keyword nor the REISSUE\_LAST keyword is present. If *none* of the *Text* argument, the NAME keyword, or the REISSUE\_LAST keyword are present, MESSAGE returns quietly.

---

## Arg<sub>*i*</sub>

When issuing a named error using the NAME (and possibly BLOCK) keyword, the *Arg<sub>*i*</sub>* arguments are substituted into the error format string, as described in the documentation for [DEFINE\\_MSGBLK](#) and [DEFINE\\_MSGBLK\\_FROM\\_FILE](#).

# Keywords

## BLOCK

Set this keyword to a string containing the name of the IDL message block to use. This keyword is ignored unless the NAME keyword is also present to specify a message name.

By default, MESSAGE throws the IDL\_M\_USER\_ERR message from the IDL\_MBLK\_CORE message block. If you wish to provide something other than the default error message, you can define your own message blocks and error messages. See the [DEFINE\\_MSGBLK](#) and [DEFINE\\_MSGBLK\\_FROM\\_FILE](#) procedures for details. You can use the HELP, /MESSAGES command to see the currently defined message blocks.

## CONTINUE

Set this keyword to return after issuing the error instead of taking the action specified by ON\_ERROR. Use this option when it is desirable to report an error and then continue processing.

## INFORMATIONAL

Set this keyword to issue informational text instead of an error. In this case, !ERROR\_STATE is not set. The !QUIET system variable controls the printing of informational messages.

## IOERROR

Set this keyword to indicate that the error occurred while performing I/O. The action specified by the ON\_IOERROR procedure is executed instead of ON\_ERROR.

## LEVEL

Many messages include the name of the routine that called MESSAGE at the beginning of the message text. Use the LEVEL keyword to an integer value to specify that the name of a routine further up in the current call chain should be used instead. Specify the value of LEVEL as described in the following table:

LEVEL value	Meaning
0	The currently active routine.
> 0	The absolute index of the routine to indicate. A value of 1 specifies the main level (\$MAIN\$), 2 indicates the routine called by \$MAIN\$, and so forth.
< 0	Negative values indicate the relative index of the desired routine moving backwards from the current one. Hence, -1 indicates the caller of the current routine.

*Table 3-94: LEVEL Keyword Values*

The LEVEL keyword can be used to hide error handling helper routines from user view. The following procedure will issue an error on behalf of its caller. The calling routine's name will appear in the resulting message, and not that of the error routine:

```

pro THROW_ERROR, text
  on_error, 2 ; Stop in caller
  MESSAGE, LEVEL=-1, text
end

```

## NAME

Set this keyword to a string containing the name of the message throw. By default, MESSAGE throws the IDL\_M\_USER\_ERR message from the IDL\_MBLK\_CORE message block. NAME is often used in conjunction with the BLOCK keyword to throw a non-default message from a non-default message block.

## NONAME

Set this keyword to suppress printing of the issuing routine's name at the beginning of the error message.

## NOPREFIX

Usually, the message includes the message prefix string (as specified by the MSG\_PREFIX field of the !ERROR\_STATE system variable) at the beginning. Set this keyword to omit the prefix.

## NOPRINT

Set this keyword to prevent the message from printing to the screen and cause the other actions to proceed quietly. The error system variables are updated as usual.

## REISSUE\_LAST

Set this keyword to reissue the last error issued by IDL. By using this keyword in conjunction with the CATCH procedure, your code can catch an error caused by called code, perform recovery actions, and issue the error normally. See the [Examples](#) below for a demonstration of this approach.

---

**Note**

If this keyword is specified, no plain arguments or other keywords may be specified.

---

## RESET

Set this keyword to set the !ERROR\_STATE system variable back to the “success” state and clear any internal traceback information being saved for use by the LAST\_ERROR keyword to the [HELP](#) procedure.

## Examples

### Example 1

As an example, assume the statement:

```
message, 'Unexpected value encountered.'
```

is executed in a procedure named `CALC`. If an error occurs, the following message would be printed:

```
% CALC: Unexpected value encountered.
```

and execution would halt.

### Example 2

This example demonstrates the use of the `CATCH` procedure and the `REISSUE_LAST` keyword to the `MESSAGE` procedure to control errors. In this example, we write a procedure named `GET_TWO_POINTERS`, which creates and returns two image variables of identical size via pointer heap variables. One possible problem with such an operation is that the system may not have enough memory to allocate both images. We want this operation to be all or nothing, so if we fail to get both variables we need to free the variable we did get before allowing our caller to see the error:

```
PRO GET_TWO_POINTERS, D1, D2, P1, P2
; [D1, D2] - Input dimensions
; P1, P2 - Variables to receive pointers to images

ON_ERROR, 2                                ; When we reissue error, have
                                           ; control returned to caller.

nullPtr = PTR_NEW()                        ; Create a NULL pointer.
P1 = (P2 = nullPtr)                        ; Set both pointers to NULL.

CATCH, error                               ; Establish catch block.
IF (error NE 0) THEN BEGIN                ; An error occurs.
    CATCH, /CANCEL                         ; Cancel catch block so an error
                                           ; here will not cause looping.
    PTR_FREE, P1, P2                       ; If P1 or P2 are non-NULL, free
    P1 = (P2 = nullPtr)                   ; them so caller sees NULL pointers.
    MESSAGE, /REISSUE_LAST                 ; Reissue the error. The caller
                                           ; will get control.
    ; This line is never reached, because MESSAGE causes an
    ; implicit return to the calling routine.
ENDIF
```

```

P1 = PTR_NEW(BYTARR(D1, D2)) ; Get first image.
P2 = PTR_NEW(BYTARR(D1, D2)) ; Get second image.

; We now have both images and can safely return.
END

```

## Version History

Pre 4.0	Introduced
5.0	Deprecated the TRACEBACK keyword
6.0	Added REISSUE_LAST keyword

For information on deprecated keywords, see [Appendix J, “Obsolete Features”](#).

# MIN

The MIN function returns the value of the smallest element of *Array*. The type of the result is the same as that of *Array*.

## Syntax

```
Result = MIN( Array [, Min_Subscript] [, /ABSOLUTE] [, DIMENSION=value]  
            [, MAX=variable] [, /NAN] [, SUBSCRIPT_MAX=variable])
```

## Return Value

Returns the smallest array element value.

## Arguments

### Array

The array to be searched.

### Min\_Subscript

A named variable that, if supplied, is converted to a long integer containing the one-dimensional subscript of the minimum element. Otherwise, the system variable !C is set to the one-dimensional subscript of the minimum element.

## Keywords

### ABSOLUTE

If this keyword is set, then the absolute value of each element is used when determining the minimum values. This keyword has no effect for arrays of type byte or unsigned integer.

### Note

---

If ABSOLUTE is set then the sign of each value is ignored when searching for the minimum. However, the return value retains the negative sign if the value was indeed negative.

---

**Tip**

For complex input, MIN by default only compares the real component of each value. Use the ABSOLUTE keyword to force MIN to compare the absolute value of each value, and to return the complex value corresponding to the minimum absolute value.

**DIMENSION**

Set this keyword to the dimension over which to find the minimum values of an array. If this keyword is not present or is zero, the minimum is found over the entire array and is returned as a scalar value. If this keyword is present and nonzero, the result is the “slice” of the input array that contains the minimum value element, and the return values for *Result*, *Min\_Subscript*, MAX, and SUBSCRIPT\_MAX will all be arrays of one dimension less than the input array. That is, if the dimensions of *Array* are *N1*, *N2*, *N3*, and DIMENSION=2, the dimensions of the result are (*N1*, *N3*), and element (*i,j*) of the result contains the minimum value of *Array*[*i*, \*, *j*].

For example:

```
arr = FINDGEN(2,3,2)
PRINT, arr
```

IDL prints:

```
0.00000    1.00000
2.00000    3.00000
4.00000    5.00000
```

```
6.00000    7.00000
8.00000    9.00000
10.00000   11.00000
```

```
PRINT, MIN(arr, DIMENSION=2)
```

IDL prints:

```
0.00000    1.00000
6.00000    7.00000
```

```
PRINT, MIN(arr, DIMENSION=1)
```

IDL prints:

```
0.00000    2.00000    4.00000
6.00000    8.00000    10.00000
```

## MAX

The name of a variable to receive the value of the maximum array element. If you need to find both the minimum and maximum array values, use this keyword to avoid scanning the array twice with separate calls to MAX and MIN.

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

---

### Note

If the MIN function is run on an array containing NaN values and the NAN keyword is not set, an invalid result will occur.

---

## SUBSCRIPT\_MAX

Set this keyword to a named variable that will contain the one-dimensional subscript of the maximum element, the value of which is available via the MAX keyword.

## Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

```
; Create a simple two-dimensional array:
D = DIST(100)
; Find the minimum value in array D and print the result:
PRINT, MIN(D)
```

## Version History

Original	Introduced
6.1	Added ABSOLUTE keyword

# MIN\_CURVE\_SURF

The MIN\_CURVE\_SURF function interpolates a regularly- or irregularly-gridded set of points, over either a plane or a sphere, with either a minimum curvature surface or a thin-plate-spline surface.

---

## Note

The accuracy of this function is limited by the single-precision floating-point accuracy of the machine.

---

## Theory

A minimum curvature spline surface is fitted to the data points described by  $x$ ,  $y$ , and  $z$ . The basis function is:

$$C(x_0, x_1, y_0, y_1) = d^2 \log(d^k)$$

where  $d$  is the distance between  $(x_0, y_0)$ ,  $(x_1, y_1)$  and  $k = 1$  for minimum curvature surface or  $k = 2$  for Thin Plate Splines. For  $n$  data points, a system of  $n+3$  simultaneous equations are solved for the coefficients of the surface. For any interpolation point, the interpolated value is:

$$f(x, y) = b_0 + b_1 \cdot x + b_2 \cdot y + \sum a_i \cdot C(x_i, x, y_i, y)$$

For a sphere the value is:

$$f(l, t) = b_0 + b_1 \cdot x + b_2 \cdot y + b_3 \cdot z + \sum a_i \cdot C(L_i, l, T_i, t)$$

On the sphere,  $l$  and  $t$  are longitude and latitude.  $C(L_i, l, T_i, t)$  is the basis function above, with distance between the two points,  $(L_i, T_i)$ , and  $(l, t)$ , measured in radians of arc length.  $x$ ,  $y$ , and  $z$  are the 3D cartesian coordinates of the point  $(l, t)$  on the unit sphere.

For a sphere with the CONST keyword set, the value is:

$$f(l, t) = b_0 + \sum a_i \cdot CL_i, l, T_i, t$$

The results obtained with the thin plate spline (TPS) and the minimum curvature surface (MCS) methods are very similar. The only difference is in the basis functions: TPS uses  $d^2 \cdot \log(d^2)$ , and MCS uses  $d^2 \cdot \log(d)$ , where  $d$  is the distance from point  $(x_i, y_i)$ .

This routine is written in the IDL language. Its source code can be found in the file `min_curve_surf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MIN_CURVE_SURF(Z [, X, Y] [, /DOUBLE] [, /TPS] [, /REGULAR]
  [, /SPHERE [, /CONST]] [, XGRID=[xstart, xspacing] | , XVALUES=array]
  [, YGRID=[ystart, yspacing] | , YVALUES=array] [, GS=[xspace, yspace]]
  [, BOUNDS=[xmin, ymin, xmax, ymax]] [, NX=value] [, NY=value]
  [, XOUT=vector] [, YOUT=vector] [, XPOUT, YPOUT=array])
```

## Return Value

This function returns a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

## Arguments

### Z, X, Y

Arrays containing the *Z*, *X*, and *Y* coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, *X* and *Y* are not used: the grid spacing is specified via the `XGRID` and `YGRID` (or `XVALUES` and `YVALUES`) keywords, and *Z* must be a two-dimensional array. For irregular grids, all three parameters must be present and have the same number of elements. If *Z* is specified as a double-precision value, the computation will be performed in double-precision arithmetic. If the `SPHERE` keyword is set, *X* and *Y* are given in degrees of longitude and latitude, respectively.

## Keywords

### CONST

Set this keyword to fit data on the sphere with a constant baseline, otherwise, data on the sphere is fit with a baseline that contains a constant term plus linear *X*, *Y*, and *Z* terms. This keyword has an effect only if `SPHERE` is set. See Theory above for the formulae.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic. If *Z* is double precision, the computations will also be done in double precision.

## SPHERE

Set this keyword to perform interpolation on the surface of a sphere. The inputs  $X$  and  $Y$  should be given in degrees of longitude and latitude, respectively.

## TPS

Set this keyword to use the thin-plate-spline method. The default is to use the minimum curvature surface method.

## Input Grid Description Keywords:

### REGULAR

If set, the  $Z$  parameter is a two-dimensional array of dimensions  $(n,m)$ , containing measurements over a regular grid. If any of  $XGRID$ ,  $YGRID$ ,  $XVALUES$ , or  $YVALUES$  are specified,  $REGULAR$  is implied.  $REGULAR$  is also implied if there is only one parameter,  $Z$ . If  $REGULAR$  is set, and no grid specifications are present, the grid is set to  $(0, 1, 2, \dots)$ .

### XGRID

A two-element array,  $[xstart, xspacing]$ , defining the input grid in the  $x$  direction. Do not specify both  $XGRID$  and  $XVALUES$ .

### XVALUES

An  $n$ -element array defining the  $x$  locations of  $Z[i,j]$ . Do not specify both  $XGRID$  and  $XVALUES$ .

### YGRID

A two-element array,  $[ystart, yspacing]$ , defining the input grid in the  $y$  direction. Do not specify both  $YGRID$  and  $YVALUES$ .

### YVALUES

An  $n$ -element array defining the  $y$  locations of  $Z[i,j]$ . Do not specify both  $YGRID$  and  $YVALUES$ .

## Output Grid Description Keywords:

### GS

The output grid spacing. If present, GS must be a two-element vector [ $x_s$ ,  $y_s$ ], where  $x_s$  is the horizontal spacing between grid points and  $y_s$  is the vertical spacing. The default is based on the extents of  $x$  and  $y$ . If the grid starts at  $x$  value  $x_{min}$  and ends at  $x_{max}$ , then the default horizontal spacing is  $(x_{max} - x_{min})/(NX-1)$ .  $y_s$  is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

### BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in  $x$  and  $y$  of the output grid: [ $x_{min}$ ,  $y_{min}$ ,  $x_{max}$ ,  $y_{max}$ ]. If not specified, the grid limits are set to the extent of  $x$  and  $y$ .

### NX

The output grid size in the  $x$  direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

### NY

The output grid size in the  $y$  direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

### XOUT

Use the XOUT keyword to specify a vector containing the output grid  $x$  values. If this parameter is supplied, GS, BOUNDS, and NX are ignored for the  $x$  output grid. XOUT allows you to specify irregularly-spaced output grids.

### YOUT

Use the YOUT keyword to specify a vector containing the output grid  $y$  values. If this parameter is supplied, GS, BOUNDS, and NY are ignored for the  $y$  output grid. YOUT allows you to specify irregularly-spaced output grids.

### XPOUT

### YPOUT

Use the XPOUT and YPOUT keywords to specify arrays that contain the  $x$  and  $y$  values for the output points. If these keywords are used, the output grid need not be regular, and all other output grid parameters are ignored. XPOUT and YPOUT must

have the same number of points, which is also the number of points returned in the result.

## Examples

### Example 1: Irregularly gridded cases

```
; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))
```

Use a 26 by 26 grid over the rectangle bounding x and y:

```
;Get the surface.
R = MIN_CURVE_SURF(Z, X, Y)
```

Alternatively, get a surface over the unit square, with spacing of 0.05:

```
R = MIN_CURVE_SURF(Z, X, Y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])
```

Alternatively, get a 10 by 10 surface over the rectangle bounding x and y:

```
R = MIN_CURVE_SURF(Z, X, Y, NX=10, NY=10)
```

### Example 2: Regularly gridded cases

```
; Make some random data:
z = RANDOMU(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, MIN_CURVE_SURF(z, /REGULAR)
```

## MK\_HTML\_HELP

The MK\_HTML\_HELP procedure, given a list of IDL procedure filenames (`.pro` files) or the names of directories containing such files, generates a file in HTML (HyperText Markup Language) format that contains documentation for those routines that contain standard IDL documentation headers. The resulting file can then be viewed with a web browser.

MK\_HTML\_HELP procedure makes a single HTML file that starts with a list of the routines documented in the file. The names of routines in that list are hypertext links to the documentation for those routines. The documentation for each routine is simply the text of the documentation header copied from the corresponding `.pro` file—no reformatting is performed.

The documentation headers of the `.pro` files in question must have the following format:

- The first line of the documentation block contains only the characters `;` `+`, starting in column 1.
- The last line of the documentation block contains only the characters `;` `-`, starting in column 1.
- All other lines in the documentation block contain a `;` in column 1.
- If a line containing the string “NAME:” exists in the documentation block, the contents of the following line are used as the name of the routine being described. If the NAME: field is not present, the name of the source file is used as the routine name.

---

### Example Code

The file `template.pro` in the `examples` subdirectory of the IDL distribution contains a template for creating your own documentation headers.

---

This routine is supplied to allow users to make online documentation from their own IDL programs. Although it could be used to create an HTML documentation file from the `lib` subdirectory of the IDL distribution, we do not recommend doing so. The documentation headers on the files in the `lib` directory are used for historical purposes—most do not contain the most current or accurate documentation for those routines. The most current documentation for IDL’s built-in and library routines is found in IDL’s online help system (enter `?` at the IDL prompt).

This routine is written in the IDL language. Its source code can be found in the file `mk_html_help.pro` in the `lib` subdirectory of the IDL distribution.

# Syntax

```
MK_HTML_HELP, Sources, Filename [, /STRICT] [, TITLE=string]
[ , /VERBOSE]
```

## Arguments

### Sources

A string array containing the names of IDL procedure files (`.pro` files) or directories containing such files. The *Sources* array may contain both individual file and directory names. Each IDL procedure file must have the file extension `.pro`. Elements of the *Sources* array that do not have either of these extensions are assumed to be directories.

All `.pro` files found in *Sources* are searched for documentation headers. The documentation headers are extracted and saved in HTML format in the file specified by *Filename*.

#### Note

---

More than one documentation block may exist in a single input file.

---

### Filename

A string containing the name of the output file to be generated. HTML files are usually saved in files named with a `.html` or `.htm` extension.

## Keywords

### STRICT

Set this keyword to force `MK_HTML_HELP` to adhere strictly to the HTML format by scanning the documentation blocks for HTML reserved characters and replacing them in the output file with the appropriate HTML syntax. HTML reserved characters include `<`, `>`, `&`, and `"`. By default, this keyword is set to zero to allow for faster processing of the input files.

### TITLE

A string that supplies the name to be used as the title of the HTML document. The default is "Extended IDL Help".

## VERBOSE

Set this keyword to display informational messages as `MK_HTML_HELP` generates the HTML file. Normally, `MK_HTML_HELP` works silently.

## Examples

To generate an HTML help file named `myhelp.html` from the `.pro` files in the directory `/usr/home/dave/myroutines`, use the command:

```
MK_HTML_HELP, '/usr/home/dave/myroutines', 'myhelp.html'
```

To generate an HTML help file for all routines in a given directory whose file names contain the word “plot”, use the following commands:

```
plotfiles=FILE_SEARCH('/usr/home/dave/myroutines/*plot*.pro')  
MK_HTML_HELP, plotfiles, 'myplot.html'
```

# MODIFYCT

The MODIFYCT procedure updates the distribution color table file `colors1.tbl`, located in the `\resource\colors` subdirectory of the main IDL directory, or a user-designated file with a new, or modified, colortable.

This routine is written in the IDL language. Its source code can be found in the file `modifyct.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
MODIFYCT, Itab, Name, R, G, B [, FILE=filename]
```

## Arguments

### **Itab**

The index of the table to be updated, numbered from 0 to 255. If the specified entry is greater than the next available location in the table, the entry will be added to the table in the available location rather than the index specified by *Itab*. On return, *Itab* contains the index for the location that was modified or extended. The modified table can be then be loaded with the IDL command: `LOADCT, Itab`.

### **Name**

A string, up to 32 characters long, that contains the name for the new color table.

### **R**

A 256-element vector that contains the values for the red colortable.

### **G**

A 256-element vector that contains the values for the green colortable.

### **B**

A 256-element vector that contains the values for the blue colortable.

## Keywords

### FILE

Set this keyword to the name of a colortable file to be modified instead of the file `colors1.tbl`.

## Examples

A derived color table created in the XPALETTE utility, shown in “[Examples](#)” on page 2870, and can be added to IDL’s list of pre-defined color tables with the TVLCT and MODIFYCT routines.

By default, TVLCT allows you to load in red, green, and blue vectors (either derived by you or imported from an image file) to load a different current color table. TVLCT also has a GET keyword. When the GET keyword is set, TVLCT returns the red, green, and blue vectors of the current color table back to you. Using this you can obtain the red, green, and blue vectors of the previously derived color table.

1. Obtain the red, green, and blue vectors of the current color table after performing the steps in the XPALETTE utility “[Examples](#)” on page 2870:

```
TVLCT, red, green, blue, /GET
```

The MODIFYCT routine uses these vectors as arguments. Now you can use MODIFYCT to add this new color table to IDL’s list of pre-defined color tables.

2. Add this modified color table to IDL’s list of pre-defined color tables and display results:

```
MODIFYCT, 41, 'Orange to White Bones', $  
red, green, blue
```

3. Display the results with XLOADCT:

```
XLOADCT
```

The modified color table has been added to IDL's list of pre-defined color tables as shown in the following figure.

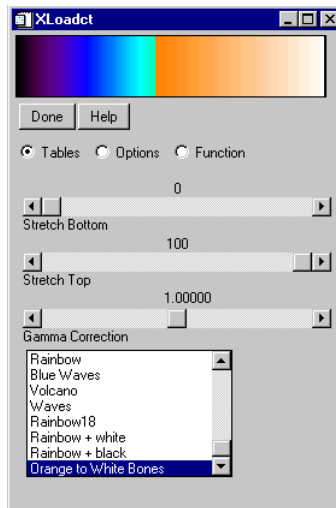

Figure 3-80: XLOADCT Showing Results of MODIFYCT

# MOMENT

The **MOMENT** function computes the mean, variance, skewness, and kurtosis of a sample population contained in an  $n$ -element vector  $X$ . When  $x = (x_0, x_1, x_2, \dots, x_{n-1})$ , the various moments are defined as follows:

$$\text{Mean} = \bar{x} = \frac{1}{N} \sum_{j=0}^{N-1} x_j$$

$$\text{Variance} = \frac{1}{N-1} \sum_{j=0}^{N-1} (x_j - \bar{x})^2$$

$$\text{Skewness} = \frac{1}{N} \sum_{j=0}^{N-1} \left( \frac{x_j - \bar{x}}{\sqrt{\text{Variance}}} \right)^3$$

$$\text{Kurtosis} = \frac{1}{N} \sum_{j=0}^{N-1} \left( \frac{x_j - \bar{x}}{\sqrt{\text{Variance}}} \right)^4 - 3$$

$$\text{Mean Absolute Deviation} = \frac{1}{N} \sum_{j=0}^{N-1} |x_j - \bar{x}|$$

$$\text{Standard Deviation} = \sqrt{\text{Variance}}$$

This routine is written in the IDL language. Its source code can be found in the file `moment.pro` in the `lib` subdirectory of the IDL distribution.

## Return Value

If the vector contains  $n$  identical elements, **MOMENT** computes the mean and variance, and returns the IEEE value NaN for the skewness and kurtosis, which are

not defined. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual.)

## Syntax

```
Result = MOMENT( X [, /DOUBLE] [, MDEV=variable] [, /NAN]
                [, SDEV=variable] )
```

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### MDEV

Set this keyword to a named variable that will contain the mean absolute deviation of  $X$ .

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for information on IEEE floating-point values.)

### SDEV

Set this keyword to a named variable that will contain the standard deviation of  $X$ .

## Examples

```
; Define an n-element sample population:
X = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]
; Compute the mean, variance, skewness and kurtosis:
result = MOMENT(X)
PRINT, 'Mean: ', result[0] & PRINT, 'Variance: ', result[1] & $
      PRINT, 'Skewness: ', result[2] & PRINT, 'Kurtosis: ', result[3]
```

IDL prints:

```
Mean:      66.7333
Variance:  7.06667
Skewness:  -0.0942851
Kurtosis:  -1.18258
```

# MORPH\_CLOSE

The MORPH\_CLOSE function applies the closing operator to a binary or grayscale image. MORPH\_CLOSE is simply a dilation operation followed by an erosion operation. The closing operation is an idempotent operator—applying it more than once produces no further effect.

Both the opening and the closing operators have the effect of smoothing the image, with the opening operation removing pixels, and the closing operation adding pixels.

This routine is written in the IDL language. Its source code can be found in the file `morph_close.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MORPH_CLOSE (Image, Structure [, /GRAY]  
                    [, PRESERVE_TYPE=bytearray | /UINT | /ULONG] [, VALUES=array] )
```

## Return Value

The result of a closing operation is that small holes and gaps within the image (smaller than the size of *Structure*) are filled, yet the original sizes of the primary foreground features are maintained.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the closing operation is to be performed. If neither of the keywords GRAY or VALUES is present, the image is treated as a binary image with all nonzero pixels considered as 1.

### Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values - either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

## Keywords

### GRAY

Set this keyword to perform a grayscale, rather than binary, operation. Nonzero elements of the *Structure* parameter determine the shape of the structuring element. If the **VALUES** keyword is not present, all elements of the structuring element are 0.

### PRESERVE\_TYPE

Set this keyword to return the same type as the input array. The input array must be of type **BYTE**, **UINT**, or **ULONG**. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of **UINT** and **ULONG**.

### UINT

Set this keyword to return an unsigned integer array. This keyword only applies for grayscale operations, and is mutually exclusive of the **ULONG** and **PRESERVE\_TYPE** keywords.

### ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies for grayscale operations, and is mutually exclusive of the **UINT** and **PRESERVE\_TYPE** keywords.

### VALUES

An array of the same dimensions as *Structure* providing the values of the structuring element. The presence of this keyword implies a grayscale operation.

## Examples

### Note

---

Also see [“Smoothing with MORPH\\_CLOSE”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then applies a threshold and a morphological closing operator with a 3 by 3 square kernel to the original image. Notice that most of the holes in the pollen grains have been filled by the closing operator.

```
;Handle TrueColor displays:  
DEVICE, DECOMPOSED=0
```

```

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

;Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

;Show original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TVSCL, img, 20, 280

;Apply the threshold creating a binary image
thresh = img GE 140B

;Load a simple color table
TEK_COLOR

;Display Edges
XYOUTS, 520, 525, 'Edges', ALIGNMENT=.5, /DEVICE
TV, thresh, 360, 280

;Apply closing operator
closing = MORPH_CLOSE(thresh, REPLICATE(1,3,3))

;Show the result
XYOUTS, 180, 265, 'Closing Operator', ALIGNMENT=.5, /DEVICE
TV, closing, 20, 20

;Show added pixels in white
XYOUTS, 520, 265, 'Added Pixels in White', ALIGNMENT=.5, /DEVICE
TV, closing + thresh, 360, 20

```

## Version History

[DILATE](#), [ERODE](#), [MORPH\\_DISTANCE](#), [MORPH\\_GRADIENT](#),  
[MORPH\\_HITORMISS](#), [MORPH\\_OPEN](#), [MORPH\\_THIN](#), [MORPH\\_TOPHAT](#)

# MORPH\_DISTANCE

The MORPH\_DISTANCE function estimates  $N$ -dimensional distance maps, which contain for each foreground pixel the distance to the nearest background pixel, using a given norm. Available norms include non-diagonal neighbors, chessboard, city block, and approximate Euclidean distance.

The distance map is useful for a variety of morphological operations: thinning, erosion and dilation by discs of radius  $r$ , and granulometry.

## Syntax

```
Result = MORPH_DISTANCE (Data [, /BACKGROUND]  
    [, NEIGHBOR_SAMPLING={1 | 2 | 3 }] [, /NO_COPY])
```

## Return Value

The returned variable is an array of the same dimension as the input array.

## Arguments

### Data

An input binary array. Zero-valued pixels are considered to be part of the background.

## Keywords

### BACKGROUND

By default, the distance is computed for the foreground (non-zero) features in the *Data* argument. Set this keyword to compute the distance of the background features instead of the foreground features. If the keyword is set, elements of *Result* that are on an edge are set to 0.

### NEIGHBOR\_SAMPLING

Set this keyword to indicate how the distance of each neighbor from a given pixel is determined. Valid values include:

- 0 = default. No diagonal neighbors. Each neighbor is assigned a distance of 1.
- 1 = chessboard. Each neighbor is assigned a distance of 1.

- 2 = city block. Each neighbor is assigned a distance corresponding to the number of pixels to be visited when travelling from the current pixel to the neighbor. (The path can only take 90 degree turns; no diagonal paths are allowed.)
- 3 = approximate Euclidean distance. Each neighbor is assigned an approximate Euclidean distance, where the distances along the diagonals and the center row and column are correct, but for speed the off-diagonal elements are approximated by adding together the distances after the square root.

### Default Two Dimensional Example

```

      1
1     X     1
      1

```

### Chessboard Two-Dimensional Example

```

  1   1   1
  1   X   1
  1   1   1

```

### City Block Two-Dimensional Example:

```

  2   1   2
  1   X   1
  2   1   2

```

### Approximate Euclidean Distance Two-Dimensional Example

```

sqrt(2)  1  sqrt(2)
      1   X   1
sqrt(2)  1  sqrt(2)

```

## NO\_COPY

Set this keyword to request that the input array be reused, if possible. If this keyword is set, the input argument is undefined upon return.

## Examples

### Note

---

Also see [“Creating Distance Maps”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then applies a threshold and the

morphological distance operator. Thresholding the result distance operator with a value of “n” produces the equivalent of eroding the thresholded image with a disc of radius “n”.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

; Display the original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TV, img, 20, 280

; Apply the threshold:
thresh = img GE 140B

; Display the thresholded image
XYOUTS, 520, 525, 'Thresholded Image', ALIGNMENT=.5, /DEVICE
TVSCL, thresh, 360, 280

;Create Euclidean distance function
edist = MORPH_DISTANCE(thresh, NEIGHBOR_SAMPLING = 3)

; Display the distance function
XYOUTS, 180, 265, 'Distance Function', ALIGNMENT=.5, /DEVICE
TVSCL, edist, 20, 20

; Display image after erosion with a disc of radius 5:
XYOUTS, 520, 265, 'After erosion with disc of radius 5', $
ALIGNMENT=.5, /DEVICE
TVSCL, edist GT 5, 360, 20

```

[MORPH\\_HITORMISS](#), [MORPH\\_OPEN](#), [MORPH\\_THIN](#), [MORPH\\_TOPHAT](#)

# MORPH\_GRADIENT

The MORPH\_GRADIENT function applies the morphological gradient operator to a grayscale image. MORPH\_GRADIENT is the subtraction of an eroded version of the original image from a dilated version of the original image.

This routine is written in the IDL language. Its source code can be found in the file `morph_gradient.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MORPH_GRADIENT (Image, Structure [, PRESERVE_TYPE=bytearray |  
/UINT | /ULONG] [, VALUES=array] )
```

## Return Value

The practical result of a morphological gradient operation is that the boundaries of features are highlighted.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the morphological gradient operation is to be performed.

### Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values - either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

## Keywords

### PRESERVE\_TYPE

Set this keyword to return the same type as the input array. The input array must be of type BYTE, UINT, or ULONG. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of the UINT and ULONG keywords.

## UINT

Set this keyword to return an unsigned integer array. This keyword is mutually exclusive of the `ULONG` and `PRESERVE_TYPE` keywords.

## ULONG

Set this keyword to return an unsigned longword integer array. This keyword is mutually exclusive of the `UINT` and `PRESERVE_TYPE` keywords.

## VALUES

An array of the same dimensions as the *Structure* argument providing the values of the structuring element. If the `VALUES` keyword is not present, all elements of the structuring element are 0.

## Examples

### Note

---

Also see [“Detecting Edges of Image Objects”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then creates disc of radius 2, in a 5 by 5 array, with all elements within a radius of 2 from the center set to 1. This disc is used as the structuring element for the morphological gradient which is then displayed as both a gray scale image, and as a thresholded image.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

;Show original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TVSCL, img, 20, 280

;Define disc radius
r = 2

```

```

;Create a binary disc of given radius.
disc = SHIFT(DIST(2*r+1), r, r) LE r

bdisc = MORPH_GRADIENT(img, disc)

;Show edges
XYOUTS, 520, 525, 'Edges', ALIGNMENT=.5, /DEVICE
TVSCL, bdisc, 360, 280

;Show thresholded edges
XYOUTS, 180, 265, 'Threshold Edges', ALIGNMENT=.5, /DEVICE
TVSCL, bdisc ge 100, 20, 20

```

## Version History

[MORPH\\_HITORMISS](#), [MORPH\\_OPEN](#), [MORPH\\_THIN](#), [MORPH\\_TOPHAT](#)

# MORPH\_HITORMISS

The MORPH\_HITORMISS function applies the hit-or-miss operator to a binary image. The hit-or-miss operator is implemented by first applying an erosion operator with a *hit* structuring element to the original image. Then an erosion operator is applied to the complement of the original image with a secondary *miss* structuring element. The result is the intersection of the two results.

This routine is written in the IDL language. Its source code can be found in the file `morph_hitormiss.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = MORPH\_HITORMISS (*Image*, *HitStructure*, *MissStructure*)

## Return Value

The resulting image corresponds to the positions where the hit structuring element lies within the image, and the miss structure lies completely outside the image. The two structures must not overlap.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the morphological operation is to be performed. The image is treated as a binary image with all nonzero pixels considered as 1.

### HitStructure

A one-, two-, or three-dimensional array to be used as the hit structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

### MissStructure

A one-, two-, or three-dimensional array to be used as the miss structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

**Note**

---

It is assumed that the HitStructure and the MissStructure arguments are disjoint.

---

## Keywords

None.

## Example

**Note**

---

Also see [“Selecting Specific Image Objects”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

The following code snippet identifies blobs with a radius of at least 2, but less than 4 in the pollen image. These regions totally enclose a disc of radius 2, contained in the 5 x 5 kernel named “hit”, and in turn, fit within a hole of radius 4, contained in the 9 x 9 array named “miss”. Executing this specific example identifies four blobs in the image with these attributes.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

WINDOW, 0, XSIZE=700, YSIZE=540

; Display the original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TV, img, 20, 280

rh = 2 ;Radius of hit disc
rm = 4 ;Radius of miss disc

;Create a binary disc of given radius.
hit = SHIFT(DIST(2*rh+1), rh, rh) LE rh

;Complement of disc for miss
miss = SHIFT(DIST(2*rm+1), rm, rm) GT rm

;Load discrete color table
TEK_COLOR

```

```

;Apply the threshold
thresh = img GE 140B

; Display the thresholded image
XYOUTS, 520, 525, 'Thresholded Image', ALIGNMENT=.5, /DEVICE
TV, thresh, 360, 280

;Compute matches
matches = MORPH_HITORMISS(thresh, hit, miss)

;Expand matches to size of hit disc
matches = DILATE(matches, hit)

;Show matches.
XYOUTS, 180, 265, 'Matches', ALIGNMENT=.5, /DEVICE
TV, matches, 20, 20

;Superimpose, showing hit regions in blue.
;(Blue = color index 4 for tek_color.)
XYOUTS, 520, 265, 'Superimposed, hit regions in blue', $
    ALIGNMENT=.5, /DEVICE
TV, thresh + 3*matches, 360, 20

```

# MORPH\_OPEN

The MORPH\_OPEN function applies the opening operator to a binary or grayscale image. MORPH\_OPEN is simply an erosion operation followed by a dilation operation. The opening operation is an idempotent operator, applying it more than once produces no further effect.

An alternative definition of the opening, is that it is the union of all sets containing the structuring element in the original image. Both the opening and the closing operators have the effect of smoothing the image, with the opening operation removing pixels, and the closing operation adding pixels.

This routine is written in the IDL language. Its source code can be found in the file `morph_open.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MORPH_OPEN (Image, Structure [, /GRAY]  
[, PRESERVE_TYPE=bytearray | /UINT | /ULONG] [, VALUES=array] )
```

## Return Value

The result of an opening operation is that small features (e.g., noise) within the image are removed, yet the original sizes of the primary foreground features are maintained.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the opening operation is to be performed. If neither of the keywords GRAY or VALUES is present, the image is treated as a binary image with all nonzero pixels considered as 1.

### Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values — either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

## Keywords

### GRAY

Set this keyword to perform a grayscale, rather than binary, operation. Nonzero elements of the *Structure* parameter determine the shape of the structuring element. If the **VALUES** keyword is not present, all elements of the structuring element are 0.

### PRESERVE\_TYPE

Set this keyword to return the same type as the input array. The input array must be of type **BYTE**, **UINT**, or **ULONG**. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of the **UINT** and **ULONG** keywords.

### UINT

Set this keyword to return an unsigned integer array. This keyword only applies for grayscale operations, and is mutually exclusive of the **ULONG** and **PRESERVE\_TYPE** keywords.

### ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies for grayscale operations and is mutually exclusive of the **UINT** and **PRESERVE\_TYPE** keywords.

### VALUES

An array of the same dimensions as *Structure* providing the values of the structuring element. The presence of this keyword implies a grayscale operation.

## Examples

### Note

---

Also see [“Smoothing with MORPH\\_OPEN”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

The following code reads a data file in the IDL Demo data directory containing an magnified image of grains of pollen. It then applies a threshold and a morphological opening operator with a 3 by 3 square kernel to the original image. Notice that much of the irregular borders of the grains have been smoothed by the opening operator.

```
; Handle TrueColor displays:  
DEVICE, DECOMPOSED=0
```

```

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

;Show original image

[MORPH\\_GRADIENT](#), [MORPH\\_HITORMISS](#), [MORPH\\_THIN](#),  
[MORPH\\_TOPHAT](#)

# MORPH\_THIN

The MORPH\_THIN function performs a thinning operation on binary images. The thinning operator is implemented by first applying a hit or miss operator to the original image with a pair of structuring elements, and then subtracting the result from the original image.

This routine is written in the IDL language. Its source code can be found in the file `morph_thin.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = MORPH\_THIN ( *Image*, *HitStructure*, *MissStructure* )

## Return Value

In typical applications, this operator is repeatedly applied with the two structuring elements, rotating them after each application, until the result remains unchanged.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the thinning operation is to be performed. The image is treated as a binary image with all nonzero pixels considered as 1.

### HitStructure

A one-, two-, or three-dimensional array to be used as the hit structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

### MissStructure

A one-, two-, or three-dimensional array to be used as the miss structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

### Note

---

It is assumed that the *HitStructure* and the *MissStructure* arguments are disjoint.

---

## Keywords

None.

## Examples

See “[Thinning Image Objects](#)” in Chapter 9 of the *Image Processing in IDL* manual for examples.

# MORPH\_TOPHAT

The MORPH\_TOPHAT function applies the top-hat operator to a grayscale image. The top-hat operator is implemented by first applying the opening operator to the original image, then subtracting the result from the original image. Applying the top-hat operator provides a result that shows the bright peaks within the image.

This routine is written in the IDL language. Its source code can be found in the file `morph_tophat.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = MORPH_TOPHAT ( Image, Structure [, PRESERVE_TYPE=bytearray |  
/UINT | /ULONG] [, VALUES=array] )
```

## Return Value

Returns the resulting one-, two-, or three-dimensional array.

## Arguments

### Image

A one-, two-, or three-dimensional array upon which the top-hat operation is to be performed.

### Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values — either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

## Keywords

### PRESERVE\_TYPE

Set this keyword to return the same type as the input array. The input array must be of type BYTE, UINT, or ULONG. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of the UINT and ULONG keywords.

## UINT

Set this keyword to return an unsigned integer array. This keyword is mutually exclusive of the `ULONG` and `PRESERVE_TYPE` keywords.

## ULONG

Set this keyword to return an unsigned longword integer array. This keyword is mutually exclusive of the `UINT` and `PRESERVE_TYPE` keywords.

## VALUES

An array of the same dimensions as the *Structure* argument providing the values of the structuring element. If the `VALUES` keyword is not present, all elements of the structuring element are 0.

## Examples

The following example illustrates an application of the top-hat operator to an image in the `examples/demo/demodata` directory:

```

; Handle TrueColor displays:
DEVICE, DECOMPOSED=0

; Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=280

; Show original
XYOUTS, 180, 265, 'Original Image', ALIGNMENT=.5, /DEVICE
TVSCL, img, 20, 20

; Radius of disc
r = 2

; Create a binary disc of given radius.
disc = SHIFT(DIST(2*r+1), r, r) LE r

; Apply top-hat operator
tophat = MORPH_TOPHAT(img, disc)

; Display stretched result.
XYOUTS, 520, 265, 'Stretched Result', ALIGNMENT=.5, /DEVICE
TVSCL, tophat < 50, 360, 20

```

**Note**

# MPEG\_CLOSE

The `MPEG_CLOSE` procedure closes an MPEG sequence opened with the `MPEG_OPEN` routine. Note that `MPEG_CLOSE` does not save the MPEG file associated with the MPEG sequence; use `MPEG_SAVE` to save the file. The specified MPEG sequence identifier will no longer be valid after calling `MPEG_CLOSE`.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_close.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

`MPEG_CLOSE`, *mpegID*

## Arguments

### **mpegID**

The unique identifier of the MPEG sequence to be freed. (MPEG sequence identifiers are returned by the `MPEG_OPEN` routine.)

## Keywords

None.

## Examples

See [MPEG\\_OPEN](#) for an example using this routine.

## Version History

Introduced: 5.1

## See Also

[MPEG\\_OPEN](#), [MPEG\\_PUT](#), [MPEG\\_SAVE](#), [XINTERANIMATE](#)

# MPEG\_OPEN

The MPEG\_OPEN function initializes an IDLgrMPEG object for MPEG encoding and returns the object reference. The MPEG routines provide a wrapper around the IDL Object Graphics IDLgrMPEG object, eliminating the need to use the Object Graphics interface to create MPEG files.

---

**Note**

The MPEG standard does not allow movies with odd numbers of pixels to be created.

---

This routine is written in the IDL language. Its source code can be found in the file `mpeg_open.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

---

## Syntax

```
mpegID = MPEG_OPEN( Dimensions [, BITRATE=value] [, FILENAME=string]  
[, IFRAME_GAP=integer value] [, MOTION_VEC_LENGTH={1 | 2 | 3}]  
[ QUALITY=value{0 to 100}] )
```

## Return Value

Returns the reference to the IDLgrMPEG object.

## Arguments

### Dimensions

A two-element vector of the form [*xsize*, *ysize*] indicating the dimensions of the images to be used as frames in the MPEG movie file. All images in the MPEG file must have the same dimensions.

**Note**

---

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth.

---

## Keywords

### BITRATE

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

*Table 3-95: BITRATE Value Range*

If you do not set this keyword, IDL computes the BITRATE value based upon the value you have specified for the QUALITY keyword.

**Note**

---

Only use the BITRATE keyword if changing the QUALITY keyword value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

---

### FILENAME

Set this keyword equal to a string representing the name of the file in which the encoded MPEG sequence is to be saved. The default file name is `idl.mpg`.

### IFRAME\_GAP

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the `IFRAME_GAP` value based upon the value you have specified for the `QUALITY` keyword.

---

**Note**

Only use the `IFRAME_GAP` keyword if changing the `QUALITY` keyword value does not produce the desired results.

---

## MOTION\_VEC\_LENGTH

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

- 1 = Small motion vectors.
- 2 = Medium motion vectors.
- 3 = Large motion vectors.

If you do not set this keyword, IDL computes the `MOTION_VEC_LENGTH` value based upon the value you have specified for the `QUALITY` keyword.

---

**Note**

Only use the `MOTION_VEC_LENGTH` keyword if changing the `QUALITY` value does not produce the desired results.

---

## QUALITY

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

---

**Note**

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting `QUALITY` to its highest setting.

---

## Examples

The following sequence of IDL commands illustrates the steps needed to create an MPEG movie file from a series of image arrays named `image0`, `image1`, ..., `imageN`, where  $n$  is the zero-based index of the last image in the movie:

```
; Open an MPEG sequence:
mpegID = MPEG_OPEN()

; Add the first frame:
MPEG_PUT, mpegID, IMAGE=image0, FRAME=0
MPEG_PUT, mpegID, IMAGE=image1, FRAME=1

; Subsequent frames:
...

; Last frame:
MPEG_PUT, mpegID, IMAGE=imagen, FRAME=n

; Save the MPEG sequence in the file myMovie.mpg:
MPEG_SAVE, mpegID, FILENAME='myMovie.mpg'

; Close the MPEG sequence:
MPEG_CLOSE, mpegID
```

[MPEG\\_CLOSE](#), [MPEG\\_PUT](#), [MPEG\\_SAVE](#), [XINTERANIMATE](#)

# MPEG\_PUT

The MPEG\_PUT procedure stores the specified image array at the specified frame index in an MPEG sequence.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_put.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
MPEG_PUT, mpegID [, /COLOR] [, FRAME=frame_number] [, IMAGE=array | ,  
WINDOW=index] [, /ORDER]
```

## Arguments

### mpegID

The unique identifier of the MPEG sequence into which the image will be inserted. (MPEG sequence identifiers are returned by the MPEG\_OPEN routine.)

## Keywords

### COLOR

Set this keyword to read off an 8-bit display and pass the information through the current color table to create a 24-bit image.

### FRAME

Set this keyword equal to an integer specifying the frame at which the image is to be loaded. If the frame number matches a previously loaded frame, the previous frame is overwritten. The default is 0.

### IMAGE

Set this keyword equal to an  $m \times n$  image array or a  $3 \times m \times n$  True Color image array representing the image to be loaded at the specified frame. This keyword is ignored if the WINDOW keyword is specified.

### ORDER

Set this keyword to indicate that the rows of the image should be drawn from top to bottom. By default, the rows are drawn from bottom to top.

## WINDOW

Set this keyword to the index of a Direct Graphics Window (or to an object reference to an IDLgrWindow or IDLgrBuffer object) to indicate that the image to be loaded is to be read from the given window or buffer. If this keyword is specified, it overrides the value of the IMAGE keyword.

## Examples

See [MPEG\\_OPEN](#) for an example using this routine.

## Version History

# MPEG\_SAVE

The MPEG\_SAVE procedure encodes and saves an open MPEG sequence.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_save.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

---

## Syntax

MPEG\_SAVE, *mpegID* [, **FILENAME**=*string*]

## Arguments

### **mpegID**

The unique identifier of the MPEG sequence to be saved to a file. (MPEG sequence identifiers are returned by the MPEG\_OPEN routine.)

## Keywords

### **FILENAME**

Set this keyword to a string representing the name of the file to which the encoded MPEG sequence is to be saved. The default is `idl.mpg`.

## Examples

See [MPEG\\_OPEN](#) for an example using this routine.

## Version History

---

5.1	Introduced

# MULTI

The MULTI procedure expands the current color table to “wrap around” some number of times.

This routine is written in the IDL language. Its source code can be found in the file `multi.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

MULTI, *N*

## Arguments

### N

The number of times the color table will wrap. This parameter need not be an integer.

## Keywords

None.

## Examples

Display an image, load color table 1, and make that color table “wrap around” 3 times. Enter:

```

;Display a simple image.
TVSCL, DIST(256)

;Load color table 1.
LOADCT, 1

;See how the new color table affects the image.
MULTI, 3

```

## Version History

Original	Introduced

## See Also

[STRETCH](#), [XLOADCT](#)

# N\_ELEMENTS

The `N_ELEMENTS` function returns the number of elements contained in an expression or variable.

## Syntax

*Result* = `N_ELEMENTS(Expression)`

## Return Value

Returns the number of elements.

## Arguments

### Expression

The expression for which the number of elements is to be returned. Scalar expressions always have one element. The number of elements in an array is equal to the product of its dimensions. If *Expression* is an undefined variable, `N_ELEMENTS` returns zero.

## Keywords

None.

## Examples

### Example 1

This example finds the number of elements in an array:

```
; Create an integer array:  
I = INTARR(4, 5, 3, 6)  
; Find the number of elements in I and print the result:  
PRINT, N_ELEMENTS(I)
```

### Example 2

A typical use of `N_ELEMENTS` is to check if an optional input is defined, and if not, set it to a default value:

```
IF (N_ELEMENTS(roo) EQ 0) THEN roo=rooDefault
```

The original value of `roo` may be altered by a called routine, passing a different value back to the caller. Unless you intend for the routine to behave in this manner, you should prevent it by differentiating `N_ELEMENTS`' parameter from your routine's variable:

```
IF (N_ELEMENTS(roo) EQ 0) THEN rooUse=rooDefault $  
ELSE rooUse=roo
```

## Version History

Original	Introduced
----------	------------

## See Also

[N\\_TAGS](#)

# N\_PARAMS

The `N_PARAMS` function returns the number of parameters used in calling an IDL procedure or function. This function is only useful within IDL procedures or functions. User-written procedures and functions can use `N_PARAMS` to determine if they were called with optional parameters.

---

**Note**

*In the case of object method procedures and functions, the `SELF` argument is not counted by `N_PARAMS`.*

---

## Syntax

*Result* = `N_PARAMS()`

## Return Value

Returns the number of non-keyword parameters.

## Arguments

None. This function always returns the number of parameters that were used in calling the procedure or function from which `N_PARAMS` is called.

## Keywords

None.

## Version History

---

Original	Introduced
----------	------------

---

## See Also

[KEYWORD\\_SET](#)

# N\_TAGS

The N\_TAGS function returns the number of structure tags contained in a structure expression.

## Syntax

```
Result = N_TAGS( Expression [, /DATA_LENGTH] [, /LENGTH] )
```

## Return Value

Returns the number of structure tags and optionally returns the size, in bytes, of the structure.

## Arguments

### Expression

The expression for which the number of structure tags is to be returned. Expressions that are not of structure type are considered to have no tags. N\_TAGS does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the number of tags in the outermost structure are counted.

## Keywords

### DATA\_LENGTH

Set this keyword to return the total length of all the data fields contained within the structure, in bytes. This differs from LENGTH in that it does not include any alignment padding required by the structure.

The length of the data for a given structure will be the same on any system, *as long as the data does not contain strings*.

If a data field contains a string, the DATA\_LENGTH keyword returns the length of the string's internal *descriptor*, rather than the length of the string data. (In IDL, strings are represented internally using a *descriptor structure* that contains information about the string, including its length and a pointer to the string data.) This means that on a given machine, the DATA\_LENGTH keyword will report the same length value for all fields containing string data, regardless of the contents of the strings.

**Note**

---

The length of a string descriptor can vary between machines, and also between 32-bit and 64-bit versions of IDL. Length differences are caused by differences in structure alignment rules or the size of a machine pointer on the system, and are fundamental properties of the underlying system.

---

**LENGTH**

Set this keyword to return the length of the structure, in bytes.

**Note**

---

The length of a structure is machine dependent. The length of a given structure will vary depending upon the host machine. IDL pads and aligns structures in a manner consistent with the host machine's C compiler.

---

**Examples**

Find the number of tags in the system variable !P and print the result by entering:

```
PRINT, N_TAGS(!P)
```

Find the length of !P, in bytes:

```
PRINT, N_TAGS(!P, /LENGTH)
```

[CREATE\\_STRUCT](#), [N\\_ELEMENTS](#), [TAG\\_NAMES](#), Chapter 16, “Structures” in the *Building IDL Applications* manual

# NCDF\_\* Routines

For information, see [Chapter 6, “Network Common Data Format”](#) in the *IDL Scientific Data Formats* manual.

# NEWTON

The NEWTON function solves a system of  $n$  non-linear equations in  $n$  dimensions using a globally-convergent Newton's method.

NEWTON is based on the routine `newt` described in section 9.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = NEWTON( X, Vecfunc [, CHECK=variable] [, /DOUBLE]
  [, ITMAX=value] [, STEPMAX=value] [, TOLF=value] [, TOLMIN=value]
  [, TOLX=value] )
```

## Return Value

The result is an  $n$ -element vector containing the solution.

## Arguments

### X

An  $n$ -element vector containing an initial guess at the solution of the system.

### Note

---

If NEWTON is complex then only the real part is used for the computation.

---

### Vecfunc

A scalar string specifying the name of a user-supplied IDL function that defines the system of non-linear equations. This function must accept an  $n$ -element vector argument  $X$  and return an  $n$ -element vector result.

For example, suppose the non-linear system is defined by the following equations:

$$y_0 = x_0 + x_1 - 3, \quad y_1 = x_0^2 + x_1^2 - 9$$

We write a function NEWTFUNC to express these relationships in the IDL language:

```
FUNCTION newtfunc, X
  RETURN, [X[0] + X[1] - 3.0, X[0]^2 + X[1]^2 - 9.0]
END
```

## Keywords

### CHECK

NEWTON calls an internal function named `fmin()` to determine whether the routine has converged to a local minimum rather than to a global minimum (see *Numerical Recipes*, section 9.7). Use the CHECK keyword to specify a named variable which will be set to 1 if the routine has converged to a local minimum or to 0 if it has not. If the routine does converge to a local minimum, try restarting from a different initial guess to obtain the global minimum.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ITMAX

The maximum allowed number of iterations. The default value is 200.

### STEPMAX

The scaled maximum step length allowed in line search. The default value is 100.0.

### TOLF

Set the convergence criterion on the function values. The default value is  $1.0 \times 10^{-4}$ .

### TOLMIN

Set the criterion for deciding whether spurious convergence to a minimum of the function `fmin()` has occurred. The default value is  $1.0 \times 10^{-6}$ .

### TOLX

Set the convergence criterion on  $X$ . The default value is  $1.0 \times 10^{-7}$ .

## Examples

Use NEWTON to solve an  $n$ -dimensional system of  $n$  non-linear equations. Systems of non-linear equations may have multiple solutions; starting the algorithms with different initial guesses enables detection of different solutions.

```
FUNCTION newtfunc, X
RETURN, [X[0] + X[1] - 3, X[0]^2 + X[1]^2 - 9]

END
```

```

PRO TEST_NEWTON

; Provide an initial guess as the algorithm's starting point:
X = [1d, 5d]

; Compute the solution:
result = NEWTON(X, 'newtfunc')

; Print the result:
PRINT, 'For X=[1.0, 5.0], result = ', result

;Try a different starting point.
X = [1d, -1d]

; Compute the solution:
result = NEWTON(X, 'newtfunc')

;Print the result.
PRINT, 'For X=[1.0, -1.0], result = ', result

END

```

IDL prints:

```

For X=[1.0, 5.0], result = -2.4871776e-006      3.0000025
For X=[1.0, -1.0], result =      3.0000000 -2.9985351e-008

```

# NORM

The NORM function computes the norm of a vector or a two-dimensional array.

By default, NORM computes the  $L_2$  (Euclidean) norm for vectors, and the  $L_\infty$  norm for arrays. You may use the LNORM keyword to specify different norms.

This routine is written in the IDL language. Its source code can be found in the file `norm.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = NORM( *A* [, /DOUBLE] [, LNORM={0 | 1 | 2 | *n*}] )

## Return Value

Returns the Euclidean or infinity norm of a vector or an array. This function always returns a float or double value.

## Arguments

### A

A can be either a real or complex vector, or a real or complex two-dimensional array.

## Keywords

### DOUBLE

Set this keyword to force the result to be returned as double precision. The default is to return a single-precision result if the input is single precision, or double precision otherwise. Internally, all computations are done using double-precision arithmetic.

## LNORM

Set this keyword to indicate which norm to compute. If  $A$  is a vector, then the possible values of this keyword are:

Value	Description
0	Compute the $L_\infty$ norm, defined as $\text{MAX}(\text{ABS}(A))$ .
1	Compute the $L_1$ norm, defined as $\text{TOTAL}(\text{ABS}(A))$ .
2	Compute the $L_2$ norm, defined as $\text{SQRT}(\text{TOTAL}(\text{ABS}(A)^2))$ . This is the default.
$n$	Compute the $L_n$ norm, defined as $(\text{TOTAL}(\text{ABS}(A)^n))^{(1/n)}$ where $n$ is any number, float-point or integer.

*Table 3-96: LNORM Keyword Values (Vector)*

If  $A$  is a two-dimensional array, then the possible values of this keyword are:

Value	Description
0	Compute the $L_\infty$ norm (the maximum absolute row sum norm), defined as $\text{MAX}(\text{TOTAL}(\text{ABS}(A), 1))$ . This is the default.
1	Compute the $L_1$ norm (the maximum absolute column sum norm), defined as $\text{MAX}(\text{TOTAL}(\text{ABS}(A), 2))$ .
2	Compute the $L_2$ norm (the spectral norm) defined as the largest singular value, computed from $\text{LA\_SVD}$ .

*Table 3-97: LNORM Keyword Values (Two-Dimensional Array)*

## Examples

```

; Define an n-element complex vector A:
A = [COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3,1)]

; Compute the Euclidean norm of A and print:
PRINT, 'Euclidian Norm of A =', NORM(A)

; Define an m by n complex array B:
B = [[COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3,1)], $
      [COMPLEX(1,-2), COMPLEX(2, 2), COMPLEX(1, 0)]]

```

```
;Compute the Infinity norm of B and print.  
PRINT, 'Infinity Norm of B =', NORM(B, /DOUBLE)
```

IDL prints:

```
Euclidian Norm of A =      4.35890  
Infinity Norm of B =      6.9907048
```

[COND](#), [LA\\_SVD](#)

# OBJ\_CLASS

The OBJ\_CLASS function identifies the name of the object class or superclass of the given argument.

## Syntax

```
Result = OBJ_CLASS( [Arg] [, COUNT=variable] [, /SUPERCLASS {must specify Arg}] )
```

## Return Value

Returns a string containing the name of the class or superclass. If the supplied argument is not an object, a null string is returned. If no argument is supplied, OBJ\_CLASS returns an array containing the names of all known object classes in the current IDL session.

## Arguments

### Arg

A scalar object reference or string variable for which the object class name is desired. If *Arg* is an object reference, its object class definition is used. If *Arg* is a string, it is taken to be the name of the class for which information is desired. Passing a string argument is primarily useful in conjunction with the SUPERCLASS keyword.

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of names returned by OBJ\_CLASS. It can be used to determine how many superclasses a class has when the SUPERCLASS keyword is specified.

### SUPERCLASS

Set this keyword to cause OBJ\_CLASS to return the names of the object's *direct* superclasses as a string array, one element per superclass. The superclasses are ordered in the order they appear in the class structure declaration. In the case where the class has no superclasses, a scalar null string is returned, and the COUNT

keyword (if specified) returns the value 0. If SUPERCLASS is specified, the Arg argument must also be supplied.

**Note**

Some IDL objects are subclassed from more generic IDL objects. You may see references to the generic IDL objects when using the SUPERCLASS keyword to the OBJ\_CLASS function to get information on an object. You may also notice that the generic objects are not documented in the “[Object Class and Method Reference](#)” in the *IDL Reference Guide* manual. This is not an oversight.

We have chosen not to document the workings of some of the generic objects from which IDL objects are subclassed because we reserve the right to make changes to their operation. We strongly recommend that you do not use the undocumented object classes directly, or subclass your own object classes from them. RSI does not guarantee that user-written code that uses undocumented features will continue to function in future releases of IDL.

## Version History

5.0	Introduced
-----	------------

# OBJ\_DESTROY

The OBJ\_DESTROY procedure is used to destroy an object. If the class (or one of its superclasses) supplies a procedure method named CLEANUP, the method is called and all arguments and keywords passed by the user are passed to it. This method should perform any required cleanup on the object and return. Whether a CLEANUP method actually exists or not, IDL will destroy the heap variable representing the object and return.

## Note

---

OBJ\_DESTROY does not recurse. That is, if `object1` contains a reference to `object2`, destroying `object1` will *not* destroy `object2`. Take care not to lose the only reference to an object by destroying an object that contains that reference. Recursive cleanup of object hierarchies is a good job for a CLEANUP method.

---

## Syntax

OBJ\_DESTROY, *ObjRef* [, *Arg*<sub>1</sub>, ..., *Arg*<sub>*n*</sub>]

## Arguments

### ObjRef

The object reference for the object to be destroyed. *ObjRef* can be an array, in which case all of the specified objects are destroyed in turn. If the NULL object reference is passed, OBJ\_DESTROY ignores it quietly.

### Arg<sub>1</sub>...Arg<sub>*n*</sub>

Any arguments accepted by the CLEANUP method for the object being destroyed can be specified as additional arguments to OBJ\_DESTROY.

## Keywords

Any keywords accepted by the CLEANUP method for the object being destroyed can be specified as keywords to OBJ\_DESTROY.

## Version History

5.0	Introduced
-----	------------

# OBJ\_ISA

When one object class is subclassed (inherits) from another class, there is an “Is A” relationship between them. The OBJ\_ISA function is used to determine if an object instance is subclassed from the specified class.

## Syntax

*Result* = OBJ\_ISA(*ObjectInstance*, *ClassName*)

## Return Value

OBJ\_ISA returns True (1) if the specified variable is an object and has the specified class in its inheritance graph, or False (0) otherwise.

## Arguments

### ObjectInstance

A scalar or array variable for which the OBJ\_ISA test should be performed. The result is of type byte, and has the same size and organization as *ObjectInstance*.

### ClassName

A string giving the name of the class for which *ObjectInstance* is being tested.

## Keywords

None.

## Version History

5.0	Introduced
-----	------------

## OBJ\_NEW

Given the name of a structure that defines an object class, the `OBJ_NEW` function returns an object reference to a new instance of the specified object type by carrying out the following operations in order:

1. If the class structure has not been defined, IDL will attempt to find and call a procedure to define it automatically. (See [“Automatic Class Structure Definition”](#) in Chapter 13 of the *Object Programming* manual for details.) If the structure is still not defined, `OBJ_NEW` fails and issues an error.
2. If the class structure has been defined, `OBJ_NEW` creates an object heap variable containing a zeroed instance of the class structure.
3. Once the new object heap variable has been created, `OBJ_NEW` looks for a *method* function named `Class::INIT` (where *Class* is the actual name of the class). If an `INIT` method exists, it is called with the new object as its implicit `SELF` argument, as well as any arguments and keywords specified in the call to `OBJ_NEW`. If the class has no `INIT` method, the usual method-searching rules are applied to find one from a superclass. For more information on methods and method-searching rules, see [“Creating Custom Object Method Routines”](#) in Chapter 13 of the *Object Programming* manual.

The `INIT` method is expected to initialize the object instance data as necessary to meet the needs of the class implementation. `INIT` should return a scalar `TRUE` value (such as 1) if the initialization is successful, and `FALSE` (such as 0) if the initialization fails.

---

### Note

`OBJ_NEW` does not call all the `INIT` methods in an object’s class hierarchy. Instead, it simply calls the first one it finds. Therefore, the `INIT` method for a class should call the `INIT` methods of its direct superclasses as necessary.

---

4. If the `INIT` method returns true, or if no `INIT` method exists, `OBJ_NEW` returns an object reference to the heap variable. If `INIT` returns false, `OBJ_NEW` destroys the new object and returns the `NULL` object reference, indicating that the operation failed. Note that in this case the `CLEANUP` method is not called. See [“Destruction”](#) in Chapter 13 of the *Object Programming* manual for more on `CLEANUP` methods.

If called without arguments, `OBJ_NEW` returns a `NULL` object reference. The `NULL` object reference is a special value that never refers to a value object. It is primarily used as a placeholder in structure definitions, and as the initial value for elements of

object arrays created via OBJARR. The null object reference is useful as an indicator that an object reference is currently not usable.

## Syntax

```
Result = OBJ_NEW( [ObjectClassName [, Arg1.....Argn]] )
```

## Return Value

Returns a reference to a new instance of the specified object type. If called without arguments, OBJ\_NEW returns a NULL object reference. The NULL object reference is a special value that never refers to a value object. It is primarily used as a placeholder in structure definitions, and as the initial value for elements of object arrays created via OBJARR. The null object reference is useful as an indicator that an object reference is currently not usable.

## Arguments

### ObjectClassName

String giving the name of the structure type that defines the object class for which a new object should be created.

If *ObjectClassName* is not provided, OBJ\_NEW does not create a new heap variable, and returns the *Null Object*, which is a special object reference that is guaranteed to never point at a valid object heap variable. The null object is a convenient value to use when defining structure definitions for fields that are object references, since it avoids the need to have a pre-existing valid object reference.

### Arg<sub>1</sub>...Arg<sub>n</sub>

Any arguments accepted by the INIT method for the class of object being created can be specified when the object is created.

## Keywords

Any keywords accepted by the INIT method for the class of object being created can be specified when the object is created.

## Version History

5.0	Introduced
-----	------------

# OBJ\_VALID

The OBJ\_VALID function verifies the validity of its argument object references, or alternatively returns a vector of references to valid objects.

## Syntax

```
Result = OBJ_VALID( [Arg] [, /CAST] [, COUNT=variable] )
```

## Return Value

If called with an integer or array of object references as its argument, OBJ\_VALID returns a byte array of the same size as the argument. Each element of the result is set to True (1) if the corresponding object reference in the argument refers to an existing object, and False (0) otherwise.

If called with an integer or array of integers as its argument and the CAST keyword is set, OBJ\_VALID returns an array of object references. Each element of the result is a reference to the heap variable indexed by the integer value. Integers used to index heap variables are shown in the output of the HELP and PRINT commands. This is useful primarily in programming/debugging when the you have lost a reference but see it with HELP and need to get a reference to it interactively in order to determine what it is and take steps to fix the code. See the “[Examples](#)” section below for an example.

If no argument is specified, OBJ\_VALID returns a vector of references to all existing valid objects. If no valid objects exist, a scalar null object reference is returned.

## Arguments

### Arg

An object reference or array of object references. If the CAST keyword is set, then *Arg* should contain a scalar integer or array of integers.

## Keywords

### CAST

Set this keyword to cast integers contained in *Arg* to their corresponding object references, and to return the object references in *Result*. If an integer contained in *Arg* does not correspond to a valid object reference, a null object is returned in that

integer's place. If *Arg* contains object references rather than integers, the object references are simply returned. See the “[Examples](#)” section below for an example.

## COUNT

Set this keyword equal to a named variable that will contain the number of currently valid objects. This value is returned as a longword integer.

## Examples

To determine if a given object reference refers to a valid heap variable, use:

```
IF (OBJ_VALID(obj)) THEN ...
```

To destroy all existing pointer heap variables:

```
OBJ_DESTROY, OBJ_VALID()
```

You can use the `CAST` keyword to “reclaim” lost object references. For example:

```
; Create a class structure:
junk = {junk, data1:0, data2:0.0}

; Create an object:
A = OBJ_NEW('junk')

; Find the integer index:
PRINT, A

; In this case, the integer index to the heap variable is 3. If we
; reassign the variable A, we will "lose" the object reference, but
; the heap variable will still exist.
; Lose the object reference:
A = 0
PRINT, A, OBJ_VALID()

; We can reclaim the lost heap variable using the CAST keyword:
A = OBJ_VALID(3, /CAST)
PRINT, A
```

IDL prints:

```
<ObjHeapVar3 (JUNK) >
0 <ObjHeapVar3 (JUNK) >
<ObjHeapVar3 (JUNK) >
```

## Version History

# OBJARR

The OBJARR function returns an object reference vector or array. The individual elements of the array are set to the NULL object reference.

## Syntax

$$Result = \text{OBJARR}(D_1 [, \dots, D_8] [, \text{NOZERO}] )$$

## Return Value

Returns an object reference to an array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

OBJARR sets every element of the result to the null object reference. If NOZERO is nonzero, this initialization is not performed and OBJARR executes faster.

### Warning

---

If you specify NOZERO, the resulting array will have whatever value happens to exist at the system memory location that the array is allocated from. You should be careful to initialize such an array to valid object reference values.

---

## Examples

Create a 3 element by 3 element object reference array with each element containing the null object reference:

```
A = OBJARR(3, 3)
```

## Version History

# ON\_ERROR

The ON\_ERROR procedure determines the action taken when an error is detected inside an IDL user procedure or function by setting state information applying to the current routine and all nested routines. If an override exists within the nested routine, it takes precedence over the ON\_ERROR call. ON\_ERROR determines the action when no error handlers established with the CATCH procedure are found.

## Syntax

ON\_ERROR, *N*

## Arguments

### N

An integer that specifies the action to take. Valid values for *N* are:

0	Stop immediately at the statement in the context of the procedure or function that caused the error. This is the default action.
1	Return to the main program level and stop.
2	Return to the caller of the program unit that called ON_ERROR and stop.
3	Return to the program unit that called ON_ERROR and stop.

## Keywords

None.

## Example

One useful option is to use `ON_ERROR` to cause control to be returned to the caller of a procedure in the event of an error. The statement:

```
ON_ERROR, 2
```

placed at the beginning of a procedure will have this effect. Include this statement in library procedures and other routines that will be used by others once the routines have been debugged. This form of error recovery makes debugging a routine difficult because the routine is exited as soon as an error occurs; therefore, it should be added once the code is completely tested.

---

**Note**

Error handlers established by `CATCH` supersede calls to `ON_ERROR` made in the same procedure.

---

## Version History

Original	Introduced
----------	------------

## See Also

[CATCH](#), [MESSAGE](#), [ON\\_IOERROR](#), and [Chapter 8, “Debugging and Error-Handling”](#) in the *Building IDL Applications* manual.

# ON\_IOERROR

The ON\_IOERROR procedure specifies a statement to be jumped to if an I/O error occurs in the current procedure. Normally, when an I/O error occurs, an error message is printed and program execution is stopped. If ON\_IOERROR is called and an I/O related error later occurs in the same procedure activation, control is transferred to the designated statement with the error code stored in the system variable !ERROR\_STATE. The text of the error message is contained in !ERROR\_STATE.MSG.

The effect of ON\_IOERROR can be canceled by using the label “NULL” in the call.

## Note

---

Note that calls to ON\_IOERROR made in the procedure that causes an I/O error supersede any error handling mechanisms created with CATCH and the program branches to the label specified by ON\_IOERROR.

---

## Syntax

ON\_IOERROR, *Label*

## Arguments

### Label

Statement to jump to when I/O error is encountered.

## Keywords

None.

## Examples

The following code segment reads an integer from the keyboard. If an invalid number is entered, the program re-prompts.

```
i = 0 ; Number to read:

valid = 0 ; Valid flag

WHILE valid EQ 0 DO BEGIN
    ON_IOERROR, bad_num
```

```

        READ, 'Enter Number: ', i
        ;If we get here, i is good.
        VALID = 1
bad_num: IF ~ valid THEN $
        PRINT, 'You entered an invalid number.'
ENDWHILE
END

```

When writing procedures and functions that are to be used by others, it is good practice to anticipate and handle errors caused by the user. For example, the following procedure segment, which opens a file specified by the user, handles the case of a nonexistent file or read error.

```

; Define a function to read, and return a 100-element,
; floating-point array.
FUNCTION READ_DATA, FILE_NAME

; Declare error label.
ON_IOERROR, BAD

; Use the GET_LUN keyword to allocate a logical file unit.
OPENR, UNIT, FILE NAME, /GET_LUN

A = FLTARR(100)      ;Define data array.

READU, UNIT, A      ;Read the data array.

; Clean up and return.
GOTO, DONE

; Exception label. Print the error message.
BAD: PRINT, !ERR_STRING

; Close and free the input/output unit.
DONE: FREE_LUN, UNIT

; Return the result. This will be undefined if an error occurred.
RETURN, A

END

```

The important things to note in this example are that the `FREE_LUN` procedure is always called, even in the event of an error, and that this procedure always returns to its caller. It returns an undefined value if an error occurs, causing its caller to encounter the error.

# ONLINE\_HELP

The `ONLINE_HELP` procedure invokes IDL's online help system. If called with no arguments, it starts the help viewer with the default IDL help file displayed.

---

**Note**

This procedure is intended for use in user-written routines. The `?` command, which is a shorthand for the `ONLINE_HELP` procedure, is intended for use at the IDL command line.

---

IDL's online help system uses a cross-platform help viewer — *IDL Assistant* — based on the help viewer used by the Qt development toolkit from Trolltech. For information on using the help viewer, see “[Getting Help with IDL](#)” in Chapter 1 of the *Using IDL* manual.

The IDL online help system comprises a set of HTML and image files governed by a special index (`*.adp`) file. For information on creating a help system that can be displayed in IDL's help viewer, see [Chapter 23, “Providing Online Help For Your Application”](#) in the *Building IDL Applications* manual.

In addition to online help systems created for the IDL help viewer, the `ONLINE_HELP` procedure can display files in the following formats:

- HTML
- Adobe Portable Document Format (PDF)
- Microsoft Windows HTML Help (`*.chm` files)
- Microsoft Windows Help (`*.hlp` files)

## Syntax

```
ONLINE_HELP [, Value] [, BOOK='filename'] [, /FULL_PATH] [, /QUIT]
```

**Windows-Only Keywords:** [, /CONTEXT]

## Arguments

### Value

An optional string that specifies the topic or sub-topic to be displayed, depending on the type of help file in use. *Value* is interpreted differently depending on the value of the `BOOK` keyword:

- If the **BOOK** keyword is not specified, IDL will search the directories in `!HELP_PATH` for a file whose base name matches *Value* and whose extension is `.html` or `.htm`, opening that file in the IDL help viewer. If no matching file is found, an error message is displayed in the IDL help viewer.
- If neither the **BOOK** keyword nor the *Value* argument is specified, IDL will display the IDL online help system's home page.
- If the **BOOK** keyword is specified, *Value* will be interpreted as described in the table following the description for the **BOOK** keyword, below.

## Keywords

### BOOK

Set this keyword to a string containing the name of the help file to be displayed. If **BOOK** is not specified, IDL will search the directories in `!HELP_PATH` for a file whose base name matches *Value*. If neither the **BOOK** keyword or the *Value* argument is specified, IDL will open the default IDL will display the IDL online help system's home page.

If **BOOK** is specified, the way it is interpreted depends on the type of file specified, as determined by the file's extension:

Extension	File Type	Behavior
<code>.adp</code>	IDL Help Viewer Profile	<p>Opens the specified IDL help viewer document profile in the IDL help viewer. If the <i>Value</i> argument is present, it is treated as the name of an HTML file included in the same directory as the <code>.adp</code> file, and opened in the main window.</p> <p><b>Note</b> - Under Microsoft Windows, <i>Value</i> is not case sensitive. Under UNIX, IDL will first attempt to find an HTML file with an uppercase file name (e.g. <code>FILE.html</code>). If no matching uppercase file is found, it IDL will look for a file with the case as specified in the <i>Value</i> argument. On all platforms, if no matching file is found, IDL displays an error topic.</p>

Table 3-98: File Types Supported by `ONLINE_HELP`

Extension	File Type	Behavior
.html .htm	HTML	<p>Opens the specified HTML file in the default web browser. If the <i>Value</i> argument is present, it is treated as an anchor value and appended to the URL for the specified HTML file. In most cases, this will cause the browser to position the file content so that the specified anchor is at the top of the viewing window. If the anchor is not present in the HTML file, the browser generally ignores it quietly.</p> <p><b>Note</b> - See <a href="#">“Displaying HTML and PDF Files under UNIX”</a> on page 1622 for additional information.</p>
.chm	Windows HTML Help	<p>Opens the specified Windows HTML Help file. If the <i>Value</i> argument is present, the <b>Index</b> tab of the HTML Help viewer is positioned to display the closest matching value. See also the CONTEXT keyword.</p>
.hlp	Windows Help	<p>Opens the specified Windows Help file. If the <i>Value</i> argument is present, the <b>Index</b> tab of the Help viewer is positioned to display the closest matching value. See also the CONTEXT keyword.</p>
.pdf	Acrobat	<p>Opens the specified PDF file in the system default PDF viewer. The <i>Value</i> argument is quietly ignored.</p> <p><b>Note</b> - See <a href="#">“Displaying HTML and PDF Files under UNIX”</a> on page 1622 for additional information.</p>

Table 3-98: File Types Supported by ONLINE\_HELP (Continued)

Extension	File Type	Behavior
None	Any type	Searches the directories specified by the !HELP_PATH environment variable for a file whose base name matches the specified value, in this order: .adp, .chm (Windows only), .hlp (Windows only), .pdf, .html, .htm. The first file found is opened and the <i>Value</i> argument interpreted as described by this table

*Table 3-98: File Types Supported by ONLINE\_HELP (Continued)*

---

### Note

If the FULL\_PATH keyword is specified, BOOK must specify a complete file path, including the directory specification and file extension for the file.

---

If no file matching the specification is found, an error message is displayed in the IDL help viewer.

## CONTEXT

*This keyword is only available on Windows platforms.*

Set this keyword to indicate that the *Value* argument is an integer value that represents the context number of a help topic to be displayed in the Microsoft Windows HTMLHelp viewer or the older Windows Help viewer. This keyword is intended for use with user-compiled Windows help files (\*.chm or \*.hlp) that contain topics that have been mapped to specific context numbers when they were compiled using the [MAP] section of the help project file. Specifying a non-existent context number causes an error dialog to be displayed. For more information on how to create help files with context numbers, see the documentation for the help system compiler that you are using.

## FULL\_PATH

Set this keyword to indicate that the value of the BOOK keyword is a full and complete path to the help file, including any necessary directory information, and a file extension. If FULL\_PATH is not specified, ONLINE\_HELP searches the directories referred to by the !HELP\_PATH system variable to locate the file, and the file extension is optional.

## QUIT

Set this keyword to close the Help viewer.

### Note

---

The QUIT keyword will close the IDL help viewer and the Windows help viewers. It has no effect on PDF viewers or web browsers.

---

## Displaying HTML and PDF Files under UNIX

To display an HTML or PDF file on a Windows system, IDL simply instructs Windows to open the specified file and leaves it to the operating system to choose the correct application based on the file type. UNIX systems have no cross-platform standard facility for associating different types of files with specific applications, so the situation is slightly more complicated.

### HTML Files

When the BOOK keyword specifies an HTML file (that is, when the file name ends with any of `.html`, `.HTML`, `.htm`, or `.HTM`), IDL calls a shell script located in the IDL distribution. The shell script then launches a web browser with the specified file as its argument. On Macintosh systems, IDL's default is to call the Open command along with the filename, allowing the operating system to choose the correct application to open the file. On other UNIX systems, IDL assumes that it should launch the Netscape web browser, and that the `netscape` command is located in one of the directories specified by the `PATH` environment variable. Individual users can override the default behavior by setting environment variables to specify either a different browser or an entirely different shell script.

See the comments in the `online_help_html` script located in the `bin` subdirectory of the IDL distribution for details on setting the relevant environment variables.

### PDF Files

When the BOOK keyword specifies a PDF file (that is, when the file name ends with either `.pdf` or `.PDF`), IDL calls a shell script located in the IDL distribution. The shell script then launches a PDF file viewer application with the specified file as its argument. On Macintosh systems, IDL's default is to call the Open command along with the filename, allowing the operating system to choose the correct application to open the file. On other UNIX systems, IDL assumes that it should launch the Acrobat Reader application, and that the `acroread` command is located in one of the directories specified by the `PATH` environment variable. Individual users can override

the default behavior by setting environment variables to specify either a different viewer or an entirely different shell script.

See the comments in the `online_help_pdf` script located in the `bin` subdirectory of the IDL distribution for details on setting the relevant environment variables.

## Examples

The following example uses the `ONLINE_HELP` procedure to launch the help viewer to display information on the `FFT` function:

```
ONLINE_HELP, 'fft'
```

This Windows-only example displays the topic corresponding to context number 100 in a traditional Windows help file.

```
ONLINE_HELP, 100, /CONTEXT, /FULL_PATH, $
BOOK='C:\keith\myfile.hlp'
```

This cross-platform example displays an HTML file in the system's default web browser.

```
ONLINE_HELP, BOOK='myfile.html'
```

## Version History

4.01	Introduced
5.6	Modified to invoke Adobe Acrobat under UNIX, to invoke the HTML Help viewer by default under Windows, to allow opening of HTML and PDF files on all platforms, and to add the UNIX-only keywords <code>FOLD_CASE</code> and <code>PAGE</code>
6.1	Added <code>SUPPRESS_PLUGIN_ERRORS</code> keyword
Pre-6.2	Deprecated <code>HTML_HELP</code> keyword
6.2	Deprecated the <code>FOLD_CASE</code> , <code>PAGE</code> , <code>SUPPRESS_PLUGIN_ERRORS</code> , and <code>TOPICS</code> keywords

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## See Also

[MK\\_HTML\\_HELP](#), Chapter 23, “Providing Online Help For Your Application” in the *Building IDL Applications* manual, “Getting Help with IDL” in Chapter 1 of the *Using IDL* manual

# OPENR/OPENU/OPENW

The three OPEN procedures open a specified file for input and/or output.

- OPENR (OPEN Read) opens an existing file for input only.
- OPENW (OPEN Write) opens a new file for input and output. If the file exists, it is truncated and its old contents are destroyed.
- OPENU (OPEN Update) opens an existing file for input and output.

## Logical Unit Numbers and Application Development

Logical Unit Numbers (LUNs) are assigned to individual files when the files are opened by the IDL OPENR/OPENU/OPENW commands, and are used to specify which file IDL should read from or write to. There are a total of 128 LUNs available for assignment to files. While it is possible to assign any of the integers between 1-99 to a given file, when writing applications for others it is good programming practice to let IDL assign and manage the LUNs itself. By using the GET\_LUN keyword to the OPEN routines, you can ask IDL to assign a free Logical Unit Number between 100-128 to the specified file. Letting IDL assign the LUN from the list of free unit numbers ensures that your application does not attempt to use a LUN already in use by someone else's application. See the [GET\\_LUN](#) keyword for details. See “[Understanding \(LUNs\)](#)” in Chapter 18 of the *Building IDL Applications* manual for additional information on LUNs.

## Syntax

There are three forms of the OPEN procedure:

OPENR, *Unit*, *File*

OPENW, *Unit*, *File*

OPENU, *Unit*, *File*

**Keywords (all platforms):** [, /APPEND | , /COMPRESS]

[, BUFSIZE={0 | 1 | *value*>512}] [, /DELETE] [, ERROR=*variable*]

[, /F77\_UNFORMATTED] [, /GET\_LUN] [, /MORE] [, /NOEXPAND\_PATH]

[, /STDIO] [, /SWAP\_ENDIAN] [, /SWAP\_IF\_BIG\_ENDIAN]

[, /SWAP\_IF\_LITTLE\_ENDIAN] [, /VAX\_FLOAT] [, WIDTH=*value*] [, /XDR]

**UNIX-Only Keywords:** [, /RAWIO]

## Arguments

### Unit

The unit number to be associated with the opened file.

### File

A string containing the name of the file to be opened. Under UNIX, the filename can contain any wildcard characters recognized by the shell specified by the SHELL environment variable. However, it is faster not to use wildcards because IDL doesn't use the shell to expand file names unless it has to.

---

#### Note

The optional *Record\_Length* argument is obsolete, and should not be used in new code. See [Appendix J, “Obsolete Features”](#) for details.

---

## Keywords

---

#### Note

Platform-specific keywords are listed at the end of this section.

---

### APPEND

Set this keyword to open the file with the file pointer at the end of the file, ready for data to be appended. Normally, the file is opened with the file pointer at the beginning of the file. Under UNIX, use of APPEND prevents OPENW from truncating existing file contents. The APPEND and COMPRESS keywords are mutually exclusive and cannot be specified together.

### BUFSIZE

Set this keyword to a value greater than 512 to specify the size of the I/O buffer (in bytes) used when reading and writing files. Setting BUFSIZE=1 (or any other value less than 512) sets the buffer to the default size, which is platform-specific. Set BUFSIZE=0 to disable I/O buffering.

Note that the buffer size is only changeable when reading and writing stream files. Under UNIX, the RAWIO keyword must not be set. Also note that the system stdio may choose to ignore the buffer size setting.

## COMPRESS

If COMPRESS is set, IDL reads and writes all data to the file in the standard GZIP format. IDL's GZIP support is based on the freely available ZLIB library by Mark Adler and Jean-loup Gailly (see [www.zlib.org](http://www.zlib.org) for details). This means that IDL's compressed files are 100% compatible with the widely available gzip and gunzip programs. COMPRESS cannot be used with the APPEND keyword.

## DELETE

Set this keyword to delete the file when it is closed.

### Warning

---

Setting the DELETE keyword *causes the file to be deleted* even if it was opened for read-only access. In addition, once a file is opened with this keyword, there is no way to cancel its operation.

---

## ERROR

A named variable to place the error status in. If an error occurs in the attempt to open *File*, IDL normally takes the error handling action defined by the ON\_ERROR and/or ON\_IOERROR procedures. OPEN always returns to the caller without generating an error message when ERROR is present. A nonzero error status indicates that an error occurred. The error message can then be found in [!ERROR\\_STATE.MSG](#).

For example, statements similar to the following can be used to detect errors:

```
; Try to open the file demo.dat:
OPENR, 1, 'demo.dat', ERROR = err

; If err is nonzero, something happened. Print the error message to
; the standard error file (logical unit -2):
IF (err NE 0) then PRINTF, -2, !ERROR_STATE.MSG
```

## F77\_UNFORMATTED

Unformatted variable-length record files produced by FORTRAN programs running on platforms that use stream files (UNIX and Microsoft Windows) contain extra information along with the data in order to allow the data to be properly recovered. This method is necessary because FORTRAN input/output is based on record-oriented files, while files that are simple byte streams do not impose any record structure. Set the F77\_UNFORMATTED keyword to read and write this extra information in the same manner as `f77(1)`, so that data can be processed by both IDL and FORTRAN. See [“Reading and Writing FORTRAN Data”](#) in Chapter 18 of the *Building IDL Applications* manual for further details.

## GET\_LUN

Set this keyword to use the GET\_LUN procedure to set the value of *Unit* before the file is opened. Instead of using the two statements:

```
GET_LUN, Unit
OPENR, Unit, 'data.dat'
```

you can use the single statement:

```
OPENR, Unit, 'data.dat', /GET_LUN
```

## MORE

If MORE is set, and the specified *File* is a terminal, then all output to this unit is formatted in a manner similar to the UNIX `more(1)` command and sent to the standard output stream. Output pauses at the bottom of each screen, at which point the user can press one of the following keys:

- Space: Display the next page of text.
- Return: Display the next line of text.
- 'q' or 'Q': Suppress all remaining output.
- 'h' or 'H': Display this list of options.

For example, the following statements show how to output a file named `text.dat` to the terminal:

```
; Open the text file:
OPENR, inunit, 'text.dat', /GET_LUN

; Open the terminal as a file:
OPENW, outunit, '/dev/tty', /GET_LUN, /MORE

; Read the first line:
line = '' & READF, inunit, line

; While there is text left, output it:
WHILE ~ EOF(inunit) DO BEGIN
    PRINTF, outunit, line
    READF, inunit, line
ENDWHILE

; Close the files and deallocate the units:
FREE_LUN, inunit & FREE_LUN, outunit
```

## NOEXPAND\_PATH

Set this keyword to specify that the *File* argument be used exactly as supplied, without applying the usual file path expansion.

## RAWIO

*This keyword is only available on UNIX platforms.*

Set this keyword to disable all use of the standard UNIX I/O for the file, in favor of direct calls to the operating system. This allows direct access to devices, such as tape drives, that are difficult or impossible to use effectively through the standard I/O.

Using this keyword has the following implications:

- No formatted or associated (ASSOC) I/O is allowed on the file. Only READU and WRITEU are allowed.
- Normally, attempting to read more data than is available from a file causes the unfilled space to be set to zero and an error to be issued. This does not happen with files opened with RAWIO. When using RAWIO, the programmer must check the transfer count, either via the TRANSFER\_COUNT keywords to READU and WRITEU, or the FSTAT function.
- The EOF and POINT\_LUN functions cannot be used with a file opened with RAWIO.
- Each call to READU or WRITEU maps directly to UNIX read(2) and write(2) system calls. The programmer must read the UNIX system documentation for these calls and documentation on the target device to determine if there are any special rules for I/O to that device. For example, the size of data that can be transferred to many cartridge tape drives is often forced to be a multiple of 512 bytes.

## STDIO

Forces the file to be opened via the standard C I/O library (stdio) rather than any other more native OS API that might usually be used. This is primarily of interest to those who intend to access the file from external code, and is not necessary for most files.

**Note**

---

If you intend to use the opened file with the `READ_JPEG` or `WRITE_JPEG` procedures using their `UNIT` keyword, you must specify the `STDIO` keyword to `OPEN` to ensure that the file is compatible.

The only exception to this rule is if the filename ends in `.jpg` or `.jpeg` and the `STDIO` keyword is not present in the call to `OPEN`. In this case `OPEN` uses `stdio` by default, covering most uses of `jpeg` files without requiring you to take special steps.

---

**SWAP\_ENDIAN**

Set this keyword to swap byte ordering for multi-byte data when performing binary I/O on the specified file. This is useful when accessing files also used by another system with byte ordering different than that of the current host.

**SWAP\_IF\_BIG\_ENDIAN**

Setting this keyword is equivalent to setting `SWAP_ENDIAN`; it only takes effect if the current system has big endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

**SWAP\_IF\_LITTLE\_ENDIAN**

Setting this keyword is equivalent to setting `SWAP_ENDIAN`; it only takes effect if the current system has little endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

**VAX\_FLOAT**

The opened file contains VAX format floating point values. This keyword implies little endian byte ordering for all data contained in the file, and supersedes any setting of the `SWAP_ENDIAN`, `SWAP_IF_BIG_ENDIAN`, or `SWAP_IF_LITTLE_ENDIAN` keywords.

The default setting for this keyword is `FALSE`.

**Warning**

---

Please read [“Note on Accessing Data in VAX Floating Point Format”](#) on page 1631 before using this feature.

---

## WIDTH

The desired output width. If no output width is specified, IDL uses the following rules to determine where to break lines:

- If the output file is a terminal, the terminal width is used.
- Otherwise, a default of 80 columns is used.

## XDR

Set this keyword to open the file for unformatted XDR (eXternal Data Representation) I/O via the READU and WRITEU procedures. Use XDR to make binary data portable between different machine architectures by reading and writing all data in a standard format. When a file is open for XDR access, the only I/O data transfer procedures that can be used with it are READU and WRITEU. XDR is described in “[Portable Unformatted Input/Output](#)” in Chapter 18 of the *Building IDL Applications* manual.

## Note on Accessing Data in VAX Floating Point Format

The floating-point number format used by a program such as IDL is determined entirely by the computer hardware upon which it runs. In the early years of computing it was common for different machines to have incompatible floating-point formats. In the 1970s and 1980s, PDP-11 and VAX minicomputers were widely used for scientific computation, and their floating-point format (known as VAX F and D floating) became the *de facto* standard for science. Early versions of IDL used these formats.

In ensuing years, the computing industry has converged upon a floating-point standard known as IEEE 754, commonly referred to as “IEEE floating” or “IEEE arithmetic.” Other formats (including the VAX formats) have diminished in importance. Now, all common computing hardware uses the IEEE format, which has significant advantages over earlier formats:

- Binary data is portable to almost all current and foreseeable computing hardware and operating systems, requiring at most simple byte-swapping.
- Special *Infinity* and *Not A Number (NaN)* values for undefined computations allow exceptional computations to be carried out in a well-defined manner (and at full speed) by modern pipelined computer architectures.

This convergence gained momentum in the 1980s as workstations and personal computers came into prominence. As a result, almost all versions of IDL since 1987

have used IEEE floating point arithmetic, and all current versions of IDL use this format.

Despite the almost universal current use of the IEEE format, valuable older data stored in the VAX floating-point formats exists at various scientific institutions around the world. In order to allow access to this data, IDL is able to read and write data in these formats. The `VAX_FLOAT` keyword to the `OPEN` procedure is used to enable this feature.

When converting between VAX and IEEE formats, you should be aware of the following basic numerical issues in order to get the best results. Translation of floating-point values from IDL's native IEEE format to the VAX format and back (that is, VAX to IEEE to VAX) is not a completely reversible operation, and should be avoided when possible. There are many cases where the recovered values will differ from the original values, including:

- The VAX floating-point format lacks support for the IEEE special values (*NaN* and *Infinity*). Hence, their special meaning is lost when they are converted to VAX format and cannot be recovered.
- The IEEE and VAX floating formats have intrinsic differences in precision and range, which can cause information to be lost in both directions. When converting from one format to another, IDL rounds the value to the nearest representable value in the target format.

As a practical matter, an initial conversion of existing VAX format data to IEEE cannot be avoided if the data is to be used on modern machines. However, each format conversion can add a small amount of error to the resulting values, so it is important to minimize the number of such conversions. RSI recommends using IEEE/VAX conversions only to read existing VAX format data, and strongly recommends that all new files be created using the native IEEE format. This introduces only a single unavoidable conversion, and minimizes the resulting conversion error.

## Examples

The following example opens the IDL distribution file `people.dat` and reads an image from that file:

```
; Open 'people.dat' on file unit number 1. The FILEPATH
; function is used to return the full path name to this
; distribution file.
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])

; Define a variable into which the image will be read:
image=BYTARR(192, 192, /NOZERO)
```

```

; Read the data:
READU, 1, image

; Display the image:
TV, image

```

## Version History

Original	Introduced
Pre-6.2	Deprecated BINARY, BLOCK, DEFAULT, EXTENDSIZE, FIXED, FORTRAN, INITIALSIZE, KEYED, LIST, MACCREATOR, MACTYPE, NON, NOAUTOMODE, NOSTDIO, PRINT, SEGMENTED, SHARED, STREAM, SUBMIT, SUPERSEDE, TRUNCATE_ON_CLOSE, UDF_BLOCK, and VARIABLE keywords

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## See Also

# O PLOT

The OPLOT procedure plots vector data over a previously-drawn plot. It differs from PLOT only in that it does not generate a new axis. Instead, it uses the scaling established by the most recent call to PLOT and simply overlays a plot of the data on the existing axis.

## Syntax

```
O PLOT, [X,] Y [, MAX_VALUE=value] [, MIN_VALUE=value] [, NSUM=value]
  [, /POLAR] [, THICK=value]
```

**Graphics Keywords:** [, CLIP=[X<sub>0</sub>, Y<sub>0</sub>, X<sub>1</sub>, Y<sub>1</sub>]] [, COLOR=value]  
 [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, PSYM=integer{0 to 10}]  
 [, SYMSIZE=value] [, /T3D] [, ZVALUE=value{0 to 1}]

### Note

---

Many of the keyword parameters correspond directly to fields in the system variables !P, !X, !Y, or !Z. When specifying a keyword parameter name and value in a call that value affects only the current call, the corresponding system-variable field is not changed. Changing the value of a system-variable field changes the default for that particular parameter and remains in effect until explicitly changed. The system variables involving graphics and their corresponding keywords are detailed in “!P” in Appendix D.

---

## Arguments

### X

A vector argument. If X is not specified, Y is plotted as a function of point number (starting at zero). If both arguments are provided, Y is plotted as a function of X.

This argument is converted to double-precision floating-point before plotting. Plots created with OPLOT are limited to the range and precision of double precision floating-point values.

### Y

The ordinate data to be plotted. This argument is converted to double-precision floating-point before plotting.

## Keywords

### MAX\_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

### MIN\_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

### NSUM

The presence of this keyword indicates the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are  $m$  data points, then  $m/\text{NSUM}$  points are displayed. On logarithmic axes a geometric average is performed.

It is convenient to use NSUM when there is an extremely large number of data points to plot because it plots fewer points, the graph is less cluttered, and it is quicker.

### POLAR

Set this keyword to produce polar plots. The  $X$  and  $Y$  vector parameters, both of which must be present, are first converted from polar to Cartesian coordinates. The first parameter is the radius, and the second is expressed in radians.

For example, to make a polar plot, use the command:

```
O PLOT, /POLAR, R, THETA
```

### THICK

Controls the thickness of the lines connecting the points. A thickness of 1.0 is normal, 2.0 is double wide, etc.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

CLIP, COLOR, LINSTYLE, NOCLIP, PSYM, SYMSIZE, T3D, ZVALUE

## Examples

```

; Create a simple dataset:
D = SIN(FINDGEN(100)/EXP(FINDGEN(100)/50))

; Create an X-Y plot of vector D:
PLOT, D

; Overplot the sine of D as a thick, dashed line:
OPLOT, SIN(D), LINSTYLE = 5, THICK = 2

```

## Overplotting

Additional data can be added to existing plots with the OPLOT procedure. Each call to PLOT establishes the plot window (the rectangular area enclosed by the axes), the plot region (the box enclosing the plot window and its annotation), the axis types (linear or log), and the scaling. This information is saved in the system variables !P, !X, and !Y and used by subsequent calls to OPLOT.

Frequently, the color index, line style, or line thickness parameters are changed in each call to OPLOT to distinguish the data sets. The *IDL Reference Guide* contains a See “[LINSTYLE](#)” on page 4782 for a table describing the line style associated with each index.

The figure below illustrates a plot showing all four data sets. Each data set except the first was plotted with a different line style and was produced by a call to OPLOT. In this example, an (11, 4) array called ALLPTS is defined and contains all the scores for the four categories using the array concatenation operator. Once this array is defined, the IDL array operators and functions can be applied to the entire data set, rather than explicitly referencing the particular sample.

Figure 3-81: Overplotting Using Different Linestyles

First, we define an  $n$ -by-4 array containing all four sample vectors. (This array is also defined by the `plot01` batch file.)

```
ALLPTS = [[COHO], [SOCKEYE], [HUMPBACK], [CHINOOK]]
```

The plot in the preceding figure was produced with the following statements:

```
; Define variables:
@plot01
; Plot first graph. Set the y-axis min and max
; from the min and max of all data sets. Default linestyle is 0.
PLOT, YEAR, COHO, YRANGE = [MIN(ALLPTS), MAX(ALLPTS)], $
    TITLE='Salmon Populations', XTITLE = 'Year', $
    YTITLE = 'Fish (thousands)', XRANGE = [1975, 1983], $
    /XSTYLE
; Loop for the three remaining scores, varying the linestyle:
FOR I = 1, 3 DO OPLOT, YEAR, ALLPTS[*], I], LINE = I
```

**Note**

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the `examples/doc/plot` subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See [!PATH](#) for information on modifying IDL's path.

You can use the XYOUTS procedure to label data lines. See [XYOUTS](#) for the code needed to label each line of data in the previous example.

# OPLOTERR

The OPLOTERR procedure plots error bars over a previously drawn plot. A plot of  $X$  versus  $Y$  with error bars drawn from  $Y - Err$  to  $Y + Err$  is written to the output device over any plot already there.

This routine is written in the IDL language. Its source code can be found in the file `oploterr.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
OPLOTERR, [ X, ] Y, Err [, Psym ]
```

## Arguments

### X

An optional array of  $X$  values. The procedure checks whether or not the third parameter passed is a vector to decide if  $X$  was passed. If  $X$  is not passed, then `INDGEN(Y)` is assumed for the  $X$  values.

### Y

The array of  $Y$  values.  $Y$  cannot be of type string.

### Err

The array of error bar values.

### Psym

The plotting symbol to use (default = +7).

# P\_CORRELATE

The P\_CORRELATE function computes the partial correlation coefficient of a dependent variable and one particular independent variable when the effects of all other variables involved are removed.

To compute the partial correlation, the following method is used:

1. Let  $Y$  and  $X$  be the variables of primary interest and let  $C_1...C_p$  be the variables held fixed.
2. Calculate the residuals after regressing  $Y$  on  $C_1...C_p$ . (These are the parts of  $Y$  that cannot be predicted by  $C_1...C_p$ .)
3. Calculate the residuals after regressing  $X$  on  $C_1...C_p$ . (These are the parts of  $X$  that cannot be predicted by  $C_1...C_p$ .)
4. The partial correlation coefficient between  $Y$  and  $X$  adjusted for  $C_1...C_p$  is the correlation between these two sets of residuals.

This routine is written in the IDL language. Its source code can be found in the file `p_correlate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = P_CORRELATE( X, Y, C [, /DOUBLE] )
```

## Return Value

Returns the correlation coefficient.

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector that specifies the independent variable data.

### Y

An  $n$ -element integer, single-, or double-precision floating-point vector that specifies the dependent variable data.

**C**

An integer, single-, or double-precision floating-point array that specifies the independent variable data whose effects are to be removed. *C* may either be an *n*-element vector containing the independent variable, or a *p*-by-*n* two-dimensional array in which each column corresponds to a separate independent variable.

**Keywords****DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

**Examples**

```

; Define three sample populations:
X0 = [64, 71, 53, 67, 55, 58, 77, 57, 56, 51, 76, 68]
X1 = [57, 59, 49, 62, 51, 50, 55, 48, 52, 42, 61, 57]
X2 = [ 8, 10, 6, 11, 8, 7, 10, 9, 10, 6, 12, 9]

; Compute the partial correlation of X0 and X1 with the effects
; of X2 removed.
result = P_CORRELATE(X0, X1, X2)

PRINT, result

```

IDL prints:

```
0.533469
```

# PARTICLE\_TRACE

The `PARTICLE_TRACE` procedure traces the path of a massless particle through a vector field. The function allows the user to specify a set of starting points and a vector field. The input seed points can come from any vertex-producing process. The points are tracked by treating the vector field as a velocity field and integrating. Each path is tracked until the path leaves the input volume or a maximum number of steps is reached. The vertices generated along the paths are returned packed into a single array along with a polyline connectivity array. The polyline connectivity array organizes the vertices into separate paths (one per seed). Each path has an orientation. The initial orientation may be set using the `SEED_NORMAL` keyword. As a path is tracked, the change in the normal is also computed and may be returned to the user as an optional argument. Path output can be passed directly to an `IDLgrPolyline` object or passed to the `STREAMLINE` procedure for generation of orientated ribbons. Control over aspects of the integration (e.g. method or stepsize) is also provided.

## Syntax

```
PARTICLE_TRACE, Data, Seeds, Verts, Conn [, Normals]
    [, MAX_ITERATIONS=value] [, ANISOTROPY=array]
    [, INTEGRATION={0 | 1}] [, SEED_NORMAL=vector]
    [, TOLERANCE=value] [, MAX_STEPSIZE=value] [, /UNIFORM]
```

## Arguments

### Data

Input data array. This array can be of dimensions  $[2, dx, dy]$  for two-dimensional vector fields or  $[3, dx, dy, dz]$  for three-dimensional vector fields.

### Seeds

Input array of seed points ( $[3, n]$  or  $[2, n]$ ).

### Verts

Array of output path vertices ( $[3, n]$  or  $[2, n]$  array of floats).

### Conn

Output path connectivity array in `IDLgrPolyline POLYLINES` keyword format. There is one set of line segments in this array for each input seed point.

## Normals

Output normal estimate at each output vertex ( $[3, n]$  array of floats).

## Keywords

### ANISOTROPY

Set this input keyword to a two- or three- element array describing the distance between grid points in each dimension. The default value is  $[1.0, 1.0, 1.0]$  for three-dimensional data and  $[1.0, 1.0]$  for two-dimensional data.

### INTEGRATION

Set this keyword to one of the following values to select the integration method:

- 0 = 2nd order Runge-Kutta (the default)
- 1 = 4th order Runge-Kutta

### SEED\_NORMAL

Set this keyword to a three-element vector which selects the initial normal for the paths. The default value is  $[0.0, 0.0, 1.0]$ . This keyword is ignored for 2-D data.

### TOLERANCE

This keyword is used with adaptive step-size control in the 4th order Runge-Kutta integration scheme. It is ignored if the UNIFORM keyword is set or the 2nd order Runge-Kutta scheme is selected.

### MAX\_ITERATIONS

This keyword specifies the maximum number of line segments to return for each path. The default value is 200.

### MAX\_STEPSIZE

This keyword specifies the maximum path step size. The default value is 1.0.

## UNIFORM

If this keyword is set, the step size will be set to a fixed value, set via the `MAX_STEPSIZE` keyword. If this keyword is not specified, and `TOLERANCE` is either unspecified or inapplicable, then the step size is computed based on the velocity at the current point on the path according to the formula:

$$\text{stepsize} = \text{MIN}(\text{MaxStepSize}, \text{MaxStepSize}/\text{MAX}(\text{ABS}(U), \text{ABS}(V), \text{ABS}(W)))$$

where  $(U,V,W)$  is the local velocity vector.

# PATH\_CACHE

The `PATH_CACHE` procedure is used to control IDL's use of the *path cache*. By default, as IDL searches directories included in the `!PATH` system variable for `.pro` or `.sav` files to compile, it creates an in-memory list of *all* `.pro` and `.sav` files contained in each directory. When IDL later searches for a `.pro` or `.sav` file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process.

The path cache is enabled by default, and in almost all cases its operation is transparent to the IDL user, save for the boost in path searching speed it provides. Because the cache automatically adjusts to changes made to IDL's path, use of `PATH_CACHE` should not be necessary in typical IDL operation. It is provided to allow complete control over the details of how and when the caching operation is performed.

- For information on when the path cache is *not* used, see [“Situations in which IDL will not use the Path Cache”](#) on page 1648.
- For information on disabling the path cache, see [“Disabling the Path Cache”](#) on page 1649.

---

## Note

Prior to IDL 6.0, IDL did not use a path cache. Aside from the improvement in performance, the behavior of IDL with the path cache is identical to that without in almost all cases. The rare cases in which it differs, and options for disabling its use, are discussed in [“Options for Avoiding Use of the Path Cache”](#) on page 1650.

---

## About the Path Cache

The first time an IDL session attempts to call a function or procedure written in the IDL language, it must locate and compile the file containing the code for that routine. The file containing the routine must have the same name as the routine, with either a `.pro` or a `.sav` extension. After trying to open the file in the user's current working directory, IDL will attempt to open the file in each of the directories listed in the `!PATH` system variable, in the order specified by `!PATH`. The search stops when a file with the desired name is found or no directories remain in `!PATH`.

By default, IDL maintains an in-memory cache of the locations of `.pro` and `.sav` files stored in directories included in the `!PATH` system variable. The path cache is built automatically during normal operation, as IDL searches the directories specified by `!PATH`. Once a directory is cached, IDL knows whether or not it contains a given file, without the need to actually attempt to open that file. This information allows IDL to bypass directories that do not contain the desired file, providing a significant boost in the speed of path searching. The path cache can significantly improve the startup speed of large, object-oriented applications, because method resolution requires extensive path searching.

The path cache operates on a per-directory basis; if IDL searches a directory for a `.pro` or `.sav` file, the locations of *all* `.pro` and `.sav` files in that directory are added to the cache, and the directory is not searched again until the cache is cleared and rebuilt.

---

**Note**

The current contents of the path cache can be viewed using the `PATH_CACHE` keyword to the `HELP` procedure.

---

## Syntax

```
PATH_CACHE[, /CLEAR] [, /ENABLE] [, /REBUILD]
```

## Arguments

None.

## Keywords

### CLEAR

Set this keyword to clear the entire contents of the path cache, leaving it completely empty. If path caching is enabled, IDL will begin rebuilding the cache the next time it needs to locate a `.pro` or `.sav` file. If you wish to prevent the rebuilding of the cache, set the `ENABLE` keyword equal to zero as well.

---

**Note**

The `.RESET_SESSION` executive command clears the entire path cache as part of resetting the IDL session.

---

## ENABLE

Set this keyword to a non-zero value to specify that IDL should use the path cache when searching for files and also add new directories to the cache as they are opened. Set this keyword to zero to disable use of the cache when searching for files, and to discontinue adding new directories.

---

### Note

Disabling the cache does not cause the current contents of the cache to be discarded. To discard the cache information, specify the CLEAR keyword.

---

## REBUILD

Set this keyword to discard the current contents of the path cache (as if the CLEAR keyword had been specified), and then immediately rebuild the cache by searching the directories specified by the current value of the !PATH system variable for .pro and .sav files.

---

### Note

If !PATH contains many directories, or if access to those directories is slow, rebuilding the cache using this method may also be slow. In many cases, the CLEAR keyword is sufficient, since IDL will rebuild the empty cache as program execution requires it to search for .pro and .sav files.

---

## Situations in which IDL will not use the Path Cache

By default, IDL uses the path cache whenever it tries to locate .pro or .sav files. However, IDL will never use the path cache in the following situations:

### Current Working Directory

The path cache is neither checked nor added to if the file being searched for exists in the current working directory. Before IDL searches !PATH for a file to compile, it always looks in the current working directory without checking the cache.

### Relative Paths

The path cache does not cache directories specified relative to the current directory, even though relative paths are allowed in the specification of !PATH.

An absolute (or *fully qualified*) path is a path that completely specifies the location of a file. Under UNIX, an absolute path is specified relative to the root of the filesystem, and therefore starts with a slash (/) character. Under Microsoft Windows, an absolute

path starts with a drive letter (C:, for example) or a double backslash (\\) (if the file is specified using the Universal Naming Convention format). In contrast, a relative path is incomplete, and must be interpreted relative to the current working directory of the IDL process. IDL only caches absolute paths.

## Executive Commands

The path cache is neither checked nor added to when a `.COMPILE` or `.RUN` executive command is issued. In such cases, IDL performs a standard directory-by-directory search of the directories included in `!PATH`.

## IDL\_NOCACHE File Present

IDL will not cache the contents of any directory that contains a file named `IDL_NOCACHE`. See [“Marking Specific Directories as Uncacheable”](#) on page 1650 for additional information on this feature.

## Path Cache Disabled

IDL will neither check nor add files to the path cache if it has been disabled. See [“Disabling the Path Cache”](#), below, for additional information.

## Disabling the Path Cache

By default, IDL caches the locations of `.pro` and `.sav` files in all directories specified by the `!PATH` system variable. Use of the path cache can be fully disabled in the following ways:

1. By issuing the `PATH_CACHE` command with the `ENABLE` keyword set equal to zero. This will disable the path cache until you manually re-enable it, or for the duration of the current IDL session. See the description of the `ENABLE` keyword, above, for details.
2. By unchecking the “Enable Path Caching” checkbox on the Path tab of the IDLDE Preferences dialog. See [“Path Preferences”](#) in Chapter 3 of the *Using IDL* manual for details.
3. By defining setting the `IDL_PATH_CACHE_DISABLE` preference to true. See [Appendix E, “IDL Preferences”](#) for details.

In addition, you can selectively disable use of the path cache for specific directories by creating a file named `IDL_NOCACHE` in the directory. See [“Marking Specific Directories as Uncacheable”](#) for details.

## Marking Specific Directories as Uncacheable

You can mark specific directories as being uncacheable even though the directory is included in `!PATH`. To do so, create a file named `IDL_NOCACHE` in that directory.

---

**Note**

IDL does not inspect the contents of an `IDL_NOCACHE` file; it can contain anything you wish, or nothing at all. Under Unix operating systems, the `IDL_NOCACHE` file must be named exactly as shown, using all uppercase characters in the name. Under Microsoft Windows, the characters can have any case, but RSI suggests you use upper case for consistency.

---

When IDL encounters a directory containing an `IDL_NOCACHE` file during normal path searching, it makes a special entry in the path cache telling it that the directory must not be cached. Once this is done, all future attempts to locate files in that directory will be done without using cached information.

---

**Note**

If the directory to which you add an `IDL_NOCACHE` file has already been added to the path cache for the current IDL session, you must clear the existing cache (using the `CLEAR` keyword to the `PATH_CACHE` procedure) before the no-cache setting will take effect.

---

To re-enable path caching for a directory that has been marked as uncacheable, remove the `IDL_NOCACHE` file, and then reset IDL's path cache in one of the following ways:

- Specify the `CLEAR` keyword to the `PATH_CACHE` procedure.
- Issue the `.RESET_SESSION` executive command.
- Exit and restart the IDL session.

## Options for Avoiding Use of the Path Cache

In most cases, the files contained in directories included in `!PATH` do not change during an IDL session. In such cases the path cache is completely transparent to the IDL user, and serves only to speed compilation of IDL routines. As a result, there is rarely a reason to globally disable the path cache.

If files are created or deleted in a directory included in `!PATH` during an IDL session, the path cache can become confused and provide bad information to IDL about the contents of that directory. There are several ways to handle this situation. The

following list of alternatives is given in rough order of preference, with the easiest and lowest-impact options given first:

1. Leave the path cache enabled, and change your current working directory to the directory in which files are created or deleted. Since IDL checks the current working directory before checking the directories in !PATH, use of the path cache does not affect IDL's ability to find these files.
2. If the addition or deletion of files in a directory included in !PATH is a rare occurrence, leave the path cache enabled and clear it in one of the following ways after the contents of the directory have changed:
  - Specify the CLEAR keyword to the PATH\_CACHE procedure.
  - Issue the .RESET\_SESSION executive command.
  - Exit and restart the IDL session.
3. Leave the path cache enabled and use the .COMPILE or .RUN executive commands to force the compilation of any file, regardless of the contents of the path cache.
4. If you have a directory (other than your current working directory) in which files are regularly added or deleted during the execution of IDL sessions, you can leave path caching enabled but explicitly disable caching of that specific directory by creating an IDL\_NOCACHE file, as described in [“Marking Specific Directories as Uncacheable”](#) on page 1650. This approach works for all IDL sessions that access the directory, and is therefore convenient in long-term or multi-user situations.
5. You can completely disable operation of the path cache using one of the methods described under [“Disabling the Path Cache”](#) on page 1649. This is not recommended, because most directories are not dynamic, and completely disabling path caching sacrifices the performance advantages of caching directories whose contents *are* static.

## Note on Behavior at Startup

Depending on the value of your !PATH system variable, you may notice that some directories are being cached immediately when IDL starts up. This will occur if your path definition string includes the <IDL\_DEFAULT> token, or if one or more entries include the “+” symbol. In these cases, in order for IDL to build the !PATH system variable, it must inspect subdirectories of the specified directories for the presence of .pro and .sav files, with the side effect of adding these directories to the path cache. See EXPAND\_PATH for a discussion of IDL's path expansion behavior.

## Examples

The following statement disables path caching for the current session:

```
PATH_CACHE, ENABLE = 0
```

The following statement disables path caching for the current session and throws away the current contents of the cache:

```
PATH_CACHE, ENABLE = 0, /CLEAR
```

Suppose you want to remove a directory included in !PATH from the cache without resetting your IDL session. The following statements cause the specified directory not to be included in future caching by creating a file named IDL\_NOCACHE in that directory:

```
OPENW, UNIT = u, '/home/idluser/idl_dev_dir/IDL_NOCACHE', /GET_LUN
FREE_LUN, u
```

The OPENW and FREE\_LUN statements create an empty file with the desired name in the target directory. Executing the following statement clears the cache so as to reflect the change in the current IDL session:

```
PATH_CACHE, /CLEAR
```

The next time IDL encounters this directory in a path search, it will see the presence of the IDL\_NOCACHE and make a note in the path cache that the directory is not cacheable.

### Note

You can also create the IDL\_NOCACHE file outside IDL using any convenient command (text editor, Unix touch command, *etc.*). If the file is created outside IDL, only the PATH\_CACHE, /CLEAR statement is necessary.

# PATH\_SEP

The `PATH_SEP` function returns the proper file path segment separator character for the current operating system. This is the character used by the host operating system for delimiting subdirectory names in a path specification. Use this function instead of hard-coding separators to make code more portable.

This routine is written in the IDL language. Its source code can be found in the file `path_sep.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = PATH_SEP( [, /PARENT_DIRECTORY] [, /SEARCH_PATH] )
```

## Return Value

Returns a string containing the specified separator character.

## Arguments

None.

## Keywords

Specify at most one of the following keywords:

### PARENT\_DIRECTORY

If set, `PATH_SEP` returns the standard directory notation used by the host operating system to indicate the parent of a directory.

### SEARCH\_PATH

If set, `PATH_SEP` returns the character used to separate entries in a search path.

# PCOMP

The PCOMP function computes the principal components of an  $m$ -column,  $n$ -row array, where  $m$  is the number of variables and  $n$  is the number of observations or samples. The principal components of a multivariate data set may be used to restate the data in terms of derived variables or may be used to reduce the dimensionality of the data by reducing the number of variables (columns).

This routine is written in the IDL language. Its source code can be found in the file `pcomp.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = PCOMP( A [, COEFFICIENTS=variable] [, /COVARIANCE]  
               [, /DOUBLE] [, EIGENVALUES=variable] [, NVARIABLES=value]  
               [, /STANDARDIZE] [, VARIANCES=variable] )
```

## Return Value

The result is an  $nvariables$ -column ( $nvariables \leq m$ ),  $n$ -row array of derived variables.

## Arguments

### A

An  $m$ -column,  $n$ -row, single- or double-precision floating-point array.

## Keywords

### COEFFICIENTS

Use this keyword to specify a named variable that will contain the principal components used to compute the derived variables. The principal components are the coefficients of the derived variables and are returned in an  $m$ -column,  $m$ -row array. The rows of this array correspond to the coefficients of the derived variables. The coefficients are scaled so that the sums of their squares are equal to the eigenvalue from which they are computed.

## COVARIANCE

Set this keyword to compute the principal components using the covariances of the original data. The default is to use the correlations of the original data to compute the principal components.

## DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE=0`.

## EIGENVALUES

Use this keyword to specify a named variable that will contain a one-column, *m*-row array of eigenvalues that correspond to the principal components. The eigenvalues are listed in descending order.

## NVARIABLES

Use this keyword to specify the number of derived variables. A value of zero, negative values, and values in excess of the input array's column dimension result in a complete set (*m*-columns and *n*-rows) of derived variables.

## STANDARDIZE

Set this keyword to convert the variables (the columns) of the input array to standardized variables (variables with a mean of zero and variance of one).

## VARIANCES

Use this keyword to specify a named variable that will contain a one-column, *m*-row array of variances. The variances correspond to the percentage of the total variance for each derived variable.

## Examples

```
PRO ex_pcomp
;Define an array with 4 variables and 20 observations.
array = [[19.5, 43.1, 29.1, 11.9], $
         [24.7, 49.8, 28.2, 22.8], $

# PLOT

The PLOT procedure draws graphs of vector arguments. If one parameter is used, the vector parameter is plotted on the ordinate versus the point number on the abscissa. To plot one vector as a function of another, use two parameters. PLOT can also be used to create polar plots by setting the POLAR keyword.

## Syntax

```
PLOT, [X,] Y [, /ISOTROPIC] [, MAX_VALUE=value] [, MIN_VALUE=value]
  [, NSUM=value] [, /POLAR] [, THICK=value] [, /XLOG] [, /YLOG]
  [, /YNOZERO]
```

```
Graphics Keywords: [, BACKGROUND=color_index] [, CHARSIZE=value]
  [, CHARTHICK=integer] [, CLIP=[X0, Y0, X1, Y1]] [, COLOR=value] [, /DATA |
  /DEVICE | /NORMAL] [, FONT=integer] [, LIFESTYLE={0 | 1 | 2 | 3 | 4 | 5}]
  [, /NOCLIP] [, /NODATA] [, /NOERASE] [, POSITION=[X0, Y0, X1, Y1]]
  [, PSYM=integer{0 to 10}] [, SUBTITLE=string] [, SYMSIZE=value] [, /T3D]
  [, THICK=value] [, TICKLEN=value] [, TITLE=string]
  [, {X | Y | Z}CHARSIZE=value]
  [, {X | Y | Z}GRIDSTYLE=integer{0 to 5}]
  [, {X | Y | Z}MARGIN=[left, right]]
  [, {X | Y | Z}MINOR=integer]
  [, {X | Y | Z}RANGE=[min, max]]
  [, {X | Y | Z}STYLE=value]
  [, {X | Y | Z}THICK=value]
  [, {X | Y | Z}TICK_GET=variable]
  [, {X | Y | Z}TICKFORMAT=string]
  [, {X | Y | Z}TICKINTERVAL= value]
  [, {X | Y | Z}TICKLAYOUT=scalar]
  [, {X | Y | Z}TICKLEN=value]
  [, {X | Y | Z}TICKNAME=string_array]
  [, {X | Y | Z}TICKS=integer]
  [, {X | Y | Z}TICKUNITS=string]
  [, {X | Y | Z}TICKV=array]
  [, {X | Y | Z}TITLE=string]
  [, ZVALUE=value{0 to 1}]
```

## Arguments

### X

A vector argument. If X is not specified, Y is plotted as a function of point number (starting at zero). If both arguments are provided, Y is plotted as a function of X.

This argument is converted to double precision floating-point before plotting. Plots created with PLOT are limited to the range and precision of double-precision floating-point values.

### Y

The ordinate data to be plotted. This argument is converted to double-precision floating-point before plotting.

## Keywords

### ISOTROPIC

Set this keyword to force the scaling of the X and Y axes to be equal.

---

**Note**

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See [“POSITION”](#) on page 4784 for more information.

---

### MAX\_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

### MIN\_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## NSUM

The presence of this keyword indicates the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are  $m$  data points, then  $m/\text{NSUM}$  points are displayed. On logarithmic axes a geometric average is performed.

It is convenient to use NSUM when there is an extremely large number of data points to plot because it plots fewer points, the graph is less cluttered, and it is quicker.

## POLAR

Set this keyword to produce polar plots. The  $X$  and  $Y$  vector parameters, both of which must be present, are first converted from polar to Cartesian coordinates. The first parameter is the radius, and the second is the angle (expressed in radians). For example, to make a polar plot, you would use a command such as:

```
PLOT, /POLAR, R, THETA
```

### Note

---

See [“Using AXIS with Polar Plots”](#) on page 131 for an example that adds axes to a polar plot.

---

## THICK

Controls the thickness of the lines connecting the points. A thickness of 1.0 is normal, 2 is double wide, etc.

## XLOG

Set this keyword to specify a logarithmic  $X$  axis, producing a log-linear plot. Set both XLOG and YLOG to produce a log-log plot. Note that logarithmic axes that have ranges of less than a decade are not labeled.

## YLOG

Set this keyword to specify a logarithmic  $Y$  axis, producing a linear-log plot. Set both XLOG and YLOG to produce a log-log plot. Note that logarithmic axes that have ranges of less than a decade are not labeled.

## YNOZERO

Set this keyword to inhibit setting the minimum  $Y$  axis value to zero when the  $Y$  data are all positive and nonzero, and no explicit minimum  $Y$  value is specified (using YRANGE, or !Y.RANGE). By default, the  $Y$  axis spans the range of 0 to the

maximum value of *Y*, in the case of positive *Y* data. Set bit 4 in `!Y.STYLE` to make this option the default.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

`BACKGROUND`, `CHARSIZE`, `CHARTHICK`, `CLIP`, `COLOR`, `DATA`, `DEVICE`,  
`FONT`, `LINestyle`, `NOCLIP`, `NODATA`, `NOERASE`, `NORMAL`, `POSITION`,  
`PSYM`, `SUBTITLE`, `SYMSIZE`, `T3D`, `THICK`, `TICKLEN`, `TITLE`,  
`[XYZ]CHARSIZE`, `[XYZ]GRIDSTYLE`, `[XYZ]MARGIN`, `[XYZ]MINOR`,  
`[XYZ]RANGE`, `[XYZ]STYLE`, `[XYZ]THICK`, `[XYZ]TICKFORMAT`,  
`[XYZ]TICKINTERVAL`, `[XYZ]TICKLAYOUT`, `[XYZ]TICKLEN`,  
`[XYZ]TICKNAME`, `[XYZ]TICKS`, `[XYZ]TICKUNITS`, `[XYZ]TICKV`,  
`[XYZ]TICK_GET`, `[XYZ]TITLE`, `ZVALUE`

---

### Note

Many of the graphic keyword parameters correspond directly to fields in the system variables `!P`, `!X`, `!Y`, or `!Z`. When specifying a keyword parameter name and value in a call that value affects only the current call, the corresponding system-variable field is not changed. Changing the value of a system-variable field changes the default for that particular parameter and remains in effect until explicitly changed. The system variables involving graphics and their corresponding keywords are detailed in [“!P”](#) in Appendix D.

---

## Examples

[“Axis Scaling”](#) on page 1665

[“Logarithmic Scaling”](#) on page 1674

[“Multiline Titles”](#) on page 1666

[“Multiple Plots on a Page”](#) on page 1675

[“Range Keyword”](#) on page 1667

[“Specifying the Location of the Plot”](#) on page 1677

[“Plotting Symbols”](#) on page 1669

[“Plotting Missing Data”](#) on page 1678

**Note**

Several of the following examples use batch files. See [“Running the Example Code”](#) on page 40 if IDL does not find the batch file.

**Simple Plot**

The PLOT procedure has many keywords that allow you to create a vast variety of plots. Here are a few simple examples using the PLOT command.

```

; Create a simple dataset:
D = FINDGEN(100)

; Create a simple plot with the title "Simple Plot":
PLOT, D, TITLE = 'Simple Plot'

; Plot one argument versus another:
PLOT, SIN(D/3), COS(D/6)

; Create a polar plot:
PLOT, D, D, /POLAR, TITLE = 'Polar Plot'

; Use plotting symbols instead of connecting lines by including the
; PSYM keyword. Label the X and Y axes with XTITLE and YTITLE:
PLOT, SIN(D/10), PSYM=4, XTITLE='X Axis', YTITLE='Y Axis'

```

**X Versus Y Plots**

This section illustrates the use of the basic *x* versus *y* plotting routines, PLOT and OPLOT. PLOT produces linear-linear plots by default, and can produce linear-log, log-linear, or log-log plots with the addition of the XLOG and YLOG keywords.

Data used in these examples are from a fictitious study of Pacific Northwest Salmon fisheries. In the example, we suppose that data were collected in the years 1967, 1970, and from 1975 to 1983. The following IDL statements create and initialize the variables SOCKEYE, COHO, CHINOOK, and HUMPBACK, which contain fictitious fish population counts, in thousands, for the 11 observations:

```

SOCKEYE=[463, 459, 437, 433, 431, 433, 431, 428, 430, 431, 430]
COHO=[468, 461, 431, 430, 427, 425, 423, 420, 418, 421, 420]
CHINOOK=[514, 509, 495, 497, 497, 494, 493, 491, 492, 493, 493]
HUMPBACK=[467, 465, 449, 446, 445, 444, 443, 443, 443, 443, 445]
; Construct a vector in which each element contains
; the year of the sample:
YEAR = [1967, 1970, INDGEN(9) + 1975]

```

### Example Code

If you prefer not to enter the data by hand, run the batch file `plot01`, located in the `examples/doc/plot` subdirectory of the IDL installation directory with the following command at the IDL prompt:

```
@plot01
```

The following IDL commands create a plot of the population of Sockeye salmon, by year:

```
PLOT, YEAR, SOCKEYE, $
    TITLE='Sockeye Population', XTITLE='Year', $
    YTITLE='Fish (thousands)'
```

The PLOT procedure, which produces an  $x$  versus  $y$  plot on a new set of axes, requires one or two parameters: a vector of  $y$  values or a vector of  $x$  values followed by a vector of  $y$  values. The first attempt at making a plot produces the figure shown below. Note that the three titles, defined by the keywords TITLE, XTITLE, and YTITLE, are optional.

Figure 3-82: Initial Population Plot

### Axis Scaling

The fluctuations in the data are hard to see because the scores range from 428 to 463, and the plot's  $y$ -axis is scaled from 0 to 500. Two factors cause this effect. By default,

IDL sets the minimum y-axis value of linear plots to zero if the y data are all positive. The maximum axis value is automatically set by IDL from the maximum y data value. In addition, IDL attempts to produce from three to six tick-mark intervals that are in increments of an integer power of 10 times 2, 2.5, 5, or 10. In this example, this rounding effect causes the maximum axis value to be 500, rather than 463.

The YNOZERO keyword parameter inhibits setting the y-axis minimum to zero when given positive, nonzero data. The figure below illustrates the data plotted using this keyword. The y-axis now ranges from 420 to 470, and IDL creates tick-mark intervals of 10.

Figure 3-83: Properly Scaled Plot

```

; Define variables:
@plot01
PLOT, YEAR, SOCKEYE, /YNOZERO, $
    TITLE='Sockeye Population', XTITLE='Year', $
    YTITLE='Fish (thousands) '

```

## Multiline Titles

The graph-text positioning command !C, starts a new line of text output. Titles containing more than one line of text are easily produced by separating each line with this positioning command.

In the above example, the main title could have been displayed on two centered lines by changing the keyword parameter `TITLE` to the following statement:

```
TITLE = 'Sockeye!CPopulation'
```

---

**Note**

When using multiple line titles you may find that the default margins are inadequate, causing the titles to run off the page. In this case, set the `[XY]MARGIN` keywords or increase the values of `!X.MARGIN` or `!Y.MARGIN`.

---

## Range Keyword

The range of the  $x$ ,  $y$ , or  $z$  axes can be explicitly specified with the `[XYZ] RANGE` keyword parameter. The argument of the keyword parameter is a two-element vector containing the minimum and maximum axis values.

As explained above, IDL attempts to produce even tick intervals, and the axis range selected by IDL may be slightly larger than that given with the `RANGE` keyword. To obtain the exact specified interval, set the axis style parameter to one (`YSTYLE = 1`).

The effect of the `YNOZERO` keyword is identical to that obtained by including the keyword parameter `YRANGE = [MIN(Y), MAX(Y)]` in the call to `PLOT`. You can make `/YNOZERO` the default in subsequent plots by setting bit 4 of `!Y.STYLE` to one (`!Y.STYLE = 16`).

See “[STYLE](#)” on page 4837 for details on the `STYLE` field of the axis system variables `!X`, `!Y`, and `!Z`. Briefly: Other bits in the `STYLE` field extend the axes by providing a margin around the data, suppress the axis and its notation, and suppress the box-style axes by drawing only left and bottom axes.

For example, to constrain the x-axis to the years 1975 to 1983, the keyword parameter `XRANGE = [1975, 1983]` is included in the call to `PLOT`. The following figure illustrates the result.

*Figure 3-84: Plot with X-Axis Range of 1975 to 1983*

Note that the *x*-axis actually extends from 1974 to 1984, as IDL elected to make five tick-mark intervals, each spanning two years. If, as explained above, the *x*-axis style is set to one, the plot will exactly span the given range. The call combining all these options is as follows:

```

; Define variables:
@plot01
PLOT, YEAR, SOCKEYE, /YNOZERO, $
    TITLE='Sockeye Population', XTITLE = 'Year', $
    YTITLE = 'Fish (thousands)', XRANGE = [1975, 1983], /XSTYLE

```

---

### Note

The keyword parameter syntax `/XSTYLE` is synonymous with the expression `XSTYLE = 1`. Setting a keyword parameter to 1 is often referred to as simply setting the keyword.

---

## Plotting Symbols

Each data point can be marked with a symbol and/or connected with lines. The value of the keyword parameter PSYM selects the marker symbol, as described in “PSYM” on page 4784. For example, a value of 1 marks each data point with the plus sign (+), 2 is an asterisk (\*), etc. Setting PSYM to minus the symbol number marks the points with a symbol and connects them with lines. A value of  $-1$  marks points with a plus sign (+) and connects them with lines. Note also that setting PSYM to a value of 10 produces histogram style plots in which a horizontal line is drawn across each  $x$  bin.

Frequently, when data points are plotted against the results of a fit or model, symbols are used to mark the data points while the model is plotted using a line. The figure below illustrates this, fitting the Sockeye population values to a quadratic function of the year. The IDL function POLY\_FIT is used to calculate the quadratic.

Figure 3-85: Plotting with Predefined Marker Symbols

The statements used to construct the above plot are as follows:

```

; Define variables.
@plot01
; Use the LINFIT function to fit the data to a line:
coeff = LINFIT(YEAR, SOCKEYE)
; YFIT is the fitted line:
YFIT = coeff[0] + coeff[1]*YEAR

```

```

; Plot the original data points with PSYM = 4, for diamonds:
PLOT, YEAR, SOCKEYE, /YNOZERO, PSYM = 4, $
    TITLE = 'Quadratic Fit', XTITLE = 'Year', $
    YTITLE = 'Sockeye Population'
; Overplot the smooth curve using a plain line:
OPLLOT, YEAR, YFIT

```

### Example Code

Alternatively, you can run the `plot03` batch file to create the plot by entering:  
`@plot03`

## Bar Charts

Bar (or box) charts are used in business-style graphics and are useful in comparing a small number of measurements within a few discrete data sets. Although not designed as a tool for business graphics, IDL can produce many business-style plots with little effort.

The following example produces a box-style chart showing the four salmon populations as boxes of differing colors or shading. The commands used to draw the next figure are shown below with annotation.

Figure 3-86: Bar Chart Drawn with `POLYFILL`

**Example Code**

You do not need to type these commands in yourself; they are collected in the files `plot05.pro`, which contains the two procedures, and the batch file, `plot06`, which creates the plot. These files are located in the `examples/doc/plot` subdirectory of the IDL distribution.

First, we define a procedure called `BOX`, which draws a box given the coordinates of two diagonal corners:

```
; Define a procedure that draws a box, using POLYFILL,
; whose corners are (X0, Y0) and (X1, Y1):
PRO BOX, X0, Y0, X1, Y1, color
    ; Call POLYFILL:
    POLYFILL, [X0, X0, X1, X1], [Y0, Y1, Y1, Y0], COL = color
END
```

Next, create a procedure to draw the bar graph:

```
PRO BARGRAPH, minval
    ; Define variables:
    @plot01
    ; Width of bars in data units:
    del = 1./5.
    ; The number of colors used in the bar graph is
    ; defined by the number of colors available on your system:
    ncol=!D.N_COLORS/5
    ; Create a vector of color indices to be used in this procedure:
    colors = ncol*INDGEN(4)+ncol
    ; Loop for each sample:
    FOR iscore = 0, 3 DO BEGIN
        ; The y value of annotation. Vertical separation is 20 data
        ; units:
        yannot = minval + 20 *(iscore+1)
        ; Label for each bar:
        XYOUTS, 1984, yannot, names[iscore]
        ; Bar for annotation:
        BOX, 1984, yannot - 6, 1988, yannot - 2, colors[iscore]
        ; The x offset of vertical bar for each sample:
        xoff = iscore * del - 2 * del
        ; Draw vertical box for each year's sample:
        FOR iy=0, N_ELEMENTS(year)-1 DO $
            BOX, year[iy] + xoff, minval, $
            year[iy] + xoff + del, $
            allpts[iy, iscore], $
            colors[iscore]
        ENDFOR
    END
END
```

Enter the following at the IDL prompt to compile these two procedures from the IDL distribution:

```
.run plot05.pro
```

To create the bar graph on your screen, enter the following commands.

```
; Load a color table:
LOADCT, 39
```

As in the previous example, the PLOT procedure is used to draw the axes and to establish the scaling using the NODATA keyword.

```
PLOT, year, CHINOOK, YRANGE = [MIN(allpts),MAX(allpts)], $
    TITLE = 'Salmon Populations', /NODATA, $
    XRANGE = [year[0], 1990]
; Get the y value of the bottom x-axis:
minval = !Y.CRANGE[0]
; Create the bar chart:
BARGRAPH, minval
```

## Specifying Tick Marks

The following figure shows a box chart illustrating the direct specification of the  $x$ -axis tick values, number of ticks, and tick names. Building upon the previous program, this program shows each of the four scores for the year 1967, the first year in our data. It uses the BOX procedure from the previous example to draw a rectangle for each sample.

Figure 3-87: Controlling Tick Marks and Their Annotation

Enter the following command at the IDL prompt to compile the BOX and BARGRAPH procedures (discussed in the previous example) from the IDL distribution:

```
.run plot05.pro
```

Enter the following commands to create the box chart:

```
; Define variables:
@plot01
; Tick x values, 0.2, 0.4, 0.6, 0.8:
XVAL = FINDGEN(4)/5. + .2
; Make a vector of scores from first year, corresponding to
; the name vector from above:
YVAL = [COHO[0], SOCKEYE[0], HUMPBACK[0], CHINOOK[0]]
; Make the axes with no data. Force x range to [0, 1],
; centering xval, which also contains the tick values.
; Force three tick intervals making four tick marks.
; Specify the tick names from the names vector:
PLOT, XVAL, YVAL, /YNOZERO, XRANGE = [0,1], XTICKV = XVAL, $
    XTICKS = 3, XTICKNAME = NAMES, /NODATA, $
    TITLE = 'Salmon Populations, 1967'
; Draw the boxes, centered over the tick marks.
; !Y.CRANGE[0] is the y value of the bottom x-axis.
FOR I = 0, 3 DO BOX, XVAL[I] - .08, !Y.CRANGE[0], $
    XVAL[I] + 0.08, YVAL[I], 128
```

### Example Code

---

Alternatively, you can enter @plot07 at the IDL command prompt to run the plot07 batch file and create the plot.
