You can display date/time data on plots, contours, and surfaces through the tick settings of the date/time axis. Date/time data can be displayed on any axis (x, y or z). The date/time data is stored as Julian dates, but the LABEL\_DATE routine and axis keywords allow you to display this data as calendar dates. See [LABEL\\_DATE](#) for examples.

---

## Logarithmic Scaling

The XLOG, YLOG, and ZLOG keywords can be used with the PLOT routine to get any combination of linear and logarithmic axes. The OPLOT procedure uses the same scaling and transformation as did the most recent plot.

*Figure 3-88: Example of Logarithmic Scaling*

The figure illustrates using PLOT to make a linear-log plot. It was produced with the following statements:

```

; Create data array:
X = FLTARR(256)
; Make a step function. Array elements 80 through 120 are set to 1:
X[80:120] = 1
; Make a filter:
FREQ = FINDGEN(256)
; Make the filter symmetrical about the value x = 128:
FREQ = FREQ < (256-FREQ)
; Second order Butterworth, cutoff frequency = 20.
FIL = 1./(1+(FREQ/20)^2)
; Plot with a logarithmic x-axis. Use exact axis range:
PLOT, /YLOG, FREQ, ABS(FFT(X,1)), $
      XTITLE = 'Relative Frequency', YTITLE = 'Power', $
      XSTYLE = 1
; Plot graph:
OPLOT, FREQ, FIL

```

### Example Code

---

Alternatively, you can run the `plot08` batch file to create the plot:

```
@plot08
```

---

## Multiple Plots on a Page

Plots can be grouped on the display or page in the horizontal and/or vertical directions using the system variable field `!P.MULTI`. IDL sets the plot window to produce the given number of plots on each page and moves the window to a new sector at the beginning of each plot. If the page is full, it is first erased. If more than two rows or columns of plots are produced, IDL decreases the character size by a factor of 2.

`!P.MULTI` controls the output of multiple plots. Set `!P.MULTI` equal to an integer vector in which:

- The first element of the vector contains the number of empty sectors remaining on the page. The display is erased if this field is zero when a new plot is begun.
- The second element of the vector contains the number of plots per page in the horizontal direction.
- The third element contains the number of plots per page in the vertical direction.
- The fourth element contains the number of plots stacked in the Z dimension.
- The fifth element controls the order in which plots are drawn. Set the fifth element equal to zero to make plots from left to right (column major), and top to bottom. Set the fifth element equal to one to make plots from top to bottom, left to right (row major).

Omitting any of the five elements from the vector is the same as setting that element equal to zero.

For example, to set up IDL to stack two plots vertically on each page, use the following statement:

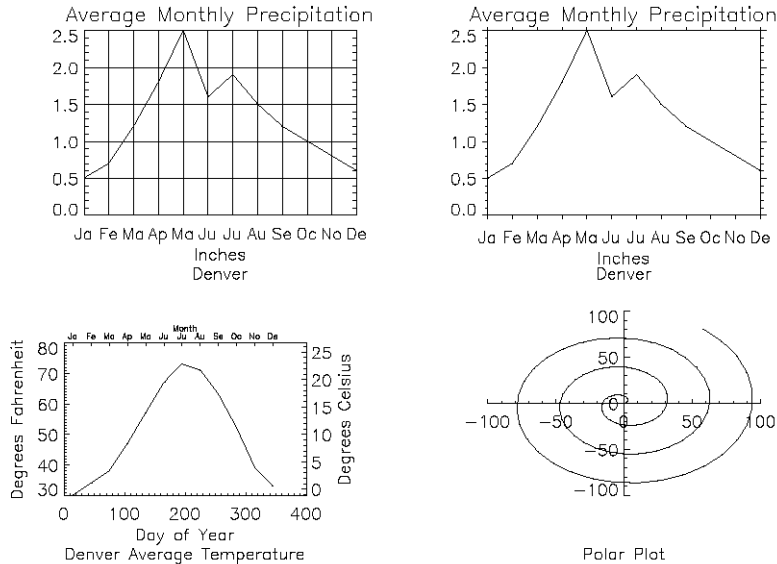

```
!P.MULTI = [0, 1, 2]
```

Note that the first element, `!P.MULTI (0)`, is set to zero to cause the next plot to begin a new page. To make four plots per page with two columns and two rows, use the following statement:

```
!P.MULTI = [0, 2, 2]
```

To reset to the default of one plot per page, set the value of !P.MULTI to 0, as shown in the following statement:

```
!P.MULTI = 0
```

*Figure 3-89: Multiple Plots Per Page, Various Tick Marks, and Multiple Axes*

This figure shows four plots in a single window.

### Example Code

For details, inspect the batch file `plot09` in the `examples/doc/plot` subdirectory of the IDL distribution or type `@plot09` at the IDL command prompt to run the example.

Note the following features of the plots in the figure:

1. The plot in the upper left has grid-style tick marks. This is accomplished by setting the `TICKLEN` keyword equal to 1.0
2. The plot in the upper right has outward-facing tick marks. This is accomplished by setting the `TICKLEN` keyword to a negative value.

3. The plot in the lower left corner has different axes on left and right, top and bottom. This is accomplished by drawing the top and right axes separately, using the AXIS procedure.
4. The plot in the lower right uses no default axes at all. The centered axes are drawn with calls to the AXIS procedure.

## Specifying the Location of the Plot

The plot-data window is the region of the page or screen enclosed by the axes. The plot region is the box enclosing the plot-data window and the titles and tick annotation.

*Figure 3-90: The Plot-Data Window, Plot Region, and Device Area Relationship*

The figure illustrates the relationship of the plot-data window, plot region, and the entire device area. These areas are determined by the following system variables and keyword parameters, in order of decreasing precedence:

**POSITION**

**!P.POSITION**

**!P.REGION**

**!P.MULTI**

[XYZ]MARGIN

![XYZ].MARGIN

## Plotting Missing Data

The `MAX_VALUE` and `MIN_VALUE` keywords to `PLOT` can be used to create missing data plots wherein bad data values are not plotted. Data values greater than the value of the `MAX_VALUE` keyword or less than the value of the `MIN_VALUE` keyword are treated as missing and are not plotted. The following code creates a dataset with bad data values and plots it with and without these keywords:

```

; Make a 100-element array where each element is
; set equal to its index:
A = FINDGEN(100)
; Set 20 random point in the array equal to 400.
; This simulates "bad" data values above the range
; of the "real" data.
A(RANDOMU(SEED, 20)*100)=400
; Set 20 random point in the array equal to -10.
; This simulates "bad" data values below the range
; of the "real" data.
A(RANDOMU(SEED, 20)*100)=-10
; Plot the dataset with the bad values. Looks pretty bad!
PLOT, A
; Plot the dataset, but don't plot any value over 101.
; The resulting plot looks better, but still shows spurious values:
PLOT, A, MAX_VALUE=101
; This time leave out both high and low spurious values.
; The resulting plot more accurately reflects the "real" data:
PLOT, A, MAX_VALUE=101, MIN_VALUE=0

```

The following plotting routines allow you to set maximum and minimum values in this manner: `CONTOUR`, `PLOT`, `SHADE_SURF`, `SURFACE`.

In addition to the maximum and minimum values specified with the `MAX_VALUE` and `MIN_VALUE` keywords, these plotting routines treat the IEEE floating-point value NaN (Not A Number) as missing data automatically. (For more information on NaN, see “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual.)

# PLOT\_3DBOX

The PLOT\_3DBOX procedure plots a function of two variables (e.g.,  $Z=f(X, Y)$ ) inside a 3-D box. Optionally, the data can be projected onto the “walls” surrounding the plot area.

This routine is written in the IDL language. Its source code can be found in the file `plot_3dbox.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
PLOT_3DBOX, X, Y, Z [, AX=degrees] [, AZ=degrees] [, GRIDSTYLE={0 | 1 | 2 | 3
| 4 | 5}] [, PSYM=integer{1 to 10}] [, /SOLID_WALLS] [, /XY_PLANE]
[, XYSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /XZ_PLANE] [, XZSTYLE={0 | 1 | 2 | 3 | 4 |
5}] [, /YZ_PLANE] [, YZSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, ZAXIS={1 | 2 | 3 | 4}]
```

**Graphics Keywords:** Accepts all graphics keywords accepted by PLOT except for: FONT, PSYM, SYMSIZE, {XYZ}TICK\_GET, and ZVALUE.

## Arguments

### X

A vector (i.e., a one-dimensional array) of X coordinates.

### Y

A vector of Y coordinates.

### Z

A vector of Z coordinates.  $Z[i]$  is a function of  $X[i]$  and  $Y[i]$ .

## Keywords

### AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D is not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by PLOT\_3DBOX is taken from the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer ( $AX > 0$ ), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted and !P.T3D is 0.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

## AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

## GRIDSTYLE

Set this keyword to the linestyle index for the type of line to be used when drawing the gridlines. Linestyles are described in the following table:

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

*Table 3-99: IDL Linestyles*

## PSYM

Set this keyword to a plotting symbol index to be used in plotting the data. For more information, see “[PSYM](#)” on page 4784.

## SOLID\_WALLS

Set this keyword to cause the boundary “walls” of the plot to be filled with the color index specified by the COLOR keyword.

## XY\_PLANE

Set this keyword to plot the  $X$  and  $Y$  values on the  $Z=0$  axis plane.

## XYSTYLE

Set this keyword to the linestyle used to draw the XY plane plot. See the table above for a list of linestyles.

## XZ\_PLANE

Set this keyword to plot the  $Y$  and  $Z$  values on the  $Y=\text{MAX}(Y)$  axis plane.

## XZSTYLE

Set this keyword to the linestyle used to draw the XZ plane plot. See the table above for a list of linestyles.

## YZ\_PLANE

Set this keyword to plot the  $Y$  and  $Z$  values on the  $X=\text{MAX}(X)$  axis plane.

## YZSTYLE

Set this keyword to the linestyle used to draw the YZ plane plot. See the table above for a list of linestyles.

## ZAXIS

This keyword specifies the placement of the  $Z$  axis for the PLOT\_3DBOX plot.

By default, PLOT\_3DBOX draws the  $Z$  axis at the upper left corner of the axis box. To suppress the  $Z$  axis, use `ZAXIS=-1` in the call. The position of the  $Z$  axis is determined from the value of `ZAXIS` as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

`BACKGROUND`, `CHARSIZE`, `CHARTHICK`, `CLIP`, `COLOR`, `DATA`, `DEVICE`, `LINestyle`, `NOCLIP`, `NOERASE`, `NORMAL`, `POSITION`, `SUBTITLE`, `T3D`, `THICK`, `TICKLEN`, `TITLE`, `[XYZ]CHARSIZE`, `[XYZ]GRIDSTYLE`, `[XYZ]MARGIN`, `[XYZ]MINOR`, `[XYZ]RANGE`, `[XYZ]STYLE`, `[XYZ]THICK`,

[\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKLEN](#), [\[XYZ\]TICKNAME](#), [\[XYZ\]TICKS](#),  
[\[XYZ\]TICKV](#), [\[XYZ\]TITLE](#)

## Examples

```
; Create some data to be plotted:
X = REPLICATE(5., 10.)
X1 = COS(FINDGEN(36)*10.*!DTOR)*2.+5.
X = [X, X1, X]
Y = FINDGEN(56)
Z = REPLICATE(5., 10)
Z1 = SIN(FINDGEN(36)*10.*!DTOR)*2.+5.
Z = [Z, Z1, Z]

; Create the box plot with data projected on all of the walls. The
; PSYM value of -4 plots the data as diamonds connected by lines:
PLOT_3DBOX, X, Y, Z, /XY_PLANE, /YZ_PLANE, /XZ_PLANE, $
/SOLID_WALLS, GRIDSTYLE=1, XYSTYLE=3, XZSTYLE=4, $
YZSTYLE=5, AZ=40, TITLE='Example Plot Box', $
XTITLE='X Coordinate', YTITLE='Y Coodinate', $
ZTITLE='Z Coordinate', SUBTITLE='Sub Title', $
/YSTYLE, ZRANGE=[0,10], XRANGE=[0,10], $
PSYM=-4, CHARSIZE=1.6
```

# PLOT\_FIELD

The PLOT\_FIELD procedure plots a 2-D field.  $N$  random points are picked, and from each point a path is traced along the field. The length of the path is proportional to the field vector magnitude.

This routine is written in the IDL language. Its source code can be found in the file `plot_field.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
PLOT_FIELD, U, V [, ASPECT=ratio] [, LENGTH=value] [, N=num_arrows]  
[, TITLE=string]
```

## Arguments

### U

A 2-D array giving the field vector at each point in the U(X) direction.

### V

A 2-D array giving the field vector at each point in the V(Y) direction.

## Keywords

### ASPECT

Set this keyword to the aspect ratio of the plot (i.e., the ratio of the X size to Y size). The default is 1.0.

### LENGTH

Set this keyword to the length of the longest field vector expressed as a fraction of the plotting area. The default is 0.1.

### N

Set this keyword to the number of arrows to draw. The default is 200.

### TITLE

Set this keyword to the title of plot. The default is "Velocity Field".

## Examples

```
; Create array X:  
X = FINDGEN(20, 20)  
  
; Create array Y:  
Y = FINDGEN(20, 20)*3  
  
; Plot X vs. Y:  
PLOT_FIELD, X, Y
```

The above commands produce the following plot:

# PLOTERR

The PLOTERR procedure plots individual data points with error bars.

This routine is written in the IDL language. Its source code can be found in the file `ploterr.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
PLOTERR, [ X, ] Y, Err [, TYPE={1 | 2 | 3 | 4}] [, PSYM=integer{1 to 10}]
```

## Arguments

### X

An optional array of X values. The procedure checks the number of arguments passed to decide if X was passed. If X is not passed, `INDGEN(Y)` is assumed for X values.

### Y

The array of Y values. Y cannot be of type string.

### Err

The array of error-bar values.

## Keywords

### TYPE

The type of plot to be produced. The possible types are:

- 1 = X Linear - Y Linear (default)
- 2 = X Linear - Y Log
- 3 = X Log - Y Linear
- 4 = X Log - Y Log

### PSYM

The plotting symbol to use. The default is `+7`.

## Version History

# PLOTS

The PLOTS procedure plots vectors or points on the current graphics device in either two or three dimensions. The coordinates can be given in data, device, or normalized form using the DATA (the default), DEVICE, or NORMAL keywords.

The COLOR keyword can be set to a scalar or vector value. If it is set to a vector value, the line segment connecting  $(X_i, Y_i)$  to  $(X_{i+1}, Y_{i+1})$  is drawn with a color index of  $COLOR_{i+1}$ . In this case, COLOR must have the same number of elements as  $X$  and  $Y$ .

## Syntax

PLOTS, X [, Y [, Z]] [, /CONTINUE]

**Graphics Keywords:** [, CLIP= $[X_0, Y_0, X_1, Y_1]$ ] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, PSYM=*integer*{0 to 10}] [, SYMSIZE=*value*] [, /T3D] [, THICK=*value*] [, Z=*value*]

## Arguments

### X

A vector or scalar argument providing the X components of the points to be connected. If only one argument is specified, X must be an array of either two or three vectors (i.e.,  $(2, *)$  or  $(3, *)$ ). In this special case,  $X[0, *]$  are taken as the X values,  $X[1, *]$  are taken as the Y values, and  $X[2, *]$  are taken as the Z values.

### Y

An optional argument providing the Y coordinate(s) of the points to be connected.

### Z

An optional argument providing the Z coordinates of the points to be connected. If Z is not provided, X and Y are used to draw lines in two dimensions.

Z has no effect if the keyword T3D is not specified and the system variable !P.T3D=0.

## Keywords

### CONTINUE

Set this keyword to continue drawing a line from the last point of the most recent call to PLOTS.

For example:

```
; Position at (0,0):
PLOTS, 0, 0

; Draws vector from (0,0) to (1,1):
PLOTS, 1, 1, /CONTINUE

; Draws two vectors from (1,1) to (2,2) to (3,3):
PLOTS, [2,3], [2,3], /CONTINUE
```

### Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [LINESTYLE](#), [NOCLIP](#), [NORMAL](#), [PSYM](#), [SYMSIZE](#), [T3D](#), [THICK](#), [Z](#)

## Examples

Draw a line from (100, 200) to (600, 700), in device coordinates:

```
PLOTS, [100,600], [200,700], /DEVICE
```

Draw a polyline where the line color is proportional to the ordinate that ends each line segment.

```
; Set IDL to use decomposed color mode and load a good
; colortable to better show the result:
DEVICE, DECOMPOSED=0
LOADCT, 13

; Create datasets X and Y:
X = SIN(FINDGEN(100)) & Y = COS(FINDGEN(100))

; Now plot X and Y in normalized coordinates with colors as
; described above:
PLOTS, X, Y, COLOR = BYTSC(L(Y), TOP=!D.N_COLORS-1), /NORMAL
```

Draw 3-D vectors over an established SURFACE plot. The SAVE keyword tells IDL to save the 3-D transformation established by SURFACE.

```
; Load the standard grayscale color table:
LOADCT, 0

; Draw a surface plot:
SURFACE, DIST(5), /SAVE

; Draw a line between (0,0,0) and (3,3,3). The T3D keyword makes
; PLOTS use the previously established 3-D transformation:
PLOTS, [0,3], [0,3], [0,3], /T3D

; Draw a line between (3,0,0) and (3,3,3):
PLOTS, [3,3], [0,3], [0,3], /T3D

; Draw a line between (0,3,0) and (3,3,3):
PLOTS, [0,3], [3,3], [0,3], /T3D
```

# PNT\_LINE

The PNT\_LINE function computes the perpendicular distance between a point  $P0$  and a line between points  $L0$  and  $L1$ . This function is limited by the machine accuracy of single precision floating point.

This routine is written in the IDL language. Its source code can be found in the file `pnt_line.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = PNT_LINE( P0, L0, L1 [, Pl] [, /INTERVAL] )
```

## Return Value

Returns the perpendicular distance.

## Arguments

### P0

The location of the point.  $P0$  may have 2 to  $n$  elements, for  $n$  dimensions.

### L0

One end-point of the line.  $L0$  must have same number of elements as  $P0$ .

### L1

The other end-point of the line.  $L1$  must have the same number of elements as  $L0$ .

### Pl

A named variable that will contain the location of the point on the line between  $L0$  and  $L1$  that is closest to  $P0$ .  $Pl$  is not necessarily in the interval  $(L0, L1)$ .

## Keywords

### INTERVAL

If set, and if the point on the line between  $L0$  and  $L1$  that is closest to  $P0$  is not within the interval  $(L0, L1)$ , PNT\_LINE will return the distance from  $P0$  to the closer of the two endpoints  $L0$  and  $L1$ .

## Examples

To print the distance between the point (2,3) and the line from (-3,3) to (5,12), and also the location of the point on the line closest to (2,3), enter the following command:

```
PRINT, PNT_LINE([2,3], [-3,3], [5,12], P1), P1
```

IDL prints:

```
3.73705      -0.793104      5.48276
```

## Version History

Pre-4.0	Introduced

# POINT\_LUN

The POINT\_LUN procedure sets or obtains the current position of the file pointer for the specified file.

---

**Note**

POINT\_LUN cannot be used with files opened with the RAWIO keyword to the OPEN routines. Depending upon the device in question, the IOCTL function might be used instead for files of this type.

---

## Use Of POINT\_LUN On Compressed Files

In general, it is not possible to arbitrarily move the file pointer within a compressed file (files opened with the COMPRESS keyword to OPEN) because the file compression code needs to maintain a compression state for the file that includes all the data that has already been passed in the stream. This limitation results in the following constraints on the use of POINT\_LUN with compressed files:

- POINT\_LUN is not allowed on compressed files open for output, except to positions beyond the current file position. The compression code emulates such motion by outputting enough zero bytes to move the pointer to the new position.
- POINT\_LUN is allowed to arbitrary positions on compressed files opened for input. However, this feature is emulated by positioning the file to the beginning of the file and then reading and discarding enough data to move the file pointer to the desired position. This can be extremely slow.

For these reasons, use of POINT\_LUN on compressed files, although possible under some circumstances, is best avoided.

## Syntax

POINT\_LUN, *Unit*, *Position*

## Arguments

### Unit

The file unit for the file in question. If *Unit* is positive, POINT\_LUN sets the file position to the position given by *Position*. If negative, POINT\_LUN gets the current

file position and assigns it to the variable given by *Position*. Note that POINT\_LUN cannot be used with the 3 standard file units (0, -1, and -2).

## Position

If *Unit* is positive, *Position* gives the byte offset into the file at which the file pointer should be set. For example, to rewind the file to the beginning, specify 0.

If *Unit* is negative, *Position* must be a named variable into which the current file position will be stored. The returned type will be a longword signed integer if the position is small enough to fit, and a 64-bit longword integer otherwise.

## Keywords

None.

## Examples

To move the file pointer 2048 bytes into the file associated with file unit number 1, enter:

```
POINT_LUN, 1, 2048
```

To return the file pointer for file unit number 2, enter:

```
POINT_LUN, -2, pos
```

# POLAR\_CONTOUR

The POLAR\_CONTOUR procedure draws a contour plot from data in polar coordinates. Data can be regularly- or irregularly-gridded. All of the keyword options supported by CONTOUR are available to POLAR\_CONTOUR.

This routine is written in the IDL language. Its source code can be found in the file `polar_contour.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
POLAR_CONTOUR, Z, Theta, R [, C_ANNOTATION=vector_of_strings]
  [, C_CHARSIZE=value] [, C_CHARTHICK=integer] [, C_COLORS=vector]
  [, C_LINestyle=vector] [, /FILL | , CELL_FILL
  [, C_ORIENTATION=degrees] [, C_SPACING=value]] [, C_THICK=vector]
  [, /CLOSED] [, /IRREGULAR] [, /ISOTROPIC] [, LEVELS=vector /
  NLEVELS=integer{1 to 29}] [, MAX_VALUE=value] [, MIN_VALUE=value]
  [, /OVERPLOT] [, TRIANGULATION=variable] [, /XLOG] [, /YLOG]
  [, /ZAXIS] [, SHOW_TRIANGULATION=color_index]
```

**Graphics Keywords:** Accepts all graphics keywords accepted by PLOT except for: LINSTYLE, PSYM, SYMSIZE. See “[Graphics Keywords Accepted](#)” on page 1700.

## Arguments

### Z

The data values to be contoured. If the data is regularly gridded, *Z* must have the dimensions  $(N\_ELEMENTS(Theta), N\_ELEMENTS(R))$ . Note that the ordering of the elements in the array *Z* is opposite that used by the POLAR\_SURFACE routine.

### Theta

A vector of angles in radians. For regularly-gridded data, *Theta* must have the same number of elements as the first dimension of *Z*. For a scattered grid, *Theta* must have the same number of elements as *Z*.

### R

A vector of radius values. For regularly-gridded data, *R* must have the same number of elements as the second dimension of *Z*. For a scattered grid, *R* must have the same number of elements as *Z*.

## Keywords

### C\_ANNOTATION

The label to be drawn on each contour. Usually, contours are labeled with their value. This parameter, a vector of strings, allows any text to be specified. The first label is used for the first contour drawn, and so forth. If the LEVELS keyword is specified, the elements of C\_ANNOTATION correspond directly to the levels specified, otherwise, they correspond to the default levels chosen by the POLAR\_CONTOUR procedure. If there are more contour levels than elements in C\_ANNOTATION, the remaining levels are labeled with their values.

#### Note

---

This keyword has no effect if the FILL or CELL\_FILL keyword is set (i.e., if the contours are drawn with solid-filled or line-filled polygons).

---

### C\_CHARSIZE

The size of the characters used to annotate contour labels. Normally, contour labels are drawn at 3/4 of the size used for the axis labels (specified by the CHARSIZE keyword or !P.CHARSIZE system variable. This keyword allows the contour label size to be specified directly. Use of this keyword implies use of the FOLLOW keyword.

### C\_CHARTHICK

The thickness of the characters used to annotate contour labels. Set this keyword equal to an integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

### C\_COLORS

The color index used to draw each contour. This parameter is a vector, converted to integer type if necessary. If there are more contour levels than elements in C\_COLORS, the elements of the color vector are cyclically repeated.

### C\_LINestyle

The line style used to draw each contour. As with C\_COLORS, C\_LINestyle is a vector of line style indices. If there are more contour levels than line styles, the line styles are cyclically repeated. See [“LINestyle”](#) on page 4782 for a list of available styles.

## C\_ORIENTATION

If the FILL keyword is set, this keyword can be set to the angle, in degrees counterclockwise from the horizontal, of the lines used to fill contours. If neither C\_ORIENTATION nor C\_SPACING are specified, the contours are solid filled.

## C\_SPACING

If the FILL keyword is set, this keyword can be used to control the distance, in centimeters, between the lines used to fill the contours.

## C\_THICK

The line used to draw each contour level. As with C\_COLORS, C\_THICK is a vector of line thickness values, although the values are floating point. If there are more contours than thickness elements, elements are repeated. If omitted, the overall line thickness specified by the THICK keyword parameter or !P.THICK is used for all contours.

## CELL\_FILL

Set this keyword to produce a filled contour plot using a “cell filling” algorithm. Use this keyword instead of FILL when you are drawing filled contours over a map, when you have missing data, or when contours that extend off the edges of the contour plot. CELL\_FILL is less efficient than FILL because it makes one or more polygons for each data cell. It also gives poor results when used with patterned (line) fills, because each cell is assigned its own pattern. Otherwise, this keyword operates identically to the FILL keyword, described below.

---

### Tip

In order for POLAR\_CONTOUR to fill the contours properly when using a map projection, the X and Y arrays (if supplied) must be arranged in increasing order. This ensures that the polygons generated will be in counterclockwise order, as required by the mapping graphics pipeline.

---

### Warning

Do not draw filled contours over the poles on Cylindrical map projections. In this case, the polar points map to lines on the map, and the interpolation becomes ambiguous, causing errors in filling. One possible work-around is to limit the latitudes to the range of -89.9 degrees to + 89.9 degrees, avoiding the poles.

---

## CLOSED

Set this keyword to a nonzero value to close contours that intersect the plot boundaries. After a contour hits a boundary, it follows the plot boundary until it connects with its other boundary intersection.

## FILL

Set this keyword to produce a filled contour plot. The contours are filled with solid or line-filled polygons. For solid polygons, use the `C_COLOR` keyword to specify the color index of the polygons for each contour level. For line fills, use `C_ORIENTATION`, `C_SPACING`, `C_COLOR`, `C_LINestyle`, and/or `C_THICK` to specify attributes for the lines.

If the current device is not a pen plotter, each polygon is erased to the background color before the fill lines are drawn, to avoid superimposing one pattern over another.

Contours that are not closed cannot be filled because their interior and exterior are undefined. Contours created from data sets with missing data may not be closed; many map projections can also produce contours that are not closed. You should not use filled contours in these cases.

You should not use this keyword when you are drawing filled contours over a map, when you have missing data, or when contours extend off the edges of the contour plot. In these cases, you should use `CELL_FILL` instead.

### Note

---

If the current graphics device is the Z-buffer, the algorithm used when the `FILL` keyword is specified will not work when a Z value is also specified with the graphics keyword `ZVALUE`. In this situation, use the `CELL_FILL` keyword instead of the `FILL` keyword.

---

## IRREGULAR

Set this keyword to indicate that the input data is irregularly gridded. Setting `IRREGULAR` is the same as performing an explicit triangulation.

## ISOTROPIC

Set this keyword to force the scaling of the X and Y axes to be equal.

**Note**

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See “POSITION” on page 4784 for more information.

**LEVELS**

Specifies a vector containing the contour levels drawn by the POLAR\_CONTOUR procedure. A contour is drawn at each level in LEVELS.

**MAX\_VALUE**

Data points with values above this value are ignored (i.e., treated as missing data) when contouring. Cells containing one or more corners with values above MAX\_VALUE will have no contours drawn through them. Note that the IEEE floating-point value NaN is also treated as missing data. (See “Special Floating-Point Values” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

**MIN\_VALUE**

Data points with values less than this value are ignored (i.e., treated as missing data) when contouring. Cells containing one or more corners with values below MIN\_VALUE will have no contours drawn through them. Note that the IEEE floating-point value NaN is also treated as missing data. (See “Special Floating-Point Values” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

**NLEVELS**

The number of equally spaced contour levels that are produced by POLAR\_CONTOUR. If the LEVELS parameter, which explicitly specifies the value of the contour levels, is present, this keyword has no effect. If neither parameter is present, approximately six levels are drawn. NLEVELS should be a positive integer.

**OVERPLOT**

Set this keyword to make POLAR\_CONTOUR “overplot”. That is, the current graphics screen is not erased, no axes are drawn and the previously established scaling remains in effect. You must explicitly specify either the values of the contour levels or the number of levels (via the NLEVELS keyword) when using this option, unless geographic mapping coordinates are in effect.

**Note**

---

When specifying overplot levels with the **NLEVELS** keyword, keep in mind that the levels are calculated according to the range set by the original **POLAR\_CONTOUR** call. If the overplot dataset has a different range, you might want to set your levels more explicitly with the **NLEVELS** keyword.

---

**SHOW\_TRIANGULATION**

Set this keyword to a color index to be used in overplotting the triangulation between datapoints.

**TRIANGULATION**

Set this keyword to a variable that contains an array of triangles returned from the **TRIANGULATE** procedure. Providing triangulation data allows you to contour irregularly gridded data directly, without gridding.

**XLOG**

Set this keyword to specify a logarithmic X axis.

**YLOG**

Set this keyword to specify a logarithmic Y axis.

**ZAXIS**

Set this keyword to an integer value to draw a Z axis for the **POLAR\_CONTOUR** plot. **POLAR\_CONTOUR** draws no Z axis by default. This keyword is of use only if a three-dimensional transformation is established. Possible values are:

- 0 - No Z axis is drawn (the default).
- 1 - Draws Z axis from the lower right-hand corner of the plot
- 2 - Draws Z axis from the lower left-hand corner of the plot
- 3 - Draws Z axis from the upper left-hand corner of the plot
- 4 - Draws Z axis from the upper right-hand corner of the plot

**Graphics Keywords Accepted**

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK\_GET, [XYZ]TITLE, ZVALUE

## Examples

This example uses POLAR\_CONTOUR with regularly-gridded data:

```
;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Load color table
TEK_COLOR

nr = 12 ; number of radii
nt = 18 ; number of Thetas

; Create a vector of radii:
r = FINDGEN(nr)/(nr-1)

; Create a vector of Thetas:
theta = 2*!PI * FINDGEN(nt)/(nt-1)

; Create some data values to be contoured:
z = COS(theta*3) # (r-0.5)^2

; Create the polar contour plot:
POLAR_CONTOUR, z, theta, r, /FILL, c_color=[2, 3, 4, 5]
```

[CONTOUR](#)

# POLAR\_SURFACE

The POLAR\_SURFACE function interpolates a surface from polar coordinates ( $R$ ,  $\Theta$ ,  $Z$ ) to rectangular coordinates ( $X$ ,  $Y$ ,  $Z$ ).

This routine is written in the IDL language. Its source code can be found in the file `polar_surface.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = POLAR_SURFACE( Z, R, Theta [, /GRID] [, SPACING=[xspacing,  
yspacing]] [, BOUNDS=[x0, y0, x1, y1]] [, /QUINTIC] [, MISSING=value] )
```

## Return Value

The function returns a two-dimensional array of the same type as  $Z$ .

## Arguments

### Z

An array containing the surface value at each point. If the data are regularly gridded in  $R$  and  $\Theta$ ,  $Z$  is a two dimensional array, where  $Z_{i,j}$  has a radius of  $R_i$  and an azimuth of  $\Theta_{tj}$ . If the data are irregularly-gridded,  $R_i$  and  $\Theta_{tj}$  contain the radius and azimuth of each  $Z_i$ . Note that the ordering of the elements in the array  $Z$  is opposite that used by the POLAR\_CONTOUR routine.

### R

The radius. If the data are regularly gridded in  $R$  and  $\Theta$ ,  $Z_{i,j}$  has a radius of  $R_i$ . If the data are irregularly-gridded,  $R$  must have the same number of elements as  $Z$ , and contains the radius of each point.

### Theta

The azimuth, in radians. If the data are regularly gridded in  $R$  and  $\Theta$ ,  $Z_{i,j}$  has an azimuth of  $\Theta_{tj}$ . If the data are irregularly-gridded,  $\Theta$  must have the same number of elements as  $Z$ , and contains the azimuth of each point.

## Keywords

### GRID

Set this keyword to indicate that  $Z$  is regularly gridded in  $R$  and  $\Theta$ .

### SPACING

A two element vector containing the desired grid spacing of the resulting array in  $x$  and  $y$ . If omitted, the grid will be approximately 51 by 51.

### BOUNDS

A four element vector,  $[x_0, y_0, x_1, y_1]$ , containing the limits of the  $xy$  grid of the resulting array. If omitted, the extent of input data sets the limits of the grid.

### QUINTIC

Set this keyword to use quintic interpolation, which is slower but smoother than the default linear interpolation.

### MISSING

Use this keyword to specify a value to use for areas within the grid but not within the convex hull of the data points. The default is 0.0.

## Examples

```
; Define radius and Theta:
R = FINDGEN(50) / 50.0
THETA = FINDGEN(50) * (2 * !PI / 50.0)

; Make a function (tilted circle):
Z = R # SIN(THETA)

; Show it:
SURFACE, POLAR_SURFACE(Z, R, THETA, /GRID)
```

# POLY

The POLY function evaluates a polynomial function of a variable.

This routine is written in the IDL language. Its source code can be found in the file `poly.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = POLY(*X*, *C*)

## Return Value

The result is equal to:

$$C_0 + C_1x + C_2x^2 + \dots$$

## Arguments

### X

The variable. This value can be a scalar, vector or array.

### C

The vector of polynomial coefficients. The degree of the polynomial is `N_ELEMENTS(C) - 1`.

## Keywords

None.

## POLY\_2D

The POLY\_2D function performs polynomial warping of images. This function performs a geometrical transformation in which the resulting array is defined by:

$$g[x, y] = f[x', y'] = f[a[x, y], b[x, y]]$$

where  $g[x, y]$  represents the pixel in the output image at coordinate  $(x, y)$ , and  $f[x', y']$  is the pixel at  $(x', y')$  in the input image that is used to derive  $g[x, y]$ . The functions  $a(x, y)$  and  $b(x, y)$  are polynomials in  $x$  and  $y$  of degree  $N$ , whose coefficients are given by  $P$  and  $Q$ , and specify the spatial transformation:

$$x' = a(x, y) = \sum_{i=0}^N \sum_{j=0}^N P_{i,j} x^j y^i$$

$$y' = b(x, y) = \sum_{i=0}^N \sum_{j=0}^N Q_{i,j} x^j y^i$$

Either the nearest neighbor or bilinear interpolation methods can be selected.

### Syntax

*Result* = POLY\_2D(*Array*, *P*, *Q* [, *Interp* [, *Dim<sub>x</sub>*, *Dim<sub>y</sub>*]] [, CUBIC={-1 to 0}] [, MISSING=*value*])

### Arguments

#### Array

A two-dimensional array of any basic type except string. The result has the same type as *Array*.

#### P and Q

*P* and *Q* are arrays containing the polynomial coefficients. Each array must contain  $(N+1)^2$  elements (where  $N$  is the degree of the polynomial). For example, for a linear transformation, *P* and *Q* contain four elements and can be a 2 x 2 array or a 4-element vector.  $P_{i,j}$  contains the coefficient used to determine  $x'$ , and is the weight of the term  $x^j y^i$ . The POLYWARP procedure can be used to fit  $(x', y')$  as a function of  $(x, y)$  and determines the coefficient arrays *P* and *Q*.

## Interp

Set this argument to 1 to perform bilinear interpolation. Set this argument to 2 to perform cubic convolution interpolation (as described under the CUBIC keyword, below). Otherwise, the nearest neighbor method is used. For the linear case, ( $N=1$ ), bilinear interpolation requires approximately twice as much time as does the nearest neighbor method.

## Dim<sub>x</sub>

If present, *Dim<sub>x</sub>* specifies the number of columns in the output. If omitted, the output has the same number of columns as *Array*.

## Dim<sub>y</sub>

If present, *Dim<sub>y</sub>* specifies the number of rows in the output. If omitted, the output has the same number of rows as *Array*.

## Keywords

### CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm. Note that cubic convolution interpolation works only with one- and two-dimensional arrays.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal,  $f$ , is a band-limited signal, with no frequency component larger than  $\omega_0$ , and  $f$  is sampled with spacing less than or equal to  $1/2\omega_0$ , then  $f$  can be reconstructed by convolving with a sinc function:  $\text{sinc}(x) = \sin(\pi x) / (\pi x)$ .

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used. Note that cubic convolution interpolation is significantly slower than bilinear interpolation.

For further details see:

Rifman, S.S. and McKinnon, D.M., “Evaluation of Digital Correction Techniques for ERTS Images; Final Report”, Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 “Image Reconstruction by Parametric Cubic Convolution”, Computer Vision, Graphics & Image Processing 23, 256.

## MISSING

Specifies the output value for points whose  $x'$ ,  $y'$  is outside the bounds of *Array*. If MISSING is not specified, the resulting output value is extrapolated from the nearest pixel of *Array*.

## Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Some simple linear (degree one) transformations are:

$P_{0,0}$	$P_{1,0}$	$P_{0,1}$	$P_{1,1}$	$Q_{0,0}$	$Q_{1,0}$	$Q_{0,1}$	$Q_{1,1}$	Effect
0	0	1	0	0	1	0	0	Identity
0	0	0.5	0	0	1	0	0	Stretch X by a factor of 2
0	0	1	0	0	2.0	0	0	Shrink Y by a factor of 2
z	0	1	0	0	1	0	0	Shift left by z pixels
0	1	0	0	0	0	1	0	Transpose

Table 3-100: Simple Transformations for Use with POLY\_2D

POLY\_2D is often used in conjunction with the POLYWARP procedure to warp images.

```

; Create and display a simple image:
A = BYTSCl(SIN(DIST(250)), TOP=!D.TABLE_SIZE) & TV, A

; Set up the arrays of original points to be warped:
XO = [61, 62, 143, 133]
YO = [89, 34, 38, 105]

; Set up the arrays of points to be fit:
XI = [24, 35, 102, 92]
YI = [81, 24, 25, 92]

; Use POLYWARP to generate the P and Q inputs to POLY_2D:
POLYWARP, XI, YI, XO, YO, 1, P, Q

; Perform an image warping based on P and Q:
B = POLY_2D(A, P, Q)

; Display the new image:
TV, B, 250, 250

```

Images can also be warped over irregularly gridded control points using the WARP\_TRI procedure.

---

[POLYWARP](#)

# POLY\_AREA

The POLY\_AREA function returns the area of a polygon given the coordinates of its vertices.

It is assumed that the polygon has  $n$  vertices with  $n$  sides and the edges connect the vertices in the order:

$$[(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n), (x_1, y_1)]$$

such that the last vertex is connected to the first vertex.

This routine is written in the IDL language. Its source code can be found in the file `poly_area.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$$Result = POLY\_AREA( X, Y [, /DOUBLE] [, /SIGNED] )$$

## Return Value

If either of the input arguments is double-precision or if the `DOUBLE` keyword is set, the result is a double-precision value, otherwise, the result is single-precision.

## Arguments

### X

An  $n$ -element vector of X coordinate locations for the vertices.

### Y

An  $n$ -element vector of Y coordinate locations for the vertices.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Explicitly set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. By default, if either of the arguments to `POLY_AREA` is double-precision, computations are done in double-precision; if both arguments are single-precision, computations are done in single-precision.

## SIGNED

If set, returns a signed area. Polygons with edges traversed in counterclockwise order have a positive area; polygons traversed in the clockwise order have a negative area.

## Version History

Original	Introduced

[DEFROI](#), [POLYFILLV](#)

# POLY\_FIT

The POLY\_FIT function performs a least-square polynomial fit with optional weighting and returns a vector of coefficients.

The POLY\_FIT routine uses matrix inversion to determine the coefficients. A different version of this routine, SVDFIT, uses singular value decomposition (SVD). The SVD technique is more flexible and robust, but may be slower.

This routine is written in the IDL language. Its source code can be found in the file `poly_fit.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = POLY_FIT( X, Y, Degree [, CHISQ=variable] [, COVAR=variable]
  [, /DOUBLE] [, MEASURE_ERRORS=vector] [, SIGMA=variable]
  [, STATUS=variable] [, YBAND=variable] [, YERROR=variable]
  [, YFIT=variable] )
```

## Return Value

POLY\_FIT returns a vector of coefficients of length *Degree*+1. If the `DOUBLE` keyword is set, or if *X* or *Y* are double precision, then the result will be double precision, otherwise the result will be single precision.

## Arguments

### X

An *n*-element vector of independent variables.

### Y

A vector of dependent variables, the same length as *X*.

### Degree

The degree of the polynomial to fit.

## Keywords

### CHISQ

Set this keyword to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

### COVAR

Set this keyword to a named variable that will contain the Covariance matrix of the coefficients.

---

**Note**

The COVAR matrix depends only upon the independent variable  $X$  and (optionally) the MEASURE\_ERRORS. The values do not depend upon  $Y$ . See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

---

### DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic. All computations are performed using double-precision arithmetic.

### MEASURE\_ERRORS

Set this keyword to a vector containing standard measurement errors for each point  $Y[i]$ . This vector must be the same length as  $X$  and  $Y$ .

---

**Note**

For Gaussian errors (e.g., instrumental uncertainties), MEASURE\_ERRORS should be set to the standard deviations of each point in  $Y$ . For Poisson or statistical weighting, MEASURE\_ERRORS should be set to  $\text{SQRT}(Y)$ .

---

### SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

**Note**

If MEASURE\_ERRORS is omitted, then you are assuming that a polynomial is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by  $\text{SQRT}(\text{CHISQ}/(N-M))$ , where  $N$  is the number of points in  $X$ , and  $M$  is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

**STATUS**

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

- 0 = Successful completion.
- 1 = Singular array (which indicates that the inversion is invalid). *Result* is NaN.
- 2 = Warning that a small pivot element was used and that significant accuracy was probably lost.
- 3 = Undefined (NaN) error estimate was encountered.

**Note**

If STATUS is not specified, any error messages will be output to the screen.

**Tip**

Status values of 2 or 3 can often be resolved by setting the DOUBLE keyword.

**YBAND**

Set this keyword to a named variable that will contain the 1 standard deviation error estimate for each point.

**YERROR**

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

**YFIT**

Set this keyword to a named variable that will contain the vector of calculated  $Y$  values. These values have an error of  $+ \text{or} - \text{YBAND}$ .

## Examples

In this example, we use X and Y data corresponding to the known polynomial  $f(x) = 0.25 - x + x^2$ . Using POLY\_FIT to compute a second degree polynomial fit returns the exact coefficients (to within machine accuracy).

```
; Define an 11-element vector of independent variable data:
X = [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]

; Define an 11-element vector of dependent variable data:
Y = [0.25, 0.16, 0.09, 0.04, 0.01, 0.00, 0.01, 0.04, 0.09, $
     0.16, 0.25]

; Define a vector of measurement errors:
measure_errors = REPLICATE(0.01, 11)

; Compute the second degree polynomial fit to the data:
result = POLY_FIT(X, Y, 2, MEASURE_ERRORS=measure_errors, $
                 SIGMA=sigma)

; Print the coefficients:
PRINT, 'Coefficients: ', result
PRINT, 'Standard errors: ', sigma
```

IDL prints:

```
Coefficients:    0.250000    -1.00000    1.00000
Standard errors:  0.00761853    0.0354459    0.0341395
```

## Version History

# POLYFILL

The POLYFILL procedure fills the interior of a region of the display enclosed by an arbitrary two or three-dimensional polygon. The available filling methods are: solid fill, parallel lines, or a pattern contained in an array. Not all methods are available on every hardware output device. See “Fill Methods” below.

---

## Note

POLYFILL uses the current graphics device’s own polygon filling methodology when possible. For some devices, polygon filling is designed to avoid filling a given pixel more than once when neighboring polygons (that is, polygons with shared edges) are drawn. If the resulting pixel fill from POLYFILL is unsatisfactory, consider using [DRAW\\_ROI](#) instead.

---

The polygon is defined by a list of connected vertices stored in X, Y, and Z. The coordinates can be given in data, device, or normalized form using the DATA, DEVICE, or NORMAL keywords.

## Fill Methods

**Line-fill method:** Filling using parallel lines is device-independent and works on all devices that can draw lines. Crosshatching can be simulated by performing multiple fills with different orientations. The spacing, linestyle, orientation, and thickness of the filling lines can be specified using the corresponding keyword parameters. The LINE\_FILL keyword selects this filling style, but is not required if either the ORIENTATION or SPACING parameters are present.

**Solid fill method:** By default, POLYFILL fills the polygon with a solid color. For devices that do not directly support filling with a solid color, the solid fill is automatically emulated using the line-fill method.

**Patterned fill:** Some output devices support filling with a pattern. For these devices, the fill pattern array can be explicitly specified with the PATTERN keyword. Refer to the description of that keyword for a list of devices that support patterned fill.

## Syntax

```
POLYFILL, X [, Y [, Z]] [, IMAGE_COORD=array] [, /IMAGE_INTERP]
  [, /LINE_FILL] [, PATTERN=array] [, SPACING=centimeters]
  [, TRANSPARENT=value]
```

**Graphics Keywords:** [, CLIP=[X<sub>0</sub>, Y<sub>0</sub>, X<sub>1</sub>, Y<sub>1</sub>]] [, COLOR=value] [, /DATA | ,  
/DEVICE | , /NORMAL] [, LINESYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP]

```
[, ORIENTATION=ccw_degrees_from_horiz] [, /T3D] [, THICK=value]  
[, Z=value]
```

## Arguments

### X

A vector argument providing the X coordinates of the points to be connected. The vector must contain at least three elements. If only one argument is specified, X must be an array of either two or three vectors (i.e., (2, \*) or (3, \*)). In this special case, the vector X[0, \*] specifies the X values, X[1, \*] specifies Y, and X[2, \*] contain the Z values.

### Y

A vector argument providing the Y coordinates of the points to be connected. Y must contain at least three elements.

### Z

An optional vector argument providing the Z coordinates of the points to be connected. If Z is not provided, X and Y are used to draw lines in two dimensions. Z must contain at least three elements. Z has no effect if the keyword T3D is not specified and the system variable !P.T3D= 0.

## Keywords

### IMAGE\_COORD

*This keyword is only available when creating output in the Z-Buffer.*

A 2 x n array containing the fill pattern array subscripts of each of the n polygon vertices. Use this keyword in conjunction with the PATTERN keyword to warp images over 2-D and 3-D polygons.

### IMAGE\_INTERP

*This keyword is only available when creating output in the Z-Buffer.*

Specifies the method of sampling the PATTERN array when the IMAGE\_COORD keyword is present. The default method is to use nearest-neighbor sampling. Bilinear interpolation sampling is performed if IMAGE\_INTERP is set.

## LINE\_FILL

Set this keyword to indicate that polygons are to be filled with parallel lines, rather than using solid or patterned filling methods. When using the line-drawing method of filling, the thickness, linestyle, orientation, and spacing of the lines may be specified with keywords.

## PATTERN

Set this keyword to a rectangular array of pixels giving the fill pattern. If this keyword parameter is omitted, POLYFILL fills the area with a solid color. The pattern array may be of any size; if it is smaller than the filled area the pattern array is cyclically repeated.

### Note

---

This keyword is supported for the following devices:

METAFILE, PRINTER, PS, WIN, X, and Z.

For the PostScript device, fill patterns are only supported with language level 2. Use the LANGUAGE\_LEVEL keyword to DEVICE to set the PostScript language level to 2 if filled patterns are to be used.

---

For example, to fill the current plot window with a grid of dots, enter the following commands:

```
; Define pattern array as 10 by 10:
PAT = BYTARR(10,10)

; Set center pixel to bright:
PAT[5,5] = 255

; Fill the rectangle defined by the four corners of the window with
; the pattern:
POLYFILL, !X.WINDOW([0,1,1,0]), $
          !Y.WINDOW([0,0,1,1]), /NORM, PAT = PAT
```

## SPACING

The spacing, in centimeters, between the parallel lines used to fill polygons.

## TRANSPARENT

*This keyword is only available when creating output in the Z-Buffer.*

Specifies the minimum pixel value to draw in conjunction with the `PATTERN` and `IMAGE_COORD` keywords. Pixels less than this value are not drawn and the Z-buffer is not updated.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

`CLIP`, `COLOR`, `DATA`, `DEVICE`, `LINestyle`, `NOCLIP`, `NORMAL`, `ORIENTATION`, `T3D`, `THICK`, `Z`

## Z-Buffer-Specific Keywords

Certain keyword parameters are only active when the Z-buffer is the currently selected graphics device: `IMAGE_COORD`, `IMAGE_INTERP`, `TRANSPARENT` and `COLOR`. These parameters allow images to be warped over 2-D or 3-D polygons, and the output of shaded polygons. See [“The Z-Buffer Device”](#) in Appendix A.

For shaded polygons, the `COLOR` keyword can specify an array that contains the color index at each vertex. Color indices are linearly interpolated between vertices. If `COLOR` contains a scalar, the entire polygon is drawn with the given color index, just as with the other graphics output devices.

Images can be warped over polygons by passing in the image with the `PATTERN` parameter, and a  $(2, n)$  array containing the image space coordinates that correspond to each of the  $N$  vertices with the `IMAGE_COORD` keyword.

The `IMAGE_INTERP` keyword indicates that bilinear interpolation is to be used, rather than the default nearest-neighbor sampling. Pixels less than the value of `TRANSPARENT` are not drawn, simulating transparency.

## Examples

Fill a rectangular polygon that has the vertices (30,30), (100, 30), (100, 100), and (30, 100) in device coordinates:

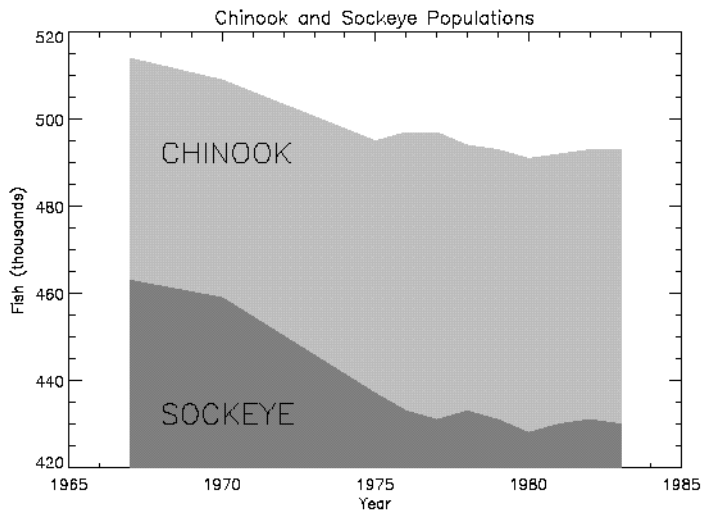

```
; Create the vectors of X and Y values:
X = [30, 100, 100, 30] & Y = [30, 30, 100, 100]

; Fill the polygon with color index 175:
POLYFILL, X, Y, COLOR = 175, /DEVICE
```

Many scientific graphs use region filling to highlight the difference between two or more curves, to illustrate boundaries, etc. The IDL `POLYFILL` procedure fills the

interior of arbitrary polygons given a list of vertices. The interior of the polygon can be filled with a solid color or with some devices, a user-defined fill pattern contained in a rectangular array.

The figure below illustrates a simple example of polygon filling by filling the region under the Chinook population graph with a color index of 25 percent the maximum, then filling the region under the Sockeye population graph with 50 percent of the maximum index. Because the Chinook populations are always higher than the Sockeye populations, the graph appears as two distinct regions.

*Figure 3-92: Filling Regions Using POLYFILL*

The program that produced this figure is shown below. It first draws a plot axis with no data, using the NODATA keyword. The minimum and maximum y values are directly specified with the YRANGE keyword. Because the y-axis range does not always exactly include the specified interval (see “X Versus Y Plots” on page 1664), the variable MINVAL, is set to the current y-axis minimum, !Y.CRANGE[0]. Next, the upper Chinook population region is shaded with a polygon that contains the vertices of the Chinook samples, preceded and followed by points on the x-axis, (YEAR[0], MINVAL), and (YEAR[n-1], MINVAL). The polygon for the Sockeye samples is drawn using the same method with a different color. Finally, the XYOUTS procedure is used to annotate the two regions.

Enter the following IDL commands to create the plot:

```

; Define variables:
@plot01
; Draw axes, no data, set the range:
PLOT, YEAR, CHINOOK, YRANGE = [MIN(SOCKEYE), MAX(CHINOOK)], $
  /NODATA, TITLE='Sockeye and Chinook Populations', $
  XTITLE='Year', YTITLE='Fish (thousands)'
; Make a vector of x values for the polygon by duplicating
; the first and last points:
PXVAL = [YEAR[0], YEAR, YEAR[N1]]
; Get y value along bottom x-axis:
MINVAL = !Y.CRANGE[0]
; Make a polygon by extending the edges down to the x-axis:
POLYFILL, PXVAL, [MINVAL, CHINOOK, MINVAL], $
  COL = 0.75 * !D.N_COLORS
; Same with second polygon.
POLYFILL, PXVAL, [MINVAL, SOCKEYE, MINVAL], $
  COL = 0.50 * !D.N_COLORS
; Label the polygons:
XYOUTS, 1968, 430, 'SOCKEYE', SIZE=2
XYOUTS, 1968, 490, 'CHINOOK', SIZE=2

```

### Example Code

---

Alternatively, you can run the plot04 batch file to create the plot:

```
@plot04
```

---

### Note

---

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the `examples/doc/plot` subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See [!PATH](#) for information on modifying IDL's path.

[POLYFILLV](#)

# POLYFILLV

The POLYFILLV function returns a vector containing the subscripts of the array elements contained inside a polygon defined by vectors.

The  $X$  and  $Y$  parameters are vectors that contain the subscripts of the vertices that define the polygon in the coordinate system of the two-dimensional  $S_x$  by  $S_y$  array. The  $S_x$  and  $S_y$  parameters define the number of columns and rows in the array enclosing the polygon. At least three points must be specified, and all points should lie within the limits:  $0 \leq X_i < S_x$  and  $0 \leq Y_i < S_y$  for all  $i$ .

As with the POLYFILL procedure, the polygon is defined by connecting each point with its successor and the last point with the first. This function is useful for defining, analyzing, and displaying regions of interest within a two-dimensional array.

The scan line coordinate system defined by Rogers in *Procedural Elements for Computer Graphics*, McGraw-Hill, 1985, page 71, is used. In this system, the scan lines are considered to pass through the center of each row of pixels. Pixels are activated if the center of the pixel is to the right of the intersection of the scan line and the polygon edge within the interval.

## Syntax

$Result = \text{POLYFILLV}( X, Y, S_x, S_y [, Run\_Length] )$

## Return Value

Returns a vector containing the one-dimensional subscripts of the array elements contained inside a polygon defined by vectors  $X$  and  $Y$ . These subscripts will be LONG64 values if the dimensions of the input array ( $S_x * S_y$ ) warrant that size for proper addressing. If no points are contained within the polygon, a -1 is returned, and an informational message is printed.

## Arguments

### X

A vector containing the X subscripts of the vertices that define the polygon.

### Y

A vector containing the Y subscripts of the vertices that define the polygon.

**S<sub>x</sub>**

The number of columns in the array surrounding the polygon.

**S<sub>y</sub>**

The number of rows in the array surrounding the polygon.

**Run\_Length**

Set this optional parameter to a nonzero value to make POLYFILLV return a vector of run lengths, rather than subscripts. For large polygons, a considerable savings in space results. When run-length encoded, each element with an even subscript result contains the length of the run, and the following element contains the starting index of the run.

**Examples**

To determine the mean and standard deviation of the elements within a triangular region defined by the vertices at pixel coordinates (100, 100), (200, 300), and (300, 100), inside a 512 x 512 array called DATA, enter the commands:

```
; Get the subscripts of the elements inside the triangle:
P = DATA[POLYFILLV([100,200,300], [100,300,100], 512, 512)]

; Use the STDEV function to obtain the mean and standard deviation
; of the selected elements:
STD = STDEV(P,MEAN)
```

[POLYFILL](#)

# POLYSHADE

The POLYSHADE function creates a shaded-surface representation of one or more solids described by a set of polygons. This function accepts, as arguments, an array of three-dimensional vertices and a list of the indices of the vertices that describe each polygon.

Shading values are determined from one of three sources: a light source model, a user-specified array containing vertex shade values, or a user-specified array containing polygon shade values.

The shaded surface is constructed using the scan line algorithm. The default shading model is a combination of diffuse reflection and depth cueing. With this shading model, polygons are shaded using either constant shading, in which each polygon is given a constant intensity, or with Gouraud shading where the intensity is computed at each vertex and then interpolated over the polygon. Use the SET\_SHADING procedure to control the direction of the light source and other shading parameters.

User-specified shading arrays allow “4-dimensional” displays that consist of a surface defined by a set of polygons, shaded with values from another variable.

## Syntax

*Result* = POLYSHADE( *Vertices*, *Polygons* )

or

*Result* = POLYSHADE(*X*, *Y*, *Z*, *Polygons*)

**Keywords:** [, /DATA | , /NORMAL] [, POLY\_SHADES=*array*] [, SHADES=*array*] [, /T3D] [, TOP=*value*] [, XSIZE=*columns*] [, YSIZE=*rows*]

## Return Value

Returns a shaded-surface representation. Output is a two-dimensional byte array containing the shaded image unless the current graphics output device is the Z-buffer. If the current output device is the Z-buffer, the results are merged with the Z-buffer's contents and the function result contains a dummy value.

# Arguments

## Vertices

A  $(3, n)$  array containing the X, Y, and Z coordinates of each vertex. Coordinates can be in either data or normalized coordinates, depending on which keywords are present.

## X, Y, Z

The X, Y, and Z coordinates of each vertex can, alternatively, be specified as three array expressions of the same dimensions.

## Polygons

An integer or longword array containing the indices of the vertices for each polygon. The vertices of each polygon should be listed in counterclockwise order when observed from outside the surface. The vertex description of each polygon is a vector of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$  and the array *Polygons* is the concatenation of the lists of each polygon. For example, to render a pyramid consisting of four triangles, *Polygons* would contain 16 elements, made by concatenating four, four-element vectors of the form  $[3, V_0, V_1, V_2]$ .  $V_0$ ,  $V_1$ , and  $V_2$  are the indices of the vertices describing each triangle.

# Keywords

## DATA

Set this keyword to indicate that the vertex coordinates are in data units, the default coordinate system.

## NORMAL

Set this keyword to indicate that coordinates are in normalized units, within the three dimensional (0,1) cube.

## POLY\_SHADES

An array expression, with the same number of elements as there are polygons defined in the *Polygons* array, containing the color index used to render each polygon. No interpolation is performed if all pixels within a given polygon have the same shade value. For most displays, this parameter should be scaled into the range of bytes.

## SHADES

An array expression, with the same number of elements as *Vertices*, containing the color index at each vertex. The shading of each pixel is interpolated from the surrounding SHADE values. For most displays, this parameter should be scaled into the range of bytes.

### Warning

---

When using the SHADES keyword on TrueColor devices, we recommend that decomposed color support be turned off by setting DECOMPOSED=0 for [DEVICE](#).

---

## T3D

Set this keyword to use the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix. The SURFACE, SCALE3, and T3D procedures (and others) can all be used to set up transformations.

## TOP

The maximum shading value when light source shading is in effect. The default value is one less than the number of colors available in the currently selected graphics device.

## XSIZE

The number of columns in the output image array. If this parameter is omitted, the number of columns is equal to the X size of the currently selected display device.

Warning: The size parameters should be explicitly specified when the current graphics device is PostScript or any other high-resolution device. Making the output image the default full device size is likely to cause an insufficient memory error.

## YSIZE

The number of rows in the output image array. If this parameter is omitted, the number of rows is equal to the Y resolution of the currently selected display device.

## Examples

POLYSHADE is often used in conjunction with SHADE\_VOLUME for volume visualization. The following example creates a spherical volume dataset and renders an isosurface from that dataset:

```

; Create an empty, 3-D array:
SPHERE = FLTARR(20, 20, 20)

; Create the spherical dataset:
FOR X=0,19 DO FOR Y=0,19 DO FOR Z=0,19 DO $
    SPHERE(X, Y, Z) = SQRT((X-10)^2 + (Y-10)^2 + (Z-10)^2)

; Find the vertices and polygons for a density level of 8:
SHADE_VOLUME, SPHERE, 8, V, P

; Set up an appropriate 3-D transformation so we can see the
; sphere. This step is very important:
SCALE3, XRANGE=[0,20], YRANGE=[0,20], ZRANGE=[0,20]

; Render the image. Note that the T3D keyword has been set so that
; the previously-established 3-D transformation is used:
image = POLYSHADE(V, P, /T3D)

; Display the image:
TV, image

```

---

# POLYWARP

The POLYWARP procedure performs polynomial spatial warping.

Using least squares estimation, POLYWARP determines the coefficients  $Kx_{i,j}$  and  $Ky_{(i,j)}$  of the polynomial functions:

$$X_i = \sum_{i,j} Kx_{i,j} \cdot Xo^j \cdot Yo^i$$

$$Y_i = \sum_{i,j} Ky_{i,j} \cdot Xo^j \cdot Yo^i$$

$Kx$  and  $Ky$  can be used as inputs  $P$  and  $Q$  to the built-in function `POLY_2D`. This coordinate transformation may be then used to map from  $Xo$ ,  $Yo$  coordinates into  $Xi$ ,  $Yi$  coordinates.

This routine is written in the IDL language. Its source code can be found in the file `polywarp.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

`POLYWARP, Xi, Yi, Xo, Yo, Degree, Kx, Ky [, /DOUBLE] [, STATUS=variable]`

## Arguments

### Xi, Yi

Vectors of X and Y coordinates to be fit as a function of  $Xo$  and  $Yo$ .

### Xo, Yo

Vectors of X and Y independent coordinates. These vectors must have the same number of elements as  $Xi$  and  $Yi$ .

### Degree

The degree of the fit. The number of coordinate pairs must be greater than or equal to  $(Degree+1)^2$ .

**Kx**

A named variable that will contain the array of coefficients for  $X_i$  as a function of  $(X_o, Y_o)$ . This parameter is returned as a  $(Degree+1)$  by  $(Degree+1)$  element array.

**Ky**

A named variable that will contain the array of coefficients for  $Y_i$ . This parameter is returned as a  $(Degree+1)$  by  $(Degree+1)$  element array.

**Keywords****DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision result. Explicitly set `DOUBLE=0` to ensure the use of single-precision for computations and to return a single-precision result. By default, POLYWARP performs computations in double precision and returns a double-precision result if any of the inputs are double-precision; computations are performed in single precision and the result returned as single-precision if all of the inputs are single-precision.

**STATUS**

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

Value	Description
0	Successful completion.
1	Singular array (which indicates that the inversion is invalid).
2	Warning that a small pivot element was used and that significant accuracy was probably lost.

*Table 3-101: STATUS Keyword Values*

**Note**

If STATUS is not specified, any warning messages will be output to the screen.

## Examples

The following example shows how to display an image and warp it using the POLYWARP and POLY\_2D routines.

```

; Create and display the original image:
A = BYTSCL(SIN(DIST(250)))
TVSCL, A

; Now set up the Xi's and Yi's:
XI = [24, 35, 102, 92]
YI = [81, 24, 25, 92]

; Enter the Xo's and Yo's:
XO = [61, 62, 143, 133]
YO = [89, 34, 38, 105]

; Run POLYWARP to obtain a Kx and Ky:
POLYWARP, XI, YI, XO, YO, 1, KX, KY

; Create a warped image based on Kx and Ky with POLY_2D:
B = POLY_2D(A, KX, KY)

; Display the new image:
TV, B

```

[POLY\\_2D](#), [WARP\\_TRI](#)

# POPD

The POPD procedure changes the current working directory to the directory saved on the top of the directory stack maintained by the PUSHHD and POPD procedures. This top entry is then removed from the stack.

Attempting to pop a directory when the stack is empty causes a warning message to be printed. The current directory is not changed in this case. The common block DIR\_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file `popd.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

# POWELL

The POWELL procedure minimizes a user-written function *Func* of two or more independent variables using the Powell method. POWELL does not require a user-supplied analytic gradient.

POWELL is based on the routine `powell` described in section 10.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
POWELL, P, Xi, Ftol, Fmin, Func [, /DOUBLE] [, ITER=variable]
      [, ITMAX=value]
```

## Arguments

### P

On input, *P* is an *n*-element vector specifying the starting point. On output, it is replaced with the location of the minimum.

### Note

---

If POWELL is complex then only the real part is used for the computation.

---

### Xi

On input, *Xi* is an initial *n* by *n* element array whose columns contain the initial set of directions (usually the *n* unit vectors). On output, it is replaced with the then-current directions.

### Ftol

An input value specifying the fractional tolerance in the function value. Failure to decrease by more than *Ftol* in one iteration signals completeness. For single-precision computations, a value of  $1.0 \times 10^{-4}$  is recommended; for double-precision computations, a value of  $1.0 \times 10^{-8}$  is recommended.

### Fmin

On output, *Fmin* contains the value at the minimum-point *P* of the user-supplied function specified by *Func*.

## Func

A scalar string specifying the name of a user-supplied IDL function of two or more independent variables to be minimized. This function must accept a vector argument  $X$  and return a scalar result.

For example, suppose we wish to minimize the function

$$f(x, y) = (x + 2y)e^{-x^2 - y^2}$$

To evaluate this expression, we define an IDL function named POWFUNC:

```
FUNCTION powfunc, X
  RETURN, (X[0] + 2.0*X[1]) * EXP(-X[0]^2 -X[1]^2)
END
```

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ITER

Use this keyword to specify an output variable that will be set to the number of iterations performed.

### ITMAX

Use this keyword to specify the maximum allowed number of iterations. The default is 200.

### Warning

---

POWELL halts once the value specified with ITMAX has been reached.

---

## Examples

We can use POWELL to minimize the function POWFUNC given above.

```
PRO TEST_POWELL
; Define the fractional tolerance:
ftol = 1.0e-4
```

```

; Define the starting point:
P = [.5d, -.25d]

; Define the starting directional vectors in column format:
xi = TRANSPOSE([[1.0, 0.0],[0.0, 1.0]])

; Minimize the function:
POWELL, P, xi, ftol, fmin, 'powfunc'

; Print the solution point:
PRINT, 'Solution point: ', P

; Print the value at the solution point:
PRINT, 'Value at solution point: ', fmin

END

FUNCTION powfunc, X
  RETURN, (X[0] + 2.0*X[1]) * EXP(-X[0]^2 -X[1]^2)
END

```

IDL prints:

```

Solution point:    -0.31622777    -0.63245552
Value at solution point:    -0.95900918

```

The exact solution point is [-0.31622777, -0.63245553].

The exact minimum function value is -0.95900918.

# PREF\_COMMIT

The [PREF\\_SET](#) procedure is used to set new values for IDL preferences. However, a preference value set in this way does not immediately take effect. Rather, it is put into a pending state, in which IDL remembers the change, but does not use it. To make a pending preference value take effect, IDL must commit it. To commit a preference, IDL takes the following steps:

1. Writes a new user preference file that merges the new changes with the previously specified preference values.
2. Updates its internal state to make the pending values current.
3. Notifies the various parts of IDL that depend on the altered preference so that they can adapt to the change.

There are two ways to commit a preference:

- **PREF\_COMMIT** — used to commit preferences already in the pending state
- **COMMIT keyword to PREF\_SET** — used to set and commit a specific preference in a single operation

The pending state is useful for applications that let a user manipulate preferences. In such an application, the user can make changes, but those changes can be discarded without taking effect if the user clicks the **Cancel** button. [PREF\\_SET](#) can be used to make the user's changes. If the user clicks **Done** to confirm the changes, [PREF\\_COMMIT](#) is used to make them permanent. Otherwise, they are discarded by using the [RESET](#) keyword. The pending state lifts the burden of tracking user changes from the high-level application and greatly simplifies its implementation.

---

## Note

Authors of IDL applications should not use this routine in their code to make preference changes. See [“Using Preference Etiquette”](#) on page 4849 for more information.

---

## Syntax

```
PREF_COMMIT [, PreferenceName] [, /RESET] [, /RESIGNAL]
```

# Arguments

## PreferenceName

A string scalar or array that supplies the names of the preferences to commit. If no arguments are supplied, all preferences currently in the pending state are committed. Any specified preferences that are not in the pending state are quietly ignored.

# Keywords

## RESET

Set this keyword to have `PREF_COMMIT` discard the pending values, if any, for the specified preferences. The preferences leave the pending state and retain their previous value.

## RESIGNAL

Set this keyword to have `PREF_COMMIT` not check or alter the pending state of the specified preferences. Instead, the procedure behaves as if the current value of the preference had just been committed and signals the part of IDL that uses that preference to reset itself.

# Examples

To commit all preferences with pending values:

```
PREF_COMMIT
```

To commit only the `IDL_PATH` preference (which supplies the value of the `!PATH` system variable), while leaving all other preferences in their current state:

```
PREF_COMMIT, 'IDL_PATH'
```

To discard the currently pending value for `IDL_PATH`:

```
PREF_COMMIT, /RESET, 'IDL_PATH'
```

To restore the `!PATH` system variable to the value given by the `IDL_PATH` preference (without discarding the pending value, if any):

```
PREF_COMMIT, /RESIGNAL, 'IDL_PATH'
```

## Version History

## See Also

[PREF\\_GET](#), [PREF\\_MIGRATE](#), [PREF\\_SET](#)

# PREF\_GET

The `PREF_GET` function returns information about IDL preferences. It can return any of the following information:

- The current effective value for a given preference (specified by *PrefName*)
- The names of all the preferences (specified by `/NAMES_ALL`)
- The number of pending preferences (specified by `/NUM_PENDING`); that is, the ones that have had a value set (`PREF_SET`), but not committed (`PREF_COMMIT`)
- Detailed information for a given preference (specified by *PrefName* and `/STRUCTURE`), including:
  - A string giving a description of the preference's purpose
  - The current effective value and its source
  - Whether the value is read-only
  - Any minimum or maximum values within which the preference must fit
  - Whether or not the preference accepts a fixed (discrete) set of values, and any mnemonic names allowed for each value

## Syntax

```
Result = PREF_GET( [PrefName] [, /NAMES_ALL | /NUM_PENDING | /STRUCTURE ] )
```

## Return Value

The default return value is a scalar returning the current effective value for the named preference (specified by *PrefName*).

If the `NAMES_ALL` keyword is set, the return value is a string array containing the names of all the preferences.

If the `NUM_PENDING` keyword is set, the return value is an integer count of the number of preferences that currently have a value that was set (by `PREF_SET`) and not committed.

If the `STRUCTURE` keyword is set, the return value is a structure providing full details on the preference specified by *PrefName*. For more information, see [“Information Returned by STRUCTURE Keyword”](#) below.

## Arguments

### PrefName

The name of the preference for which information is desired.

## Keywords

### NAMES\_ALL

If this keyword is set, `PREF_GET` returns a string array containing the names of all the preferences.

### NUM\_PENDING

If this keyword is set, `PREF_GET` returns the number of preferences within IDL that currently have a value that was set (by [PREF\\_SET](#)) and not yet committed.

### STRUCTURE

Set this keyword to cause `PREF_GET` to return a structure giving detailed information about the preference specified by *PrefName*. For more information, see [“Information Returned by STRUCTURE Keyword”](#) below.

## Information Returned by STRUCTURE Keyword

If the [STRUCTURE](#) keyword is set, `PREF_GET` returns a structure giving detailed information about the preference. The type and number of fields present in the returned structure depends on the preference in question. Every such result will contain the same set of initial fields. Based on the information provided by these initial fields, there may be additional fields that supply extra information.

The fields contained in the returned structure are:

- **NAME** — a string giving the name of the preference.
- **DESCRIPTION** — a string giving a one line description of the preference.
- **CURRENT\_SOURCE** — a string that reports the source of the current effective value. The following values for this field are possible (listed in ascending order of the source’s priority):

DEFAULT	IDL's built in default value for this preference
---------	--

USERFILE	User preference file
DISTFILE	Preference file from the <code>resource/pref</code> directory of the IDL distribution.
ENV	Environment variable
CMDLINE	Command line option

- **COMMIT\_SEEN** — a string that describes when IDL will begin to use the new value of the preference once it has been committed. The following values are possible:

IMMEDIATE	Value will take effect immediately after commit
RESET	Value will take effect after the next <code>.reset_session</code> or <code>.full_reset_session</code> , or in subsequent IDL sessions
RESTART	Value will not take effect in this IDL session, but will be used in subsequent IDL sessions

- **READONLY** — true (1) if the preference is read-only and false (0) otherwise. A preference is read-only if its value is currently being set by a source with a higher precedence than that of the user's preference file. See `CURRENT_SOURCE` above for the hierarchy of source priority.
- **HAS\_MIN, VALUE\_MIN** — `HAS_MIN` is true (1) if the preference value is required to be greater than or equal to a minimum value. It is false (0) if there is no minimum value. If `HAS_MIN` is true, the returned structure also contains a field named `VALUE_MIN` that contains the minimum value. If `HAS_MIN` is false, `VALUE_MIN` is not present.
- **HAS\_MAX, VALUE\_MAX** — `HAS_MAX` is true (1) if the preference value is required to be less than or equal to a maximum value. It is false (0) if there is no maximum value. If `HAS_MAX` is true, the returned structure will also

contain a field named `VALUE_MAX` that contains the maximum value. If `HAS_MAX` is false, `VALUE_MAX` is not present.

- **HAS\_DISCRETE\_VALUES, NUM\_VALUES, VALUES, NUM\_ALIAS, ALIAS\_VALUES** — `HAS_DISCRETE_VALUES` is true (1) if the preference value must come from a predefined list of possible values. It is false (0) otherwise. Although preferences with discrete values are always numeric, IDL lets the values be referenced by mnemonic names called aliases. If `HAS_DISCRETE_VALUES` is true, the returned structure also contains fields that supply additional information about the values. If `HAS_DISCRETE_VALUES` is false (0), these extra fields are not present (listed in the order in which they appear in the structure):

<code>NUM_VALUES</code>	The number of discrete values.
<code>VALUES</code>	An array of <code>NUM_VALUES</code> elements. Each element contains one of the allowed values for this preference.
<code>NUM_ALIAS</code>	An array of <code>NUM_VALUES</code> elements. Each element reports the number of alias names that exist for the corresponding value in <code>VALUES</code> .
<code>ALIAS_VALUES</code>	An array of size <code>[MAX(NUM_ALIAS), NUM_VALUES]</code> . Each row of <code>ALIAS_VALUES</code> gives the alias names that are allowed for the corresponding element of <code>VALUES</code> . For example, the aliases allowed for the first value ( <code>VALUES[0]</code> ) is <code>ALIAS_VALUES[0:NUM_ALIAS[0], 0]</code> .

- **HAS\_PENDING** — true (1) if the preference has a currently pending value. A pending value is a value that has been set (by `PREF_SET`) but not yet committed. If `HAS_PENDING` is true, the `VALUE_PENDING` field contains the pending value.
- **VALUE\_EFFECTIVE** — the current effective value for the preference.
- **VALUE\_DEFAULT** — IDL's built in default value for the preference. This is the value IDL uses if no other source is present.

- **VALUE\_PENDING** — if **HAS\_PENDING** is true (1), this field contains the pending value. Otherwise, it will contain 0 (numeric) or a NULL string, depending on the type of the preference.

# PREF\_MIGRATE

The PREF\_MIGRATE procedure is used to import IDL user preferences from other versions of IDL for use by the currently running version. Under Microsoft Windows, it is also used to import IDLDE macros.

IDL user preferences are maintained on a per-release basis, meaning that a different user preference file exists for each version of IDL you use on your system. When you first use a new version of IDL, it is common to want to carry over the preference settings you were using with the previous version of IDL. The PREF\_MIGRATE procedure exists to help you with this migration. You can run it at any time. In addition, each new version of IDL runs it once the first time you run that version if you have migratable preferences from other versions of IDL on your system.

This routine is written in the IDL language. Its source code can be found in the file `pref_migrate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
PREF_MIGRATE [, /MACRO] [, /PREFERENCE] [, /STARTUP]
```

## Arguments

None

## Keywords

### MACRO

If this keyword is set, the migration process migrates only IDLDE macros. This option is allowed only under Microsoft Windows because it has no meaning to the Motif (UNIX) version of the IDLDE.

### PREFERENCE

If this keyword is set, the migration process migrates only IDLDE preferences and not macros. This option has meaning only under Microsoft Windows. It is quietly ignored on other platforms.

### STARTUP

At startup, if IDL determines that the user does not have a user preference file, it runs PREF\_MIGRATE with the STARTUP keyword set prior to running the startup file (if

any) or prompting the user for input. STARTUP mode differs from a regular call in a few ways:

- A dialog is used to explain what is happening and to ask for the user's permission to continue, before moving into the main application.
- It runs in a blocking mode so that any changes it makes will be in effect before the startup file (if any) runs and the user is able to enter commands at the IDL prompt.

## See Also

[PREF\\_COMMIT](#), [PREF\\_GET](#), [PREF\\_SET](#)

# PREF\_SET

The `PREF_SET` procedure is used to set new values for IDL preferences. Once committed, these values are written to the user's IDL preference file and persist between IDL sessions. For more information on committing preference values, see the discussion of the [COMMIT](#) keyword below, as well as the documentation for [PREF\\_COMMIT](#).

---

**Note**

A preference is considered to be read-only if its value is currently being set by a source with a higher precedence than that of the user's preference file (command line, environment variable, or IDL distribution preference file). You cannot use `PREF_SET` to change the value of such a preference. You must instead change the preference's value at its source and then restart IDL.

---

---

**Note**

Authors of IDL applications should not use this routine in their code to make preference changes. See [“Using Preference Etiquette”](#) on page 4849 for more information.

---

## Syntax

```
PREF_SET, PrefName1, Value1 [, ... PrefNamen, Valuen] [, /COMMIT]
```

*or*

```
PREF_SET, PrefName1 [, ... PrefNamen] , /DEFAULT, [, /COMMIT]
```

*or*

```
PREF_SET, FILENAME=file [, /COMMIT]
```

The first syntax uses a preference-value pair to set the value for each preference named. The second syntax uses the default value for each preference named. The third syntax imports values from the named preference file.

## Arguments

### **PrefName<sub>i</sub>**

A string containing the name of the preference being set.

## Value<sub>i</sub>

The value of the preference being set.

## Keywords

### COMMIT

Set this keyword to immediately commit all of the preferences made by this call. Normally, `PREF_SET` puts new preference values into a pending state in which IDL remembers the change, but does not use it. In order to make a pending preference value take effect, it must first be committed. Alternatively, you can use the [PREF\\_COMMIT](#) procedure after this call.

### DEFAULT

If this keyword is set, each specified preference is set to IDL's default value for it. You can see the default value for each preference by issuing the following command:

```
HELP, /PREFERENCES, /FULL
```

---

**Note**

If `DEFAULT` is set, you must use the *PrefName* argument to specify a preference (or more than one preference with *PrefName<sub>1</sub> ... PrefName<sub>n</sub>*).

---

### FILENAME

Set this keyword to supply the path to an existing IDL preference file. `PREF_SET` reads the file and sets all preferences referenced within to the specified values. `FILENAME` is used to migrate preferences from other IDL versions. It is, for example, the method by which the [PREF\\_MIGRATE](#) procedure works.

---

**Note**

If `FILENAME` is set, you cannot use the *PrefName* and *Value* arguments.

---

## Examples

Under UNIX, issue the following command to set the default value of the `!PATH` system variable to use a locally installed library of IDL programs in `/usr/local/idllib`, followed by the default IDL libraries, and to immediately commit the change:

```
PREF_SET, 'IDL_PATH', '+/usr/local/idllib:<IDL_DEFAULT>', /COMMIT
```

Under Microsoft Windows, issue the following commands to set the default value of the !PATH system variable to use a locally installed library of IDL programs in C:\local\_idllib, followed by the default IDL libraries, but defer the commit step to a later call to IDL\_COMMIT:

```
PREF_SET, 'IDL_PATH', '+C:\local_idllib;<IDL_DEFAULT>'
...
PREF_COMMIT
```

To revert to using IDL's default for the initial value of !PATH:

```
PREF_SET, 'IDL_PATH', /DEFAULT
```

# PRIMES

The PRIMES function computes the first  $K$  prime numbers.

This routine is written in the IDL language. Its source code can be found in the file `primes.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = PRIMES(*K*)

## Return Value

The result is a  $K$ -element long integer vector.

## Arguments

### K

An integer or long integer scalar that specifies the number of primes to be computed.

## Examples

To compute the first 25 prime numbers:

```
PRINT, PRIMES(25)
```

IDL prints:

```
  2    3    5    7   11   13
 17   19   23   29   31   37
 41   43   47   53   59   61
 67   71   73   79   83   89
 97
```

## Version History

4.0	Introduced
-----	------------

# PRINT/PRINTF

The two PRINT procedures perform formatted output. PRINT performs output to the standard output stream (IDL file unit -1), while PRINTF requires a file unit to be explicitly specified.

---

## Note

IDL uses the standard I/O function `printf` to do its formatting. Different platforms implement this function in different ways, which may lead to slight inconsistencies in the appearance of the output. In most cases, specifying an explicit output format via the `FORMAT` keyword allows better control over the appearance than simply using the default formatting.

---

## Format Compatibility

If the `FORMAT` keyword is not present and `PRINT` is called with more than one argument, and the first argument is a scalar string starting with the characters “\$(”, this initial argument is taken to be the format specification, just as if it had been specified via the `FORMAT` keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

## Syntax

```
PRINT [, Expr1, ..., Exprn]
```

```
PRINTF [, Unit, Expr1, ..., Exprn]
```

**Keywords:** [, `AM_PM`=[string, string]] [, `DAYS_OF_WEEK`=string\_array{7 names}] [, `FORMAT`=value] [, `MONTHS`=string\_array{12 names}] [, `/STDIO_NON_FINITE`]

## Arguments

### Unit

For `PRINTF`, *Unit* specifies the file unit to which the output is sent.

### Expr<sub>*i*</sub>

The expressions to be output.

## Keywords

### AM\_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

### DAYS\_OF\_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

### FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the output. FORMAT allows the format of the output to be specified in precise detail, using a FORTRAN-style specification. See [“Using Explicitly Formatted Input/Output”](#) in Chapter 18 of the *Building IDL Applications* manual.

### MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

### STDIO\_NON\_FINITE

Set this keyword to allow the writing of data files readable by C or FORTRAN programs on a given platform; it is otherwise unnecessary. The various systems supported by IDL differ widely in the representation used for non-finite floating point values (i.e., NaN and Infinity). Consider that the following are all possible representations for NaN on at least one IDL platform:

```
NaN, NanQ, ?.0000, nan0x2, nan0x7, 1.#QNAN, -1.#IND0.
```

And the following are considered to be Infinity:

```
Inf, Infinity, ++.0000, ----.0000, 1.#INF
```

On input, IDL can recognize any of these, but on output, it uses the same standard representation on all platforms. This promotes cross-platform consistency. To cause IDL to use the system C library `sprintf()` function to format such values, yielding the native representation for that platform, set the `STDIO_NON_FINITE` keyword.

## Examples

To print the string “IDL is fun.” enter the command:

```
PRINT, 'IDL is fun.'
```

To print the same message to the open file associated with file unit number 2, use the command:

```
PRINTF, 2, 'IDL is fun.'
```

# PRO

The PRO statement defines an IDL procedure.

**Note**

For information on using the PRO statement, see [Chapter 2, “Creating and Running Programs in IDL”](#) and [Chapter 5, “Creating Procedures and Functions”](#) in the *Building IDL Applications* manual.

## Syntax

```
PRO Procedure_Name, argument_1, ..., argument_n
```

```
...
```

```
END
```

## Arguments

**argument<sub>n</sub>**

A parameter that is passed to the procedure.

## Keywords

None.

## Examples

The following example demonstrates the use of arguments in a PRO statement:

```
PRO MYPROCEDURE
  X = 5
  ; Call the ADD procedure:
  ADD, 3, X
END

PRO ADD, A, B
  PRINT, 'A = ', A
  PRINT, 'B = ', B
  A = A + B
  PRINT, 'A = ', A
END
```

After you run `myprocedure.pro`, IDL returns:

A = 3

B = 5

A = 8

## Version History

----------	------------

# PRODUCT

The `PRODUCT` function returns the product of elements within an array. The product of the array elements over a given dimension is returned if the *Dimension* argument is present. Because the product can easily overflow, the product is computed using double-precision arithmetic and the *Result* is double precision.

---

**Tip**

If your array has a mix of very large and very small values, the product may underflow or overflow during the computation, even though the final result would be within double-precision limits. In this case, you should not use `PRODUCT`, but instead compute the product by taking the logarithm, using the `TOTAL` function, and then taking the exponential:  $Result = EXP(TOTAL(ALOG(Array)))$ .

---

## Syntax

```
Result = PRODUCT(Array [, Dimension] [, /CUMULATIVE] [, /INTEGER]
                [, /NAN] [, /PRESERVE_TYPE] )
```

## Return Value

Returns the product of the elements of *Array*.

## Arguments

### Array

The array for which to compute the product. This array can be of any basic type except string.

### Dimension

An optional argument specifying the dimension over which to compute the product, starting at one. If this argument is not present or zero, the product of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*.

For example, if the dimensions of *Array* are  $N_1$ ,  $N_2$ ,  $N_3$ , and *Dimension* is 2, the dimensions of the result are  $(N_1, N_3)$ , and element  $(i,j)$  of the result contains the product:

$$R_{i,j} = \prod_{k=0}^{N_2-1} A_{i,k,j}$$

## Keywords

### CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element,  $i$ , containing the product of the input array elements 0 to  $i$ . This keyword also works with the *Dimension* parameter, in which case the cumulative product is performed over the given dimension.

#### Tip

---

If the input array is a temporary variable or an expression, and the result type matches the input type (for example by using the `PRESERVE_TYPE` keyword), then `PRODUCT` will perform the cumulative product in place and no additional memory will be used.

---

### INTEGER

Set this keyword to perform the `PRODUCT` using integer arithmetic, and to return an integer result. If *Array* is of type `ULONG64` then unsigned 64-bit integers are used for the computation and the Result is of type `ULONG64`, otherwise signed 64-bit integers are used and the Result is of type `LONG64`. If *Array* is complex and `INTEGER` is set, then only the real part of each value is used for the computation.

#### Note

---

If *Array* has a large number of values or the values themselves are large, then the `PRODUCT` with the `INTEGER` keyword may easily overflow the largest 64-bit integer and return an incorrect result. In this case you may want to avoid using the `INTEGER` keyword.

---

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data with the value 1. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## PRESERVE\_TYPE

Set this keyword to perform the `PRODUCT` using the input type, and to return a result of the same type. The `INTEGER` keyword is ignored if `PRESERVE_TYPE` is set.

### Note

---

For byte or integer data the `PRODUCT` with `PRESERVE_TYPE` may easily overflow the largest value for that type. In these cases you may want to use the `INTEGER` keyword instead.

---

## Thread Pool Keywords

This routine is written to make use of IDL's thread pool, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#).

## Examples

To find the product of all elements in a one-dimensional array:

```
; Define a one-dimensional array:
array = [20, 10, 5, 5, 3]

; Find the product of the array elements:
prod = PRODUCT(array)

; Print the results:
PRINT, 'Product of Array = ', prod
```

IDL prints:

```
Product of Array =          15000.000
```

Now find the product of elements in a two-dimensional array:

```

; Define a two-dimensional array:
array = FINDGEN(4,4) + 1

; Find the product of all array elements:
prodAll = PRODUCT(array)

; Find the product along the first dimension:
prod1 = PRODUCT(array, 1)

; Find the product along the second dimension:
prod2 = PRODUCT(array, 2)

; Print the results:
PRINT, 'Product of all elements = ', prodAll
PRINT, 'Product along first dimension: '
PRINT, prod1
PRINT, 'Product along second dimension: '
PRINT, prod2

```

IDL prints:

```

Product of all elements      2.0922790e+013
Product along first dimension:
 24.000000      1680.0000      11880.000      43680.000
Product along second dimension:
 585.00000      1680.0000      3465.0000      6144.0000

```

# PROFILE

The PROFILE function extracts a profile from an image and returns the values of the image along the profile line marked by the user.

This routine is written in the IDL language. Its source code can be found in the file `profile.pro` in the `lib` subdirectory of the IDL distribution.

## Using PROFILE

To mark a profile line after calling PROFILE, click in the image with the left mouse button to mark the beginning and ending points. The pixel coordinates of the selected points are displayed in the IDL command log.

## Syntax

```
Result = PROFILE( Image [, XX, YY] [, /NOMARK] [, XSTART=value]
                [, YSTART=value] )
```

## Return Value

Returns a floating-point vector containing the values along the profile line.

## Arguments

### Image

The data array representing the image. This array can be of any type except complex.

### XX

A named variable that will contain the X coordinates of the points along the selected profile.

### YY

A named variable that will contain the Y coordinates of the points along the selected profile.

## Keywords

### NOMARK

Set this keyword to inhibit marking the image with the profile line.

### XSTART

The starting X location of the lower-left corner of *Image*. If this keyword is not specified, 0 is assumed.

### YSTART

The starting Y location of the lower-left corner of *Image*. If this keyword is not specified, 0 is assumed.

## Examples

This example displays an image, selects a profile, and plots that profile in a new window:

```
; Create an image:  
A = BYTSCL(DIST(256))  
  
; Display the image:  
TV, A  
  
; Extract a profile from the image:  
R = PROFILE(A)
```

Mark two points on the image with the mouse.

```
; Create a new plotting window:  
WINDOW, /FREE  
  
; Plot the profile:  
PLOT, R
```

---

### Note

The `PROFILES` procedure is an interactive version of this routine.

---

## Version History

Original	Introduced

[PROFILES](#)

# PROFILER

The PROFILER procedure allows you to access the IDL Code Profiler. The IDL Code Profiler helps you analyze the performance of your applications. You can easily monitor the calling frequency and execution time for procedures and functions.

## Syntax

```
PROFILER [, Module] [, /CLEAR] [, DATA=variable] [, OUTPUT=variable]
[, /REPORT] [, /RESET] [, /SYSTEM]
```

## Arguments

### Module

The program to which changes in profiling will be applied. If *Module* is not specified, profiling changes will be applied to all currently-compiled programs.

#### Note

---

The *Module* is often named with respect to the file in which it is stored. For example, the file `build_it.pro` may contain the module, `build_it`. If you specify the file name, you will incur a syntax error.

---

## Keywords

### CLEAR

Set this keyword to disable profiling of *Module* or of all compiled modules if *Module* is not specified.

### DATA

Set this keyword to a specified variable containing output of the report as an unnamed structure with the following tags and data types:

```
{NAME:char, COUNT:long, ONLY_TIME:double, TIME:double,
SYSTEM:byte}
```

### OUTPUT

Set this keyword to a specified variable in which to store the results of the REPORT keyword.

## REPORT

Set this keyword to report the results of profiling. If you enter a program at the command line, the PROFILER procedure will report the status of all the specified modules used either since the beginning of the IDL session, or since the PROFILER was reset.

## RESET

Set this keyword to clear the results of profiling.

## SYSTEM

Set this keyword to profile IDL system procedures and functions. By default, only user-written or library files, which have been compiled, are profiled.

## Examples

```
; Include IDL system procedures and functions when profiling:
PROFILER, /SYSTEM

; Create a dataset using the library function DIST. Note that DIST
; is immediately compiled:
A= DIST(500)

; Display the image:
TV, A

; Retrieve the profiling results:
PROFILER, /REPORT
```

IDL prints:

Module	Type	Count	Only(s)	Avg. (s)	Time(s)	Avg. (s)
FINDGEN	(S)	1	0.000239	0.000239	0.000239	0.000239
FLTARR	(S)	1	0.010171	0.010171	0.010171	0.010171
N_ELEMENTS	(S)	1	0.000104	0.000104	0.000104	0.000104
ON_ERROR	(S)	1	0.000178	0.000178	0.000178	0.000178
SQRT	(S)	251	0.099001	0.000394	0.099001	0.000394
TV	(S)	1	2.030000	2.030000	2.030000	2.030000

5.1	Introduced
-----	------------

## See Also

[Chapter 8, “Debugging and Error-Handling”](#) in the *Building IDL Applications* manual.

# PROFILES

The `PROFILES` procedure interactively draws row or column profiles of an image in a separate window. A new window is created and the mouse location in the original window is used to plot profiles in the new window.

This routine is written in the IDL language. Its source code can be found in the file `profiles.pro` in the `lib` subdirectory of the IDL distribution.

## Using PROFILES

Moving the mouse within the original image interactively creates profile plots in the newly-created profile window. Pressing the left mouse button toggles between row and column profiles. The right mouse button exits.

## Syntax

```
PROFILES, Image [, /ORDER] [, SX=value] [, SY=value] [, WSIZE=value]
```

## Arguments

### Image

The variable that represents the image displayed in the current window. This data need not be scaled into bytes. The profile graphs are made from this array, even if it is not currently displayed.

## Keywords

### ORDER

Set this keyword to 1 for images written top down or 0 for bottom up. Default is the current value of `!ORDER`.

### SX

Starting X position of the image in the window. If this keyword is omitted, 0 is assumed.

### SY

Starting Y position of the image in the window. If this keyword is omitted, 0 is assumed.

## WSIZE

The size of the PROFILES window as a fraction or multiple of 640 by 512.

## Examples

Create and display an image and use the PROFILES routine on it.

```
; Create an image:  
A = BYTSCL(DIST(256))  
  
; Display the image:  
TV, A  
  
; Run the PROFILES routine:  
PROFILES, A, WSIZE = .5
```

A 320 x 256 pixel PROFILES window should appear. Move the cursor over the original image to see the profile at the cursor position. Press the left mouse button to toggle between row and column profiles. Press the right mouse button (with the cursor over the original image) to exit the routine.

[PROFILE](#)

# PROJECT\_VOL

The `PROJECT_VOL` function returns a two-dimensional image that is the projection of a 3-D volume of data onto a plane (similar to an X-ray). The returned image is a translucent rendering of the volume (the highest data values within the volume show up as the brightest regions in the returned image). Depth queuing and opacity may be used to affect the image. The volume is projected using a 4x4 matrix, so any type of projection may be used including perspective. Typically the system viewing matrix (!P.T) is used as the 4x4 matrix.

---

**Note**

The `VOXEL_PROJ` procedure performs many of the same functions as this routine, and is faster.

---

This routine is written in the IDL language. Its source code can be found in the file `project_vol.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = PROJECT_VOL( Vol, X_Sample, Y_Sample, Z_Sample  
    [, /AVG_INTENSITY] [, /CUBIC] [, DEPTH_Q=value] [, OPAQUE=3D_array]  
    [, TRANS=array] [, XSIZE=longword integer] [, YSIZE=longword integer]  
    [, /Z_BUFFER] )
```

## Return Value

Returns a projection of the volumetric data.

## Arguments

### Vol

A 3-D array of any type except string or structure containing the three-dimensional volume of data to project.

### X\_Sample

A long integer specifying the number of rays to project along the X dimension of the image. The returned image will have the dimensions *X\_sample* by *Y\_sample*.

## Y\_Sample

A long integer specifying the number of rays to project along the Y dimension of the image. To preserve the correct aspect ratio of the data, *Y\_sample* should equal *X\_sample*.

## Z\_Sample

A long integer specifying the number of samples to take along each ray. Higher values for *X\_sample*, *Y\_sample*, and *Z\_sample* increase the image resolution as well as execution time.

## Keywords

### AVG\_INTENSITY

If this keyword is set, the average intensity method of projection is used. The default is a maximum intensity projection. This keyword is ignored if the *Z\_BUFFER* keyword is set.

### CUBIC

If this keyword is set, the cubic method of interpolation is used. The default is bilinear interpolation.

### DEPTH\_Q

Set this keyword to indicate that the image should be created using depth queuing. The depth queuing should be a single floating-point value between 0.0 and 1.0. This value specifies the brightness of the farthest regions of the volume relative to the closest regions of the volume. A value of 0.0 will cause the back side of the volume to be completely blacked out, while a value of 1.0 indicates that the back side will show up just as bright as the front side. The default is 1.0 (indicating no depth queuing).

### OPAQUE

A 3-D array of any type except string or structure, with the same size and dimensions as *Vol*. This array specifies the opacity of each cell in the volume. OPAQUE values of 0 allow all light to pass through. OPAQUE values are cumulative. For example, if a ray emanates from a data value of 50, and then passes through 10 opaque cells (each with a data value of 0 and an opacity value of 5) then that ray would be completely blocked out (the cell with the data value of 50 would be invisible on the returned image). The default is no opacity.

## TRANS

A 4x4 floating-point array to use as the transformation matrix when projecting the volume. The default is to use the system viewing matrix (!P.T).

## XSIZE

The  $x$  size of the returned image to return. CONGRID is used to resize the final image to be XSIZE by YSIZE. The default is the  $x$  size of the current window (or the  $x$  size of the Z-buffer). If no current window exists, then the default is  $X\_sample$ .

## YSIZE

The  $y$  size of the returned image. CONGRID is used to resize the final image to be XSIZE by YSIZE. The default is the  $y$  size of the current window (or the  $y$  size of the Z-buffer). If no current window exists, then the default is  $Y\_sample$ .

## Z\_BUFFER

If this keyword is set, the projection is combined with the contents of the Z-buffer. The default is to not use the Z-buffer contents.

## Examples

Use the T3D routine to set up a viewing projection and render a volume of data using PROJECT\_VOL.

```

; First, create some data:
vol = RANDOMU(S, 40, 40, 40)
FOR I=0, 10 DO vol = SMOOTH(vol, 3)
vol = BYTSCL(vol(3:37, 3:37, 3:37))
opaque = RANDOMU(S, 40, 40, 40)
FOR I=0, 10 DO opaque = SMOOTH(opaque, 3)
opaque = BYTSCL(opaque(3:37, 3:37, 3:37), TOP=25B)

; Set up the view:
xmin = 0 & ymin = 0 & zmin = 0
xmax = 34 & ymax = 34 & zmax = 34
!X.S = [-xmin, 1.0] / (xmax - xmin)
!Y.S = [-ymin, 1.0] / (ymax - ymin)
!Z.S = [-zmin, 1.0] / (zmax - zmin)
T3D, /RESET
T3D, TRANSLATE=[-0.5, -0.5, -0.5]
T3D, SCALE=[0.7, 0.7, 0.7]
T3D, ROTATE=[30, -30, 60]
T3D, TRANSLATE=[0.5, 0.5, 0.5]
WINDOW, 0, XSIZE=512, YSIZE=512

```

```
; Generate and display the image:  
img = PROJECT_VOL(vol, 64, 64, 64, DEPTH_Q=0.7, $  
    OPAQUE=opaque, TRANS=(!P.T))  
TVSCL, img
```

# PS\_SHOW\_FONTS

The PS\_SHOW\_FONTS procedure displays all the PostScript fonts that IDL knows about, with both the StandardAdobe and ISOLatin1 encodings. Each display takes a separate page, and each character in each font is shown with its character index.

A PostScript file is produced, one page per font/mapping combination. The output file contains almost 70 pages of output. A PostScript previewer is recommended rather than sending it to a printer.

This routine is written in the IDL language. Its source code can be found in the file `ps_show_fonts.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
PS_SHOW_FONTS [, /NOLATIN]
```

## Arguments

None.

## Keywords

### NOLATIN

Set this keyword to prevent output of ISOLatin1 encodings.

## Version History

Pre-4.0	Introduced
---------	------------

## See Also

[PSAFM](#)

# PSAFM

The PSAFM procedure takes an Adobe Font Metrics file as input and generates a new AFM file in the format that IDL likes. This new file differs from the original in the following ways:

- Information not used by IDL is removed.
- AFM files with the AdobeStandardEncoding are supplemented with an ISOLatin1Encoding.

This routine is written in the IDL language. Its source code can be found in the file `psafm.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*PSAFM, Input\_Filename, Output\_Filename*

## Arguments

### Input\_Filename

A string that contains the name of existing AFM file from Adobe.

### Output\_Filename

A string that specifies the name of new IDL-format AFM file to be created.

## Keywords

None.

## Version History

Pre-4.0	Introduced

[PS\\_SHOW\\_FONTS](#)

# PSEUDO

The PSEUDO procedure creates a pseudo-color table based on the LHB (Lightness, Hue, and Brightness) system and loads it.

The pseudo-color mapping used is generated by first translating from the LHB coordinate system to the LAB coordinate system, finding  $N$  colors spread out along a helix that spans this LAB space (supposedly a near maximal entropy mapping for the eye, given a particular  $N$ ) and remapping back into the RGB (Red, Green, and Blue) colorspace. The result is loaded as the current colortable.

This routine is written in the IDL language. Its source code can be found in the file `pseudo.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

PSEUDO, *Litlo*, *Lithi*, *Satlo*, *Sathi*, *Hue*, *Loops* [, *Colr*]

## Arguments

### Litlo

Starting lightness, from 0 to 100%.

### Lithi

Ending lightness, from 0 to 100%.

### Satlo

Starting saturation, from 0 to 100%.

### Sathi

Ending saturation, from 0 to 100%.

### Hue

Starting hue, in degrees, from 0 to 360.

### Loops

The number of loops of hue to make in the color helix. This value can range from 0 to around 3 to 5 and need not be an integer.

## Colr

An optional (256,3) integer array in which the new R, G, and B values are returned.  
Red = *Colr*[:,0], green = *Colr*[:,1], blue = *Colr*[:,2].

## Keywords

None.

[COLOR\\_CONVERT](#), [COLOR\\_QUAN](#)

# PTR\_FREE

The PTR\_FREE procedure destroys the heap variables pointed at by its pointer arguments. Any memory used by the heap variable is released, and the variable ceases to exist. No change is made to the arguments themselves and all pointers to the destroyed variables continue to exist. Such pointers are known as *dangling references*. PTR\_FREE is the only way that pointer heap variables can be destroyed. If PTR\_FREE is not called on a heap variable, it continues to exist until the IDL session ends, even if no pointers remain that can be used to reference it.

## Note

---

PTR\_FREE is not recursive. That is, if the heap variable pointed at by `pointer1` contains `pointer2`, destroying `pointer1` will *not* destroy the heap variable pointed at by `pointer2`. Take care not to lose the only pointer to a heap variable by destroying a pointer to a heap variable that contains that pointer.

---

## Syntax

PTR\_FREE,  $P_1$ , ... ..,  $P_n$

## Arguments

$P_i$

Scalar or array arguments of pointer type. If the NULL pointer is passed, PTR\_FREE ignores it quietly.

## Keywords

None.

## Version History

5.0	Introduced
-----	------------

# PTR\_NEW

The PTR\_NEW function provides the primary mechanism for creating heap variables.

## Syntax

```
Result = PTR_NEW( [InitExpr] [, /ALLOCATE_HEAP] [, /NO_COPY] )
```

## Return Value

It returns a pointer to the created variable.

## Arguments

### InitExpr

If *InitExpr* is provided, PTR\_NEW uses it to initialize the newly created heap variable. Note that the new heap variable does not point at the *InitExpr* variable in any sense—the new heap variable simply contains a copy of its value.

If *InitExpr* is not provided, PTR\_NEW does not create a new heap variable, and returns the *Null Pointer*, a special pointer with a fixed known value that can never point at a heap variable. The null pointer is useful as a terminator in dynamic data structures, or as a placeholder in structure definitions.

## Keywords

### ALLOCATE\_HEAP

Set this keyword to cause PTR\_NEW to allocate an undefined heap variable rather than return a null pointer when *InitExpr* is not specified.

### NO\_COPY

Usually, when the *InitExpr* argument is provided, PTR\_NEW allocates additional memory to make a copy. If the NO\_COPY keyword is set, the value data is taken away from the *InitExpr* variable and attached directly to the heap variable. This feature can be used to move data very efficiently. However, it has the side effect of causing the *InitExpr* variable to become undefined.

Using the `NO_COPY` keyword is completely equivalent to the statement:

```
Result = PTR_NEW(TEMPORARY(InitExpr))
```

and is provided as a syntactic convenience.

## Version History

5.0	Introduced
-----	------------

# PTR\_VALID

The PTR\_VALID function verifies the validity of its pointer arguments, or alternatively returns a vector of pointers to all the existing valid pointer heap variables.

## Syntax

*Result* = PTR\_VALID( [*Arg*] [, /CAST] [, COUNT=*variable*] )

## Return Value

If called with a pointer or array of pointers as its argument, PTR\_VALID returns a byte array of the same size as the argument. Each element of the result is set to True (1) if the corresponding pointer in the argument refers to an existing valid heap variable, or to False (0) otherwise.

If called with an integer or array of integers as its argument and the CAST keyword is set, PTR\_VALID returns an array of pointers. Each element of the result is a pointer to the heap variable indexed by the integer value. Integers used to index heap variables are shown in the output of the HELP and PRINT commands. This is useful primarily in programming/debugging when you have lost a reference but see it with HELP and need to get a reference to it interactively in order to determine what it is and take steps to fix the code. See the “Examples” section below for an example.

If no argument is specified, PTR\_VALID returns a vector of pointers to all existing valid pointer heap variables—even if there are currently no pointers to the heap variable. This usage allows you to “reclaim” pointer heap variables to which all pointers have been lost. If no valid pointer heap variables exist, a scalar null pointer is returned.

## Arguments

### Arg

*Arg* can be one of the following:

1. A scalar or array argument of pointer type.
2. If the CAST keyword is set, an integer index or array of integer indices to heap variables. Integers used to index heap variables are shown in the output of the HELP and PRINT commands.

## Keywords

### CAST

Set this keyword to create a new pointer to each heap variable index specified in *Arg*.

### COUNT

Set this keyword equal to a named variable that will contain the number of currently valid heap variables. This value is returned as a longword integer.

## Examples

To determine if a given pointer refers to a valid heap variable:

```
IF (PTR_VALID(p)) THEN ...
```

To destroy all existing pointer heap variables:

```
PTR_FREE, PTR_VALID()
```

You can use the CAST keyword to “reclaim” lost heap variables. For example:

```
A = PTR_NEW(10)
PRINT, A
```

IDL prints:

```
<PtrHeapVar2>
```

In this case, the integer index to the heap variable is 2. If we reassign the variable A, we will “lose” the pointer, but the heap variable will still exist:

```
A=0
PRINT, A, PTR_VALID()
```

IDL prints:

```
0 <PtrHeapVar2>
```

We can reclaim the lost heap variable using the CAST keyword:

```
A = PTR_VALID(2, /CAST)
PRINT, A
```

IDL prints:

```
<PtrHeapVar2>
```

# PTRARR

The PTRARR function returns a pointer vector or array. The individual elements of the array are set to the Null Pointer.

## Syntax

*Result* = PTRARR(  $D_1, \dots, D_8$  [, /ALLOCATE\_HEAP | , /NOZERO] )

## Return Value

Returns a vector or array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### ALLOCATE\_HEAP

Normally, PTRARR sets every element of the result to the null pointer. If you wish IDL to allocate heap variables for every element of the array instead, set the ALLOCATE\_HEAP keyword. In this case, every element of the array will be initialized to point at an undefined heap variable.

### NOZERO

If ALLOCATE\_HEAP is not specified, PTRARR sets every element of the result to the null pointer. If NOZERO is nonzero, this initialization is not performed and PTRARR executes faster. NOZERO is ignored if ALLOCATE\_HEAP is specified.

### Warning

---

If you specify NOZERO, the resulting array will have whatever value happens to exist at the system memory location that the array is allocated from. You should be careful to initialize such an array to valid pointer values.

---

## Example

Create P, a 3 element by 3 element pointer array with each element containing the Null Pointer by entering:

```
P = PTRARR(3, 3)
```

## Version History

# PUSHD

The PUSHD procedure pushes a directory onto the top of the directory stack maintained by the PUSHD and POPD procedures. The name of the current directory is pushed onto the directory stack. This directory becomes the next directory used by POPD. IDL changes directories to the one specified by the *Dir* argument. The common block DIR\_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file `pushd.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

PUSHD, *Dir*

## Arguments

### Dir

A string containing the name of the directory to change to. The current directory is pushed onto the top of the directory stack.

## Keywords

None.

## Version History

Pre-4.0	Introduced

## QGRID3

The QGRID3 function linearly interpolates the dependent variable values to points in a regularly sampled volume. Its inputs are a triangulation of scattered data points in three dimensions, and the value of a dependent variable for each point.

### Note

---

QGRID3 accepts complex input but only utilizes the real part of any complex number.

---

## Syntax

```
Result = QGRID3( XYZ, F, Tetrahedra [, DELTA=vector ] [, DIMENSION=vector ]
  [, MISSING=value ] [, START=vector ] )
```

or

```
Result = QGRID3( X, Y, Z, F, Tetrahedra [, DELTA=array ] [, DIMENSION=array ]
  [, MISSING=value ] [, START=array ] )
```

## Return Value

*Result* is a 3-dimensional array of either single or double precision floating type, of the specified dimensions.

## Arguments

### XYZ

This is a 3-by-*n* array containing the scattered points.

### X, Y, Z

One-dimensional vectors containing the *X*, *Y*, and *Z* point coordinates.

### F

The function value at each location in the form of an *n*-element vector.

### Tetrahedra

A longword array containing the point indices of each tetrahedron, as created by QHULL.

## Keywords

### Note

Any of the keywords may be set to a scalar if all elements are the same.

### DELTA

A scalar or three element array specifying the grid spacing in X, Y, and Z. If this keyword is not specified, it is set to create a grid of DIMENSION cells, enclosing the volume from START to [max(x), max(y), max(z)].

### DIMENSION

A three-element array specifying the grid dimensions in X, Y, and Z. If only one or two elements are supplied, the first element is used for the missing elements. The dimensions must be greater than or equal to 2. If an element is less than 2, the default value of 25 is used for that dimension.

### MISSING

The value to be used for grid points that lie outside the convex hull of the scattered points. The default is 0.

### START

A three element array specifying the start of the grid in X, Y, and Z. Default value is [min(x), min(y), min(z)].

## Examples

### Example 1

This example interpolates a data set measured on an irregular grid.

```
; Create a dataset of N points.
n = 200
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)
z = RANDOMU(seed, n)

; Create dependent variable.
f = x^2 - x*y + z^2 + 1

; Obtain a tetrahedra using the QHULL procedure.
QHULL, x, y, z, tet, /DELAUNAY
```

```

; Create a volume with dimensions [51, 51, 51]
; over the unit cube.
volume = QGRID3(x, y, z, f, tet, START=0, DIMENSION=51, $
    DELTA=0.02)

; Display the volume.
XVOLUME, BYTSCL(volume)

```

## Example 2

This example is similar to the previous one, however in this example we use a  $[3, n]$  array of points.

```

; Create a dataset of N points.
n = 200
p = RANDOMU(seed, 3, n)

; Create dependent variable.
f = p[0,*]^2 - p[0,*]*p[1,*] + p[2,*]^2 + 1

; Obtain a tetrahedra.
QHULL, p, tet, /DELAUNAY

; Create a volume with dimensions [51, 51, 51] over the unit cube.
volume = QGRID3(p, f, tet, START=0, DIMENSION=51, DELTA=0.02)

; Display the volume.
XVOLUME, BYTSCL(volume)

```

## Example 3

The following example uses the data from the `irreg_grid2.txt` ASCII file. This file contains scattered three-dimensional data. This file contains bore hole data for a square mile of land. The QHULL procedure is used to triangulate the three-dimensional locations. The QGRID3 function uses the results from QHULL to grid the data into a volume. The scattered data is displayed as symbol polyline objects in the XOBJVIEW utility. The resulting gridded volume is displayed in the XVOLUME utility:

```

; Import the Data:

; Determine the path to the file. This file contains bore hole
; data for a square mile of land. The bore hole samples were
; roughly taken diagonally from the upper left corner of the
; square to the lower right corner.
file = FILEPATH('irreg_grid2.txt', $
    SUBDIRECTORY = ['examples', 'data'])

```

```

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
z = dataArray[*, 2]
data = dataArray[*, 3]

; Determine number of data points.
nPoints = N_ELEMENTS(data)

; Triangulate the Data with QHULL:

; Construct the convex hulls of the volume.
QHULL, x, y, z, tetrahedra, /DELAUNAY

; Grid the Data and Display the Results:

; Initialize volume parameters.
cubeSize = [51, 51, 51]
; Grid the data into a volume.
volume = QGRID3(x, y, z, data, tetrahedra, START = 0, $
    DIMENSION = cubeSize, DELTA = 0.02)
; Scale the volume to be able to view the full data value range
; with the color tables provided in the XVOLUME utility.
scaledVolume = BYTSCL(volume)

; Display the results in the XVOLUME utility.
XVOLUME, scaledVolume

; Derive the isosurface for mineral deposits with the data value
; of 2.5.
ISOSURFACE, volume, 2.5, vertices, connectivity

; Initialize a model to contain the isosurface.
oModel = OBJ_NEW('IDLgrModel')

; Initialize the polygon object of the isosurface.
oPolygon = OBJ_NEW('IDLgrPolygon', vertices, $
    POLYGONS = connectivity, COLOR = [0, 0, 255])

; Determine the range in each direction.

```

```

xRange = [0, cubeSize[0]]
yRange = [0, cubeSize[1]]
zRange = [0, cubeSize[2]]

; Initialize an axis for each direction.
oAxes = OBJARR(3)
oAxes[0] = OBJ_NEW('IDLgrAxis', 0, RANGE = xRange, $
    LOCATION = [xRange[0], yRange[0], zRange[0]], /EXACT, $
    TICKLEN = (0.02*(yRange[1] - yRange[0])))
oAxes[1] = OBJ_NEW('IDLgrAxis', 1, RANGE = yRange, $
    LOCATION = [xRange[0], yRange[0], zRange[0]], /EXACT, $
    TICKLEN = (0.02*(xRange[1] - xRange[0])))
oAxes[2] = OBJ_NEW('IDLgrAxis', 2, RANGE = zRange, $
    LOCATION = [xRange[0], yRange[1], zRange[0]], /EXACT, $
    TICKLEN = (0.02*(xRange[1] - xRange[0])))

; Add the polygon and axes object to the model.
oModel->Add, oPolygon
oModel->Add, oAxes

; Rotate the model for a better perspective.
oModel->Rotate, [0, 0, 1], 30.
oModel->Rotate, [1, 0, 0], -45.

; Display the model, which contains the isosurface.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75, $
    TITLE = 'Isosurface at the Value of 2.5'

; Cleanup object references.
OBJ_DESTROY, [oModel]

```

[QHULL](#)

# QHULL

The QHULL procedure constructs convex hulls, Delaunay triangulations, and Voronoi diagrams of a set of points of 2-dimensions or higher. It uses and is based on the program QHULL, which is described in Barber, Dobkin and Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," *ACM Transactions on Mathematical Software*, Vol. 22, No 4, December 1996, Pages 469-483.

---

## Note

QHULL accepts complex input but only utilizes the real part of any complex number.

---

For more information about QHULL see <http://www.geom.umn.edu/software/qhull/>.

## Syntax

QHULL, *V*, *Tr*

or,

QHULL, *V0*, *V1*, [, *V2* ... [, *V6*] ], *Tr*

**Keywords:** [, **BOUNDS**=*variable*] [, **CONNECTIVITY**=*variable*] [, **/DELAUNAY**] [, **SPHERE**=*variable*] [, **VDIAGRAM**=*array*] [, **VNORMALS**=*array*] [, **VVERTICES**=*array*]

## Arguments

### V

An input argument providing an *nd*-by-*np* array containing the locations of *np* points, in *nd* dimensions. The number of dimensions, *nd*, must be greater than or equal to 2.

### V0, V1, V2, ..., V(N-1)

Input vectors of dimension *np*-by-1 elements each containing the *i*-th coordinate of *np* points in *nd* dimensions. A maximum of seven input vectors may be specified.

### Tr

An *nd1*-by-*nt* array containing the indices of either the convex hull (*nd1* is equal to *nd*), or the Delaunay triangulation (*nd1* is equal to *nd*+1) of the input points.

## Keywords

### BOUNDS

Set this keyword equal to a named variable that will contain the indices of the vertices of the convex hull.

**Note** \_\_\_\_\_

The order of the vertices returned in this variable is unspecified.

---

### CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the  $np$  nodes is returned. The list has the following form:

Each element  $i$ ,  $0 \leq i < np$ , contains the starting index of the connectivity list (*list*) for node  $i$  within the list array. To obtain the adjacency list for node  $i$ , extract the list elements from  $list[i]$  to  $list[i+1] - 1$ . The adjacency list is not ordered. To obtain the connectivity list, either the DELAUNAY or SPHERE keywords must also be specified.

For example, to perform a spherical triangulation, use the following procedure call:

```
QHULL, lon, lat, CONNECTIVITY = list, SHPERE = sphere
```

which returns the adjacency list in the variable *list*. The subscripts of the nodes adjacent to  $lon[i]$  and  $lat[i]$  are contained in the array:  $list[list[i] : list[i+1] - 1]$ .

### DELAUNAY

Performs a Delaunay triangulation and returns the vertex indices of the resulting polyhedra; otherwise, the convex hull of the data are returned.

### SPHERE

Computes the Delaunay triangulation of the points which lie on the surface of a sphere. The *V0* argument contains the longitude, in degrees, and *V1* contains the latitude, in degrees, of each point.

### VDIAGRAM

When specified, this keyword returns the connectivity of the Voronoi diagram.

For two-dimensional arrays, VDIAGRAM is a 4-by- $nv$  integer array. For each Voronoi ridge,  $i$ , VDIAGRAM[0:1,  $i$ ] contains the index of the two input points the ridge bisects. VDIAGRAM [2:3,  $i$ ] contains the indices within VVERTICES of the

Voronoi vertices. In the case of an unbounded half-space, `VDIAGRAM[2, i]` is set to a negative index,  $j$ , indicating that the corresponding Voronoi ridge is unbounded, and that the equation for the ridge is contained in `VNORMAL[* , -j-1]`, and starts at Voronoi vertex `[3, i]`.

For three-dimensional or higher dimensional arrays, `VDIAGRAM` is returned as a connectivity vector. This vector has the form `[n, v0, v1, i0, i1, ..., in-3]`, where  $n$  is the number of points needed to describe that particular Voronoi ridge,  $v0$  and  $v1$  contain the indices for the two input points that the ridge bisects, and  $i0...in-3$  contain the indices within `VVERTICES` of the Voronoi vertices. In the case of an unbounded half-space, `VDIAGRAM[i]` is set to a negative index,  $j$ , indicating that the corresponding Voronoi ridge is unbounded, and that the equation for the ridge is contained in `VNORMAL[* , -j-1]`.

## VNORMALS

When specified, this keyword returns the normals of each Voronoi ridge that is unbounded. The normals consist of a  $(nd+1)$ -by- $nu$  array, where  $nd$  is the number of dimensions and  $nu$  is the number of unbounded vertices. Each row contains the equation for the unbounded ridge in the form:

$$V_0X_0 + V_1X_1 + V_2X_2 + \dots + V_{nd}X_{nd} + V_{nd+1} = 0$$

where  $V_*$  are the elements of the row within `VNORMALS`, and  $x_*$  are the multidimensional coordinates. See the preceding description of `VDIAGRAM` for details.

## VVERTICES

When specified, this keyword returns the Voronoi vertices.

## Examples

```
PRO ex_qhull

; Create a collection of random points.
n = 20
seed = 15
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Construct the Delaunay triangulation
; and the Voronoi diagram.
QHULL, x, y, triangle, /DELAUNAY, $
      VDIAGRAM=vdiagram, VVERTICES=vvert, VNORM=vnorm
```

```

; Plot our input points.
PLOT, [-0.1, 1.1], [-0.1, 1.1], /NODATA, $
    XSTYLE=4, YSTYLE=4
PLOTS, x, y, PSYM=4

; Plot the Voronoi diagram.
FOR i=0,N_ELEMENTS(vdiagram[2,*])-1 DO BEGIN
    vdiag = vdiagram[*, i]
    j = vdiag[2] + 1
    ; Bounded or unbounded?
    IF (j gt 0) THEN BEGIN ; Bounded.
        PLOTS, vvert[*, vdiag[2:3]], PSYM=-5
        CONTINUE
    ENDIF

    ; Unbounded, retrieve starting vertex.
    xystart = vvert[*, vdiag[3]]
    ; Determine the line equation.
    ; Vnorm[0]*x + Vnorm[1]*y + Vnorm[2] = 0
    slope = -vnorm[0,-j]/vnorm[1,-j]
    intercept = -vnorm[2,-j]/vnorm[1,-j]

    ; Need to determine the line direction.
    ; Pick a point on one side along the line.
    xunbound = xystart[0] + 5
    yunbound = slope*xunbound + intercept

    ; Find the closest original vertex.
    void = MIN( (x-xunbound)^2 + (y-yunbound)^2, idx)
    ; By definition of Voronoi diagram, the line should
    ; be closest to one of the bisected points. If not,
    ; our line went in the wrong direction.
    IF (idx ne vdiag[0] && idx ne vdiag[1]) THEN BEGIN
        xunbound = xystart[0] - 5
        yunbound = slope*xunbound + intercept
    ENDIF

    PLOTS, [[xystart], [xunbound, yunbound]]

ENDFOR

END

```

For some other examples using the QHULL procedure, see the [QGRID3](#) function.

[QGRID3](#)

# QROMB

The QROMB function evaluates the integral of a function over the closed interval  $[A, B]$  using Romberg integration.

QROMB is based on the routine `qromb` described in section 4.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = QROMB( Func, A, B [, /DOUBLE] [, EPS=value] [, JMAX=value]
               [, K=value] )
```

## Return Value

The result will have the same structure as the smaller of  $A$  and  $B$ , and the resulting type will be single- or double-precision floating, depending on the input types.

## Arguments

### Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument  $X$  and return a scalar result. It must be defined over the closed interval  $[A, B]$ .

For example, if we wish to integrate the cubic polynomial

$$y = x^3 + (x - 1)^2 + 3$$

we define a function CUBIC to express this relationship in the IDL language:

```
FUNCTION cubic, X
  RETURN, X^3 + (X - 1.0)^2 + 3.0
END
```

### Note

---

If QROMB is complex then only the real part is used for the computation.

---

### A

The lower limit of the integration.  $A$  can be either a scalar or an array.

**B**

The upper limit of the integration.  $B$  can be either a scalar or an array.

**Note**

---

If arrays are specified for  $A$  and  $B$ , then QROMB integrates the user-supplied function over the interval  $[A_i, B_i]$  for each  $i$ . If either  $A$  or  $B$  is a scalar and the other an array, the scalar is paired with each array element in turn.

---

**Keywords****DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

**EPS**

The desired fractional accuracy. For single-precision calculations, the default value is  $1.0 \times 10^{-6}$ . For double-precision calculations, the default value is  $1.0 \times 10^{-12}$ .

**JMAX**

$2^{(\text{JMAX} - 1)}$  is the maximum allowed number of steps. If this keyword is not specified, a default of 20 is used.

**K**

Integration is performed by Romberg's method of order  $2K$ . If not specified, the default is  $K=5$ . ( $K=2$  is Simpson's rule).

**Examples****Example 1**

To integrate the CUBIC function (listed above) over the interval  $[0, 3]$  and print the result:

```
PRINT, QROMB('cubic', 0.0, 3.0)
```

IDL prints:

```
32.2500
```

This is the exact solution.

## Example 2

This example evaluates the volume under a surface using the following double integration:

$$\text{volume} = \int_0^1 \int_0^1 (9x^2y^2 + 4xy + 1) dx dy$$

The exact solution to this equation is 3.

The example consists of four routines: the main routine, the integration in the y direction, the second integration of the x coefficient, and the second integration of the x<sup>2</sup> coefficient. The main routine is the last routine in the program. To run this example, copy the text of all four routines, paste them into an IDL editor window, and save the window's contents as `DoubleIntegration.pro`.

```

FUNCTION XSquaredCoef, x

    ; Integration of the x squared coefficient.
    secondIntegration = 9.*x^2
    RETURN, secondIntegration

END

FUNCTION XCoef, x

    ; Integration of the linear x coefficient.
    secondIntegration = x
    RETURN, secondIntegration

END

FUNCTION YDirection, y

    ; Re-write equation to consider both x coefficients.
    firstIntegration = QROMB('XSquaredCoef', 0., 1.)*y^2 $
    + 4.*(QROMB('XCoef', 0., 1.))*y + 1.
    RETURN, firstIntegration

END

PRO DoubleIntegration

    ; Determine the volume under the surface represented
    ; by 9x^2y^2 + 4xy + 1 over a specific region.
    volume = QROMB('YDirection', 0., 1. )

```

```

; Output results.
PRINT, 'Resulting Volume: ', volume

END

```

### Example 3

This example evaluates the mass of a volume using the following triple integration on a three-dimensional equation representing its density:

$$\text{mass} = \int_0^1 \int_0^1 \int_0^1 (9x^2y^2 + 8xyz + 1) dx dy dz$$

The exact solution to this equation is 3.

The example consists of six routines: the main routine, the integration in the z-direction, the second integration of the xy coefficient, the second integration of the second  $x^2y^2$  coefficient, the third integration in the x coefficient, and the third integration in the  $x^2$  coefficient. The main routine is the last routine in the program. To run this example, copy the text of all six routines, paste them into an IDL editor window, and save the window's contents as `TripleIntegration.pro`.

```

FUNCTION XSquaredCoef, x

; Integration of the x squared coefficient.
thirdIntegration = 9.*x^2
RETURN, thirdIntegration

END

FUNCTION XCoef, x

; Integration of the linear x coefficient.
thirdIntegration = x
RETURN, thirdIntegration

END

FUNCTION XSquaredYSquaredCoef, y

; Integration of the y squared coefficient.
secondIntegration = QROMB('XSquaredCoef', 0., 1.)*y^2
RETURN, secondIntegration

END

```

```

FUNCTION XYCoef, y
    ; Integration of the linear y coefficient.
    secondIntegration = QROMB('XCoef', 0., 1.)*y
    RETURN, secondIntegration

END

FUNCTION ZDirection, z
    ; Re-write equation to consider all the x and y
    ; coefficients.
    firstIntegration = QROMB('XSquaredYSquaredCoef', 0., 1.) + $
    8.*(QROMB('XYCoef', 0., 1.))*z + 1.
    RETURN, firstIntegration

END

PRO TripleIntegration
    ; Determine the mass of the density represented
    ; by  $9x^2y^2 + 8xyz + 1$  over a specific region.
    mass = QROMB('ZDirection', 0., 1. )

    ; Output results.
    PRINT, 'Resulting Mass: ', mass

END

```

[INT\\_2D](#), [INT\\_3D](#), [INT\\_TABULATED](#), [QROMO](#), [QSIMP](#)

# QROMO

The QROMO function evaluates the integral of a function over the open interval ( $A$ ,  $B$ ) using a modified Romberg's method.

QROMO is based on the routine `qromo` described in section 4.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = QROMO(Func, A [, B] [, /DOUBLE] [, EPS=value] [, JMAX=value]
           [, K=value] [, /MIDEXP | /MIDINF | /MIDPNT | /MIDSQL | /MIDSQU ] )
```

## Return Value

Returns the integral of the function.

## Arguments

### Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument  $X$  and return a scalar result. It must be defined over the open interval ( $A$ ,  $B$ ).

For example, if we wish to integrate the fourth-order polynomial

$$y = 1 / x^4$$

we define a function `HYPHER` to express this relationship in the IDL language:

```
FUNCTION hyper, X
    RETURN, 1.0 / X^4
END
```

### Note

---

If QROMO is complex then only the real part is used for the computation.

---

### A

The lower limit of the integration.  $A$  can be either a scalar or an array.

## B

The upper limit of the integration.  $B$  can be either a scalar or an array. If the MIDEXP keyword is specified,  $B$  is assumed to be infinite, and should not be supplied by the user.

Note: If arrays are specified for  $A$  and  $B$ , then QROMO integrates the user-supplied function over the interval  $[A_i, B_i]$  for each  $i$ . If either  $A$  or  $B$  is a scalar and the other an array, the scalar is paired with each array element in turn.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### EPS

The fractional accuracy desired, as determined by the extrapolation error estimate. For single-precision calculations, the default value is  $1.0 \times 10^{-6}$ . For double-precision calculations, the default value is  $1.0 \times 10^{-12}$ .

### JMAX

Set to specify the maximum allowed number of mid quadrature points to be  $3^{(JMAX-1)}$ . The default value is 14.

### K

Integration is performed by Romberg's method of order  $2K$ . If not specified, the default is  $K=5$ .

### MIDEXP

Use the `midexp()` function (see *Numerical Recipes*, section 4.4) as the integrating function. If the MIDEXP keyword is specified, argument  $B$  is assumed to be infinite, and should not be supplied by the user.

### MIDINF

Use the `midinf()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

## MIDPNT

Use the `midpnt()` function (see *Numerical Recipes*, section 4.4) as the integrating function. This is the default if no other integrating function keyword is specified.

## MIDSQL

Use the `midsql()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

## MIDSQU

Use the `midsqu()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

## Examples

Consider the following function:

```
FUNCTION hyper, X
  RETURN, 1.0 / X^4
END
```

This example integrates the `HYPER` function over the open interval  $(2, \infty)$  and prints the result:

```
PRINT, QROMO('hyper', 2.0, /MIDEXP)
```

IDL prints:

```
0.0412050
```

### Warning

---

When using the `MIDEXP` keyword, the upper integration limit is assumed to be infinity and is not supplied.

---

[INT\\_2D](#), [INT\\_3D](#), [INT\\_TABULATED](#), [QROMB](#), [QSIMP](#)

# QSIMP

The QSIMP function performs numerical integration of a function over the closed interval  $[A, B]$  using Simpson's rule.

QSIMP is based on the routine `qsimp` described in section 4.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = QSIMP( *Func*, *A*, *B* [, /DOUBLE] [, EPS=*value*] [, JMAX=*value*] )

## Return Value

The result will have the same structure as the smaller of *A* and *B*, and the resulting type will be single- or double-precision floating, depending on the input types.

## Arguments

### Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument *X* and return a scalar result. It must be defined over the closed interval  $[A, B]$ .

For example, if we wish to integrate the fourth-order polynomial

$$y = (x^4 - 2x^2) \sin(x)$$

we define a function SIMPSON to express this relationship in the IDL language:

```
FUNCTION simpson, X
    RETURN, (X^4 - 2.0 * X^2) * SIN(X)
END
```

### Note

---

If QSIMP is complex then only the real part is used for the computation.

---

### A

The lower limit of the integration. *A* can be either a scalar or an array.

**B**

The upper limit of the integration.  $B$  can be either a scalar or an array.

**Note**

---

If arrays are specified for  $A$  and  $B$ , then QSIMP integrates the user-supplied function over the interval  $[A_i, B_i]$  for each  $i$ . If either  $A$  or  $B$  is a scalar and the other an array, the scalar is paired with each array element in turn.

---

**Keywords****DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

**EPS**

The desired fractional accuracy. For single-precision calculations, the default value is  $1.0 \times 10^{-6}$ . For double-precision calculations, the default value is  $1.0 \times 10^{-12}$ .

**JMAX**

$2^{(JMAX - 1)}$  is the maximum allowed number of steps. If not specified, a default of 20 is used.

**Examples**

To integrate the SIMPSON function (listed above) over the interval  $[0, \pi/2]$  and print the result:

```
; Define lower limit of integration:
A = 0.0

; Define upper limit of integration:
B = !PI/2.0

PRINT, QSIMP('simpson', A, B)
```

IDL prints:

```
-0.479158
```

The exact solution can be found using the integration-by-parts formula:

```
FB = 4.*B*(B^2-7.)*SIN(B) - (B^4-14.*B^2+28.)*COS(B)
FA = 4.*A*(A^2-7.)*SIN(A) - (A^4-14.*A^2+28.)*COS(A)
exact = FB - FA
```

```
PRINT, exact
IDL prints:
-0.479156
```

## QUERY\_\* Routines

Query routines allow users to obtain information about an image or ASCII file without having to read the file. The following QUERY\_\* routines are available in IDL:

- [QUERY\\_BMP](#)
- [QUERY\\_DICOM](#)
- [QUERY\\_GIF](#)
- [QUERY\\_IMAGE](#)
- [QUERY\\_JPEG](#)
- [QUERY\\_MRSID](#)
- [QUERY\\_PICT](#)
- [QUERY\\_PNG](#)
- [QUERY\\_PPM](#)
- [QUERY\\_SRF](#)
- [QUERY\\_TIFF](#)
- [QUERY\\_WAV](#)

### Return Values

All of the QUERY\_\* routines return a result, which is a long with the value of 1 if the query was successful (and the file type was correct) or 0 on failure. If the query was successful, the return argument is an anonymous structure containing all of the available information for that format.

The status is intended to be used to determine if it is appropriate to use the corresponding READ\_ routine for a given file. The return status of the QUERY\_\* will indicate success if the corresponding READ\_ routine is likely to be able to read the file. The return status will indicate failure for cases that contain formats that are not supported by the READ\_ routines, even though the files may be valid outside of the IDL environment. For example, IDL's READ\_BMP does not support 1-bit-deep images and so the QUERY\_BMP function would return failure in the case of a monochrome BMP file.

For image formats, the returned anonymous structure has (minimally) the following fields. If the file does not support multiple images in a single file, the NUM\_IMAGES field will always be 1 and the IMAGE\_INDEX field will always be 0. Individual routines document additional fields which are returned for a specific format.

The [QUERY\\_ASCII](#) routine has its own return structure; for more information, see its documentation.

## General Query \* Routine Info Structures

Field	IDL data type	Description
CHANNELS	Long	Number of samples per pixel
DIMENSIONS	2-D long array	Size of the image in pixels
HAS_PALETTE	Integer	True if a palette is present
NUM_IMAGES	Long	Number of images in the file
IMAGE_INDEX	Long	Image number for which this structure is valid
PIXEL_TYPE	Integer	IDL basic type code for a pixel sample
TYPE	String	String identifying the file format

*Table 3-102: Query Routines Info Structure*

All the routines accept the IMAGE\_INDEX keyword although formats which do not support multiple images in a single file will ignore this keyword.

## QUERY\_TIFF-Specific Routine Info Structures

Field	IDL data type	Description
BITS_PER_SAMPLE	Long	Number of bits per channel. Possible values are 1, 4, 8, 16, or 32.
DESCRIPTION	String	The contents of the TIFF ImageDescription tag, or a null string of undefined.
DOCUMENT_NAME	String	The contents of the TIFF DocumentName tag, or a null string if undefined.

*Table 3-103: QUERY\_TIFF Routine Info Structure*

Field	IDL data type	Description
DATE_TIME	String	The contents of the TIFF DateTime tag, or a null string if undefined.
ORIENTATION	Long	Image orientation (columns, rows): <ul style="list-style-type: none"> <li>• 1 = Left to right, top to bottom (default)</li> <li>• 2 = Right to left, top to bottom</li> <li>• 3 = Right to left, bottom to top</li> <li>• 4 = Left to right, bottom to top</li> <li>• 5 = Top to bottom, left to right</li> <li>• 6 = Top to bottom, right to left</li> <li>• 7 = Bottom to top, right to left</li> <li>• 8 = Bottom to top, left to right</li> </ul>
PLANAR_CONFIG	Long	How the components of each pixel are stored. Possible values are: <ul style="list-style-type: none"> <li>• 1 = Pixel interleaved RGB image or a two-dimensional image (no interleaving exists). Pixel components (such as RGB) are stored contiguously.</li> <li>• 2 = Image interleaved. Pixel components are stored in separate planes.</li> </ul>

Table 3-103: QUERY\_TIFF Routine Info Structure (Continued)

Field	IDL data type	Description
POSITION	Float array	Two-element vector [ <i>X</i> position, <i>Y</i> position] containing the <i>X</i> and <i>Y</i> offsets in the same units as reported in the UNITS field. The <i>X</i> position is relative to the left side of the image. The <i>Y</i> position is relative to the top of the image, with positive <i>Y</i> increasing downwards. If the <i>XPosition</i> or <i>YPosition</i> tag is not defined in the file then a value of 0.0 is returned for that element.
PHOTOMETRIC	Long	Color mode used for the image data. Possible values are: <ul style="list-style-type: none"> <li>• 0 = White is zero</li> <li>• 1 = Black is zero</li> <li>• 2 = RGB color model</li> <li>• 3 = Palette color model</li> <li>• 4 = Transparency mask</li> <li>• 5 = Separated (usually CMYK)</li> </ul>
RESOLUTION	Float array	Two-element vector [ <i>X resolution</i> , <i>Y resolution</i> ] containing the number of pixels per <i>unit</i> (as reported in the UNITS field).
UNITS	Long	Units of measurement for RESOLUTION: <ul style="list-style-type: none"> <li>• 1 = No units</li> <li>• 2 = Inches (the default)</li> <li>• 3 = Centimeters</li> </ul> For example, if the UNITS field contains the value 2, then the values in the RESOLUTION field represent pixels per inch.

Table 3-103: QUERY\_TIFF Routine Info Structure (Continued)

Field	IDL data type	Description
TILE_SIZE	Long array	Two-element vector [ <i>Tile width</i> , <i>Tile height</i> ]. Non-tiled images will contain [ <i>Image width</i> , 1]

Table 3-103: QUERY\_TIFF Routine Info Structure (Continued)

# QUERY\_ASCII

The QUERY\_ASCII function tests a file for compatibility with READ\_ASCII and returns an optional structure containing information about the file.

This routine is written in the IDL language. Its source code can be found in the file `query_ascii.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = QUERY\_ASCII( *Filename* [, *Info*] )

## Return Value

This routine returns a long integer with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure. The following criteria are used to decide whether a file is a valid ASCII file:

- If 80% of the first 32768 bytes in the file are valid ASCII characters, then the file is considered to be valid
- Byte values in the range 7-13 (bell, backspace, horizontal tab, line feed, vertical tab, form feed, carriage return) or in the range 32-127 (standard characters) are considered valid ASCII characters

These criteria provide an efficient and robust method to filter ASCII files from non-ASCII files. The 80% figure lets an ASCII file have a certain number of non-ASCII characters, perhaps in a header portion or for special characters such as fractions or symbols.

## Arguments

### Filename

A scalar string containing the full pathname of the file to query.

## Info

Set this optional argument to a named variable in which to return an anonymous structure containing information about the file. This structure is valid only when the return value of the function is 1. The structure has the following fields:

Field	IDL Type	Description
NAME	String	File name, including full path
TYPE	String	File format (always 'ASCII')
BYTES	Long64	File length in bytes
LINES	Long64	Number of lines
WORDS	Long64	Number of words

*Table 3-104: The Info Argument's Anonymous Structure*

For the WORDS field, words are assumed to be separated by whitespace, including carriage returns, line feeds, tabs, and spaces.

### Note

IDL uses the file's first 32768 characters to determine whether it is ASCII or not. If the file is valid, IDL processes the remainder of the file and fills in the *Info* structure for the complete file. If the file is not valid, IDL does not modify the *Info* variable.

### Tip

If you have a data file that contains only columns of data (without any header lines), the number of lines (LINES) divided by the number of words (WORDS) should give you the number of columns.

## Keywords

None

## Example

Use the following code to retrieve information from a text file:

```
file = FILEPATH( "irreg_grid1.txt", $
  SUBDIRECTORY=['examples','data'] )
result = QUERY_ASCII( file, info )
```

```
if (result) then HELP, info, /STRUCTURES $
else PRINT, 'File not found or is not a valid ASCII file.'
```

# QUERY\_BMP

QUERY\_BMP is a method of obtaining information about a BMP image file without having to read the file. See [“QUERY\\_\\* Routines”](#) on page 1805 for more information.

## Syntax

```
Result = QUERY_BMP ( Filename [, Info] )
```

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the BMP file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'BMP'.

### Note

See [“General Query \\* Routine Info Structures”](#) on page 1806 for detailed structure information.

## Keywords

There are no keywords for this routine.

## Version History

5.2	Introduced

# QUERY\_DICOM

The QUERY\_DICOM function tests a file for compatibility with READ\_DICOM and returns an optional structure containing information about images in the DICOM file. This function supports cases in which a blank DICOM tag is supplied.

This routine is written in the IDL language. Its source code can be found in the file `query_dicom.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = QUERY_DICOM( Filename [, Info] [, IMAGE_INDEX=index]  
                    [, /DICOMEX] )
```

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful or 0 (zero) on failure. A result of 1 means it is likely that the file can be read by READ\_DICOM.

## Arguments

### Filename

A scalar string containing the full pathname of the file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'DICOM'.

### Note

---

See [“General Query \\* Routine Info Structures”](#) on page 1806 for detailed structure information.

---

## Keywords

### IMAGE\_INDEX

Set this keyword to the index (zero based) of the image being queried in the file. This keyword has no effect on files containing a single image.

## DICOMEX

This keyword is set by default. When an additional cost DICOM Read/Write license or Read/Write runtime license is available, and an [IDLffDicomEx](#) object can be created, IDL uses the [IDLffDicomEx](#) object to query the DICOM file. If these conditions are not met, or if this keyword is set to 0, IDL uses the [IDLffDICOM](#) object to query the DICOM file instead.

## Examples

DICOM palette vectors are 16 bit quantities and may not cover the entire dynamic range of the image. To view a paletted DICOM image use the following:

```
IF (QUERY_DICOM('file.dcm',info)) THEN BEGIN
  IF (info.has_palette) THEN BEGIN
    TV, READ_IMAGE('file.dcm',r, g, b), /ORDER
    TVLCT,r/256, g/256, b/256
  ENDIF
ENDIF
```

## Version History

5.2	Introduced
6.2	Added DICOMEX keyword

# QUERY\_GIF

QUERY\_GIF is a method of obtaining information about a GIF image file without having to read the file. See [“QUERY\\_\\* Routines”](#) on page 1805 for more information.

---

**Note**

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact RSI for information about licensing options.

---

## Syntax

*Result* = QUERY\_GIF ( *Filename* [, *Info*] )

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the GIF file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'GIF'.

---

**Note**

See [“QUERY\\_\\* Routines”](#) on page 1805 for detailed structure info.

[QUERY\\_\\* Routines](#), [READ\\_GIF](#), [WRITE\\_GIF](#)

# QUERY\_IMAGE

The QUERY\_IMAGE function determines whether a file is recognized as a supported image file. QUERY\_IMAGE first checks the filename suffix, and if found, calls the corresponding QUERY\_ routine. For example, if the specified file is image.bmp, QUERY\_BMP is called to determine if the file is a valid .bmp file. If the file does not contain a filename suffix, or if the query fails on the specified filename suffix, QUERY\_IMAGE checks against all supported file types.

## Syntax

```
Result = QUERY_IMAGE( Filename [, Info] [, CHANNELS=variable]  
    [, DIMENSIONS=variable] [, HAS_PALETTE=variable]  
    [, IMAGE_INDEX=index] [, NUM_IMAGES=variable]  
    [, PIXEL_TYPE=variable] [, SUPPORTED_READ=variable]  
    [, SUPPORTED_WRITE=variable] [, TYPE=variable] )
```

## Return Value

Result is a long with the value of 1 if the query was successful (the file was recognized as an image file) or 0 on failure. The return status will indicate failure for files that contain formats that are not supported by the corresponding READ\_\* routine, even though the file may be valid outside the IDL environment.

If the file is a supported image file, an optional structure containing information about the image is returned. If the file is not a supported image file, QUERY\_IMAGE returns 0.

## Arguments

### Filename

A required scalar string containing the name of the file to query.

## Info

An optional anonymous structure containing information about the image. This structure is valid only when the return value of the function is 1. The Info structure for all image types has the following fields:

Tag	Type
CHANNELS	Long
DIMENSIONS	Two-dimensional long array
FILENAME	Scalar string
HAS_PALETTE	Integer
IMAGE_INDEX	Long
NUM_IMAGES	Long
PIXEL_TYPE	Integer
TYPE	Scalar string

*Table 3-105: The Info Structure for All Image Types*

## Keywords

### CHANNELS

Set this keyword to a named variable to retrieve the number of channels in the image.

### DIMENSIONS

Set this keyword to a named variable to retrieve the image dimensions as a two-dimensional array.

### HAS\_PALETTE

Set this keyword to a named variable to equal to 1 if a palette is present, else 0.

## **IMAGE\_INDEX**

Set this keyword to the index of the image to query from the file. The default is 0, the first image.

## **NUM\_IMAGES**

Set this keyword to a named variable to retrieve the number of images in the file.

## **PIXEL\_TYPE**

Set this keyword to a named variable to retrieve the IDL Type Code of the image pixel format. See the documentation for the `SIZE` routine for a complete list of IDL Type Codes.

The valid types for `PIXEL_TYPE` are:

- 1 = Byte
- 2 = Integer
- 3 = Longword Integer
- 4 = Floating Point
- 5 = Double-precision Floating Point
- 12 = Unsigned Integer
- 13 = Unsigned Longword Integer
- 14 = 64-bit Integer
- 15 = Unsigned 64-bit Integer

## **SUPPORTED\_READ**

Set this keyword to a named variable to retrieve a string array of image types recognized by `READ_IMAGE`. If the `SUPPORTED_READ` keyword is used the filename and info arguments are optional.

## **SUPPORTED\_WRITE**

Set this keyword to a named variable to retrieve a string array of image types recognized by `WRITE_IMAGE`. If the `SUPPORTED_WRITE` keyword is used the filename and info arguments are optional.

## TYPE

Set this keyword to a named variable that will contain the image type as a scalar string. Possible return values are BMP, GIF, JPEG, JPEG2000, PNG, PPM, SRF, TIFF, or DICOM.

## Examples

The following example uses `QUERY_IMAGE` to determine whether or not an image has an associated palette. For an example that uses `QUERY_IMAGE` to determine the interleaving of an RGB image, see [“Returning Image File Information”](#) in Chapter 7 of the *Using IDL* manual.

## Displaying Indexed Images with Direct Graphics

An indexed image contains up to 256 colors, typically defined by a color table associated with the image. The value of each pixel relates to a color within the associated color table. Combinations of the primary colors (red, green, and blue) make up the colors within the color table. Most indexed images are stored as byte and therefore do not require scaling prior to display.

The following example imports an indexed image from the `avhrr.png` image file. This indexed image is a satellite photograph of the world. Complete the following steps for a detailed description of the process.

### Example Code

---

See `displayindexedimage_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. The `BLOCK` keyword is set when using the `XLOADCT` utility to force the example routine to wait until the **Done** button is pressed to continue.

---

1. Determine the path to the `avhrr.png` file:

```
file = FILEPATH('avhrr.png', $
SUBDIRECTORY = ['examples', 'data'])
```

2. Use `QUERY_IMAGE` to query the file to determine image parameters:

```
queryStatus = QUERY_IMAGE(file, imageInfo)
```

3. Output the results of the file query:

```
PRINT, 'Query Status = ', queryStatus
HELP, imageInfo, /STRUCTURE
```

The following text appears in the Output Log:

```
Query Status = 1
** Structure <141d0b0>, 7 tags, length=36, refs=1:
CHANNELS      LONG      1
DIMENSIONS    LONG      Array [2]
HAS_PALETTE   INT       1
IMAGE_INDEX   LONG      0
NUM_IMAGES    LONG      1
PIXEL_TYPE    INT       1
TYPE          STRING   'PNG'
```

4. Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

The HAS\_PALETTE tag has a value of 1. Thus, the image has a palette (color table), which is also contained within the file. The color table is made up of its three primary components (the red component, the green component, and the blue component).

5. Use [READ\\_IMAGE](#) to import the image and its associated color table from the file:

```
image = READ_IMAGE(file, red, green, blue)
```

6. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

7. Load the red, green, and blue components of the image's associated color table:

```
TVLCT, red, green, blue
```

8. Create a window and display the original image with the TV procedure:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'An Indexed Image'
TV, image
```

9. Use the XLOADCT utility to display the associated color table:

```
XLOADCT
```

Click on the **Done** button of XLOADCT to exit out of the utility.

The following figure shows the resulting indexed image and its color table.

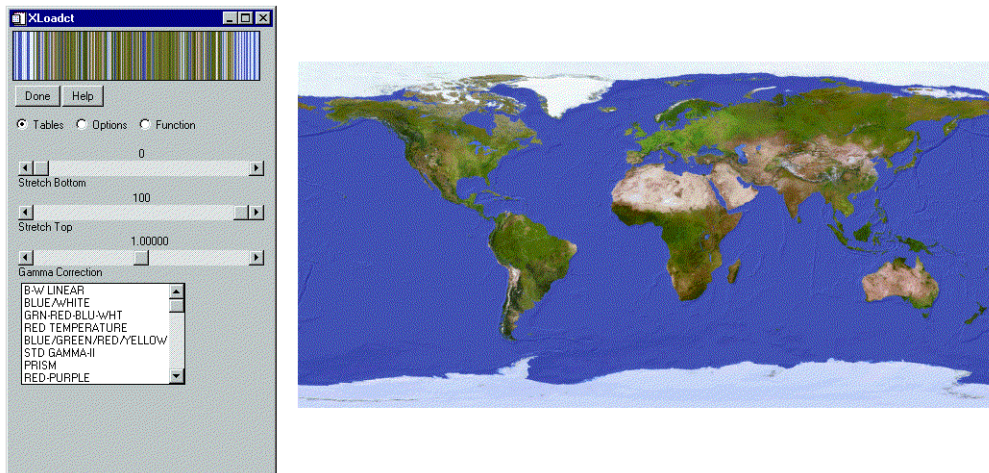

Figure 3-93: Indexed Image and Associated Color Table in Direct Graphics

The data values within the image are indexed to specific colors within the table. You can change the color table associated with this image to show how an indexed image is dependent upon its related color table.

- Change the current color table to the EOS B pre-defined color table:

```
LOADCT, 27
```

- Redisplay the image to show the color table change:

```
TV, image
```

---

**Note**

This step is not always necessary to redisplay the image. On PseudoColor (8-bit) or DirectColor systems, the display will update automatically when the current color table is changed.

---

- Use the XLOADCT utility to display the current color table:

```
XLOADCT
```

Click on the **Done** button of XLOADCT to exit out of the utility.

The following figure shows the indexed image with the EOS B color table.

Figure 3-94: Indexed Image and EOS B Color Table in Direct Graphics

# QUERY\_JPEG

QUERY\_JPG is a method of obtaining information about a JPEG image file without having to read the file. See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.

## Syntax

*Result* = QUERY\_JPEG ( *Filename* [, *Info*] )

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the JPEG file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘JPEG’.

### Note

---

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

---

## Keywords

None.

# QUERY\_JPEG2000

The QUERY\_JPEG2000 function allows you to obtain information about a JPEG2000 image file without having to read the file. It is a wrapper around the IDLffJPEG2000 object interface that presents JPEG2000 image loading in a way familiar to users of the QUERY\_\* image routines. (See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.) However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “[IDLffJPEG2000](#)” in Chapter 6 of the *IDL Reference Guide* manual for information about the object interface.

## Syntax

*Result* = QUERY\_JPEG2000(*Filename* [, *Info*] )

## Return Value

This routine returns a long integer with the value of 1 if the query was successful (and the file type was correct) or 0 on failure.

## Arguments

### Filename

A scalar string containing the full path and filename of the JPEG2000 file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'JPEG2000'.

### Note

---

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

---

In addition to the standard structure fields, the JPEG2000 query structure contains the following additional fields:

Field	IDL Data Type	Description
N_LAYERS	Long	The number of quality layers.
N_LEVELS	Long	The number of wavelet decomposition levels.
OFFSET	Two-element vector	The X and Y offsets for all image components.

Table 3-106: JPEG2000 Query Structure

## Keywords

# QUERY\_MRSID

The QUERY\_MRSID function allows you to obtain information about a MrSID image file without having to read the file. It is a wrapper around the object interface that presents MrSID image loading in a familiar way to users of the QUERY\_\* image routines. (See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.) However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “[IDLffMrSID](#)” on page 3123 for information about the object interface.

---

**Note**

This routine is only available under Microsoft Windows.

---

## Syntax

*Result* = QUERY\_MRSID( *Filename* [, *Info*] [, LEVEL=*lvl*] )

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the full path and filename of the MrSID file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'MrSID'.

---

**Note**

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

---

The info structure also has the following the MRSID-specific fields:

- info.LEVELS – a named variable that will contain a two-element integer vector of the form [minlvl, maxlvl] that specifies the range of levels within the

current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

- Info.GEO\_VALID – a long integer with a value of 1 if the file contains valid georeferencing data, or 0 if the georeferencing data is nonexistent or unsupported.

---

### Note

Always verify that this keyword returns 1 before using the data returned by any other GEO\_\* keyword.

---

- Info.GEO\_PROJTYPE – unsigned integer.
- Info.GEO\_ORIGIN – 2-element double precision array.
- Info.GEO\_RESOLUTION – 2-element double precision array.

See “[IDLffMrSID::GetProperty](#)” on page 3131 for more information on GEO\_\* values.

## Keywords

### LEVEL

Set this keyword to an integer that specifies the level to which the DIMENSIONS field of the info structure corresponds. This can be used, for example, to determine what level is required to fit the image into a certain area. If this keyword is not specified, the dimensions at level 0 are returned.

## Examples

```
; Select the image file.
file = QUERY_MRSID(FILEPATH('test_gs.sid', $
    SUBDIRECTORY=['examples', 'data']), info, LEVEL = -2)

HELP, file
; IDL returns 1 indicating the correct file type
; and successful query.

; Print the range of levels of resolution available within
; the file.
PRINT, 'Range of image levels = ', info.LEVELS

; Print the image dimensions when the image level is set to -2
; as specified by LEVEL = -2 in the QUERY_MRSID statement.
PRINT, 'dimensions of image at LEVEL is -2 =', info.DIMENSIONS
```

```
; IDL returns 2048 by 2048

; Check for valid georeferencing data.
PRINT, 'Result of georeferencing query', info.GEO_VALID
; IDL returns 0 indicating that the file does not contain
; georeferencing data.
```

# QUERY\_PICT

QUERY\_PICT is a method of obtaining information about a PICT image file without having to read the file. See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.

## Syntax

```
Result = QUERY_PICT ( Filename [, Info] )
```

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the PICT file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'PICT'.

### Note

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

# QUERY\_PNG

QUERY\_PNG is a method of obtaining information about a PNG image file without having to read the file. See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.

## Syntax

```
Result = QUERY_PNG ( Filename [, Info] )
```

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the PNG file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘PNG’.

### Note

---

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

---

## Keywords

None

## Examples

Query included in creating RGBA (16-bit/channel) and Color Indexed (8-bits/channel) image.

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = indgen(256)
```

```

green = indgen(256)
blue = indgen(256)
WRITE_PNG, 'rgb_image.png', rgbdata
WRITE_PNG, 'ci_image.png', cidata, red, green, blue

; Query and Read the data:
names = ['rgb_image.png', 'ci_image.png', 'unknown.png']

FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
  ok = QUERY_PNG(names[i],s)
  IF (ok) THEN BEGIN
    HELP,s,/STRUCTURE
    IF (s.HAS_PALETTE) THEN BEGIN
      img = READ_PNG(names[i],rpal,gpal,bpal)
      HELP,img,rpal,gpal,bpal
    ENDIF ELSE BEGIN
      img = READ_PNG(names[i])
      HELP,img
    ENDELSE

# QUERY\_PPM

QUERY\_PPM is a method of obtaining information about a PPM image file without having to read the file. See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.

## Syntax

```
Result = QUERY_PPM ( Filename [, Info] [, MAXVAL=variable] )
```

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the PPM file to query.

### Info

Returns an anonymous structure containing information about the image. The Info.TYPE field will return the value ‘PPM’.

Additional field in the Info structure: MAXVAL - maximum pixel value in the image.

### Note

---

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

---

## Keywords

### MAXVAL

Set this keyword to a named variable to retrieve the maximum pixel value in the image.

# QUERY\_TIFF

QUERY\_TIFF is a method of obtaining information about a TIFF image file without having to read the file. See “[QUERY\\_\\* Routines](#)” on page 1805 for more information.

## Syntax

```
Result = QUERY_TIFF ( Filename [, Info] [, GEOTIFF=variable]
                    [, IMAGE_INDEX=index] )
```

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the pathname of the TIFF file to query.

### Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘TIFF’.

---

### Note

See “[General Query \\* Routine Info Structures](#)” on page 1806 for detailed structure information.

---

### Note

In addition to the fields returned in the Info structure for all image types, there are a number of extra fields in the Info structure for TIFF images. See “[QUERY\\_TIFF-Specific Routine Info Structures](#)” on page 1806 for detailed structure info.

---

## Keywords

### GEOTIFF

Set this keyword to a named variable in which to return an anonymous structure containing the GeoTIFF tags and keys found in the file. If no GeoTIFF information is present in the file, the returned variable is set to a scalar zero. For a description of the possible GeoTIFF tags see the GEOTIFF keyword in READ\_TIFF.

#### Tip

---

This keyword returns the same information as the GEOTIFF keyword to READ\_TIFF, but avoids the overhead of reading in the entire image.

---

### IMAGE\_INDEX

Image number index. If this value is larger than the number of images in the file, the function returns 0 (failure).

## Examples

This is an example of using QUERY\_TIFF to write and read a multi-image TIFF file. The first image is a 16-bit, single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF, 'multi.tif', data, COMPRESSION=1, /SHORT
WRITE_TIFF, 'multi.tif', rgbdata, /LONG, /APPEND

; Read the image data back:
ok = QUERY_TIFF('multi.tif', s)
IF (ok) THEN BEGIN
  FOR i=0, s.NUM_IMAGES-1 DO BEGIN
    imp = QUERY_TIFF('multi.tif', t, IMAGE_INDEX=i)
    img = READ_TIFF('multi.tif', IMAGE_INDEX=i)
    HELP, t, /STRUCTURE
    HELP, img
  ENDFOR
ENDIF
```

# QUERY\_WAV

The QUERY\_WAV function checks that the file is actually a .WAV file and that the READ\_WAV function can read the data in the file. Optionally, it can return additional information about the data in the file.

## Syntax

*Result* = QUERY\_WAV ( *Filename* [, *Info*] )

## Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

## Arguments

### Filename

A scalar string containing the full pathname of the .WAV file to read.

### Info

An anonymous structure containing information about the data in the file. The fields are defined as:

Tag	Type	Definition
CHANNELS	INT	Number of data channels in the file.
SAMPLES_PER_SEC	LONG	Data sampling rate in samples per second.
BITS_PER_SAMPLE	INT	Number of valid bits in the data.

# R\_CORRELATE

The R\_CORRELATE function computes Spearman's (rho) or Kendall's (tau) rank correlation of two sample populations  $X$  and  $Y$ . The result is a two-element vector containing the rank correlation coefficient and the two-sided significance of its deviation from zero. The significance is a value in the interval [0.0, 1.0]; a small value indicates a significant correlation.

$$\text{rho} = \frac{\sum_{i=0}^{N-1} (R_{x_i} - \bar{R}_x)(R_{y_i} - \bar{R}_y)}{\sqrt{\sum_{i=0}^{N-1} (R_{x_i} - \bar{R}_x)^2} \sqrt{\sum_{i=0}^{N-1} (R_{y_i} - \bar{R}_y)^2}}$$

where  $R_{x_i}$  and  $R_{y_i}$  are the magnitude-based ranks among  $X$  and  $Y$ , respectively. Elements of identical magnitude are ranked using a rank equal to the mean of the ranks that would otherwise be assigned.

This routine is written in the IDL language. Its source code can be found in the file `r_correlate.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = R\_CORRELATE(  $X$ ,  $Y$  [, **D**=variable] [, /**KENDALL**] [, **PROBD**=variable] [, **ZD**=variable] )

## Return Value

Returns a two-element vector indicating the rank correlation coefficient and the significance of its deviation from zero.

## Arguments

### **X**

An  $n$ -element integer, single-, or double-precision floating-point vector.

### **Y**

An  $n$ -element integer, single-, or double-precision floating-point vector.

## Keywords

### D

Set this keyword to a named variable that will contain the sum-squared difference of ranks. If the KENDALL keyword is set, this parameter is returned as zero.

### KENDALL

Set this keyword to compute Kendalls's (tau) rank correlation. By default, Spearman's (rho) rank correlation is computed.

### PROBD

Set this keyword to a named variable that will contain the two-sided significance level of ZD. If the KENDALL keyword is set, this parameter is returned as zero.

### ZD

Set this keyword to a named variable that will contain the number of standard deviations by which D deviates from its null-hypothesis expected value. If the KENDALL keyword is set, this parameter is returned as zero.

## Examples

```
; Define two n-element sample populations:
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute Spearman's (rho) rank correlation of X and Y.
result = R_CORRELATE(X, Y)
PRINT, 'Spearman's (rho) rank correlation: ', result

; Compute Kendalls's (tau) rank correlation of X and Y:
result = R_CORRELATE(X, Y, /KENDALL)
PRINT, 'Kendalls's (tau) rank correlation: ', result
```

IDL prints:

```
Spearman's (rho) rank correlation:    0.835967  4.42899e-006
Kendalls's (tau) rank correlation:    0.624347  0.000118729
```

# R\_TEST

The `R_TEST` function tests the hypothesis that a binary population (a sequence of 1s and 0s) represents a “random sampling”.

This routine is written in the IDL language. Its source code can be found in the file `r_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = R_TEST( X [, NO=variable] [, N1=variable] [, R=variable] )
```

## Return Value

The result is a two-element vector containing the nearly-normal test statistic  $Z$  and its associated probability. This two-tailed test is based on the “theory of runs” and is often referred to as the “Runs Test for Randomness.”

## Arguments

### **X**

An  $n$ -element integer, single-, or double-precision floating-point vector. Elements not equal to 0 or 1 are removed and the length of  $X$  is correspondingly reduced.

## Keywords

### **NO**

Set this keyword to a named variable that will contain the number of 0s in  $X$ .

### **N1**

Set this keyword to a named variable that will contain the number of 1s in  $X$ .

### **R**

Set this keyword to a named variable that will contain the number of runs (clusters of 0s and 1s) in  $X$ .

## Examples

```

; Define a binary population:
X = [0, 1, 1, 0, 1, 0, 0, 0, 1, 0, 1, 1, 0, 1, 0, 1, 0, 0, $
     1, 0, 1, 1, 0, 1, 0, 0, 1, 0, 1]

; Test the hypothesis that X represents a random sampling against
; the hypothesis that it does not represent a random sampling at
; the 0.05 significance level:
result = R_TEST(X, R = r, N0 = n0, N1 = n1)
PRINT, result

```

IDL prints:

```
[2.26487, 0.0117604]
```

Print the values of the keyword parameters:

```

PRINT, 'Runs: ', r & PRINT, 'Zeros: ', n0 & PRINT, 'Ones: ', n1
Runs:      22
Zeros:     16
Ones:      14

```

The computed probability (0.0117604) is less than the 0.05 significance level and therefore we reject the hypothesis that  $X$  represents a random sampling. The results show that there are too many runs, indicating a non-random cyclical pattern.

# RADON

The RADON function implements the Radon transform, used to detect features within a two-dimensional image. This function can be used to return either the Radon transform, which transforms lines through an image to points in the Radon domain, or the Radon backprojection, where each point in the Radon domain is transformed to a straight line in the image.

## Radon Transform Theory

The Radon transform is used to detect features within an image. Given a function  $A(x, y)$ , the Radon transform is defined as:

$$R(\theta, \rho) = \int_{-\infty}^{\infty} A(\rho \cos \theta - s \sin \theta, \rho \sin \theta + s \cos \theta) ds$$

This equation describes the integral along a line  $s$  through the image, where  $\rho$  is the distance of the line from the origin and  $\theta$  is the angle from the horizontal.

Figure 3-95: The Radon Transform

In medical imaging, each point  $R(\theta, \rho)$  is called a ray-sum, while the resulting image is called a shadowgram. An image can be reconstructed from its ray-sums using the backprojection operator:

$$B(x, y) = \int_0^{\pi} R(\theta, x \cos \theta + y \sin \theta) d\theta$$

where the output,  $B(x, y)$ , is an image of  $A(x, y)$  blurred by the Radon transform.

## How IDL Implements the Radon Transform

To avoid the use of a two-dimensional interpolation and decrease the interpolation errors, the Radon transform equation is rotated by  $\theta$ , and the interpolation is then done along the line  $s$ . The transform is divided into two regions, one for nearly-horizontal lines ( $\theta \leq 45^\circ$ ;  $135^\circ \leq \theta \leq 180^\circ$ ), and the other for steeper lines ( $45^\circ < \theta < 135^\circ$ ), where  $\theta$  is assumed to lie on the interval  $[0^\circ, 180^\circ]$ .

For nearest-neighbor interpolation (the default), the discrete transform formula for an image  $A(m, n)$  [ $m = 0, \dots, M-1, n = 0, \dots, N-1$ ] is:

$$R(\theta, \rho) = \begin{cases} \frac{\Delta x}{|\sin \theta|} \sum_m A(m, [am + b]) & |\sin \theta| > \frac{\sqrt{2}}{2} \\ \frac{\Delta y}{|\cos \theta|} \sum_n A([a'n + b'], n) & |\sin \theta| \leq \frac{\sqrt{2}}{2} \end{cases}$$

where brackets  $[ ]$  indicate rounding to the nearest integer, and the slope and offsets are given by:

$$a = -\frac{\Delta x \cos \theta}{\Delta y \sin \theta} \qquad b = \frac{\rho - x_{\min} \cos \theta - y_{\min} \sin \theta}{\Delta y \sin \theta}$$

$$a' = \frac{1}{a} \qquad b' = \frac{\rho - x_{\min} \cos \theta - y_{\min} \sin \theta}{\Delta x \cos \theta}$$

For linear interpolation, the transform is:

$$R(\theta, \rho) = \begin{cases} \frac{\Delta x}{|\sin \theta|} \sum_m (1-w)A(m, \lfloor am + b \rfloor) + wA(m, \lfloor am + b \rfloor + 1) & |\sin \theta| > \frac{\sqrt{2}}{2} \\ \frac{\Delta y}{|\cos \theta|} \sum_n (1-w)A(\lfloor a'n + b' \rfloor, n) + wA(\lfloor a'n + b' \rfloor + 1, n) & |\sin \theta| \leq \frac{\sqrt{2}}{2} \end{cases}$$

where the slope and offsets are the same as above, and  $\lfloor \rfloor$  indicates flooring to the nearest lower integer. The weighting  $w$  is given by the difference between  $am + b$  and its floored value, or between  $a'n + b'$  and its floored value.

## How IDL Implements the Radon Backprojection

For the backprojection transform, the discrete formula for nearest-neighbor interpolation is:

$$B(m,n) = \Delta\theta \sum_t R(\theta_t, \lfloor \rho \rfloor)$$

with the nearest-neighbor for  $\rho$  given by:

$$\rho = \{ (m\Delta x + x_{\min}) \cos \theta_t + (n\Delta y + y_{\min}) \sin \theta_t - \rho_{\min} \} \Delta \rho^{-1}$$

For backprojection with linear interpolation:

$$B(m,n) = \Delta\theta \sum_t (1-w)R(\theta_t, \lfloor \rho \rfloor) + wR(\theta_t, \lfloor \rho \rfloor + 1)$$

$$w = \rho - \lfloor \rho \rfloor$$

and  $\rho$  is the same as in the nearest-neighbor.

## Syntax

### Radon Transform:

```
Result = RADON( Array [, /DOUBLE] [, DRHO=scalar] [, DX=scalar]
  [, DY=scalar] [, /GRAY] [, /LINEAR] [, NRHO=scalar] [, NTHETA=scalar]
  [, RHO=variable] [, RMIN=scalar] [, THETA=variable] [, XMIN=scalar]
  [, YMIN=scalar] )
```

### Radon Backprojection:

```
Result = RADON( Array, /BACKPROJECT, RHO=variable, THETA=variable
  [, /DOUBLE] [, DX=scalar] [, DY=scalar] [, /LINEAR] [, NX=scalar]
  [, NY=scalar] [, XMIN=scalar] [, YMIN=scalar] )
```

## Return Value

The result of this function is a two-dimensional floating-point array, or a complex array if the input image is complex. If *Array* is double-precision, or if the `DOUBLE` keyword is set, the result is double-precision, otherwise, the result is single-precision.

## Arguments

### Array

The two-dimensional array of size  $M$  by  $N$  to be transformed.

## Keywords

### BACKPROJECT

If set, the backprojection is computed, otherwise, the forward transform is computed.

#### Note

---

The Radon backprojection does not return the original image. Instead, it returns an image blurred by the Radon transform. Because the Radon transform is not one-to-one, multiple  $(x, y)$  points are mapped to a single  $(\theta, \rho)$ .

---

### DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

### DRHO

Set this keyword equal to a scalar specifying the spacing between  $\rho$  coordinates, expressed in the same units as *Array*. The default is one-half of the diagonal distance between pixels,  $0.5[(DX^2 + DY^2)]^{1/2}$ . Smaller values produce finer resolution, and are useful for zooming in on interesting features. Larger values may result in undersampling, and are not recommended. If BACKPROJECT is specified, this keyword is ignored.

### DX

Set this keyword equal to a scalar specifying the spacing between the horizontal ( $x$ ) coordinates. The default is 1.0.

### DY

Set this keyword equal to a scalar specifying the spacing between the vertical ( $y$ ) coordinates. The default is 1.0.

## GRAY

Set or omit this keyword to perform a weighted Radon transform, with the weighting given by the pixel values. If GRAY is explicitly set to zero, the image is treated as a binary image with all nonzero pixels considered as 1.

## LINEAR

Set this keyword to use linear interpolation rather than the default nearest-neighbor sampling. Results are more accurate but slower when linear interpolation is used.

## NRHO

Set this keyword equal to a scalar specifying the number of  $\rho$  coordinates to use. The default is  $2 \text{ CEIL}([\text{MAX}(x^2 + y^2)]^{1/2} / \text{DRHO}) + 1$ . If BACKPROJECT is specified, this keyword is ignored.

## NTHETA

Set this keyword equal to a scalar specifying the number of  $\theta$  coordinates to use over the interval  $[0, \pi]$ . The default is  $\text{CEIL}(\pi [(M^2 + N^2)/2]^{1/2})$ . Larger values produce smoother results, and are useful for filtering before backprojection. Smaller values result in broken lines in the transform, and are not recommended. If BACKPROJECT is specified, this keyword is ignored.

## NX

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of horizontal coordinates in the output *Result*. The default is  $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$ . For the forward transform this keyword is ignored.

## NY

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of vertical coordinates in the output *Result*. The default is  $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$ . For the forward transform, this keyword is ignored.

## RHO

For the forward transform, set this keyword to a named variable that will contain the radial ( $\rho$ ) coordinates, in units defined by the DX and DY keywords (pixels by default). If BACKPROJECT is specified, this keyword must contain the  $\rho$  coordinates of the input *Array*. The  $\rho$  coordinates should be evenly spaced and in increasing order.

## RMIN

Set this keyword equal to a scalar specifying the minimum  $\rho$  coordinate to use for the forward transform. The default is  $-0.5(NRHO - 1) DRHO$ . If `BACKPROJECT` is specified, this keyword is ignored.

## THETA

For the forward transform, set this keyword to a named variable containing a vector of angular ( $\theta$ ) coordinates (in radians) to use for the transform. If `NTHETA` is specified instead, and `THETA` is set to a named variable, on exit `THETA` will contain the  $\theta$  coordinates. If `BACKPROJECT` is specified, this keyword must contain the  $\theta$  coordinates of the input *Array*.

## XMIN

Set this keyword equal to a scalar specifying the  $x$ -coordinate of the lower-left corner of the input *Array*. The default is  $-(M-1)/2$ , where *Array* is an  $M$  by  $N$  array. If `BACKPROJECT` is specified, set this keyword equal to a scalar specifying the  $x$ -coordinate of the lower-left corner of the *Result*. In this case the default is  $-DX (NX-1)/2$ .

## YMIN

Set this keyword equal to a scalar specifying the  $y$ -coordinate of the lower-left corner of the input *Array*. The default is  $-(N-1)/2$ , where *Array* is an  $M$  by  $N$  array. If `BACKPROJECT` is specified, set this keyword equal to a scalar specifying the  $y$ -coordinate of the lower-left corner of the *Result*. In this case, the default is  $-DY (NY-1)/2$ .

## Examples

### Note

---

Also see [“Transforming to and from the Hough and Radon Domains”](#) in Chapter 7 of the *Image Processing in IDL* manual.

---

This example displays the Radon transform and the Radon backprojection:

```
PRO radon_example

    DEVICE, DECOMPOSED=0

    ;Create an image with a ring plus random noise:
    x = (LINDGEN(128,128) MOD 128) - 63.5
```

```

y = (LINDGEN(128,128)/128) - 63.5
radius = SQRT(x^2 + y^2)
array = (radius GT 40) AND (radius LT 50)
array = array + RANDOMU(seed,128,128)

;Create display window, set graphics properties:
WINDOW, XSIZE=440,YSIZE=700, TITLE='Radon Example'
!P.BACKGROUND = 255 ; white
!P.COLOR = 0 ; black
!P.FONT=2
ERASE

XYOUTS, .05, .94, 'Ring and Random Pixels', /NORMAL
;Display the image. 255b changes black values to white:
TVSCL, 255b - array, .05, .75, /NORMAL

;Calculate and display the Radon transform:
XYOUTS, .05, .70, 'Radon Transform', /NORMAL
result = RADON(array, RHO=rho, THETA=theta)
TVSCL, 255b - result, .08, .32, /NORMAL

# RANDOMN

The RANDOMN function returns one or more normally-distributed, floating-point, pseudo-random numbers with a mean of zero and a standard deviation of one. RANDOMN uses the Box-Muller method for generating normally-distributed (Gaussian) random numbers.

## Syntax

```
Result = RANDOMN( Seed [, D1 [, ..., Dg]] [ [, BINOMIAL=[trials, probability]]
  [, /DOUBLE] [, GAMMA=integer{>0}] [, /NORMAL] [, POISSON=value]
  [, /UNIFORM] | [, /LONG] ] )
```

## Return Value

Returns an array containing the random numbers of the specified dimensions.

## Arguments

### Seed

A variable or constant used to initialize the random sequence on input, and in which the state of the random number generator is saved on output.

The state of the random number generator is contained in a long integer vector. This state is saved in the Seed argument when the argument is a named variable. To continue the pseudo-random number sequence, input the variable containing the saved state as the Seed argument in the next call to RANDOMN or RANDOMU. Each independent random number sequence should maintain its own state variable. To maintain a state over repeated calls to a procedure, the seed variable may be stored in a COMMON block.

In addition to states maintained by the user in variables, the RANDOMU and RANDOMN functions contain a single shared generic state that is used if a named variable is not supplied as the Seed argument or the named variable supplied is undefined. The generic state is initialized once using the time-of-day, and may be re-initialized by providing a Seed argument that is a constant or expression.

If the Seed argument is:

- An undefined variable — the generic state is used and the resulting generic state array is stored in the variable.

- A named variable that contains a longword array of the proper length — it is used to continue the pseudo-random sequence, and is updated.
- A named variable containing a scalar — the scalar value is used to start a new sequence and the resulting state array is stored back in the variable.
- A constant or expression — the value is used to re-initialize the generic state.

---

**Note**

RANDOMN and RANDOMU use the same sequence. Starting or restarting the sequence for one starts or restarts the sequence for the other. Some IDL routines use the random number generator, so using them will initialize the seed sequence. An example of such a routine is CLUST\_WTS.

---

**Note**

Do not alter the seed value returned by this function. The only valid use for the seed argument is to pass it back to a subsequent call. Changing the value of the seed will corrupt the random sequence.

---

**D<sub>i</sub>**

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If no dimensions are specified, RANDOMN returns a scalar result

## Keywords

The formulas for the binomial, gamma, and Poisson distributions are from section 7.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

### BINOMIAL

Set this keyword to a 2-element array,  $[n, p]$ , to generate random deviates from a binomial distribution. If an event occurs with probability  $p$ , with  $n$  trials, then the number of times it occurs has a binomial distribution.

---

**Note**

For  $n > 1.0 \times 10^7$ , you should set the DOUBLE keyword.

---

## DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

RANDOMN constructs double-precision uniform random deviates using the formula:

$$Y = \frac{(i1 - 1) \cdot imax + i2}{imax^2 + 1}$$

where  $i1$  and  $i2$  are integer random deviates in the range  $[1...imax]$ , and  $imax = 2^{31} - 2$  is the largest possible integer random deviate. The  $Y$  values will be in the range  $0 < Y < 1$ .

## GAMMA

Set this keyword to an integer order  $i > 0$  to generate random deviates from a gamma distribution. The gamma distribution is the waiting time to the  $i$ th event in a Poisson random process of unit mean. A gamma distribution of order equal to 1 is the same as the exponential distribution.

### Note

---

For  $GAMMA > 1.0 \times 10^7$ , you should set the DOUBLE keyword.

---

## LONG

Set this keyword to return integer uniform random deviates in the range  $[1...2^{31} - 2]$ . If LONG is set, all other keywords are ignored.

## NORMAL

Set this keyword to generate random deviates from a normal distribution.

## POISSON

Set this keyword to the mean number of events occurring during a unit of time. The POISSON keyword returns a random deviate drawn from a Poisson distribution with that mean.

### Note

---

For  $POISSON > 1.0 \times 10^7$ , you should set the DOUBLE keyword.

---

## UNIFORM

Set this keyword to generate random deviates from a uniform distribution.

### Examples

If you start the sequence with an *undefined* variable—if RANDOMN has already been called, *Seed* is no longer undefined—IDL initializes the sequence with the system time:

```
; Generate one random variable and initialize the sequence with an
; undefined variable:
randomValue = RANDOMN(seed)
```

The new state is saved in *seed*. To generate repeatable experiments, begin the sequence with a particular seed:

```
seed_value = 5L

; Generate one random variable and initialize the sequence with 5:
randomValue = RANDOMN(seed_value)

PRINT, randomValue
```

IDL prints:

```
0.521414
```

To restart the sequence with a particular seed, re-initialize the variable:

```
seed = 5L

;Get a normal random number, and restart the sequence with a seed
;of 5.
randomValue = RANDOMN(seed)

PRINT, randomValue
```

IDL prints:

```
0.521414
```

To continue the same sequence:

```
PRINT, RANDOMN(seed)
```

IDL prints:

```
-0.945489
```

To create a 10 by 10 array of normally-distributed, random numbers, type:

```
R = RANDOMN(seed, 10, 10)
```

Since seed is undefined, the generic state is used to initialize the random number generator. Print the resulting values by entering:

```
PRINT, R
```

A more interesting example plots the probability function of 2000 numbers returned by RANDOMN. Type:

```
PLOT, HISTOGRAM(RANDOMN(SEED, 2000), BINSIZE=0.1)
```

To obtain a sequence of 1000 exponential (gamma distribution, order 1) deviates, type:

```
Result = RANDOMN(seed, 1000, GAMMA=1)
```

Intuitively, the result contains a random series of waiting times for events occurring an average of one per time period.

To obtain a series of 1000 random elapsed times required for the arrival of two events, type:

```
;Returns a series of 1000 random elapsed times required for the
;arrival of two events.
Result = RANDOMN(seed, 1000, GAMMA=2)
```

To obtain a 128 x 128 array filled with Poisson deviates, with a mean of 1.5, type:

```
Result = RANDOMN(seed, 128, 128, POISSON=1.5)
```

To simulate the count of “heads” obtained when flipping a coin 10 times, type:

```
Result = RANDOMN(seed, BINOMIAL=[10, .5])
```

[RANDOMU](#)

# RANDOMU

The RANDOMU function returns one or more uniformly-distributed, floating-point, pseudo-random numbers in the range  $0 < Y < 1.0$ .

The random number generator is taken from: “Random Number Generators: Good Ones are Hard to Find”, Park and Miller, *Communications of the ACM*, Oct 1988, Vol 31, No. 10, p. 1192. To remove low-order serial correlations, a Bays-Durham shuffle is added, resulting in a random number generator similar to ran1() in Section 7.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

## Syntax

```
Result = RANDOMU( Seed [, D1 [, ..., D8]] [ [, BINOMIAL=[trials, probability]]
  [, /DOUBLE] [, GAMMA=integer{>0}] [, /NORMAL] [, POISSON=value]
  [, /UNIFORM] | [, /LONG] ] )
```

## Return Value

Returns an array of uniformly distributed random numbers of the specified dimensions.

## Arguments

### Seed

A variable or constant used to initialize the random sequence on input, and in which the state of the random number generator is saved on output.

The state of the random number generator is contained in a long integer vector. This state is saved in the Seed argument when the argument is a named variable. To continue the pseudo-random number sequence, input the variable containing the saved state as the Seed argument in the next call to RANDOMN or RANDOMU. Each independent random number sequence should maintain its own state variable. To maintain a state over repeated calls to a procedure, the seed variable may be stored in a COMMON block.

In addition to states maintained by the user in variables, the RANDOMU and RANDOMN functions contain a single shared generic state that is used if a named variable is not supplied as the Seed argument or the named variable supplied is

undefined. The generic state is initialized once using the time-of-day, and may be re-initialized by providing a Seed argument that is a constant or expression.

If the Seed argument is:

- an undefined variable — the generic state is used and the resulting generic state array is stored in the variable.
- a named variable that contains a longword array of the proper length — it is used to continue the pseudo-random sequence, and is updated.
- a named variable containing a scalar — the scalar value is used to start a new sequence and the resulting state array is stored back in the variable.
- a constant or expression — the value is used to re-initialize the generic state.

---

**Note**

RANDOMN and RANDOMU use the same sequence, so starting or restarting the sequence for one starts or restarts the sequence for the other. Some IDL routines use the random number generator, so using them will initialize the seed sequence. An example of such a routine is CLUST\_WTS.

---

**Note**

Do not alter the seed value returned by this function. The only valid use for the seed argument is to pass it back to a subsequent call. Changing the value of the seed will corrupt the random sequence.

---

**D<sub>i</sub>**

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If no dimensions are specified, RANDOMU returns a scalar result

## Keywords

The formulas for the binomial, gamma, and Poisson distributions are from Section 7.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

## BINOMIAL

Set this keyword to a 2-element array,  $[n, p]$ , to generate random deviates from a binomial distribution. If an event occurs with probability  $p$ , with  $n$  trials, then the number of times it occurs has a binomial distribution.

### Note

---

For  $n > 1.0 \times 10^7$ , you should set the DOUBLE keyword.

---

## DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

RANDOMU constructs double-precision uniform random deviates using the formula:

$$Y = \frac{(i1 - 1) \cdot imax + i2}{imax^2 + 1}$$

where  $i1$  and  $i2$  are integer random deviates in the range  $[1...imax]$ , and  $imax = 2^{31} - 2$  is the largest possible integer random deviate. The  $Y$  values will be in the range  $0 < Y < 1$ .

## GAMMA

Set this keyword to an integer order  $i > 0$  to generate random deviates from a gamma distribution. The gamma distribution is the waiting time to the  $i$ th event in a Poisson random process of unit mean. A gamma distribution of order equal to 1 is the same as the exponential distribution.

### Note

---

For GAMMA  $> 1.0 \times 10^7$ , you should set the DOUBLE keyword.

---

## LONG

Set this keyword to return integer uniform random deviates in the range  $[1...2^{31} - 2]$ . If LONG is set, all other keywords are ignored.

## NORMAL

Set this keyword to generate random deviates from a normal distribution.

## POISSON

Set this keyword to the mean number of events occurring during a unit of time. The POISSON keyword returns a random deviate drawn from a Poisson distribution with that mean.

### Note

---

For POISSON  $> 1.0 \times 10^7$ , you should set the DOUBLE keyword.

---

## UNIFORM

Set this keyword to generate random deviates from a uniform distribution.

## Examples

This example simulates rolling two dice 10,000 times and plots the distribution of the total using RANDOMU. Enter:

```
PLOT, HISTOGRAM(FIX(6 * RANDOMU(S, 10000)) + $
    FIX(6 * RANDOMU(S, 10000)) + 2)
```

In the above statement, the expression RANDOMU(S, 10000) is a 10,000-element, floating-point array of random numbers greater than or equal to 0 and less than 1. Multiplying this array by 6 converts the range to  $0 \leq Y < 6$ .

Applying the FIX function yields a 10,000-point integer vector with values from 0 to 5, one less than the numbers on one die. This computation is done twice, once for each die, then 2 is added to obtain a vector from 2 to 12, the total of two dice.

The HISTOGRAM function makes a vector in which each element contains the number of occurrences of dice rolls whose total is equal to the subscript of the element. Finally, this vector is plotted by the PLOT procedure.

An example of reusing a state vector to generate a repeatable sequence:

```
; Init seed for a repeatable sequence:
seed = 1001L

; Print 1st 5 numbers of sequence:
print, randomu(seed, 5)
```

IDL prints:

```
0.705884    0.285924    0.231151    0.715447    0.532836
```

Reuse a state vector:

```
; Re-init seed to same sequence:  
seed = 1001L  
  
; Get 5 number of sequence with 5 calls:  
for i=0,4 do print, randomu(seed)
```

IDL prints:

```
0.705884  
0.285924  
0.231151  
0.715447  
0.532836
```

[RANDOMN](#)

# RANKS

The RANKS function computes the magnitude-based ranks of a sample population  $X$ . Elements of identical magnitude “ties” are ranked according to the mean of the ranks that would otherwise be assigned.

This routine is written in the IDL language. Its source code can be found in the file `ranks.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = RANKS(*X*)

## Return Value

The result is a vector of ranks equal in length to  $X$ .

## Arguments

### $X$

An  $n$ -element integer, single-, or double-precision floating-point vector. The elements of this vector must be in ascending order based on their magnitude.

## Keywords

None.

## Examples

```

; Define an n-element sample population:
X = [-0.8, 0.1, -2.3, -0.6, 0.2, 1.1, -0.3, 0.6, -0.2, 1.1, $
      -0.7, -0.2, 0.6, 0.4, -0.1, 1.1, -0.3, 0.3, -1.3, 1.1]

; Allocate a two-column, n-row array to store the results:
array = FLTARR(2, N_ELEMENTS(X))

; Sort the sample population and store in the 0th column of ARRAY:
array[0, *] = X[SORT(X)]
; Compute the ranks of the sorted sample population and store in
; the 1st column of ARRAY:
array[1, *] = RANKS(X[SORT(X)])

```

```
; Display the sorted sample population and corresponding ranks  
; with a two-decimal format:  
PRINT, array, FORMAT = '(2(5x, f5.2))'
```

IDL prints:

```
-2.30      1.00  
-1.30      2.00  
-0.80      3.00  
-0.70      4.00

[R\\_CORRELATE](#)

# RDPIX

The RDPIX procedure interactively displays the X position, Y position, and pixel value at the cursor.

This routine is written in the IDL language. Its source code can be found in the file `rdpix.pro` in the `lib` subdirectory of the IDL distribution.

## Using RDPIX

RDPIX displays a stream of X, Y, and pixel values when the mouse cursor is moved over a graphics window. Press the left or center mouse button to create a new line of output. Press the right mouse button to exit the procedure.

## Syntax

```
RDPIX, Image [, X0, Y0]
```

## Arguments

### Image

The array that contains the image being displayed. This array may be of any type. Rather than reading pixel values from the display, values are taken from this parameter, avoiding scaling difficulties.

### X0, Y0

The location of the lower-left corner of the image area on screen. If these parameters are not supplied, they are assumed to be zero.

## Keywords

None.

# READ/READF

The READ procedures perform formatted input into variables.

READ performs input from the standard input stream (IDL file unit 0), while READF requires a file unit to be explicitly specified.

## Syntax

```
READ, [Prompt,] Var1, ..., Varn
```

```
READF, [Prompt,] Unit, Var1, ..., Varn
```

**Keywords:** [, **AM\_PM**=*[string, string]*] [, **DAYS\_OF\_WEEK**=*string\_array*{7 names}] [, **FORMAT**=*value*] [, **MONTHS**=*string\_array*{12 names}] [, **PROMPT**=*string*]

## Arguments

### Prompt

#### Note

---

The PROMPT keyword should be used instead of the *Prompt* argument for compatibility with window-based versions of IDL.

---

A string or explicit expression (i.e., not a named variable) to be used as a prompt. This argument should not be included if the FORMAT keyword is specified. Also, if this argument begins with the characters “\$(”, it is taken to be a format specification as described below under “Format Compatibility”.

Using the *Prompt* argument does not work well with IDL for Windows. The desired prompt string is written to the log window instead of the command input window. To create custom prompts compatible with these versions of IDL, use the PROMPT keyword, described below.

### Unit

For READF, Unit specifies the file unit from which the input is taken.

### Var<sub>*i*</sub>

The named variables to receive the input.

**Note**

$Var_i$  may *not* be an element of an array variable (`arrayvar [n]`) or a field within a structure variable (`structvar.tag`). See “[Parameter Passing Mechanism](#)” in Chapter 5 of the *Building IDL Applications* manual for details.

If the variable specified for the  $Var_i$  argument has not been previously defined, the input data is assumed to be of type float, and the variable will be created as a float.

## Keywords

### AM\_PM

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

### DAYS\_OF\_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

### FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the input. FORMAT allows the format of the input to be specified in precise detail, using a FORTRAN-style specification. See “[Using Explicitly Formatted Input/Output](#)” in Chapter 18 of the *Building IDL Applications* manual.

### MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

### PROMPT

Set this keyword to a scalar string to be used as a customized prompt for the READ command. If the PROMPT keyword or *Prompt* argument is not supplied, IDL uses a colon followed by a space (“: ”) as the input prompt.

## Format Compatibility

If the `FORMAT` keyword is not present and `READ` is called with more than one argument, and the first argument is a scalar string starting with the characters “\$(”, this initial argument is taken to be the format specification, just as if it had been specified via the `FORMAT` keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

## Examples

To read a string value into the variable `B` from the keyboard, enter:

```
; Define B as a string before reading:
B = ''

; Read input from the terminal:
READ, B, PROMPT='Enter Name: '
```

To read formatted data from the previously-opened file associated with logical unit number 7 into variable `C`, use the command:

```
READF, 7, C
```

## Version History

# READ\_ASCII

The READ\_ASCII function reads data from an ASCII file into an IDL structure variable. READ\_ASCII may be used with templates created by the [ASCII\\_TEMPLATE](#) function.

This routine handles ASCII files consisting of an optional header of a fixed number of lines, followed by columnar data. One or more rows of data constitute a *record*. Each data element within a record is considered to be in a different column, or *field*. The data in one field must be of, or promotable to, a single type (e.g., FLOAT). Adjacent fields may be collected into multi-column fields, called *groups*. Files may also contain comments, which exist between a user-specified comment string and the corresponding end-of-line.

READ\_ASCII is designed to be used with templates created by the ASCII template function.

This routine is written in the IDL language. Its source code can be found in the file `read_ascii.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = READ_ASCII( [Filename] [, COMMENT_SYMBOL=string]
  [, COUNT=variable] [, DATA_START=lines_to_skip] [, DELIMITER=string]
  [, HEADER=variable] [, MISSING_VALUE=value] [, NUM_RECORDS=value]
  [, RECORD_START=index] [, TEMPLATE=value] [, /VERBOSE] )
```

## Return Value

The result is an IDL structure array containing the data. Each field in the structure corresponds to a different column of data and each element in the array corresponds to a different record (a row of data).

## Arguments

### Filename

A string containing the name of an ASCII file to read into an IDL variable. If *filename* is not specified, a dialog allows the user to choose a file.

## Keywords

You can define the attributes of a field in two ways. If you use a template, you can either use a previously generated template, or create a template with [ASCII\\_TEMPLATE](#). You can use `COMMENT_SYMBOL`, `DATA_START`, `DELIMITER`, or `MISSING_VALUE` to either override template attributes or to provide one-time attributes for the file to be read, without a template.

### **COMMENT\_SYMBOL**

Set this keyword to a string that identifies the character used to delineate comments in the ASCII file to be read. When `READ_ASCII` encounters the comment character, it discards data from that point until it reaches the end of the current line, identifying the rest of the line as a comment. The default character is the null string, `'`, specifying that no comments will be recognized.

### **COUNT**

Set this keyword equal to a named variable that will contain the number of records read.

### **DATA\_START**

Set this keyword equal to the number of header lines you want to skip. The default value is 0 if no template is specified.

### **DELIMITER**

Set this keyword to a string that identifies the end of a field. If no delimiter is specified, `READ_ASCII` uses information provided by the template in use. The default is a space, `' '`, specifying that an empty element constitutes the end of a field.

### **HEADER**

Set this keyword equal to a named variable that will contain the header in a string array of length `DATA_START`. If no header exists, an empty string is returned.

### **MISSING\_VALUE**

Set this keyword equal to a value used to replace any missing or invalid data. The default value, if no template is supplied, is `!VALUES.F_NAN`. See ["!VALUES"](#) on page 4805 for details.

## NUM\_RECORDS

Set this keyword equal to the number of records to read. The default is to read up to and including the last record.

## RECORD\_START

Set this keyword equal to the index of the first record to read. The default is the first record of the file (record 0).

## TEMPLATE

Use this keyword to specify the ASCII file template (generated by the function [ASCII\\_TEMPLATE](#)), that defines attributes of the file to be read. Specific attributes of the template may be overridden by the following keywords: COMMENT\_SYMBOL, DATA\_START, DELIMITER, MISSING\_VALUE.

## VERBOSE

Set this keyword to print runtime messages.

## Examples

To read ASCII data using default file attributes, except for setting the number of skipped header lines to 10, type:

```
data = READ_ASCII(file, DATA_START=10)
```

To use a template to define file attributes, overriding the number of skipped header lines defined in the template, type:

```
data = READ_ASCII(file, TEMPLATE=template, DATA_START=10)
```

To use the ASCII\_TEMPLATE GUI to generate a template within the function, type:

```
data = READ_ASCII(myfile, TEMPLATE=ASCII_TEMPLATE(myfile))
```

## Working with a READ\_ASCII Data Structure

READ\_ASCII returns a structure containing ASCII data, which is formatted according to specified keywords or a template. The following example returns a structure containing the data in the `sine_waves.txt` file, found in the `examples/data` subdirectory of the IDL installation directory.

1. Enter the following statement at the IDL command line to open the **ASCII Template** dialog:

```
sTemplate = ASCII_TEMPLATE()
```

2. Complete the steps described in “Using the ASCII Template Dialog” on page 109 to define the format of the data.
3. Use `READ_ASCII` to access the data, defined by the template created in the previous step;

```
data = READ_ASCII(FILEPATH('sine_waves.txt', $
    SUBDIRECTORY=['examples', 'data']), TEMPLATE = sTemplate)
```

4. The variable `data` now contains the ASCII data. Use the format *structureName.fieldName* to access individual fields of data. The following lines plot each data field in an `iPlot` display:

```
iPLOT, data.SmoothSine
iPLOT, data.NoisySine, color = [255, 0, 0], /OVERPLOT
```

---

### Note

The Variable Watch window contains the `sTemplate` and `data` structures. Expand these items for information about the structure fields.

## See Also

[ASCII\\_TEMPLATE](#), [QUERY\\_ASCII](#)

# READ\_BINARY

The READ\_BINARY function reads the contents of a binary file using a passed template or basic command line keywords. Data is read from the given filename or from the current file position in the open file pointed to by *FileUnit*. If no template is provided, keywords can be used to read a single IDL array of data.

## Syntax

```
Result = READ_BINARY ([Filename] | FileUnit [, TEMPLATE=template] |  
    [[, DATA_START=value] [, DATA_TYPE=typecodes] [, DATA_DIMS=array]  
    [, ENDIAN=string] )
```

## Return Value

The result is an array or anonymous structure containing all of the entities read from the file.

## Arguments

### Filename

A scalar string containing the name of the binary file to read. If *filename* and file unit are not specified, a dialog allows the user to choose a file.

### FileUnit

A scalar containing an open IDL file unit number to read from.

## Keywords

### DATA\_DIMS

Set this keyword to a scalar or array of up to eight elements specifying the size of the data to be read and returned. For example, DATA\_DIMS=[512,512] specifies that a two-dimensional, 512 by 512 array be read and returned. DATA\_DIMS=0 specifies that a single, scalar value be read and returned. Default is -1, which, if a TEMPLATE is not supplied that specifies otherwise, indicates that READ\_BINARY will read to end-of-file and store the result in a 1-D array.

## DATA\_START

Set this keyword to specify where to begin reading in a file. This value is as an offset, in bytes, that will be applied to the initial position in the file. The default is 0.

## DATA\_TYPE

Set this keyword to an IDL typecode of the data to be read. See documentation for the [SIZE](#) function for a listing of typecodes. Default is 1 (IDL's BYTE typecode).

## ENDIAN

Set this keyword to one of three string values: “big”, “little” or “native” which specifies the byte ordering of the file to be read. If the computer running `READ_BINARY` uses byte ordering that is different than that of the file, `READ_BINARY` will swap the order of bytes in multi-byte data types read from the file. (Default: “native” = perform no byte swapping.) See “Files and I/O” in Chapter 9 of the *Building IDL Applications* manual for more information on byte order and cross-platform programming.

## TEMPLATE

Set this keyword to a template structure (created using the [BINARY\\_TEMPLATE](#) function) describing the file to be read. The `TEMPLATE` keyword cannot be used simultaneously with keywords `DATA_START`, `DATA_TYPE`, `DATA_DIMS`, or `ENDIAN`.

When a template is used with `READ_BINARY`, the return value is a structure containing fields specified by the template. If a template is not used, the return value is an array.

## Examples

The following reads the data in a binary file, `head.data`, and passes the data to an `iVolume` display:

```
vHeadData = READ_BINARY(FILEPATH('head.dat', $
    SUBDIRECTORY=['examples', 'data']), DATA_DIMS=[80,100,57])
iVOLUME, vHeadData
```

When the `iVolume` window appears, click **Render** on the Volume panel to display the data.

Also see the following examples:

- “[Working with a READ\\_Binary Data Structure](#)” on page 1883

- “[Displaying Binary Images with Direct Graphics](#)” on page 1883
- “[Displaying a Grayscale Binary Image](#)” on page 1885

## Working with a READ\_BINARY Data Structure

READ\_BINARY returns a structure containing binary data, which is formatted according to specified keywords or a template. The following example returns a structure containing the data in the `surface.dat` file, found in the `examples/data` subdirectory of the IDL installation directory.

1. Enter the following statement at the IDL command line to open the **Binary Template** dialog:

```
sTemplate = BINARY_TEMPLATE()
```

2. Complete the steps described in “[Using the BINARY\\_TEMPLATE Interface](#)” on page 164 to define the format of the data.
3. Use READ\_BINARY to access the data, defined by the template created in the previous step;

```
data = READ_BINARY(FILEPATH('surface.dat', $
    SUBDIRECTORY=['examples', 'data']), TEMPLATE = sTemplate)
```

4. The variable `data` now contains the binary data. Use the format *structureName.fieldName* to access individual fields of data. The following lines display the data in an iSurface tool:

```
ISURFACE, data.marbells
```

---

### Note

The Variable Watch window contains the `sTemplate` and `data` structures. Expand these items for information about the structure fields.

---

## Displaying Binary Images with Direct Graphics

Binary images are composed of pixels having one of two values, usually zero or one. With most color tables, pixels having values of zero or one are displayed with almost the same color, such as with a the default grayscale color table. Thus, a binary image is usually scaled to display the zeros as black and the ones as white.

The following example imports a binary image of the world from the `continent_mask.dat` binary file. In this image, the oceans are zeros (black) and the continents are ones (white). This type of image can be used to mask out data over the oceans. The image contains byte data values and is 360 pixels by 360 pixels.

Complete the following steps for a detailed description of the process.

**Example Code**

See `displaybinaryimage_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `continent_mask.dat` file:

```
file = FILEPATH('continent_mask.dat', $
  SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
imageSize = [360, 360]
```

3. Use **READ\_BINARY** to import the image from the file:

```
image = READ_BINARY(file, DATA_DIMS = imageSize)
```

4. If you are running IDL on a TrueColor display, set the **DECOMPOSED** keyword to the **DEVICE** command to zero before your first color table related routine is used within an IDL session or program. This command implies a color table will be used.

```
DEVICE, DECOMPOSED = 0
```

5. Load a grayscale color table:

```
LOADCT, 0
```

6. Create a window and display the original image with the **TV** procedure:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'A Binary Image, Not Scaled'
TV, image
```

The resulting window should be all black (blank). The binary image contains zeros and ones, which are almost the same color (black). Binary images should be displayed with the **TVSCL** procedure in order to scale the ones to white.

7. Create another window and display the scaled binary image:

```
WINDOW, 1, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'A Binary Image, Scaled'
TVSCL, image
```

The following figure shows the results of scaling this display.

*Figure 3-97: Binary Image in Direct Graphics*

## Displaying a Grayscale Binary Image

Features within grayscale images are created by pixels that have varying intensities. Pixel values range from least intense (black) to the most intense (white). Since a grayscale image is composed of pixels of varying intensities, it is best displayed with a color table that progresses linearly from black to white. Although IDL has several such predefined color tables, the grayscale color table (B-W LINEAR), is the most fitting choice when displaying grayscale images. IDL's B-W LINEAR color table is represented by an index value of 0. See "[Loading a Default Color Table](#)" in Chapter 8 of the *Using IDL* manual for more information on IDL's predefined color tables.

The following example imports a grayscale image from the `convec.dat` binary file. This grayscale image shows the convection of the Earth's mantle. The image contains byte data values and is 248 pixels by 248 pixels. Since the data type is byte, this image does not need to be scaled before display. If the data was of any type other than byte and the data values were not within the range from 0 to 255, the image would need to be scaled prior to being displayed. (See the [TVSCL](#) description for more information.) Complete the following steps for a detailed description of the process.

**Example Code**

See `displaygrayscaleimage_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `convec.dat` file:

```
file = FILEPATH('convec.dat', $
  SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
imageSize = [248, 248]
```

3. Using [READ\\_BINARY](#), import the image from the file:

```
image = READ_BINARY(file, DATA_DIMS = imageSize)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Load a grayscale color table:

```
LOADCT, 0
```

6. Create a window and display the original image with the `TV` procedure:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'A Grayscale Image'
TV, image
```

The following figure shows the resulting grayscale image display.

*Figure 3-98: Grayscale Image in Direct Graphics*

[BINARY\\_TEMPLATE](#)

# READ\_BMP

The READ\_BMP function reads a Microsoft Windows Version 3 device independent bitmap file (.BMP) and returns the image.

READ\_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file `read_bmp.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

To find information about a potential BMP file before trying to read its data, use the [QUERY\\_BMP](#) function.

---

## Syntax

```
Result = READ_BMP( Filename, [, R, G, B] [, Ihdr] [, /RGB] )
```

## Return Value

Returns a byte array containing the image. Dimensions are taken from the BITMAPINFOHEADER of the file. In the case of 4-bit or 8-bit images, the dimensions of the resulting array are (biWidth, biHeight).

For 24-bit images, the dimensions are (3, biWidth, biHeight). Color interleaving is blue, green, red; i.e., `Result[0,i,j]` = blue, `Result[1,i,j]` = green, etc.

## Arguments

### Filename

A scalar string specifying the full path name of the bitmap file to read.

### R, G, B

Named variables that will contain the color tables from the file. There 16 elements each for 4 bit images, 256 elements each for 8 bit images. Color tables are not defined or used for 24 bit images.

## lhdr

A named variable that will contain a structure holding the BITMAPINFOHEADER from the file. Tag names are as defined in the MS Windows Programmer's Reference Manual.

## Keywords

### RGB

If this keyword is set, color interleaving of 16- and 24-bit images will be R, G, B, i.e.,  $\text{Result}[0,i,j] = \text{red}$ ,  $\text{Result}[1,i,j] = \text{green}$ ,  $\text{Result}[2,i,j] = \text{blue}$ .

## Examples

To open, read, and display the BMP file named `foo.bmp` in the current directory and store the color vectors in the variables `R`, `G`, and `B`, enter:

```
; Read and display an image:
TV, READ_BMP('foo.bmp', R, G, B)

; Load its colors:
TVLCT, R, G, B
```

Many applications that use 24-bit BMP files outside IDL expect BMP files to be stored as BGR. For example, enter the following commands.

```
; Make a red square image:
a = BYTARR(3, 200, 200)
a[0, *, *] = 255

;View the image:
TV, a, /TRUE
WRITE_BMP, 'foo.bmp', a
```

If you open the `.bmp` file in certain bitmap editors, you may find that the square is blue.

```
image = READ_BMP('foo.bmp')

; IDL reads the image back in and interprets it as red:
TV, image, /TRUE

; Flip the order of the indices by adding the RGB keyword:
image = READ_BMP('foo.bmp', /RGB)

; Displays the image in blue:
TV, image, /TRUE
```

## Version History

Pre-4.0	Introduced
---------	------------

## See Also

[WRITE\\_BMP](#), [QUERY\\_BMP](#)

# READ\_DICOM

The READ\_DICOM function reads an image from a DICOM file along with any associated color table. The return array type depends on the DICOM image pixel type.

This routine is written in the IDL language. Its source code can be found in the file `read_dicom.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = READ_DICOM (Filename [, Red, Green, Blue] [, IMAGE_INDEX=index]  
[, /DICOMEX] )
```

## Return Value

The return value can be a 2-D array for grayscale or a 3-D array for TrueColor images. TrueColor images are always returned in pixel interleaved format.

## Arguments

### Filename

This argument is a scalar string that contains the full pathname of the file to read.

### Red, Green, Blue

Named variables that will contain the red, green, and blue color vectors from the DICOM file if they exist.

### Note

---

DICOM color vectors contain 16-bit color values that may need to be converted for use with IDL graphics routines.

---

## Keywords

### IMAGE\_INDEX

Set this keyword to the index of the image to read from the file.

## DICOMEX

This keyword is set by default. When an additional cost DICOM Read/Write license or Read/Write runtime license is available, and an [IDLffDicomEx](#) object can be created, IDL uses the [IDLffDicomEx](#) object to read the DICOM file. If these conditions are not met, or if this keyword is set to 0, IDL uses the [IDLffDICOM](#) object to read the DICOM file instead.

### Note

---

`READ_DICOM` always returns the image array in DICOM format where the first pixel in the returned array is the top left-hand pixel in the frame. By default, the [IDLffDicomEx::GetPixelData](#) method returns pixel data in standard IDL format where the first pixel in the returned array is the bottom left-hand pixel in the frame. Set the `GetPixelData ORDER` keyword to return the array in DICOM format.

---

## Examples

```
TVSCL, READ_DICOM(FILEPATH('mr_knee.dcm'), $
SUBDIR=['examples', 'data'])
```

## Version History

5.2	Introduced
6.2	Added DICOMEX keyword

## See Also

[QUERY\\_DICOM](#)

# READ\_GIF

The READ\_GIF procedure reads the contents of a GIF format image file and returns the image and color table vectors (if present) in the form of IDL variables. Only 8-bit images are supported, and local colormaps are not supported.

---

**Note**

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact RSI for information about licensing options.

---

This routine is written in the IDL language. Its source code can be found in the file `read_gif.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

To find information about a potential GIF file before trying to read its data, use the QUERY\_GIF function.

---

## Syntax

```
READ_GIF, Filename, Image [, R, G, B] [, /CLOSE] [, /MULTIPLE]
```

## Arguments

### Filename

A scalar string specifying the full path name of the image file to read.

### Image

A named variable that will contain the image data read from the file.

### R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the rasterfile contains colormaps.

## Keywords

### CLOSE

Set this keyword to close any open files. The CLOSE keyword is only useful if a file containing multiple images (as specified by the MULTIPLE keyword) is in use. Note that you do not need to specify the normal arguments to READ\_GIF (*Filename*, *Image*, etc.) when using this keyword.

### MULTIPLE

Set this keyword to read files that contain multiple images. Each call to READ\_GIF returns the next image, with the file remaining open between calls. The *Filename* argument is ignored and may be omitted after the first call. Reading past the last image returns a scalar value of -1 in the variable specified in the *Image* argument, and closes the file. R, G, and B color vectors are returned only once, along with the first image.

## Example

To open and read the GIF image file named `foo.gif` in the current directory, store the image in the variable `image1`.

```
; Store the color vectors in the variables R, G, and B:
READ_GIF, 'foo.gif', image1, R, G, B

; Load the new color table and display the image:
TVLCT, R, G, B
TV, image1
```

## Version History

Pre-4.0	Introduced
---------	------------

## See Also

# READ\_IMAGE

The READ\_IMAGE function reads the image contents of a file and returns the image in an IDL variable. If the image contains a palette it can be returned as well in three IDL variables. READ\_IMAGE returns the image in the form of a two-dimensional array (for grayscale images) or a (3, n, m) array (for TrueColor images). READ\_IMAGE can read most types of image files supported by IDL. See QUERY\_IMAGE for a list of supported formats.

## Syntax

```
Result = READ_IMAGE (Filename [, Red, Green, Blue] [, IMAGE_INDEX=index] )
```

## Return Value

Result is the image array read from the file or scalar value of -1 if the file could not be read.

## Arguments

### Filename

A scalar string containing the name of the file to read.

### Red

An optional named variable to receive the red channel of the color table if a color table exists.

### Green

An optional named variable to receive the green channel of the color table if a color table exists.

### Blue

An optional named variable to receive the blue channel of the color table if a color table exists.

## Keywords

### IMAGE\_INDEX

Set this keyword to the index of the image to read from the file. The default is 0, the first image.

## Example

The following statements open and display a DICOM image file:

```
image = READ_IMAGE (FILEPATH('mr_knee.dcm', $
    SUBDIR=['examples', 'data']))
TV, image
```

## Version History

5.3	Introduced
-----	------------

# READ\_INTERFILE

The `READ_INTERFILE` procedure reads image data stored in Interfile (v3.3) format.

`READ_INTERFILE` can only read a series of images if all images have the same height and width. It does not get additional keyword information beyond what is needed to read the image data. If any problems occur when reading the file, `READ_INTERFILE` prints a message and stops.

If the data is stored on a bigendian machine and read on a littleendian machine (or vice versa) the order of bytes in each pixel element may be reversed, requiring a call to `BYTEORDER`

This routine is written in the IDL language. Its source code can be found in the file `read_interfile.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

`READ_INTERFILE, File, Data`

## Return Value

Returns a 3-D array containing the image data.

## Arguments

### File

A scalar string containing the name of the Interfile to read. Note: if the Interfile has a header file and a data file, this should be the name of the header file (also called the administrative file).

### Data

A named variable that will contain a 3-D array of data as read from the file. Assumed to be a series of 2-D images.

## Keywords

None.

## Examples

```
READ_INTERFILE, '0_11.hdr', X
```

## Version History

Pre-4.0	Introduced
---------	------------

# READ\_JPEG

The READ\_JPEG procedure reads JPEG (Joint Photographic Experts Group) format compressed images from files or memory. JPEG is a standardized compression method for full-color and gray-scale images. This procedure reads JFIF, the JPEG File Interchange Format, including those produced by WRITE\_JPEG. Such files are usually simply called JPEG files

READ\_JPEG can optionally quantize TrueColor images contained in files to a pseudo-color palette with a specified number of colors, and with optional color dithering.

This procedure is based in part on the work of the Independent JPEG Group. For a brief explanation of JPEG, see “[WRITE\\_JPEG](#)” on page 2765.

---

## Note

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

---

---

## Note

To find information about a potential JPEG file before trying to read its data, use the [QUERY\\_JPEG](#) function.

---

## Syntax

```
READ_JPEG [, Filename], Image [, Colortable] [, BUFFER=variable]
  [, COLORS=value{8 to 256}] [, DITHER={0 | 1 | 2}] [, /GRAYSCALE]
  [, /ORDER] [, TRUE={1 | 2 | 3}] [, UNIT=lun][, /TWO\_PASS\_QUANTIZE]
```

## Arguments

### Filename

A scalar string specifying the full pathname of the JFIF format (JPEG) file to be read. If this parameter is not present, the UNIT and/or the BUFFER keywords must be specified.

### Image

A named variable to contain the image data read from the file.

## Colortable

A named variable to contain the colormap, when reading a TrueColor image that is to be quantized. On completion, this variable contains a byte array with dimensions (NCOLORS, 3). This argument is filled only if the image is color quantized (refer to the COLORS keyword).

## Keywords

### BUFFER

Set this keyword to a named variable that is used for a buffer. A buffer variable need only be supplied when reading multiple images per file. Initialize the buffer variable to empty by setting it to 0.

### COLORS

If the image file contains a TrueColor image that is to be displayed on an indexed color destination, set COLORS to the desired number of colors to be quantized. COLORS can be set to a value from 8 to 256. The DITHER and TWO\_PASS\_QUANTIZE keywords affect the method, speed, and quality of the color quantization. These keywords have no effect if the file contains a grayscale image.

### DITHER

Set this keyword to use dithering with color quantization (i.e., if the COLORS keyword is in use). Dithering is a method that distributes the color quantization error to surrounding pixels, to achieve higher-quality results. Set the DITHER keyword to one of the following values:

- 0 = No dithering. Images are read quickly, but quality is low.
- 1 = Floyd-Steinberg dithering. This method is relatively slow, but produces the highest quality results. This is the default behavior.
- 2 = Ordered dithering. This method is faster than Floyd-Steinberg dithering, but produces lower quality results.

### GRAYSCALE

Set this keyword to return a monochrome (grayscale) image, regardless of whether the file contains an RGB or grayscale image.

## ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image is to be stored into the *Image* array in the standard IDL order (from bottom-to-top) set ORDER to 0. This is the default. If the image array is to be top-to-bottom order, set ORDER to 1.

## TRUE

Use this keyword to specify the index of the dimension for color interleaving when reading a TrueColor image. The default is 1, for pixel interleaving,  $(3, m, n)$ . A value of 2 indicates line interleaving  $(m, 3, n)$ , and 3 indicates band interleaving,  $(m, n, 3)$ .

## TWO\_PASS\_QUANTIZE

Set this keyword to use a two-pass color quantization method when quantization is in effect (i.e., the COLORS keyword is in use). This method requires more memory and time, but produces superior results to the default one-pass quantization method.

## UNIT

This keyword can be used to designate the logical unit number of an already open JFIF file, allowing the reading of multiple images per file or the embedding of JFIF images in other data files. When using this keyword, *Filename* should not be specified.

### Note

---

When opening a file intended for use with the UNIT keyword, if the filename does not end in `.jpg`, or `.jpeg`, you must specify the STDIO keyword to OPEN in order for the file to be compatible with READ\_JPEG.

---

## Examples

```
; Read a JPEG grayscale image:
READ_JPEG, 'test.jpg', a

; Display the image:
TV, a

; Read and display a JPEG TrueColor image on a TrueColor display:
READ_JPEG, 'test.jpg', a, TRUE=1

; Display the image returned with pixel interleaving
; (i.e., with dimensions 3, m, n):
```

```
TV, a, TRUE=1
```

Read the image, setting the number of colors to be quantized to the maximum number of available colors.

```
; Read a JPEG TrueColor image on an 8-bit pseudo-color display:
READ_JPEG, 'test.jpg', a, ctable, COLORS=!D.N_COLORS-1

; Display the image:
TV, a

; Load the quantized color table:
TVLCT, ctable
```

We could have also included the `TWO_PASS_QUANTIZE` and `DITHER` keywords to improve the image's appearance.

Using the `BUFFER` keyword.

```
; Initialize buffer:
buff = 0
OPENR, 1, 'images.jpg'

; Process each image:
FOR i=1, nimages DO BEGIN
  ; Read next image:
  READ_JPEG, UNIT=1, BUFFER=buff, a

  ; Display the image:
  TV, a
ENDFOR

; Done:
CLOSE, 1
```

# READ\_JPEG2000

The `READ_JPEG2000` function extracts and returns image data from a JPEG2000 file. This function is a wrapper around the `IDLffJPEG2000` object interface that presents JPEG2000 image loading in a familiar way to users of the `READ_*` image routines. However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “`IDLffJPEG2000`” in Chapter 6 of the *IDL Reference Guide* manual for information about the object interface.

## Syntax

```
Result = READ_JPEG2000(Filename [, Red, Green, Blue]  
    [, DISCARD_LEVELS=value] [, MAX_LAYERS=value] [, /ORDER]  
    [, REGION=[StartX, StartY, Width, Height] ] )
```

## Return Value

The *Result* is a two or three-dimensional array containing the image data. The dimensions of the result are [*nComponents*, *Width*, *Height*], where *nComponents* is the number of components present in the file. Images with only one component will be returned as a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depth = 8 the result will be of type byte. For bit-depths  $\geq 9$  and  $\leq 16$  the result will be of type integer or uint. For bit-depths  $> 16$  the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

---

### Note

The returned image is automatically ordered from bottom-to-top, where the first pixel returned is located at the bottom-left corner of the image. The `ORDER` keyword may be used to override this behavior.

---

## Arguments

### Filename

A scalar string containing the full path and filename of the JPEG2000 file to read.

## Red, Green, Blue

Set these arguments to named variables that will contain the Red, Green, and Blue color vectors of the color palette from the file.

## Keywords

### DISCARD\_LEVELS

Set this keyword to an integer giving the number of highest resolution levels which will not appear in the result.

The resulting image dimensions are given by:

$$\text{CEIL}((\text{Dimensions} + \text{Offset}) / (2^{\text{DL}})) - \text{CEIL}(\text{Offset} / (2^{\text{DL}}))$$

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of DISCARD\_LEVELS.

For example, if the image in the file has dimensions of 1024 x 1026, and DISCARD\_LEVELS is set to 3, the resulting image will have dimensions of 128 x 129, which is the ceiling of [1024, 1026] divided by  $2^3$ . The number of resolution levels in a file may be determined by checking the value of the N\_LEVELS field within the QUERY\_JPEG2000 structure.

### MAX\_LAYERS

Set this keyword to an integer giving the maximum number of quality layers which will be returned in the result. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, implies that all layers should be returned. For example, specifying MAX\_LAYERS=4 processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the N\_LAYERS field within the QUERY\_JPEG2000 structure.

### ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (ORDER = 0), READ\_JPEG2000 will automatically flip the result to match IDL's bottom-to-top order. Setting ORDER to a nonzero value will return the JPEG2000 image without doing the vertical flip.

## REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read, in the canvas coordinate system. The region is specified as [*StartX*, *StartY*, *Width*, *Height*], where *StartX* and *StartY* must be in the range  $0 \dots 2^{32}-2$ , and *Width* and *Height* must be in the range  $1 \dots 2^{32}-1$ . The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

### Note

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions. The dimensions and offset may be determined from the QUERY\_JPEG2000 structure. See “[The JPEG2000 Canvas Coordinate System](#)” in Chapter 6 of the *IDL Reference Guide* manual for more information.

## Example

```
; Read in a 24-bit JPEG image.
input = FILEPATH('marsglobe.jpg', SUBDIR=['examples','data'])
READ_JPEG, input, image

; Create a JPEG2000 with 6 quality layers.
WRITE_JPEG2000, 'marsglobe.jp2', image, N_LAYERS=6

; Verify the file information.
success = QUERY_JPEG2000('marsglobe.jp2', info)
help, info, /STRUCT

WINDOW, 0, XSIZE=2*info.dimensions[0], YSIZE=info.dimensions[1]

; Use the DISCARD_LEVELS keyword.
for discard=0,5 do TV, /TRUE, $
    READ_JPEG2000('marsglobe.jp2', DISCARD_LEVELS=discard)

; Extract a region.
image = READ_JPEG2000('marsglobe.jp2', $
    REGION=[0,0,200,100])
TV, REBIN(image, 3, 400, 200), 400, 0, /TRUE

; Use the MAX_LAYERS keyword.
image = READ_JPEG2000('marsglobe.jp2', MAX_LAYERS=1, $
    REGION=[0,0,200,100])
TV, REBIN(image, 3, 400, 200), 400, 200, /TRUE
```

*Figure 3-99: Varying Quality Images*

In the previous figure, the left-hand side shows the full resolution image, plus the 5 lower resolution versions (`DISCARD_LEVELS=1,2,3,4,5`). The right-hand side shows a magnified portion of the full quality image (bottom), and a lower quality version (top, `MAX_LAYERS=1`).

# READ\_MRSID

The READ\_MRSID function extracts and returns image data from a MrSID file at the specified level and location. It is a wrapper around the object interface that presents MrSID image loading in a familiar way to users of the READ\_\* image routines. However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “IDLffMrSID” on page 3123 for information about the object interface.

---

**Note**

This routine is only available under Microsoft Windows.

---

## Syntax

*Result* = READ\_MRSID ( *Filename* [, **LEVEL**=*lvl*] [, **SUB\_RECT**=*rect*] )

## Return Value

*ImageData* returns an *n*-by-*w*-by-*h* array containing the image data where *n* is 1 for grayscale or 3 for RGB images, *w* is the width and *h* is the height.

---

**Note**

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left of the image.

---

## Arguments

### Filename

A scalar string containing the full path and filename of the MrSID file to read.

## Keywords

### LEVEL

Set this keyword to an integer that specifies the level at which to read the image. If this keyword is not set, the maximum level (see [QUERY\\_MRSID](#)) is used which returns the minimum resolution.

## SUB\_RECT

Set this keyword to a four-element vector [x, y, xdim, ydim] specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying only a portion of the high-resolution image. If this keyword is not set, the entire image will be returned. This may require significant memory if a high-resolution level is selected. If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

### Note

The elements of SUB\_RECT are measured in pixels at the current level. This means the point x = 10, y = 10 at level 1 will be located at x = 20, y = 20 at level 0 and x = 5, y = 5 at level 2.

## Examples

```

; Query the file.
result = QUERY_MRSID(FILE_SEARCH(!DIR, 'test_gs.sid'), info)

; If result is not zero, read in an image from the file and
; display it.
IF (result NE 0) THEN BEGIN
  PRINT, info
  imageData = READ_MRSID(FILE_SEARCH(!DIR, 'test_gs.sid'), $
    SUB_RECT = [0, 0, 200, 200], LEVEL = 3)
  oImage = OBJ_NEW('IDLgrImage', imageData, ORDER = 0)
  XOBJVIEW, oImage, BACKGROUND = [255,255,0]
ENDIF

; Use the file access object to query the file.
oMrSID = OBJ_NEW('IDLffMrSID', FILE_SEARCH(!DIR, 'test_gs.sid'))
oMrSID->GetProperty, PIXEL_TYPE=pt, $
  CHANNELS = chan, DIMENSIONS = dims, $
  TYPE = type, LEVELS = lvls
PRINT, pt, chan, dims, type, lvls

; Use the object to read in an image from the file.
lvls = -3
dimsatlvl = oMrSID->GetDimsAtLevel(lvls)
PRINT, dimsatlvl
imageData = oMrSID->GetImageData(LEVEL = 3)
PRINT, size(imageData)
OBJ_DESTROY, oImage

```

# READ\_PICT

The READ\_PICT procedure reads the contents of a PICT (version 2) format image file and returns the image and color table vectors (if present) in the form of IDL variables. The PICT format is used by Apple Macintosh computers.

This routine is written in the IDL language. Its source code can be found in the file `read_pict.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

To find information about a potential PICT file before trying to read its data, use the [QUERY\\_PICT](#) function.

---

## Syntax

READ\_PICT, *Filename*, *Image* [, *R*, *G*, *B*]

## Arguments

### Filename

A scalar string specifying the full pathname of the PICT file to read.

### Image

A named variable that will contain the 2-D image read from *Filename*.

### R, G, B

Named variables that will contain the Red, Green, and Blue color vectors read from the PICT file.

## Keywords

None.

## Examples

To open and read the PICT image file named `foo.pict` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables `R`, `G`, and `B`, enter:

```
READ_PICT, 'foo.pict', image1, R, G, B
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B  
TV, image1
```

## Version History

[WRITE\\_PICT](#), [QUERY\\_PICT](#)

# READ\_PNG

The READ\_PNG routine reads the image contents of a Portable Network Graphics (PNG) file and returns the image in an IDL variable. If the image contains a palette (see [QUERY\\_PNG](#)), it can be returned as well in three IDL variables. READ\_PNG supports 1, 2, 3 and 4 channel images with channel depths of 8 or 16 bits.

---

## Note

IDL supports version 1.2.7 of the PNG Library.

---

---

## Note

Only single channel 8-bit images may have palettes. If an 8-bit, single-channel image has index values marked as “transparent,” these can be retrieved as well.

---

---

## Note

To find information about a potential PNG file before trying to read its data, use the [QUERY\\_PNG](#) function.

---

## Syntax

```
Result = READ_PNG ( Filename [, R, G, B] [,/ORDER] [, /VERBOSE]
                  [, TRANSPARENT=variable] )
```

or

```
READ_PNG, Filename, Image [, R, G, B] [,/ORDER] [, /VERBOSE]
          [, TRANSPARENT=variable]
```

## Return Value

For 8-bit images, *Result* will be a two- or three-dimensional array of type byte. For 16-bit images, *Result* will be of type unsigned integer (UINT).

## Arguments

### Filename

A scalar string containing the full pathname of the PNG file to read.

## Image

A named variable in which the image array will be stored, if `READ_PNG` is called as a procedure. For 8-bit images, *Image* will be a two- or three-dimensional array of type byte. For 16-bit images, *Image* will be of type unsigned integer (UINT).

## R, G, B

Named variables that will contain the Red, Green, and Blue color vectors if a color table exists.

## Keywords

### ORDER

Set this keyword to indicate that the rows of the image should be read from bottom to top. The rows are read from top to bottom by default. `ORDER` provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

### VERBOSE

Set this keyword to produce additional diagnostic output during the read operation.

### TRANSPARENT

Set this keyword equal to a named variable that will contain an array of pixel index values that are to be treated as “transparent” for the purposes of image display. If there are no transparent values then `TRANSPARENT` will be set to a long-integer scalar with the value 0.

## Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bit/channel) image with a palette:

```

rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = indgen(256)
green = indgen(256)
blue = indgen(256)
WRITE_PNG, 'rgb_image.png', rgbdata
WRITE_PNG, 'ci_image.png', cidata, red, green, blue
;Query and read the data
names = ['rgb_image.png', 'ci_image.png', 'unknown.png']

```

```
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
    ok = QUERY_PNG(names[i],s)
    IF (ok) THEN BEGIN
        HELP,s,/STRUCTURE
        IF (s.HAS_PALETTE) THEN BEGIN
            img = READ_PNG(names[i],rpal,gpal,bpal)
            HELP,img,rpal,gpal,bpal
        ENDIF ELSE BEGIN
            img = READ_PNG(names[i])
            HELP,img
        ENDELSE
    ENDIF ELSE BEGIN
        PRINT,names[i],' is not a PNG file'
    ENDELSE
ENDFOR
END
```

# READ\_PPM

The READ\_PPM procedure reads the contents of a PGM (gray scale) or PPM (portable pixmap for color) format image file and returns the image in the form of a 2-D byte array (for grayscale images) or a  $(3, n, m)$  byte array (for TrueColor images).

Files to be read should adhere to the PGM/PPM standard. The following file types are supported: P2 (graymap ASCII), P5 (graymap RAWBITS), P3 (TrueColor ASCII pixmaps), and P6 (TrueColor RAWBITS pixmaps). Maximum pixel values are limited to 255. Images are always stored with the top row first.

PPM/PGM format is supported by the PBMPLUS toolkit for converting various image formats to and from portable formats, and by the Netpbm package.

This routine is written in the IDL language. Its source code can be found in the file `read_ppm.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

To find information about a potential PPM file before trying to read its data, use the [QUERY\\_PPM](#) function.

---

## Syntax

```
READ_PPM, Filename, Image [, MAXVAL=variable]
```

## Arguments

### Filename

A scalar string specifying the full path name of the PGM or PPM file to read.

### Image

A named variable that will contain the image. For grayscale images, *Image* is a 2-D byte array. For TrueColor images, *Image* is a  $(3, n, m)$  byte array.

## Keywords

### MAXVAL

A named variable that will contain the maximum pixel value.

## Examples

To open and read the PGM image file named “foo.pgm” in the current directory and store the image in the variable IMAGE1:

```
READ_PPM, 'foo.pgm', IMAGE1
```

# READ\_SPR

The READ\_SPR function reads a row-indexed sparse array. Row-indexed sparse arrays are created using the SPRSIN function and written to a file using the WRITE\_SPR function.

This routine is written in the IDL language. Its source code can be found in the file `read_spr.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = READ_SPR(Filename)
```

## Return Value

Returns the row-indexed sparse array from the specified file.

## Arguments

### Filename

A scalar string specifying the name of the file containing a row-indexed sparse array.

## Examples

Suppose we have already saved a row-indexed sparse array to a file named `sprs.as`, as described in the documentation for the WRITE\_SPR routine. To read the sparse array from the file and store it in a variable `sprs`, use the following command:

```
sprs = READ_SPR('sprs.as')
```

# READ\_SRF

The READ\_SRF procedure reads the contents of a Sun rasterfile and returns the image and color table vectors (if present) in the form of IDL variables.

READ\_SRF only handles 1-, 8-, 24-, and 32-bit rasterfiles of type RT\_OLD and RT\_STANDARD. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `read_srf.pro` in the `lib` subdirectory of the IDL distribution.

---

**Note**

To find information about a potential SRF file before trying to read its data, use the [QUERY\\_SRF](#) function.

---

## Syntax

`READ_SRF, Filename, Image [, R, G, B]`

## Arguments

### Filename

A scalar string containing the name of the rasterfile to read.

### Image

A named variable that will contain the 2-D byte array (image).

### R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the rasterfile contains colormaps.

## Keywords

None

## Examples

To open and read the Sun rasterfile named `sun.srf` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables `R`, `G`, and `B`, enter:

```
READ_SRF, 'sun.srf', image1, R, G, B
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B  
TV, image1
```

# READ\_SYLK

The `READ_SYLK` function reads the contents of a SYLK (Symbolic Link) format spreadsheet data file and returns the contents of the file, or of a cell data range, in an IDL variable.

## Note

---

This routine reads only numeric and string SYLK data. It ignores all spreadsheet and cell formatting information (cell width, text justification, font type, date, time, and monetary notations, etc). Note also that the data in a given cell range must be of the same data type (all integers, for example) in order for the read operation to succeed. See the example below for further information.

---

This routine is written in the IDL language. Its source code can be found in the file `read_sylk.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = READ_SYLK( File [, /ARRAY] [, /COLMAJOR] [, NCOLS=columns]
  [, NROWS=rows] [, STARTCOL=column] [, STARTROW=row]
  [, /USEDoubles] [, /USELONGS] )
```

## Return Value

`READ_SYLK` returns either a vector of structures or a 2-D array containing the spreadsheet cell data. By default, `READ_SYLK` returns a vector of structures, each of which contains the data from one *row* of the table being read. In this case, the individual fields in the structures have the tag names “Col0”, “Col1”, ..., “Col*n*”. If the `COLMAJOR` keyword is specified, each of the structures returned contains data from one *column* of the table, and the tag names are “Row0”, “Row1”, ..., “Row*n*”.

## Arguments

### File

A scalar string specifying the full path name of the SYLK file to read.

## Keywords

### ARRAY

Set this keyword to return an IDL array rather than a vector of structures. Note that all the data in the cell range specified must be of the same data type to successfully return an array.

### COLMAJOR

Set this keyword to create a vector of structures each containing data from a single *column* of the table being read. If you are creating an array rather than a vector of structures (the ARRAY keyword is set), setting COLMAJOR has the same effect as transposing the resulting array.

This keyword should be set when importing spreadsheet data which has column major organization (data stored in columns rather than rows).

### NCOLS

Set this keyword to the number of spreadsheet columns to read. If not specified, all of the cell columns found in the file are read.

### NROWS

Set this keyword to the number of spreadsheet rows to read. If not specified, all of the cell rows found in the file are read.

### STARTCOL

Set this keyword to the first column of spreadsheet cells to read. If not specified, the read operation begins with the first column found in the file (column 0).

### STARTROW

Set this keyword to the first row of spreadsheet cells to read. If not specified, the read operation begins with the first row of cells found in the file (row 0).

### USEDoubles

Set this keyword to read any floating-point cell data as double-precision rather than the default single-precision.

## USELONGS

Set this keyword to read any integer cell data as long integer type rather than the default integer type.

## Examples

Suppose the following spreadsheet table, with the upper left cell (value = “Index”) at location (0, 0), has been saved as the SYLK file “file.slk”:

Index	Name	Gender	Platform
1	Beth	F	Windows
2	Lubos	M	UNIX
3	Louis	M	Windows
4	Thierry	M	UNIX

Note that the data format of the title row (*string, string, string, string*) is inconsistent with the following four rows (*int, string, string, string*) in the table. Because of this, it is impossible to read all of the table into a single IDL variable. The following two commands, however, will read all of the data:

```
title = READ_SYLK("file.slk", NROWS = 1)
table = READ_SYLK("file.slk", STARTROW = 1)

;Display the top row of the table.
PRINT, title
```

IDL prints:

```
{ Index Name Gender Platform}
```

Print the table:

```
PRINT, table
```

IDL prints:

```
{1 Beth F Windows}{2 Lubos M UNIX}{3 Louis M Windows}{4 Thierry M
UNIX}
```

To retrieve only the “Name” column:

```
names = READ_SYLK("file.slk", /ARRAY, STARTROW = 1, $
    STARTCOL = 1, NCOLS = 1)
PRINT, names
```

IDL prints:

```
Beth Lubos Louis Thierry
```

To retrieve the “Name” column in column format:

```
namescol = READ_SYLK("file.slk", /ARRAY, /COLMAJOR, $
    STARTROW = 1, STARTCOL = 1, NCOLS = 1)
PRINT, namescol
```

IDL prints:

```
Beth
Lubos
Louis
Thierry
```

# READ\_TIFF

The `READ_TIFF` function reads single or multi-channel images from TIFF format files and returns the image and color table vectors in the form of IDL variables.

## Note

To find information about a potential TIFF file before trying to read its data, use the [QUERY\\_TIFF](#) function. The obsolete routine `TIFF_DUMP` may also be used to examine the structure and tags of a TIFF file.

## Syntax

```
Result = READ_TIFF( Filename [, R, G, B] [, CHANNELS=scalar or vector]
  [, DOT_RANGE=variable] [, GEOTIFF=variable] [, ICC_PROFILE=variable]
  [, IMAGE_INDEX=value] [, INTERLEAVE={0 | 1 | 2}]
  [, ORIENTATION=variable] [, PHOTOSHOP=variable]
  [, PLANARCONFIG=variable] [, SUB_RECT=[x, y, width, height]]
  [, /VERBOSE] )
```

## Return Value

`READ_TIFF` returns a byte, unsigned integer, long, or float array (based on the data format in the TIFF file) containing the image data. The dimensions of the *Result* are [*Columns*, *Rows*] for single-channel images, or [*Channels*, *Columns*, *Rows*] for multi-channel images, unless a different type of interleaving is specified with the `INTERLEAVE` keyword.

For 1-bit (bilevel) images, the image values are 0 or 1. For 4-bit grayscale images the image values are in the range 0 to 15.

RGB images are a special case of multi-channel images, and contain three channels. Most TIFF readers and writers can handle only images with one or three channels.

As a special case, for three-channel TIFF image files that are stored in planar interleave format, and if four parameters are provided, `READ_TIFF` returns the integer value zero, sets the variable defined by the `PLANARCONFIG` keyword to 2, and returns three separate images in the variables defined by the *R*, *G*, and *B* arguments.

## Arguments

### Filename

A scalar string specifying the full pathname of the TIFF file to read.

### R, G, B

Named variables that will contain the Red, Green, and Blue color vectors of the color table from the file if one exists. If the TIFF file is written as a three-channel image, interleaved by plane, and the R, G, and B parameters are present, the three channels of the image are returned in the R, G, and B variables.

## Keywords

### CHANNELS

Set this keyword to a scalar or vector giving the channel numbers to be returned for a multi-channel image, starting with zero. The default is to return all of the channels. This keyword is ignored for single-channel images, or for three-channel planar-interleaved images when the *R*, *G*, and *B* arguments are specified.

### DOT\_RANGE

Set this keyword to a named variable in which to return a two-element integer array containing the TIFF DotRange tag value. If DotRange is not defined in the TIFF file, then a scalar zero will be returned instead. The DotRange tag is typically only present in CMYK TIFF files. DOT\_RANGE[0] gives the image value that corresponds to a 0% dot, while DOT\_RANGE[1] gives the image value that corresponds to a 100% dot.

### GEOTIFF

Returns an anonymous structure containing one field for each of the GeoTIFF tags and keys found in the file. If no GeoTIFF information is present in the file, the returned variable is undefined.

The GeoTIFF structure is formed using fields named from the following table.

<b>Anonymous Structure Field Name</b>	<b>IDLDatatype</b>
<b>TAGS:</b>

*Table 3-108: GEOTIFF Structures (Continued)*

---

**Note**

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

---

## IMAGE\_INDEX

Selects the image number within the file to be read (see [QUERY\\_TIFF](#) to determine the number of images in the file).

## ICC\_PROFILE

Set this keyword to a named variable in which to return a byte array containing the TIFF ICC\_PROFILE tag value. If the ICC\_PROFILE tag is not contained in the TIFF file then a scalar zero will be returned instead. The ICC\_PROFILE array is returned as an opaque array of byte values which the user can then pass to the WRITE\_TIFF routine.

---

**Note**

The ICC\_PROFILE tag is returned as an opaque array of byte values. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

---

## INTERLEAVE

For multi-channel images, set this keyword to one of the following values to force the *Result* to have a specific interleaving, regardless of the type of interleaving in the file being read:

Value	Description
0	Pixel interleaved: <i>Result</i> will have dimensions [ <i>Channels</i> , <i>Columns</i> , <i>Rows</i> ].
1	Scanline (row) interleaved: <i>Result</i> will have dimensions [ <i>Columns</i> , <i>Channels</i> , <i>Rows</i> ].
2	Planar interleaved: <i>Result</i> will have dimensions [ <i>Columns</i> , <i>Rows</i> , <i>Channels</i> ].

Table 3-109: INTERLEAVE Keyword Values

If this keyword is not specified, the *Result* will always be pixel interleaved, regardless of the type of interleaving in the file being read. For files stored in planar-interleave format, this keyword is ignored if the *R*, *G*, and *B* arguments are specified.

## ORIENTATION

Set this keyword to a named variable that will contain the orientation value from the TIFF file. Possible return values are:

Value	Description
0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.
2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.

Table 3-110: ORIENTATION Keyword Values

Value	Description
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

*Table 3-110: ORIENTATION Keyword Values (Continued)*

If an orientation value does not appear in the TIFF file, an orientation of 0 is returned.

## PHOTOSHOP

Set this keyword to a named variable in which to return a byte array containing the TIFF PHOTOSHOP tag value. If the PHOTOSHOP tag is not contained in the TIFF file, then a scalar zero will be returned instead. The PHOTOSHOP array is returned as an opaque array of byte values which the user can then pass to the WRITE\_TIFF routine.

### Note

The PHOTOSHOP tag is returned as an opaque array of byte values. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

## PLANARCONFIG

Set this keyword to a named variable that will contain the interleave parameter for the TIFF file. This parameter is returned as 1 for TIFF files that are GrayScale, Palette, or interleaved by pixel. This parameter is returned as 2 for multi-channel TIFF files interleaved by image.

## SUB\_RECT

Set this keyword to a four-element array, [*x*, *y*, *width*, *height*], that specifies a rectangular region within the file to extract. Only the rectangular portion of the image selected by this keyword is read and returned. The rectangle is measured in pixels from the lower left corner (right hand coordinate system).

### Tip

---

For tiled TIFF images, use the `TILE_SIZE` tag returned by `QUERY_TIFF` to determine the optimal sizes for the `SUB_RECT` keyword.

---

## VERBOSE

Produce additional diagnostic output during the read.

## Examples

### Example 1

Read the file `my.tif` in the current directory into the variable `image`, and save the color tables in the variables, `R`, `G`, and `B` by entering:

```
image = READ_TIFF('my.tif', R, G, B)
```

To view the image, load the new color table and display the image by entering:

```
TVLCT, R, G, B
TV, image
```

### Example 2

Write and read a multi-image TIFF file. The first image is a 16-bit single-channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF, 'multi.tif', data, COMPRESSION=1, /SHORT
WRITE_TIFF, 'multi.tif', rgbdata, /LONG, /APPEND

; Read the image data back:
ok = QUERY_TIFF('multi.tif', s)
IF (ok) THEN BEGIN
FOR i=0, s.NUM_IMAGES-1 DO BEGIN
imp = QUERY_TIFF('multi.tif', t, IMAGE_INDEX=i)
img = READ_TIFF('multi.tif', IMAGE_INDEX=i)
```

```

HELP, t, /STRUCTURE
HELP, img
ENDFOR
ENDIF

```

### Example 3

Write and read a multi-channel image:

```

data = LINDGEN(10, 256, 256) ; 10 channels

; Write the image data:
WRITE_TIFF, 'multichannel.tif', data, /LONG

; Read back only channels [0,2,4,6,8], using planar-interleaving
img = READ_TIFF('multichannel.tif', CHANNELS=[0,2,4,6,8], $
INTERLEAVE=2)

HELP, img

```

IDL prints:

```

IMG      LONG      = Array[256, 256, 5]

```

## Version History

# READ\_WAV

The READ\_WAV function reads the audio stream from the named .WAV file. Optionally, it can return the sampling rate of the audio stream.

## Syntax

```
Result = READ_WAV ( Filename [, Rate] )
```

## Return Value

In the case of a single channel stream, the returned variable is a BYTE or INT (depending on the number of bits per sample) one-dimensional array. In the case of a file with multiple channels, a similar two-dimensional array is returned, with the leading dimension being the channel number.

## Arguments

### Filename

A scalar string containing the full pathname of the .WAV file to read.

### Rate

Returns an IDL long containing the sampling rate of the stream in samples per second.

## Keywords

None.

## Version History

5.3	Introduced
-----	------------

# READ\_WAVE

The READ\_WAVE procedure reads a .wave or .bwave file created by the Wavefront Advanced Data Visualizer into a series of IDL variables.

---

## Note

READ\_WAVE only preserves the structure of the variables if they are regularly gridded.

---

This routine is written in the IDL language. Its source code can be found in the file `read_wave.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

READ\_WAVE, *File*, *Variables*, *Names*, *Dimensions* [, MESHNAMES=*variable*]

## Arguments

### File

A scalar string containing the name of the Wavefront file to read.

### Variables

A named variable that will contain a block of the variables contained in the wavefront file. Since each variable in a wavefront file can have more than one field (for instance, a vector variable has 3 fields), the fields of each variable make up the major index into the variable block. For instance, if a Wavefront file had one scalar variable and one vector variable, the scalar would be extracted as follows:

```
scalar_variable = variables[0,*,*,*]
```

and the vector variable would be extracted as follows:

```
vector_variable = variables[1:3,*,*,*]
```

To find the dimensions of the returned variable, see the description of the *Dimensions* argument.

### Names

A named variable that will contain the string names of each variable contained in the file.

## Dimensions

A named variable that will contain a long array describing how many fields in the large returned variable block each variable occupies. In the above example of one scalar variable followed by a vector variable, the dimension variable would be [1, 3].

This indicates that the first field of the returned variable block would be the scalar variable and the following 3 fields would comprise the vector variable.

## Keywords

### MESHNAMES

Set this keyword to a named variable that will contain the name of the mesh used in the Wavefront file for each variable.

[WRITE\\_WAVE](#)

# READ\_X11\_BITMAP

The `READ_X11_BITMAP` procedure reads bitmaps stored in the X Windows X11 format. The X Windows `bitmap` program produces a C header file containing the definition of a bitmap produced by that program. This procedure reads such a file and creates an IDL byte array containing the bitmap. It is used primarily to read bitmaps to be used as IDL widget button labels.

This routine is written in the IDL language. Its source code can be found in the file `read_x11_bitmap.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
READ_X11_BITMAP, File, Bitmap [, X, Y] [, /EXPAND_TO_BYTES]
```

## Arguments

### File

A scalar string containing the name of the file containing the bitmap.

### Bitmap

A named variable that will contain the bitmap. This variable is returned as a byte array.

### X

A named variable that will contain the width of the bitmap.

### Y

A named variable that will contain the height of the bitmap.

## Keywords

### EXPAND\_TO\_BYTES

Set this keyword to instruct `READ_X11_BITMAP` to return a 2-D array which has one bit per byte (0 for a 0 bit, 255 for a 1 bit) instead.

## Examples

To open and read the X11 bitmap file named `my.x11` in the current directory, store the bitmap in the variable `bitmap1`, and the width and height in the variables `X` and `Y`, enter:

```
READ_X11_BITMAP, 'my.x11', bitmap1, X, Y
```

To display the new bitmap, enter:

```
READ_X11_BITMAP, 'my.x11', image, /EXPAND_TO_BYTES  
TV, image, /ORDER
```

[READ\\_XWD](#)

# READ\_XWD

The `READ_XWD` function reads the contents of a file created by the `xwd` (X Windows Dump) command and returns the image and color table vectors in the form of IDL variables.

## Note

---

This function is intended to be used only on files containing 8-bit pixmaps created with `xwd` version 6 or later.

---

This routine is written in the IDL language. Its source code can be found in the file `read_xwd.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = `READ_XWD`( *Filename*[, *R*, *G*, *B*] )

## Return Value

`READ_XWD` returns a 2-D byte array containing the image. If the file cannot be open or read, the return value is zero.

## Arguments

### Filename

A scalar string specifying the full pathname of the XWD file to read.

### R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the XWD file contains color tables.

## Keywords

None

## Examples

To open and read the X Windows Dump file named `my.xwd` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables, `R`, `G`, and `B`, enter:

```
image1 = READ_XWD('my.xwd', R, G, B)
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B  
TV, image1
```

[READ\\_X11\\_BITMAP](#)

# READS

The READS procedure performs formatted input from a string variable and writes the results into one or more output variables. This procedure differs from the READ procedure only in that the input comes from memory instead of a file.

This routine is useful when you need to examine the format of a data file before reading the information it contains. Each line of the file can be read into a string using READF. Then the components of that line can be read into variables using READS.

## Syntax

```
READS, Input, Var1, ..., Varn [, AM_PM=[string, string]]
    [, DAYS_OF_WEEK=string_array{7 names}] [, FORMAT=value]
    [, MONTHS=string_array{12 names}]
```

## Arguments

### Input

The string variable from which the input is taken. If the supplied argument is not a string, it is automatically converted. The argument can be scalar or array. If *Input* is an array, the individual string elements are treated as successive lines of input.

### *Var*<sub>*i*</sub>

The named variables to receive the input.

### Note

---

If the variable specified for the *Var*<sub>*i*</sub> argument has not been previously defined, the input data is assumed to be of type float, and the variable will be cast as a float.

---

## Keywords

### AM\_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

## DAYS\_OF\_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

## FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the input. FORMAT allows the format of the input to be specified in precise detail, using a FORTRAN-style specification. See [“Using Explicitly Formatted Input/Output”](#) in Chapter 18 of the *Building IDL Applications* manual.

## MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

## Version History

4.0	Introduced
-----	------------

## See Also

[READ/READF, READU](#)

# READU

The READU procedure reads unformatted binary data from a file into IDL variables. READU transfers data directly with no processing of any kind performed on the data.

## Syntax

```
READU, Unit, Var1, ..., Varn [, TRANSFER_COUNT=variable]
```

## Arguments

### Unit

The IDL file unit from which input is taken.

### Var<sub>i</sub>

Named variables to receive the data. For non-string variables, the number of bytes required for *Var* are read. When READU is used with a variable of type string, IDL reads exactly the number of bytes contained in the existing string. For example, to read a 5-character string, enter:

```
temp = '12345'  
READU, unit, temp
```

If the variable specified for the *Var<sub>i</sub>* argument has not been previously defined, the input data is assumed to be of type float, and the variable will be created as a float.

## Keywords

### TRANSFER\_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the input operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, attempting to read more data than is available from a file causes the unfilled space to be zeroed and an error to be issued. This does not happen with files opened with the RAWIO keyword. Instead, the programmer must keep track of the transfer count.

## Examples

The following commands can be used to open the IDL distribution file `people.dat` and read an image from that file:

```

; Open the file for reading as file unit 1:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])

; The image is a 192 by 192 byte array, so make B that size:
B = BYTARR(192, 192)

; Read the data into B:
READU, 1, B

; Close the file:
CLOSE, 1

; Display the image:
TV, B

```

## Version History

# REAL\_PART

The `REAL_PART` function returns the real part of its complex-valued argument.

## Syntax

*Result* = `REAL_PART(Z)`

## Return Value

If the complex-valued argument is double-precision, the result will be double-precision, otherwise the result will be single-precision floating-point. If the argument is not complex, then the result will be double-precision if the argument is double-precision, otherwise the result will be single-precision.

## Arguments

### Z

A scalar or array for which the real part is desired. Z may be of any numeric type.

## Examples

The following example demonstrates how you can use `REAL_PART` to obtain the real parts of an array of complex variables.

```
; Create an array of complex values:
cValues = COMPLEX([1, 2, 3],[4, 5, 6])

; Print just the real parts of each element in cValues:
PRINT, REAL_PART(cValues)
```

IDL prints:

```
1.00000  2.00000  3.00000
```

## Version History

5.5	Introduced
-----	------------

## See Also

[COMPLEX](#), [DCOMPLEX](#), [IMAGINARY](#)

# REBIN

The REBIN function resizes a vector or array to dimensions given by the parameters  $D_i$ . The supplied dimensions must be integral multiples or factors of the original dimension. The expansion or compression of each dimension is independent of the others, so that each dimension can be expanded or compressed by a different value.

If the dimensions of the desired result are not integer multiples of the original dimensions, use the CONGRID function.

## Syntax

$$Result = REBIN(Array, D_1 [, \dots, D_8] [, /SAMPLE])$$

## Return Value

Returns the resized array or vector of the specified dimensions.

## Arguments

### Array

The array to be resampled. *Array* can be of any basic type except complex or string.

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

### Note

---

The dimensions of the resulting resampled array must be integer multiples or factors of the corresponding original dimensions.

---

## Keywords

### SAMPLE

Normally, REBIN uses bilinear interpolation when magnifying and neighborhood averaging when minifying. Set the SAMPLE keyword to use nearest neighbor

sampling for both magnification and minification. Bilinear interpolation gives higher quality results but requires more time.

## Rules Used by REBIN

Assume the original vector  $X$  has  $n$  elements and the result is to have  $m$  elements.

Let  $f = n/m$ , the ratio of the size of the original vector,  $X$  to the size of the result.  $1/f$  must be an integer if  $n < m$  (expansion).  $f$  must be an integer if compressing, ( $n > m$ ). The various resizing options can be described as:

- Expansion,  $n < m$ , SAMPLE = 0:  $Y_i = F(X, f \cdot i) \quad i = 0, 1, \dots, m-1$

The linear interpolation function,  $F(X, p)$  that interpolates  $X$  at location  $p$ , is defined as:

$$F(X, p) = \begin{cases} X_{\lfloor p \rfloor} + (p - \lfloor p \rfloor) \cdot (X_{\lfloor p \rfloor + 1} - X_{\lfloor p \rfloor}) & \text{if } p < n - 1 \\ X_{\lfloor p \rfloor} & \text{if } p \geq n - 1 \end{cases}$$

- Expansion,  $n < m$ , SAMPLE = 1:

$$Y_i = X_{\lfloor fi \rfloor}$$

- Compression,  $n > m$ , SAMPLE = 0:

$$Y_i = (1/f) \sum_{j=fi}^{f(i+1)-1} X_j$$

- Compression,  $n > m$ , SAMPLE = 1:

$$Y_i = X_{\lfloor fi \rfloor}$$

- No change,  $n = m$ :  $Y_i = X_i$

## Endpoint Effects When Expanding

When expanding an array, REBIN *interpolates*, it never *extrapolates*. Each of the  $n-1$  intervals in the  $n$ -element input array produces  $m/n$  interpolates in the  $m$ -element output array. The last  $m/n$  points of the result are obtained by duplicating element  $n-1$  of the input array because their interpolates would lie outside the input array.

For example

```
; A four point vector:
A = [0, 10, 20, 30]

; Expand by a factor of 3:
B = REBIN(A, 12)

PRINT, B
```

IDL prints:

```
0 3 6 10 13 16 20 23 26 30 30 30
```

Note that the last element is repeated three times. If this effect is undesirable, use the `INTERPOLATE` function. For example, to produce 12 equally spaced interpolates from the interval 0 to 30:

```
B = INTERPOLATE(A, 3./11. * FINDGEN(12))
PRINT, B
```

IDL prints:

```
0 2 5 8 10 13 16 19 21 24 27 30
```

Here, the sampling ratio is  $(n - 1)/(m - 1)$ .

## Examples

Create and display a simple image by entering:

```
D = SIN(DIST(50)/4) & TVSCL, D
```

Resize the image to be 5 times its original size and display the result by entering:

```
D = REBIN(D, 250, 250) & TVSCL, D
```

[CONGRID](#)

# RECALL\_COMMANDS

The `RECALL_COMMANDS` function returns a string array containing the entries in IDL's command recall buffer.

## Syntax

*Result* = `RECALL_COMMANDS()`

## Return Value

The size of the returned array is the size of recall buffer, even if fewer than commands have been entered (any “empty” buffer entries will contain null strings). The default size of the command recall buffer is 20 lines. (See “[!EDIT\\_INPUT](#)” on page 4815 for more information about the command recall buffer.)

Element zero of the returned array contains the most recent command.

## Arguments

None.

## Keywords

None.

# RECON3

The RECON3 function can reconstruct a three-dimensional data array from two or more images (or projections) of an object. For example, if you placed a dark object in front of a white background and then photographed it three times (each time rotating the object a known amount) then these three images could be used with RECON3 to approximate a 3-D volumetric representation of the object. RECON3 also works with translucent projections of an object. RECON3 returns a 3-D byte array.

This routine is written in the IDL language. Its source code can be found in the file `recon3.pro` in the `lib` subdirectory of the IDL distribution.

## Using RECON3

Images used in reconstruction should show strong light/dark contrast between the object and the background. If the images contain low (dark) values where the object is and high (bright) values where the object isn't, the `MODE` keyword should be set to `+1` and the returned volume will have low values where the object is, and high values where the object isn't. If the images contain high (bright) values where the object is and low (dark) values where the object isn't, the `MODE` keyword should be set to `-1` and the returned volume will have high values where the object is, and low values where the object isn't.

In general, the object must be `CONVEX` for a good reconstruction to be possible. Concave regions are not easily reconstructed. An empty coffee cup, for example, would be reconstructed as if it were full.

The more images the better. Images from many different angles will improve the quality of the reconstruction. It is also important to supply images that are parallel and perpendicular to any axes of symmetry. Using the coffee cup as an example, at least one image should be looking through the opening in the handle. Telephoto images are also better for reconstruction purposes than wide angle images.

## Syntax

```
Result = RECON3(Images, Obj_Rot, Obj_Pos, Focal, Dist, Vol_Pos, Img_Ref,  
               Img_Mag, Vol_Size [, /CUBIC] [, MISSING=value] [, MODE=value]  
               [, /QUIET])
```

## Return Value

Returns a 3-D data array.

# Arguments

## Images

A 3-D array containing the images to use to reconstruct the volume. Execution time increases linearly with more images. *Images* must be an 8-bit (byte) array with dimensions  $(x, y, n)$  where  $x$  is the horizontal image dimension,  $y$  is the vertical image dimension, and  $n$  is the number of images. Note that  $n$  must be at least 2.

## Obj\_Rot

A  $3 \times n$  floating-point array specifying the amount the object is rotated to make it appear as it does in each image. The object is first rotated about the X axis, then about the Y axis, and finally about the Z axis (with the object's reference point at the origin). *Obj\_Rot*[0, \*] is the X rotation for each image, *Obj\_Rot*[1, \*] is the Y rotation, and *Obj\_Rot*[2, \*] is the Z rotation.

## Obj\_Pos

A  $3 \times n$  floating-point array specifying the position of the object's reference point relative to the camera lens. The camera lens is located at the coordinate origin and points in the negative Z direction (the view up vector points in the positive Y direction). *Obj\_Pos* should be expressed in this coordinate system. *Obj\_Pos*[0, \*] is the X position for each image, *Obj\_Pos*[1, \*] is the Y position, and *Obj\_Pos*[2, \*] is the Z position. All the values in *Obj\_Pos*[2, \*] should be less than zero. Note that the values for *Obj\_Pos*, *Focal*, *Dist*, and *Vol\_Pos* should all be expressed in the same units (mm, cm, m, in, ft, etc.).

## Focal

An  $n$ -element floating-point array specifying the focal length of the lens for each image. Focal may be set to zero to indicate a parallel image projection (infinite focal length).

## Dist

An  $n$ -element floating-point array specifying the distance from the camera lens to the image plane (film) for each image. *Dist* should be greater than *Focal*.

## Vol\_Pos

A  $3 \times 2$  floating-point array specifying the two opposite corners of a cube that surrounds the object. *Vol\_Pos* should be expressed in the object's coordinate system

relative to the object's reference point. *Vol\_Pos*[\*, 0] specifies one corner and *Vol\_Pos*[\*, 1] specifies the opposite corner.

## Img\_Ref

A  $2 \times n$  integer or floating-point array that specifies the pixel location at which the object's reference point appears in each of the images. *Img\_Ref*[0, \*] is the X coordinate for each image and *Img\_Ref*[1, \*] is the Y coordinate.

## Img\_Mag

A  $2 \times n$  integer or floating-point array that specifies the magnification factor for each image. This number is actually the length (in pixels) that a test object would appear in an image if it were  $n$  units long and  $n$  units distant from the camera lens. *Img\_Mag*[0, \*] is the X dimension (in pixels) of a test object for each image, and *Img\_Mag*[1, \*] is the Y dimension. All elements in *Img\_Mag* should be greater than or equal to 1.

## Vol\_Size

A 3-element integer or floating-point array that specifies the size of the 3-D byte array to return. Execution time (and resolution) increases exponentially with larger values for *Vol\_Size*. *Vol\_Size*[0] specifies the X dimension of the volume, *Vol\_Size*[1] specifies the Y dimension, and *Vol\_Size*[2] specifies the Z dimension.

## Keywords

### CUBIC

Set this keyword to use cubic interpolation. The default is to use tri-linear interpolation, which is slightly faster.

### MISSING

Set this keyword equal to a byte value for cells in the 3-D volume that do not map to any of the supplied images. The value of MISSING is passed to the INTERPOLATE function. The default value is zero.

### MODE

Set this keyword to a value less than zero to define each cell in the 3-D volume as the *minimum* of the corresponding pixels in the images. Set MODE to a value greater than zero to define each cell in the 3-D volume as the *maximum* of the corresponding pixels in the images. If MODE is set equal to zero then each cell in the 3-D volume is defined as the *average* of the corresponding pixels in the images.

MODE should usually be set to -1 when the images contain a bright object in front of a dark background or to +1 when the images contain a dark object in front of a light background. Setting MODE=0 (the default) requires more memory since the volume array must temporarily be kept as an integer array instead of a byte array.

## QUIET

Set this keyword to suppress the output of informational messages when the processing of each image is completed.

## Examples

Assumptions for this example:

- The object's major axis is parallel to the Z axis.
- The object's reference point is at its center.
- The camera lens is pointed directly at this reference point.
- The reference point is 5000 mm in front of the camera lens.
- The focal length of the camera lens is 200 mm.

If the camera is focused on the reference point, then the distance from the lens to the camera's image plane must be:

$$\text{dist} = (d * f) / (d - f) = (5000 * 200) / (5000 - 200) = (1000000 / 4800) = 208.333 \text{ mm}$$

The object is roughly 600 mm wide and 600 mm high. The reference point appears in the exact center of each image.

If the object is 600 mm high and 5000 mm distant from the camera lens, then the object image height must be:

$$\text{hi} = (h * f) / (d - f) = (600 * 200) / (5000 - 200) = (120000 / 4800) = 25.0 \text{ mm}$$

The object image appears 200 pixels high so the final magnification factor is:

$$\text{img\_mag} = (200 / 25) = 8.0$$

From these assumptions, we can set up the following reconstruction:

```
; First, define the variables:
imgx = 256
imgy = 256
frames = 3
images = BYTARR(imgx, imgy, frames)
obj_rot = Fltarr(3, frames)
obj_pos = Fltarr(3, frames)
focal = Fltarr(frames)
```

```

dist = Fltarr(frames)
vol_pos = Fltarr(3, 2)
img_ref = Fltarr(2, frames)
img_mag = Fltarr(2, frames)
vol_size = [40, 40, 40]

; The object is 5000 mm directly in front of the camera:
obj_pos[0, *] = 0.0
obj_pos[1, *] = 0.0
obj_pos[2, *] = -5000.0

; The focal length of the lens is constant for all the images:
focal[*] = 200.0

; The distance from the lens to the image plane is also constant:
dist[*] = 208.333

; The cube surrounding the object is 600 mm x 600 mm:
vol_pos[* , 0] = [-300.0, -300.0, -300.0]
vol_pos[* , 1] = [ 300.0, 300.0, 300.0]

; The image reference point appears at the center of all the
; images:
img_ref[0, *] = imgx / 2
img_ref[1, *] = imgy / 2

; The image magnification factor is constant for all images.
; (The images haven't been cropped or resized):
img_mag[*,*] = 8.0

; Only the object rotation changes from one image to the next.
; Note that the object is rotated about the X axis first, then Y,
; and then Z. Create some fake images for this example:
images[30:160, 20:230, 0] = 255
images[110:180, 160:180, 0] = 180
obj_rot[* , 0] = [-90.0, 0.0, 0.0]
images[70:140, 100:130, 1] = 255
obj_rot[* , 1] = [-70.0, 75.0, 0.0]
images[10:140, 70:170, 2] = 255
images[80:90, 170:240, 2] = 150
obj_rot[* , 2] = [-130.0, 215.0, 0.0]

; Reconstruct the volume:
vol = RECON3(images, obj_rot, obj_pos, focal, dist, $
  vol_pos, img_ref, img_mag, vol_size, Missing=255B, Mode=(-1))

; Display the volume:
shade_volume, vol, 8, v, p
scale3, xrange=[0,40], yrange=[0,40], zrange=[0,40]

```

```
image = polyshade(v, p, /t3d, xs=400, ys=400)  
tvsc1, image
```

# REDUCE\_COLORS

The REDUCE\_COLORS procedure reduces the number of colors used in an image by eliminating pixel values without members.

The pixel distribution histogram is obtained and the WHERE function is used to find bins with non-zero values. Next, a lookup table is made where table[old\_pixel\_value] contains new\_pixel\_value, and is then applied to the image.

This routine is written in the IDL language. Its source code can be found in the file reduce\_colors.pro in the lib subdirectory of the IDL distribution.

## Syntax

REDUCE\_COLORS, *Image*, *Values*

## Arguments

### Image

On input, a variable that contains the original image array. On output, this variable contains the color-reduced image array, writing over the original.

### Values

A named variable that, on output, contains a vector of non-zero pixel values. If *Image* contains pixel values from 0 to M, *Values* will be an M+1 element vector containing the mapping from the old values to the new. *Values[i]* contains the new color index of old pixel index *i*.

## Keywords

None.

## Examples

To reduce the number of colors and display an image with the original color tables R, G, B enter the commands:

```
REDUCE_COLORS, image, v
TVLCT, R[V], G[V], B[V]
```

## Version History

[COLOR\\_QUAN](#)

# REFORM

The REFORM function changes the dimensions of an array without changing the total number of elements.

## Syntax

```
Result = REFORM( Array, D1 [, ..., D8] [, /OVERWRITE] )
```

## Return Value

If no dimensions are specified, REFORM returns a copy of *Array* with all dimensions of size 1 removed. If dimensions are specified, the result is given those dimensions. Only the dimensions of *Array* are changed – the actual data remains unmodified.

## Arguments

### Array

The array to have its dimensions modified.

### *D*<sub>*i*</sub>

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. *Array* must have the same number of elements as specified by the product of the new dimensions.

## Keywords

### OVERWRITE

Set this keyword to cause the specified dimensions to overwrite the present dimensions of the *Array* parameter. No data are copied, only the internal array descriptor is changed. The result of the function, in this case, is the *Array* parameter with its newly-modified dimensions. For example, to change the dimensions of the variable *a*, without moving data, enter:

```
a = REFORM(a, n1, n2, /OVERWRITE)
```

## Examples

REFORM can be used to remove “degenerate” leading dimensions of size one. Such dimensions can appear when a subarray is extracted from an array with more dimensions. For example

```
; a is a 3-dimensional array:
a = INTARR(10,10,10)

; Extract a "slice" from a:
b = a[5,*,*]

; Use HELP to show what REFORM does:
HELP, b, REFORM(b)
```

Executing the above statements produces the output:

```
B          INT = Array[1, 10, 10]
<Expression> INT = Array[10, 10]
```

The statements:

```
b = REFORM(a,200,5)
b = REFORM(a,[200,5])
```

have identical effect. They create a new array, b, with dimensions of (200, 5), from a.

## Converting RGB Images to Grayscale Images

The following example extracts the three channels of an RGB image contained in the `glowing_gas.jpg` file, which is in the `examples/data` directory. This file is provided by the Hubble Heritage Team, which is made of AURA, STScI, and NASA.

This example uses REFORM to extract individual channels as grayscale (intensity) images from the original RGB image. These images are converted to floating-point data and then added together to form a single image, which is a grayscale version of the original RGB image. Complete the following steps for a detailed description of the process.

### Example Code

---

See `rgbtograyscale.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

---

1. Determine the path to the file:

```
file = FILEPATH('glowing_gas.jpg', $
SUBDIRECTORY = ['examples', 'data'])
```

2. Query the file to determine the image parameters:

```
queryStatus = QUERY_JPEG(file, imageInfo)
```

3. Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

4. Import the image from the file:

```
READ_JPEG, file, image
```

5. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to one before your first RGB image is displayed within an IDL session or program.

```
DEVICE, DECOMPOSED = 1
```

6. Create a window and display the image:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $  
  TITLE = 'Glowing Gas RGB Image'  
TV, image, TRUE = 1
```

The following figure shows the original RGB image.

*Figure 3-100: The Glowing Gas RGB Image*

7. Extract the channels (as images) from the RGB image:

```
redChannel = REFORM(image[0, *, *])
greenChannel = REFORM(image[1, *, *])
blueChannel = REFORM(image[2, *, *])
```

8. Initialize the grayscale display:

```
DEVICE, DECOMPOSED = 0
LOADCT, 0
```

9. Create another window and display each channel of the RGB image:

```
WINDOW, 1, XSIZE = 3*imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'Red (left), Green (middle), ' + $
  'and Blue (right) Channels of the RGB Image'
TV, redChannel, 0
TV, greenChannel, 1
TV, blueChannel, 2
```

The following figure shows the RGB channels. The red channel is on the left, the green channel is in the middle, and the blue channel is on the right.

*Figure 3-101: The Channels of the Glowing Gas RGB Image*

10. Convert the channels into a single grayscale image.

```
grayscaleImage = BYTE(0.299*FLOAT(redChannel) + $
  0.587*FLOAT(greenChannel) + 0.114*FLOAT(blueChannel))
```

The pixel values of the channels are converted from byte values to floating-point values because byte values cannot exceed 255. The adjustment factors (0.299, 0.587, and 0.114) are used to enhance visual perception and to scale the results to a range from 0 to 255. The BYTE function is used to restore the pixel values back to their original data type.

11. Create another window and display the grayscale image:

```
WINDOW, 2, XSIZE = 2*imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'Resulting Grayscale Image' + $
  TV, grayscaleImage
```

The following figure shows the result of creating a grayscale image from the individual channels of an RGB image.

*Figure 3-102: Resulting Grayscale Image*

# REGION\_GROW

The REGION\_GROW function performs region growing for a given region within an N-dimensional array by finding all pixels within the array that are connected neighbors to the region pixels and that fall within provided constraints. The constraints are specified either as a threshold range (a minimum and maximum pixel value) or as a multiple of the standard deviation of the region pixel values. If the threshold is used (this is the default), the region is grown to include all connected neighboring pixels that fall within the given threshold range. If the standard deviation multiplier is used, the region is grown to include all connected neighboring pixels that fall within the range of the mean (of the region's pixel values) plus or minus the given multiplier times the sample standard deviation.

## Syntax

```
Result = REGION_GROW(Array, ROIPixels [, /ALL_NEIGHBORS] [, /NAN]  
[, STDDEV_MULTIPLIER=value | THRESHOLD=[min,max]] )
```

## Return Value

REGION\_GROW returns the vector of array indices that represent pixels within the grown region. The grown region will not include pixels at the edges of the input array. If no pixels fall within the grown region, this function will return the value -1.

## Arguments

### Array

An N-dimensional array of data values. The region will be grown according to the data values within this array.

### ROIPixels

A vector of indices into *Array* that represent the initial region that is to be grown.

## Keywords

### ALL\_NEIGHBORS

Set this keyword to indicate that all adjacent neighbors to a given pixel should be considered during region growing (sometimes known as 8-neighbor searching when

the array is two-dimensional). The default is to search only the neighbors that are exactly one unit in distance from the current pixel (sometimes known as 4-neighbor searching when the array is two-dimensional).

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## STDDEV\_MULTIPLIER

Set this keyword to a scalar value that serves as the multiplier of the sample standard deviation of the original region pixel values. The expanded region includes neighboring pixels that fall within the range of the mean of the region’s pixel values plus or minus the given multiplier times the sample standard deviation as follows:

$$\text{Mean} \pm \text{StdDevMultiplier} * \text{StdDev}$$

This keyword is mutually exclusive of THRESHOLD. If both keywords are specified, a warning message will be issued and the THRESHOLD value will be used.

## THRESHOLD

Set this keyword to a two-element vector,  $[min,max]$ , of the inclusive range within which the pixel values of the grown region must fall. The default is the range of pixel values within the initial region. This keyword is mutually exclusive of STDDEV\_MULTIPLIER. If both keywords are specified, a warning message will be issued and the THRESHOLD value will be used.

### Note

---

If neither keyword is specified, THRESHOLD is used by default. The range of threshold values is based upon the pixel values within the original region and therefore does not have to be provided.

---

## Examples

The following example demonstrates how you can grow a pre-defined region within an image of human red blood cells.

```
; Load an image.
fname = FILEPATH('rbcells.jpg', SUBDIR=['examples','data'])
```

```

READ_JPEG, fname, img
imgDims = SIZE(img, /DIMENSIONS)

; Define original region pixels.
x = FINDGEN(16*16) MOD 16 + 276.
y = LINDGEN(16*16) / 16 + 254.
roiPixels = x + y * imgDims[0]

; Grow the region.
newROIPixels = REGION_GROW(img, roiPixels)

; Load a grayscale color table.
DEVICE, DECOMPOSED = 0
LOADCT, 0

; Set the topmost color table entry to red.
topClr = !D.TABLE_SIZE-1
TVLCT, 255, 0, 0, topClr

; Show the results.
tmpImg = BYTSCL(img, TOP=(topClr-1))
tmpImg[roiPixels] = topClr
WINDOW, 0, XSIZE=imgDims[0], YSIZE=imgDims[1], $
    TITLE='Original Region'
TV, tmpImg

tmpImg = BYTSCL(img, TOP=(topClr-1))
tmpImg[newROIPixels] = topClr
WINDOW, 2, XSIZE=imgDims[0], YSIZE=imgDims[1], $
    TITLE='Grown Region'
TV, tmpImg

```

6.1	Added NAN keyword

# REGISTER\_CURSOR

The REGISTER\_CURSOR procedure associates the given name with the given cursor information. This name can then be used with the IDLgrWindow::SetCurrentCursor method.

---

**Tip**

You can use the [CREATE\\_CURSOR](#) function to translate a string array into an image array suitable for the *Image* argument. You can also return values for the MASK and HOTSPOT keywords using this function.

---

## Syntax

```
REGISTER_CURSOR, Name, Image[, MASK=value] [, HOTSPOT=value]  
[, /OVERWRITE]
```

## Arguments

### Name

This argument sets the name to associate with this cursor. The name is case-insensitive. Once registered, the name can be used with the IDLgrWindow::SetCurrentCursor method.

### Image

Set this argument to a 16 line by 16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the hot spot can be provided using the [HOTSPOT](#) keyword.

## Keywords

### MASK

This keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are masked out.

## HOTSPOT

Set this keyword to a two-element vector specifying the  $[x, y]$  pixel offset of the cursor "hot spot", the point which is considered to be the mouse position, from the lower-left corner of the cursor image. The cursor image is displayed top-down (the first row is displayed at the top).

## OVERWRITE

By default, if the cursor already exists, the values are not changed. By setting this keyword to true, the current cursor value is updated with the values provided by this routine call.

## Version History

5.6	Introduced

[IDLgrWindow::SetCurrentCursor](#)

# REGRESS

The REGRESS function performs a multiple linear regression fit and returns an *Nterm*-element column vector of coefficients.

REGRESS fits the function:

$$y_i = \text{const} + a_0x_{0,i} + a_1x_{1,i} + \dots + a_{Nterms-1}x_{Nterms-1,i}$$

This routine is written in the IDL language. Its source code can be found in the file `regress.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = REGRESS( X, Y, [, CHISQ=variable] [, CONST=variable]
  [, CORRELATION=variable] [, /DOUBLE] [, FTEST=variable]
  [, MCORRELATION=variable] [, MEASURE_ERRORS=vector]
  [, SIGMA=variable] [, STATUS=variable] [, YFIT=variable] )
```

## Return Value

REGRESS returns a 1 x *Nterm* array of coefficients. If the DOUBLE keyword is set, or if *X* or *Y* are double-precision, then the result will be double precision, otherwise the result will be single precision.

## Arguments

### X

An *Nterms* by *Npoints* array of independent variable data, where *Nterms* is the number of coefficients (independent variables) and *Npoints* is the number of samples.

### Y

An *Npoints*-element vector of dependent variable points.

## Keywords

### CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

## CONST

Set this keyword to a named variable that will contain the constant term of the fit.

## CORRELATION

Set this keyword to a named variable that will contain the vector of linear correlation coefficients.

## DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

## FTEST

Set this keyword to a named variable that will contain the F-value for the goodness-of-fit test.

## MCORRELATION

Set this keyword to a named variable that will contain the multiple linear correlation coefficient.

## MEASURE\_ERRORS

Set this keyword to a vector containing standard measurement errors for each point  $Y[i]$ . This vector must be the same length as  $X$  and  $Y$ .

---

**Note**

For Gaussian errors (e.g., instrumental uncertainties), `MEASURE_ERRORS` should be set to the standard deviations of each point in  $Y$ . For Poisson or statistical weighting, `MEASURE_ERRORS` should be set to `SQRT(Y)`.

---

## SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

**Note**

---

If MEASURE\_ERRORS is omitted, then you are assuming that the regression model is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by  $\text{SQRT}(\text{CHISQ}/(N-M))$ , where  $N$  is the number of points in  $X$ , and  $M$  is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

---

**STATUS**

Set this keyword to a named variable that will contain the status of the operation. Possible status values are:

- 0 = successful completion
- 1 = singular array (which indicates that the inversion is invalid)
- 2 = warning that a small pivot element was used and that significant accuracy was probably lost.

**Note**

---

If STATUS is not specified, any error messages will be output to the screen.

---

**YFIT**

Set this keyword to a named variable that will contain the vector of calculated  $Y$  values.

**Examples**

```

; Create two vectors of independent variable data:
X1 = [1.0, 2.0, 4.0, 8.0, 16.0, 32.0]
X2 = [0.0, 1.0, 2.0, 3.0, 4.0, 5.0]
; Combine into a 2x6 array
X = [TRANPOSE(X1), TRANPOSE(X2)]

; Create a vector of dependent variable data:
Y = 5 + 3*X1 - 4*X2

; Assume Gaussian measurement errors for each point:
measure_errors = REPLICATE(0.5, N_ELEMENTS(Y))

```

```

; Compute the fit, and print the results:
result = REGRESS(X, Y, SIGMA=sigma, CONST=const, $
    MEASURE_ERRORS=measure_errors)
PRINT, 'Constant: ', const
PRINT, 'Coefficients: ', result[*]
PRINT, 'Standard errors: ', sigma

```

IDL prints:

```

Constant:      4.99999
Coefficients:   3.00000   -3.99999
Standard errors: 0.0444831   0.282038

```

# REPEAT...UNTIL

The REPEAT...UNTIL statement repeats its subject statement(s) until an expression evaluates to true. The condition is checked after the subject statement is executed. Therefore, the subject statement is always executed at least once, even if the expression evaluates to true the first time.

---

## Note

For information on using REPEAT\_UNTIL and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

---

## Syntax

REPEAT *statement* UNTIL *expression*

or

REPEAT BEGIN

*statements*

ENDREP UNTIL *expression*

## Examples

This example shows that because the subject of a REPEAT statement is evaluated before the expression, it is always executed at least once:

```
i = 1

REPEAT BEGIN

    PRINT, i

ENDREP UNTIL (i EQ 1)
```

## Version History

Original	Introduced

# REPLICATE

The REPLICATE function returns an array with the given dimensions, filled with the scalar value specified as the first parameter.

## Syntax

$$Result = \text{REPLICATE}(Value, D_1 [, \dots, D_8])$$

## Return Value

Returns the array of the given dimensions.

## Arguments

### Value

The scalar value with which to fill the resulting array. The type of the result is the same as that of *Value*. *Value* can be any single element expression such as a scalar or 1 element array. This includes structures.

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Create D, a 5-element by 5-element array with every element set to the string “IDL” by entering:

```
D = REPLICATE('IDL', 5, 5)
```

REPLICATE can also be used to create arrays of structures. For example, the following command creates a structure named “emp” that contains a string name field and a long integer employee ID field:

```
employee = {emp, NAME:' ', ID:0L}
```

To create a 10-element array of this structure, enter:

```
emps = REPLICATE(employee, 10)
```

## Version History

[MAKE\\_ARRAY](#)

# REPLICATE\_INPLACE

The REPLICATE\_INPLACE procedure updates an existing array by replacing all or selected parts of it with a specified value. REPLICATE\_INPLACE can be faster and use less memory than the IDL function REPLICATE or the IDL array notation for large arrays that already exist.

---

**Note**

REPLICATE\_INPLACE is much faster when operating on entire arrays and rows, than when used on columns or higher dimensions.

---

## Syntax

```
REPLICATE_INPLACE, X, Value [, D1, Loc1 [, D2, Range]]
```

## Arguments

### X

The array to be updated. *X* can be of any numeric type. REPLICATE\_INPLACE does not change the size and type of *X*.

### Value

The value which will fill all or part of *X*. *Value* may be any scalar or one-element array that IDL can convert to the type of *X*. REPLICATE\_INPLACE does not change *Value*.

### D1

An optional parameter indicating which dimension of *X* is to be updated.

### Loc1

An array with the same number of elements as the number of dimensions of *X*. The *Loc1* and *D1* arguments together determine which one-dimensional subvector (or subvectors, if *D1* and *Range* are provided) of *X* is to be updated.

### D2

An optional parameter, indicating in which dimension of *X* a group of one-dimensional subvectors are to be updated. *D2* should be different from *D1*.

## Range

An array of indices of dimension  $D2$  of  $X$ , indicating where to put one-dimensional updates of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

```
; Create a multidimensional zero array:
A = FLTARR( 40, 90, 10)

; Populate it with the value 4.5. (i.e., A[*]= 4.5 ):
REPLICATE_INPLACE, A, 4.5
;Update a single subvector.(i.e., A[* ,4,0]= 20. ):
REPLICATE_INPLACE, A, 20, 1, [0,4,0]

; Update a group of subvectors.(i.e., A[ 0, [0, 5,89], * ] = -8 ):
REPLICATE_INPLACE, A, -8, 3, [0,0,0], 2, [0,5,89]

; Update a 2-dimensional slice of A (i.e., A[9,*, *] = 0.):
REPLICATE_INPLACE, A, 0., 3, [9,0,0], 2, LINDGEN(90)
```

[REPLICATE](#), [BLAS\\_AXPY](#)

# RESOLVE\_ALL

The `RESOLVE_ALL` procedure iteratively resolves (by compiling) any uncompiled procedures or functions that are called in any already-compiled procedure or function. The process ends when there are no unresolved routines left to compile. If an unresolved procedure or function is not in the IDL search path, `RESOLVE_ALL` exits with an error, and no additional routines are compiled.

`RESOLVE_ALL` is of special interest when using `SAVE` to construct an IDL `SAVE` file containing the compiled code for a package of routines. If you are constructing such a `SAVE` file and it contains calls to built-in IDL system functions that are not present under all operating systems (e.g., `IOCTL`), you must make sure to use `FORWARD_FUNCTION` to tell IDL that these names are functions. Otherwise, IDL may interpret them as arrays and generate unintended results. If you are creating a `SAVE` file that relies upon `iTools` components, you must use `ITRESOLVE` instead of `RESOLVE_ALL` to create a valid `SAVE` file.

## Warning

---

`RESOLVE_ALL` does not resolve procedures or functions that are called via quoted strings such as `CALL_PROCEDURE`, `CALL_FUNCTION`, or `EXECUTE`, or in keywords that can contain procedure names such as `TICKFORMAT` or `EVENT_PRO`. You must manually compile these routines if they are not called normally elsewhere.

Similarly, `RESOLVE_ALL` does not resolve widget event handler procedures based on a call to the widget routine that uses the event handler. In general, it is best to include the event handling routine in the same program file as the widget creation routine—building widget programs in this way ensures that `RESOLVE_ALL` will “catch” the event handler for a widget application.

---

This routine is written in the IDL language. Its source code can be found in the file `resolve_all.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
RESOLVE_ALL [, CLASS=string] [, /CONTINUE_ON_ERROR] [, /QUIET]
  [, RESOLVE_EITHER=string] [, RESOLVE_FUNCTION=string]
  [, RESOLVE_PROCEDURE=string] [, SKIP_ROUTINES=string]
  [, UNRESOLVED=variable]
```

**Note**

To properly resolve routines, make sure you run `RESOLVE_ALL` in an IDL session in which no compilation errors have occurred. This is important because if IDL has previously attempted (and failed) to compile a routine, that routine will be added to IDL's list of user-defined routines as an uncompiled routine. A subsequent call to `RESOLVE_ALL` will attempt to compile the uncompiled routine, potentially causing another error.

You can ensure that an IDL session is "clean" either by exiting and restarting IDL or by issuing the `.RESET_SESSION` executive command.

## Arguments

None

## Keywords

### **CLASS**

Set this keyword to a string or string array containing object class names.

`RESOLVE_ALL`'s rules for finding uncompiled functions and procedures are not able to find object definitions or methods, because those things are not known to IDL until the object classes are actually instantiated and the methods called. However, if the `CLASS` keyword is set, `RESOLVE_ALL` will ensure that the `*__define.pro` files for the specified classes and their superclasses are compiled and executed.

`RESOLVE_ALL` then locates all methods for the specified classes and their superclasses, and makes sure they are also compiled.

### **CONTINUE\_ON\_ERROR**

Set this keyword to allow continuation upon error.

### **QUIET**

Set this keyword to suppress informational messages.

### **RESOLVE\_EITHER**

Set this keyword to a string or string array of routine names to resolve.

Use this keyword instead of `RESOLVE_FUNCTION` or `RESOLVE_PROCEDURE` if you do not know the type of the routine being resolved. If the routines are already compiled, they are not recompiled.

## RESOLVE\_FUNCTION

Set this keyword to a string or string array of function names to resolve. If the functions are already compiled, they are not recompiled.

## RESOLVE\_PROCEDURE

Set this keyword to a string or string array of procedure names to resolve. If the procedures are already compiled, they are not recompiled.

## SKIP\_ROUTINES

Set this keyword to a string array containing the names of routines *not* to resolve. Using this keyword is useful when a library file containing the designated routines will be later included.

## UNRESOLVED

Set this keyword to a variable that will contain the names of the unresolved procedures and functions if `CONTINUE_ON_ERROR` is set. Routines in the `SKIP_ROUTINES` list are also included in the result.

## Version History

4.0	Introduced
6.0	Added <code>CLASS</code> keyword

## See Also

[.COMPILE](#), [RESOLVE\\_ROUTINE](#), [ROUTINE\\_INFO](#)

# RESOLVE\_ROUTINE

The RESOLVE\_ROUTINE procedure compiles user-written or library procedures or functions, given their names. Routines are compiled even if they are already defined. RESOLVE\_ROUTINE looks for the given filename in IDL's search path. If the file is not found in the path, then the routine exits with an error.

## Syntax

```
RESOLVE_ROUTINE, Name [, /COMPILE_FULL_FILE ]  
                [, /EITHER | , /IS_FUNCTION] [, /NO_RECOMPILE]
```

## Arguments

### Name

A scalar string or string array containing the name or names of the procedures to compile. If *Name* contains functions rather than procedures, set the IS\_FUNCTION keyword. The *Name* argument cannot contain the path to the .pro file—it must contain only a .pro filename. If you want to specify a path to the .pro file, use the .COMPILE executive command.

## Keywords

### COMPILE\_FULL\_FILE

When compiling a file to find a specified routine, IDL normally stops compiling when the desired routine (*Name*) is found. If set, COMPILE\_FULL\_FILE compiles the entire file.

### EITHER

If set, indicates that the caller does not know whether the supplied routine names are functions or procedures, and will accept either. This keyword overrides the IS\_FUNCTION keyword.

### IS\_FUNCTION

Set this keyword to compile functions rather than procedures.

## NO\_RECOMPILE

Normally, RESOLVE\_ROUTINE compiles all specified routines even if they have already been compiled. Setting NO\_RECOMPILE indicates that such routines are not recompiled.

## Version History

4.0	Introduced
-----	------------

## See Also

[.COMPILE](#), [RESOLVE\\_ALL](#), [ROUTINE\\_INFO](#)

# RESTORE

The RESTORE procedure restores the IDL variables and routines saved in a file by the SAVE procedure.

RESTORE provides a very simple interface that restores the entire contents of the specified SAVE file in a single atomic operation. If you wish to query the contents of a SAVE file without first restoring the data, or if you wish to restore only selected items, use the interface provided by the [IDL\\_Savefile](#) object class instead.

## Warning

---

While files containing IDL data variables can be restored by any version of IDL that supports the data types of the saved variables (in particular, by any version of IDL later than the version that created the SAVE file), files containing IDL routines and system variables can only be restored by versions of IDL that share the same internal code representation. Since the internal code representation changes regularly, you should always archive the IDL language source files (`.pro` files) for routines you are placing in IDL `.sav` files so you can recompile the code when a new version of IDL is released.

---

## Syntax

```
RESTORE [, Filename] | [, FILENAME=name] [, DESCRIPTION=variable]
      [, /RELAXED_STRUCTURE_ASSIGNMENT]
      [, RESTORED_OBJECTS=variable] [, /VERBOSE]
```

## Arguments

### Filename

A scalar string that contains the name of the SAVE file to be restored. If *Filename* is not an absolute path name, it is considered to be relative to the current working directory. If neither the *Filename* argument or the FILENAME keyword are present, IDL attempts to restore a file named `idlsave.dat` in the current working directory.

## Keywords

### DESCRIPTION

Set this keyword equal to a named variable that will contain the user-supplied *description string* for the specified save file. If no description was provided when the

save file was created (via the DESCRIPTION keyword to the [SAVE](#) routine), the variable specified by this keyword will contain a null string.

## FILENAME

This keyword serves exactly the same purpose as the *Filename* argument—only one of them needs to be provided. If both the *Filename* argument and the FILENAME keyword are provided, the file specified by the *Filename* argument is restored.

## RELAXED\_STRUCTURE\_ASSIGNMENT

Normally, RESTORE is unable to restore a structure variable if the definition of its type has changed since the SAVE file was written. A common case where this occurs is when objects are saved and the class structure of the objects change before they are restored in another IDL session. In such cases, RESTORE issues an error, skips the structure, and continues restoring the remainder of the SAVE file.

Setting the RELAXED\_STRUCTURE\_ASSIGNMENT keyword causes RESTORE to restore such incompatible values using “relaxed structure assignment,” in which all possible data are restored using a field-by-field copy. (See the description of the [STRUCT\\_ASSIGN](#) procedure for additional details.)

## RESTORED\_OBJECTS

Set this keyword equal to a named variable that will contain an array of object references for any objects restored. The resulting list of objects is useful for programmatically calling the objects’ restore methods. If no objects are restored, the variable will contain a null object reference.

## VERBOSE

Set this keyword to have IDL print an informative message for each restored object.

## Examples

Suppose that you have saved all the variables from a previous IDL session with the command:

```
SAVE, /VARIABLES, FILENAME = 'session1.sav'
```

If the file `session1.sav` is located in your current working directory, the variable associated with the file can be restored by entering:

```
RESTORE, 'session1.sav'
```

**Note**

To restore a file that is not in your current working directory, you must specify the file path.

## Version History

# RETALL

The RETALL command returns control to the main program level. The effect is the same as entering the RETURN command at the interactive command prompt until the main level is reached.

## Syntax

RETALL

## Arguments

None

## Version History

Original	Introduced
----------	------------

## See Also

[RETURN](#)

# RETURN

The RETURN command causes the program context to revert to the next-higher program level. RETURN can be called at the interactive command prompt (see “.RETURN” on page 53), inside a procedure definition, or inside a function definition.

Calling RETURN from the main program level has no effect other than to print an informational message in the command log.

Calling RETURN inside a procedure definition returns control to the calling routine, or to the main level. Since the END statement in a procedure definition also returns control to the calling routine, it is only necessary to use RETURN in a procedure definition if you wish control to revert to the calling routine before the procedure reaches its END statement.

In a function definition, RETURN serves to define the value passed out of the function. Only a single value can be returned from a function.

---

**Note**

The value can be an array or structure containing multiple data items.

---

## Syntax

```
RETURN [, Return_value]
```

## Arguments

### Return\_value

In a function definition, the *Return\_value* is the value passed out of the function when it completes its processing.

Return values are not allowed in procedure definitions, or when calling RETURN at the interactive command prompt.

## Examples

You can use RETURN within a procedure definition to exit the procedure at some point other than the end. For example, note the following procedure:

```
PRO RET_EXAMPLE, value
  IF (value NE 0) THEN BEGIN
```

```
        PRINT, value, ' is nonzero'
        RETURN
    END
    PRINT, 'Input argument was zero.'
END
```

If the input argument is non-zero, the routine prints the value and exits back to the calling procedure or main level. If the input argument is zero, control proceeds until the END statement is reached.

When defining functions, use RETURN to specify the value returned from the function. For example, the following function:

```
FUNCTION RET_EXAMPLE2, value
    RETURN, value * 2
END
```

multiplies the input value by two and returns the result. If this function is defined at the main level, calling it from the IDL command prompt produces the following:

```
PRINT, RET_EXAMPLE2(4)
```

IDL prints:

```
8
```

## Version History

[RECALL](#)

# REVERSE

The REVERSE function reverses the order of one dimension of an array.

This routine is written in the IDL language. Its source code can be found in the file `reverse.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = REVERSE( Array [, Subscript_Index] [, /OVERWRITE] )
```

## Return Value

Returns the reversed dimension of the array.

## Arguments

### Array

The array containing the original data.

### Subscript\_Index

An integer specifying the dimension index (1, 2, 3, etc.) that will be reversed. This argument must be less than or equal to the number of dimensions of *Array*. If this argument is omitted, the first subscript is reversed.

## Keywords

### OVERWRITE

Set this keyword to conserve memory by doing the transformation “in-place.” The result overwrites the previous contents of the array. This keyword is ignored for one- or two-dimensional arrays.

## Examples

Reverse the order of an array where each element is set to the value of its subscript:

```
; Create an array:  
A = [[0,1,2], [3,4,5], [6,7,8]]
```

```

; Print the array:
PRINT, 'Original Array:'
PRINT, A

; Reverse the columns of A.
PRINT, 'Reversed Columns:'
PRINT, REVERSE(A)

; Reverse the rows of A:
PRINT, 'Reversed Rows:'
PRINT, REVERSE(A, 2)

```

IDL prints:

```

Original Array:
    0      1      2
    3      4      5
    6      7      8
Reversed Columns:
    2      1      0
    5      4      3
    8      7      6
Reversed Rows:
    6      7      8
    3      4      5
    0      1      2

```

---

### Note

# RK4

The RK4 function uses the fourth-order Runge-Kutta method to advance a solution to a system of ordinary differential equations one time-step  $H$ , given values for the variables  $Y$  and their derivatives  $Dydx$  known at  $X$ .

RK4 is based on the routine `rk4` described in section 16.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

$Result = RK4( Y, Dydx, X, H, Derivs [, /DOUBLE] )$

## Return Value

Returns the integrations of the ordinary differential equations.

## Arguments

### Y

A vector of values for  $Y$  at  $X$

### Note

---

If RK4 is complex then only the real part is used for the computation.

---

### Dydx

A vector of derivatives for  $Y$  at  $X$ .

### X

A scalar value for the initial condition.

### H

A scalar value giving interval length or step size.

### Derivs

A scalar string specifying the name of a user-supplied IDL function that calculates the values of the derivatives  $Dydx$  at  $X$ . This function must accept two arguments: A

scalar floating value  $X$ , and one  $n$ -element vector  $Y$ . It must return an  $n$ -element vector result.

For example, suppose the values of the derivatives are defined by the following relations:

$$dy_0/dx = -0.5y_0, \quad dy_1/dx = 4.0 - 0.3y_1 - 0.1y_0$$

We can write a function `DIFFERENTIAL` to express these relationships in the IDL language:

```
FUNCTION differential, X, Y
  RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END
```

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To integrate the example system of differential equations for one time step,  $H$ :

```
; Define the step size:
H = 0.5

; Define an initial X value:
X = 0.0

; Define initial Y values:
Y = [4.0, 6.0]

; Calculate the initial derivative values:
dydx = DIFFERENTIAL(X,Y)

; Integrate over the interval (0, 0.5):
result = RK4(Y, dydx, X, H, 'differential')

; Print the result:
PRINT, result
```

IDL prints:

```
3.11523 6.85767
```

This is the exact solution vector to five-decimal precision.

[BROYDEN, NEWTON](#)

# ROBERTS

The ROBERTS function returns an approximation to the Roberts edge enhancement operator for images:

$$G_{jk} = |F_{jk} - F_{j+1, k+1}| + |F_{j, k+1} - F_{j+1, k}|$$

where  $(j, k)$  are the coordinates of each pixel  $F_{jk}$  in the *Image*. This is equivalent to a convolution using the masks,

$$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \text{ and } \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

where the underline indicates the current pixel  $F_{jk}$ . The last column and row are set to zero.

## Syntax

*Result* = ROBERTS(*Image*)

## Return Value

ROBERTS returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer, then the result is of integer type, otherwise the result is of the same type as *Image*.

### Note

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

## Arguments

### Image

The two-dimensional array containing the image to which edge enhancement is applied.

## Keywords

None.

## Examples

If the variable `myimage` contains a two-dimensional image array, a Roberts sharpened version of `myimage` can be displayed with the command:

```
TVSCL, ROBERTS(myimage)
```

---

[SOBEL](#)

# ROT

The ROT function rotates an image by an arbitrary amount. At the same time, it can magnify, demagnify, and/or translate an image.

---

**Note**

If you want to rotate an array by a multiple of 90 degrees, you should use the ROTATE function for faster results.

---

This routine is written in the IDL language. Its source code can be found in the file `rot.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$$\text{Result} = \text{ROT}(A, \text{Angle}, [\text{Mag}, X_0, Y_0] [, /\text{INTERP}] [, \text{CUBIC}=\text{value}\{-1 \text{ to } 0\}] [, \text{MISSING}=\text{value}] [, /\text{PIVOT}] )$$

## Return Value

Returns the rotated and optionally transformed image.

## Arguments

### A

The image array to be rotated. This array can be of any type, but must have two dimensions. The output image has the same dimensions and data type of the input image.

### ANGLE

Angle of rotation in degrees *clockwise*.

### MAG

An optional magnification factor. A value of 1.0 results in no change. A value greater than one performs magnification. A value less than one but greater than zero performs demagnification.

**X<sub>0</sub>**

X subscript for the center of rotation. If omitted,  $X_0$  equals the number of columns in the image divided by 2.

**Y<sub>0</sub>**

Y subscript for the center of rotation. If omitted,  $Y_0$  equals the number of rows in the image divided by 2.

**Keywords****INTERP**

Set this keyword to use bilinear interpolation. The default is to use nearest neighbor sampling.

**CUBIC**

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal,  $f$ , is a band-limited signal, with no frequency component larger than  $\omega_0$ , and  $f$  is sampled with spacing less than or equal to  $1/(2\omega_0)$ , then  $f$  can be reconstructed by convolving with a sinc function:  $\text{sinc}(x) = \sin(\pi x) / (\pi x)$ .

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used.

**Note**

---

Cubic convolution interpolation is significantly slower than bilinear interpolation.

---

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 “Image Reconstruction by Parametric Cubic Convolution”, *Computer Vision, Graphics & Image Processing* 23, 256.

## MISSING

Set this keyword to a value to be substituted for pixels in the output image that map outside the input image.

## PIVOT

Set this keyword to cause the image to pivot around the point  $(X_0, Y_0)$  so that this point maps into the same point in the output image. By default, the point  $(X_0, Y_0)$  in the input image is mapped into the center of the output image.

## Examples

```
; Create a byte image:
A = BYTSCL(DIST(256))

; Display it:
TV, A

; Rotate the image 33 degrees, magnify it 15 times, and use
; bilinear interpolation to make the output look nice:
B = ROT(A, 33, 1.5, /INTERP)

; Display the rotated image:
TV, B
```

### Note

Also see “[Rotating Images](#)” in Chapter 2 of the *Image Processing in IDL* manual for a more extensive example.

## Version History

Original	Introduced
----------	------------

## See Also

[ROTATE](#)

# ROTATE

The ROTATE function returns a rotated and/or transposed copy of *Array*. ROTATE can only rotate arrays in multiples of 90 degrees. To rotate by amounts other than multiples of 90 degrees, use the ROT function. Note, however, that ROTATE is more efficient.

ROTATE can also be used to reverse the order of elements in vectors. For example, to reverse the order of elements in the vector *X*, use the expression ROTATE (*X*, 2) . If *X* = [0,1,2,3] then ROTATE (*X*, 2) yields the resulting array, [3,2,1,0].

## Note

---

Transposition, if specified, is performed before rotation.

---

## Syntax

*Result* = ROTATE(*Array*, *Direction*)

## Return Value

Returns the rotated and/or transposed array.

## Arguments

### Array

The array to be rotated. *Array* can have only one or two dimensions. The result has the same type as *Array*. The dimensions of the result are the same as those of *Array* if *Direction* is equal to 0 or 2. The dimensions are transposed if the direction is 4 or greater.

### Direction

*Direction* specifies the operation to be performed as follows:

Direction	Transpose?	Rotation Counterclockwise	$X_1$	$Y_1$
0	No	None	$X_0$	$Y_0$
1	No	90°	$-Y_0$	$X_0$

Table 3-111: Rotation Directions

Direction	Transpose?	Rotation Counterclockwise	$X_1$	$Y_1$
2	No	180°	$-X_0$	$-Y_0$
3	No	270°	$Y_0$	$-X_0$
4	Yes	None	$Y_0$	$X_0$
5	Yes	90°	$-X_0$	$Y_0$
6	Yes	180°	$-Y_0$	$-X_0$
7	Yes	270°	$X_0$	$-Y_0$

Table 3-111: Rotation Directions (Continued)

In the table above,  $(X_0, Y_0)$  are the original subscripts, and  $(X_1, Y_1)$  are the subscripts of the resulting array. The notation  $-Y_0$  indicates a reversal of the Y axis,  $Y_1 = N_y - Y_0 - 1$ . *Direction* is taken modulo 8, so a rotation of -1 is the same as 7, 9 is the same as 1, etc.

**Note**

The assertion that *Array* is rotating counterclockwise may cause some confusion. Remember that when arrays are displayed on the screen (using TV or TVSCL, for example), the image is drawn by default with the origin (0,0) at the bottom left corner of the window. (This default can be changed by changing the value of the !ORDER system variable.) When arrays are printed on the console or command log window (using the PRINT command, for example), the (0,0) element is drawn in the upper left corner of the array. This means that while an image displayed in a graphics window appears to rotate counterclockwise, an array printed in the command log appears to rotate clockwise.

## Examples

Create and display a wedge image by entering:

```
F = REPLICATE(1, 256) # FINDGEN(256) & TVSCL, F
```

To display the image rotated 90 degrees counterclockwise, enter:

```
TVSCL, ROTATE(F, 1)
```

**Note**

Also see “[Rotating Images](#)” in Chapter 2 of the *Image Processing in IDL* manual for a more extensive example.

# ROUND

The ROUND function rounds the argument to its closest integer.

## Syntax

*Result* = ROUND(*X* [, /L64 ] )

## Return Value

Returns the integer closest to its argument. If the input value *X* is integer type, *Result* has the same value and type as *X*. Otherwise, *Result* is returned as a 32-bit longword integer with the same structure as *X*.

## Arguments

### X

The value for which the ROUND function is to be evaluated. This value can be any numeric type (integer, floating, or complex). Note that only the real part of a complex argument is rounded and returned.

## Keywords

### L64

If set, the result type is 64-bit integer no matter what type the input has. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

Print the rounded values of a 2-element vector:

```
PRINT, ROUND([5.1, 5.9])
```

IDL prints:

```
5      6
```

Print the result of rounding 3000000000.1, a value that is too large to represent in a 32-bit integer:

```
PRINT, ROUND(3000000000.1D, /L64)
```

IDL prints:

```
3000000000
```

# ROUTINE\_INFO

The ROUTINE\_INFO function provides information about currently-compiled procedures and functions.

## Syntax

```
Result = ROUTINE_INFO( [Routine] [, /PARAMETERS] [, /SOURCE ]  
[, /UNRESOLVED] [, /VARIABLES] [, /SYSTEM] [, /DISABLED]  
[, /ENABLED] [, /FUNCTIONS] )
```

## Return Value

Returns a string array consisting of the names of defined procedures or functions, or of parameters or variables used by a single procedure or function.

## Arguments

### Routine

A scalar string containing the name of routine for which information will be returned. *Routine* can be either a procedure or a function. If *Routine* is not supplied, ROUTINE\_INFO returns a list of all currently-compiled procedures.

## Keywords

### DISABLED

Set this keyword to get the names of currently disabled system procedures or functions (in conjunction with the FUNCTIONS keyword). Use of DISABLED implies use of the SYSTEM keyword, since user routines cannot be disabled.

### ENABLED

Set this keyword to get the names of currently enabled system procedures or functions (in conjunction with the FUNCTIONS keyword). Use of ENABLED implies use of the SYSTEM keyword, since user routines cannot be disabled.

### FUNCTIONS

Set this keyword to return a string array containing currently-compiled functions. By default, ROUTINE\_INFO returns a list of compiled procedures. If the SYSTEM

keyword is also set, `ROUTINE_INFO` returns a list of all IDL built-in internal functions.

## PARAMETERS

Set this keyword to return an anonymous structure with the following fields:

- **NUM\_ARGS** — An integer containing the number of positional parameters used in *Routine*.
- **NUM\_KW\_ARGS** — An integer containing the number of keyword parameters used in *Routine*.
- **ARGS** — A string array containing the names of the positional parameters used in *Routine*.
- **KW\_ARGS** — A string array containing the names of the keyword parameters used in *Routine*.

You must supply the *Routine* argument when using this keyword. If *Routine* is a function, you must specify the `FUNCTIONS` keyword as well. Note that specifying the `SYSTEM` keyword along with this keyword will generate an error.

If *Routine* does not take any arguments, the `ARGS` field is not included in the anonymous structure. Similarly, if *Routine* does not take any keywords, the `KW_ARGS` field is not included.

## SOURCE

Set this keyword to return an array of anonymous structures with the following fields:

- **NAME** — A string containing the name of the procedure or function.
- **PATH** — A string containing the full path specification of the file that contains the definition of the procedure or function.

If *Routine* is specified, information for the specified procedure is returned. If *Routine* is not specified, information for all compiled procedures is returned. If the `FUNCTIONS` keyword is also set, `ROUTINE_INFO` returns information for the specified function or for all compiled functions.

If a routine is unresolved or its path information is unavailable, the `PATH` field will contain a null string. If a routine has been `SAVED` and then `RESTORED`, the `PATH` field will contain the path to the `SAVE` file.

---

### Note

Specifying the `SYSTEM` keyword along with this keyword will generate an error.

---

## SYSTEM

Set this keyword to return a string array listing all IDL built-in internal procedures. Built-in internal procedures are part of the IDL executable, and are *not* written in the IDL language. If the FUNCTIONS keyword is also set, ROUTINE\_INFO returns a list of all IDL built-in internal functions.

## UNRESOLVED

Set this keyword to return a string array listing procedures that are referenced in any currently-compiled procedure or function, but which are themselves not yet compiled. If the FUNCTIONS keyword is also set, ROUTINE\_INFO returns a list of functions that are referenced but not yet compiled.

Note that specifying the SYSTEM keyword along with this keyword will generate an error.

## VARIABLES

Set this keyword to return a string array listing variables defined in the procedure. If the FUNCTIONS keyword is also set, ROUTINE\_INFO returns a string array listing variables defined in the function.

You must supply the *Routine* argument when using this keyword. Note that specifying the SYSTEM keyword along with this keyword will generate an error.

# RS\_TEST

The RS\_TEST function tests the hypothesis that two sample populations  $X$  and  $Y$  have the same mean of distribution against the hypothesis that they differ.  $X$  and  $Y$  may be of different lengths. This type of test is often referred to as the “Wilcoxon Rank-Sum Test” or the “Mann-Whitney U-Test.”

The Mann-Whitney statistics for  $X$  and  $Y$  are defined as follows:

$$U_x = N_x N_y + \frac{N_x(N_x + 1)}{2} - W_x$$

$$U_y = N_x N_y + \frac{N_y(N_y + 1)}{2} - W_y$$

where  $N_x$  and  $N_y$  are the number of elements in  $X$  and  $Y$ , respectively, and  $W_x$  and  $W_y$  are the rank sums for  $X$  and  $Y$ , respectively. The test statistic  $Z$ , which closely follows a normal distribution for sample sizes exceeding 10 elements, is defined as follows:

$$Z = \frac{U_x - (N_x N_y)/2}{\sqrt{(N_x N_y (N_x + N_y + 1))/12}}$$

This routine is written in the IDL language. Its source code can be found in the file `rs_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = RS\_TEST(  $X$ ,  $Y$  [, **UX**=variable] [, **UY**=variable] )

## Return Value

The result is a two-element vector containing the nearly-normal test statistic  $Z$  and the one-tailed probability of obtaining a value of  $Z$  or greater.

## Arguments

### **X**

An  $n$ -element integer, single-, or double-precision floating-point vector.

## Y

An  $m$ -element integer, single-, or double-precision floating-point vector.

## Keywords

### UX

Set this keyword to a named variable that will contain the Mann-Whitney statistic for  $X$ .

### UY

Set this keyword to a named variable that will contain the Mann-Whitney statistic for  $Y$ .

## Examples

```
; Define two sample populations:
X = [-14, 3, 1, -16, -21, 7, -7, -13, -22, -17, -14, -8, $
      7, -18, -13, -9, -22, -25, -24, -18, -13, -13, -18, -5]
Y = [-18, -9, -16, -14, -3, -9, -16, 10, -11, -3, -13, $
      -21, -2, -11, -16, -12, -13, -6, -9, -7, -11, -9]

; Test the hypothesis that two sample populations, {xi, yi}, have
; the same mean of distribution against the hypothesis in that they
; differ at the 0.05 significance level:
PRINT, RS_TEST(X, Y, UX = ux, UY = uy)

; Print the Mann-Whitney statistics:
PRINT, 'Mann-Whitney Statistics: Ux = ', ux, ', Uy = ', uy
```

IDL prints:

```
[1.45134, 0.0733429]
Mann-Whitney Statistics: Ux = 330.000, Uy = 198.000
```

The computed probability (0.0733429) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that  $X$  and  $Y$  have the same mean of distribution.

# S\_TEST

The `S_TEST` function tests the hypothesis that two sample populations  $X$  and  $Y$  have the same mean of distribution against the hypothesis that they differ.

This routine is written in the IDL language. Its source code can be found in the file `s_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = `S_TEST`(  $X$ ,  $Y$  [, `ZDIFF`=*variable*] )

## Return Value

The result is a two-element vector containing the maximum number of signed differences between corresponding pairs of  $x_i$  and  $y_i$  and its one-tailed significance. This type of test is often referred to as the “Sign Test.”

## Arguments

### $X$

An  $n$ -element integer, single-, or double-precision floating-point vector.

### $Y$

An  $n$ -element integer, single-, or double-precision floating-point vector.

## Keywords

### `ZDIFF`

Set this keyword to a named variable that will contain the number of differences between corresponding pairs of  $x_i$  and  $y_i$  resulting in zero. Paired data resulting in a difference of zero are excluded from the ranking and the sample size is correspondingly reduced.

## Examples

```
; Define two n-element sample populations:  
X = [47, 56, 54, 49, 36, 48, 51, 38, 61, 49, 56, 52]  
Y = [71, 63, 45, 64, 50, 55, 42, 46, 53, 57, 75, 60]
```

```
; Test the hypothesis that the two sample populations have the same  
; mean of distribution against the hypothesis that they differ at  
; the 0.05 significance level:  
PRINT, S_TEST(X, Y, ZDIFF = zdiff)
```

IDL prints:

```
[9.00000, 0.0729981]
```

The computed probability (0.0729981) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that  $X$  and  $Y$  have the same mean of distribution.

# SAVE

The SAVE procedure saves variables, system variables, and IDL routines in a SAVE file using the XDR (eXternal Data Representation) format for later recovery by RESTORE. Note that variables and routines cannot be saved in the same file. Note also that SAVE files containing routines may not be compatible between different versions of IDL, but that files containing data are always backwards-compatible.

---

**Note**

While IDL routines or data can be saved in a file with any extension, it is common to use the extension `.sav` for SAVE files. Using the `.sav` extension has two benefits: it makes it clear to another IDL user that the file contains IDL routines or data that can be restored, and it allows IDL to locate routines with the same base name as the file in SAVE files located in IDL's path.

---

## Syntax

```
SAVE [, Var1, ..., Varn] [, /ALL] [, /COMM, /VARIABLES] [, /COMPRESS]  
    [, DESCRIPTION=string] [, /EMBEDDED] [, FILENAME=string]  
    [, /ROUTINES] [, /SYSTEM_VARIABLES] [, /VERBOSE]
```

## Arguments

### *Var*<sub>*n*</sub>

The names of one or more variables that are to be saved. If the ROUTINES keyword is present, the *Var* arguments should be strings containing the names of the routines to be saved. If no *Var* arguments are provided, the items specified by the supplied keywords are saved.

## Keywords

### ALL

Set this keyword to save all common blocks, system variables, and local variables from the current IDL session.

---

**Note**

Routines and variables cannot be saved in the same file. Setting the ALL keyword does not save routines.

---

## COMM

Set this keyword to save all main level common block definitions. Note that setting this keyword does not cause the contents of the common block to be saved unless the `VARIABLES` keyword is also set.

## COMPRESS

If `COMPRESS` is set, IDL writes all data to the `SAVE` file using the `ZLIB` compression library to reduce its size. IDL's `SAVE` file compression support is based on the freely available `ZLIB` library by Mark Adler and Jean-loup Gailly.

Compressed `SAVE` files can be restored by the `RESTORE` procedure in exactly the same manner as any other `SAVE` file. The only visible differences are that the files will be smaller, and writing and reading them will be somewhat slower under typical conditions.

## DESCRIPTION

Set this keyword equal to a string that will be saved in the `SAVE` file:

```
SAVE, data, $
    DESCRIPTION="Solar Obs: 2452884.9, 40 deg 0' N 105 deg 16' W"
```

This string can be later recovered using the [RESTORE](#) procedure or the [IDL\\_Savefile](#) object class. The ability to associate a descriptive string to a `SAVE` file can be used by IDL programs to identify data, and can also be used as an aid in managing large collections of data.

## EMBEDDED

Set this keyword to request that the generated `SAVE` file contain an embedded license. The `SAVE` procedure will add an embedded license to the `SAVE` file if the IDL session has access to a Developer's Kit license. Use of this keyword is equivalent to selecting the **Licensed Save File (.sav)** option in the **Project Options** dialog. (See "[Setting the Options for a Project](#)" in Chapter 22 of the *Building IDL Applications* manual for details.)

### Note

---

Use this keyword with the `ROUTINES` keyword.

---

## FILENAME

A string containing the name of the file into which the IDL objects should be saved. While there are no arbitrary limitations on the name of a file created with the `SAVE`

procedure, RSI recommends that you use the `.sav` extension for your files. If this keyword is not specified, the file `idlsave.dat` is used.

## ROUTINES

Set this keyword to save user defined procedures and functions in a machine independent, binary form. If parameters are present, they must be strings containing the names of the procedures and/or functions to be saved. If no parameters are present, all compiled routines are saved. Routines and variables cannot be saved in the same file.

### Warning

---

`.sav` files containing routines are not guaranteed to be compatible between successive versions of IDL. You will not be able to `RESTORE` `.sav` files containing routines if they are made with incompatible versions of IDL. In this case, you should recompile your original code with the newer version of IDL. A `.sav` file containing data will always be restorable.

---

## SYSTEM\_VARIABLES

Set this keyword to save the current state of all system variables.

### Warning

---

Saving system variables is not recommended, as the structure may change between versions of IDL.

---

## VARIABLES

Set this keyword to save all variables in the current program unit. This option is the default.

## VERBOSE

Set this keyword to print an informative message for each saved object.

## Examples

Save the status of all currently-defined variables in the file `variables1.sav` by entering:

```
SAVE, /VARIABLES, FILENAME = 'variables1.sav'
```

The variables can be restored with the `RESTORE` procedure.

Save the user procedures MYPROC and MYFUN:

```
SAVE, /ROUTINES, 'MYPROC', 'MYFUN', FILENAME = 'myroutines.sav'
```

## Version History

Original	Introduced
6.1	Added DESCRIPTION keyword
6.2	Added EMBEDDED keyword

[IDL\\_Savefile](#)

# SAVGOL

The SAVGOL function returns the coefficients of a Savitzky-Golay smoothing filter, which can then be applied using the CONVOL function. The Savitzky-Golay smoothing filter, also known as least squares or DISPO (digital smoothing polynomial), can be used to smooth a noisy signal.

The filter is defined as a weighted moving average with weighting given as a polynomial of a certain degree. The returned coefficients, when applied to a signal, perform a polynomial least-squares fit within the filter window. This polynomial is designed to preserve higher moments within the data and reduce the bias introduced by the filter. The filter can use any number of points for this weighted average.

This filter works especially well when the typical peaks of the signal are narrow. The heights and widths of the curves are generally preserved.

---

**Tip**

You can use this function in conjunction with the CONVOL function for smoothing and optionally for numeric differentiation.

---

This routine is written in the IDL language. Its source code can be found in the file `savgol.pro` in the `lib` subdirectory of the IDL distribution.

SAVGOL is based on the Savitzky-Golay Smoothing Filters described in section 14.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

$$Result = SAVGOL( Nleft, Nright, Order, Degree [, /DOUBLE] )$$

## Return Value

This function returns an array of floating-point numbers that are the coefficients of the smoothing filter.

## Arguments

### Nleft

An integer specifying the number of data points to the left of each point to include in the filter.

## Nright

An integer specifying the number of data points to the right of each point to include in the filter.

---

**Note**

Larger values of *Nleft* and *Nright* produce a smoother result at the expense of flattening sharp peaks.

---

## Order

An integer specifying the order of the derivative desired. For smoothing, use order 0. To find the smoothed first derivative of the signal, use order 1, for the second derivative, use order 2, etc.

---

**Note**

*Order* must be less than or equal to the value specified for *Degree*.

---

---

**Note**

For  $ORDER > 0$ , SAVGOL returns unnormalized coefficients. To use the SAVGOL coefficients with CONVOL, you should multiply the returned coefficients by  $FACTORIAL(ORDER)/(dx^{ORDER})$ , where  $dx$  is the sampling interval between data points. See the example below.

---

## Degree

An integer specifying the degree of smoothing polynomial. Typical values are 2 to 4. Lower values for *Degree* will produce smoother results but may introduce bias, higher values for *Degree* will reduce the filter bias, but may “over fit” the data and give a noisier result.

---

**Note**

*Degree* must be less than the filter width ( $Nleft + Nright + 1$ ).

---

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

**Tip**

The DOUBLE keyword is recommended for *Degree* greater than 9.

## Examples

The following example creates a noisy 400-point vector with 4 Gaussian peaks of decreasing width. It then plots the original vector, the vector smoothed with a 33-point Boxcar smoother (the SMOOTH function), and the vector smoothed with 33-point wide Savitzky-Golay filter of degree 4. The bottom plot shows the second derivative of the signal (without noise) and the second derivative of the noisy data using the Savitzky-Golay filter of degree 4:

```

PRO Savgol_example

n = 401 ; number of points
np = 4  ; number of peaks

; Form the baseline:
y = REPLICATE(0.5, n)

; Sampling interval:
dt = 0.1

; Index the array:
x = dt*FINDGEN(n)

; Add each Gaussian peak:
FOR i=0, np-1 DO BEGIN
  c = dt*(i + 0.5) * FLOAT(n)/np; Center of peak
  peak = 3 * (x-c) / (dt*(75. / 1.5 ^ i))
  ; Add Gaussian. Cutoff of -50 avoids underflow errors for
  ; tiny exponentials:
  y = y + EXP((-peak^2)>(-50))
ENDFOR

; Add noise:
y1 = y + 0.10 * RANDOMN(-121147, n)

; Display first plot
iPlot, x, y1, NAME='Signal+Noise', VIEW_GRID=[1,2]

; Get an object reference to the iTool and insert legend.

# SCALE3

The SCALE3 procedure sets up transformation and scaling parameters for basic 3-D viewing. This procedure is similar to SURFR and SCALE3D, except that the data ranges must be specified and the scaling does not vary with rotation. Results are stored in the system variables !P.T, !X.S, !Y.S, and !Z.S.

This routine is written in the IDL language. Its source code can be found in the file `scale3.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SCALE3 [, XRANGE=vector] [, YRANGE=vector] [, ZRANGE=vector]  
      [, AX=degrees] [, AZ=degrees]
```

## Arguments

None.

## Keywords

### XRANGE

A two-element vector containing the minimum and maximum X values. If omitted, the X-axis scaling remains unchanged.

### YRANGE

A two-element vector containing the minimum and maximum Y values. If omitted, the Y-axis scaling remains unchanged.

### ZRANGE

A two-element vector containing the minimum and maximum Z values. If omitted, the Z-axis scaling remains unchanged.

### AX

Angle of rotation about the X axis. The default is 30 degrees.

### AZ

Angle of rotation about the Z axis. The default is 30 degrees.

## Examples

Set up a 3-D transformation where the data range is 0 to 20 for each of the 3 axes and the viewing area is rotated 20 degrees about the X axis and 55 degrees about the Z axis:

```
SCALE3, XRANGE=[0, 20], YRANGE=[0, 20], ZRANGE=[0, 20], AX=20,
      AZ=55
```

### SCALE3 and More Complicated Transformations

The figure below illustrates the application of three-dimensional transforms to the output of `CONTOUR` and `PLOT`. Using the two-dimensional Gaussian array `z` defined in “[Surface of a Gaussian Function](#)” on page 2260, it draws a three-dimensional contour plot with the contours stacked above the axes in the `z` direction. It then plots the sum of the columns, also a Gaussian, in the `xz`-plane, and the sum of the rows in the `yz` plane.

Figure 3-104: `PLOT` and `CONTOUR` with a Three-dimensional Transform

It was constructed as follows:

- First, the `SCALE3` procedure is called to establish the default three- to two-dimensional transformation used by `SURFACE`, as explained in “[Transformation Created by SURFACE](#)” on page 2263. The default rotations are 30 degrees about both the `x`- and `z`-axes.

- Next, a vector, POS, defining the cube containing the plot window is defined in normalized coordinates. The cube extends from 0.1 to 1.0 in the  $x$  and  $y$  directions and from 0 to 1 in the  $z$  direction. Each call to CONTOUR and PLOT must explicitly specify this window to align the plots. This is necessary because the default margins around the plot window are different in each direction.
- CONTOUR is called to draw the stacked contours with the axes at  $z = 0$ . Clipping is disabled to allow drawing outside the default plot window, which is only two-dimensional.
- The procedure T3D is called to exchange the  $y$ - and  $z$ -axes. The original  $xyz$  coordinate system is now  $xzy$ .
- PLOT is called to draw the column sums which appear in front of the contour plot. The expression  $Z\#REPLICATE(1., N_y)$  creates a row vector containing the sum of each row in the two-dimensional array  $z$ . The NOERASE and NOCLIP keywords are specified to prevent erasure and clipping. This plot appears in the  $xz$ -plane because of the previous axis exchange.
- T3D is called again to exchange the  $x$ - and  $z$ -axes. This makes the original  $xyz$  coordinate system, which was converted to  $xzy$ , now correspond to  $yzx$ .
- PLOT is called to produce the column sums in the  $yz$ -plane in the same manner as the first plot. The original  $x$ -axis is drawn in the  $y$ -plane, and the  $y$ -axis is in the  $z$ -plane. One unavoidable side effect of this method is that the annotation of this plot is backwards. If the plot is transformed so the letters read correctly, the  $x$ -axis of the plot would be reversed in relation to the  $y$ -axis of the contour plot.

The IDL code used to draw the figure is as follows:

```

; Create the Z variable:
Z = SHIFT(DIST(40), 20, 20)
Z = EXP(-(Z/10)^2)
; NX and NY are the X and Y dimensions of the Z array:
NX = (SIZE(Z))(1)
NY = (SIZE(Z))(2)
; Set up !P.T with default SURFACE transformation.
SCALE3
; Define the three-dimensional plot
; window: x = 0.1 to 1, Y=0.1 to 1, and z = 0 to 1.
POS=[.1, .1, 1, 1, 0, 1]
; Make the stacked contours. Use 10 contour levels.

PLOT, Z#REPLICATE(1., NY), /NOERASE, /NOCLIP, /T3D, $
    TITLE='COLUMN SUMS', POSITION = POS, CHARSIZE = 2
; Swap x and z—original xyz is now yzx:
T3D, /XZEXCH
; Plot the row sums along the right side of the contour plot:
PLOT, REPLICATE(1., NX)#Z, /NOERASE, /T3D, /NOCLIP, $
    TITLE = 'ROW SUMS', POSITION = POS, CHARSIZE = 2

```

### Example Code

---

If you prefer not to enter the IDL code by hand, run the batch file `cntour06` with the following command at the IDL prompt:

```
@cntour06
```

---

See [“Running the Example Code”](#) on page 40 if IDL does not find the batch file.

# SCALE3D

The SCALE3D procedure scales the 3-D unit cube (a cube with the length of each side equal to 1) into the viewing area. Eight data points are created at the vertices of the 3-D unit cube. The vertices are then transformed by the value of the system variable !P.T. The system is translated to bring the minimum ( $x,y,z$ ) point to the origin, and then scaled to make each coordinate's maximum value equal to 1. The !P.T system variable is modified as a result.

This routine is written in the IDL language. Its source code can be found in the file `scale3D.pro` in the `lib` subdirectory of the IDL distribution.

[HELP](#), [SCOPE\\_VARFETCH](#), [SCOPE\\_TRACEBACK](#), [SCOPE\\_VARNAME](#), [ROUTINE\\_INFO](#)

# SCOPE\_TRACEBACK

The `SCOPE_TRACEBACK` function is used to obtain an array containing the current interpreter call stack, which is a list describing the sequence of routine calls that have brought IDL execution to the current point. Each element of the array describes the routine as well as the source file and line number at which it was running at a given interpreter level. See “[Interpreter Frames, Level, and Variable Scope](#)” on page 2029 for more information.

In general, you should strive to write routines that execute properly no matter how they are called or by which routines. As such, your programs should rarely require call-stack information. Code that looks at what routine called it and alters its behavior accordingly can quickly become difficult to understand and maintain, and is generally considered to represent poor programming style. For this reason, RSI recommends against the use of the `SCOPE` functions.

## Syntax

```
Result = SCOPE_TRACEBACK( [ /STRUCTURE ] [ , /SYSTEM ] )
```

## Return Value

Returns an array containing the current interpreter call stack. Each element of this result corresponds to one routine. Element 0 of the result contains information about the outer main program (`$MAIN$`), and each subsequent element contains information about the following routine. The final element of the result describes the currently executing caller of `SCOPE_TRACEBACK`.

If the `STRUCTURE` keyword is set, the array contains one `IDL_TRACEBACK` structure per stack frame containing detailed information about that invocation. Otherwise, a string array is returned, each element of which contains the name of the program module, source file name, and line number.

## Keywords

### STRUCTURE

Set this keyword to return an array of IDL\_TRACEBACK structures containing detailed information about the call stack. Each IDL\_TRACEBACK structure contains the following fields:

Field	Description
ROUTINE	Name of the routine.
FILENAME	If the routine was compiled from an IDL program file, FILENAME gives the name of the file. If it was restored from an IDL SAVE file, it gives the name of the SAVE file. FILENAME is a null string if the routine is a built-in system routine.
LINE	If the routine was compiled from an IDL program file, LINE contains the current line number within the file given by FILENAME. It is 0 if the routine is from an IDL SAVE file or is a built-in system routine.
LEVEL	For user-level IDL language routines, the interpreter level of this frame of execution. See the documentation of the <a href="#">SCOPE_LEVEL</a> function for more information on interpreter level. Interpreter levels only apply to routines written in the IDL language and are 0 (zero) or greater. This field is set to -1 for system routines.
FUNCTION	This field is 1 if the routine is a function and 0 (zero) if it is a procedure.
METHOD	This field is 1 if the routine is an object method and 0 (zero) if it is a regular routine.
RESTORED	This field is 1 if the routine was restored from an IDL SAVE file and 0 (zero) otherwise.
SYSTEM	This field is 1 if the routine is a built-in system routine and 0 (zero) if it is a user-level routine written in the IDL language.

Table 3-112: IDL\_TRACEBACK Structure Fields

## SYSTEM

By default, `SCOPE_TRACEBACK` shows the call stack of IDL routines. Set the `SYSTEM` keyword to have the function also include any IDL system routines that are currently active within the call chain. Such system routines are present whenever an IDL system routine makes a nested call to the IDL interpreter to run a routine written in the IDL language. For example, `WIDGET_CONTROL`, `WIDGET_EVENT`, and any call to an IDL object method all involve such interpreter callbacks.

[HELP](#), [SAVE](#), [SCOPE\\_LEVEL](#), [SCOPE\\_VARFETCH](#), [SCOPE\\_VARNAME](#)

# SCOPE\_VARFETCH

The `SCOPE_VARFETCH` function returns variables outside the local scope of the currently running procedure or function. You can use it to examine or alter variables that are not otherwise visible, or to create new variables in other scopes.

In normal IDL operation, routines are not allowed to see variables outside their own scope. This restriction is a fundamental and important property of structured modular programming. Code that accesses non-local scope to alter variables within other active routines can quickly become extremely difficult to understand and maintain. For this reason, RSI recommends against the use of the IDL scope routines.

Despite this warning, there is an important class of application that requires the functionality provided by these routines. Programs, usually with graphical user interfaces, that import and export data from the callers' scope need to be able to access the user's data variables directly, and without requiring them to explicitly pass those variables to the application as parameters. The `SCOPE_VARFETCH` function is used to access those variables, and `SCOPE_VARNAME` is used to obtain the correct names with which to refer to them. `SCOPE_LEVEL` returns the scope level of the currently executing routine. The IDL iTools and the ENVI image processing software are examples of programs that need to be able to perform these operations.

---

**Note**

To use this routine successfully, you need to understand the information in [“Altering Accessed Variables and Avoiding Unwanted Copies”](#) on page 2032.

---

## Interpreter Frames, Level, and Variable Scope

When IDL starts, it is implicitly running within a main program named `$MAIN$`. You can call procedures or functions from `$MAIN$`, and those routines can in turn call other routines. Each such routine invocation is represented internally by IDL using an *interpreter frame*, which IDL uses to maintain access to all variables known to that invocation of that routine. These variables can be local to the routine, parameters passed into the routine by its caller, or global variables (such as common block variables or heap variables). The set of variables visible within a given interpreter frame forms the *variable scope* of the corresponding routine. As routines are called, IDL pushes interpreter frames onto a call stack, and as those routines return, their frames are removed from the call stack. In the case of a recursive routine (a routine that calls itself), each invocation of the routine is given its own distinct and unshared frame.

The frames on the interpreter stack are numbered starting at 1 and increasing by 1 for each routine. This number is the *level* of the frame and, by implication, the scope that the frame accesses. The call stack always contains the frame for \$MAIN\$, which is the routine in which IDL execution starts and the only routine in IDL from which you cannot return. \$MAIN\$ is therefore always level 1. Any routine called from \$MAIN\$ will be at level 2, routines called from there will be level 3, and so forth.

## Syntax

```
Result = SCOPE_VARFETCH(VarName [, COMMON=string] [, /ENTER]
    [, LEVEL=value] [, /REF_EXTRA])
```

## Return Value

Returns the variable specified by *VarName* relative to the scope specified by the **LEVEL** keyword. The value returned by `SCOPE_VARFETCH` can be used by the caller to directly access, or alter, that variable.

## Arguments

### VarName

If the **COMMON** keyword is not set: *VarName* is the name of the variable to be returned from scope specified by the **LEVEL** keyword.

If the **COMMON** keyword is set: If *VarName* is of non-string type, it is the positional index of the variable to be returned within the specified common block. If *VarName* is a string, it is the name of the variable to be returned within the common block. In this case, the name corresponds to the name used for that common block variable in the first routine that defined the common block.

### Note

---

For more information, see “**COMMON Variable Names**” on page 2039.

---

## Keywords

### COMMON

Set this keyword to a string containing the name of a common block to cause `SCOPE_VARFETCH` to return a variable contained within the specified block. The variable to return is determined by the value of *VarName*, as discussed above.

The **COMMON** keyword cannot be used in conjunction with **ENTER**, **LEVEL**, or **REF\_EXTRA**.

## ENTER

By default, **SCOPE\_VARFETCH** will return only variables that already exist in the specified scope. Attempts to access a nonexistent variable will cause IDL to issue an error and halt execution of the program. Set this keyword to alter this behavior. If **ENTER** is set and the desired variable does not exist in the specified scope, **SCOPE\_VARFETCH** will create a new variable within that scope and return the new variable. This keyword can be used to export data into other scopes. Generally, the scope of the calling routine and that of **\$MAIN\$** are most likely to be useful destinations.

The **ENTER** keyword cannot be used in conjunction with either **COMMON** or **REF\_EXTRA**.

## LEVEL

Set this keyword to an integer that specifies the scope within which the desired variable should be found. The level can be either an absolute value or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine. This is the default value.
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, <b>SCOPE_VARFETCH</b> clips the value not to go past <b>\$MAIN\$</b> .
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is <b>\$MAIN\$</b> , level 2 is the routine called from <b>\$MAIN\$</b> , and so forth. If you specify a level that is past the currently executing routine, <b>SCOPE_VARFETCH</b> clips the value to the level of the current routine.

*Table 3-113: LEVEL Values*

The **LEVEL** keyword cannot be used in conjunction with the **COMMON** keyword.

## REF\_EXTRA

Set this keyword to cause `SCOPE_VARFETCH` to return the variable with the keyword name given by *VarName* from the `_REF_EXTRA` keywords within the specified level. Normally, a routine is not able to access the `_REF_EXTRA` keywords passed to it, and can pass them on only to other routines it calls. However, the `SCOPE_VARFETCH REF_EXTRA` keyword provides a mechanism by which a routine can examine its own `_REF_EXTRA` keywords.

### Note

See “[Keyword Inheritance](#)” in Chapter 5 of the *Building IDL Applications* manual for more information.

The `REF_EXTRA` keyword cannot be used in conjunction with either `COMMON` or `ENTER`.

## Altering Accessed Variables and Avoiding Unwanted Copies

The variable returned by `SCOPE_VARFETCH` can be used directly in IDL expressions to access the value of a variable from another scope. For example, the following statements access the value of a variable named `mydata` within the scope of the main program, `$MAIN$`:

```
PRINT, SCOPE_VARFETCH('mydata', LEVEL=1)
local_data = SCOPE_VARFETCH('mydata', LEVEL=1) + 100
```

Note that `local_data` contains only a copy of `mydata`, not a reference, so you can change `local_data` without affecting `mydata`.

If you do want to alter the value of a variable such as `mydata`, you must surround the call to `SCOPE_VARFETCH` with parentheses. For example, the following statements set `mydata` to a `FINDGEN` vector, and then increment it and add a constant to it. Finally, the value of the 5th element of the array is changed to 1000:

```
(SCOPE_VARFETCH('mydata', LEVEL=1)) = FINDGEN(100)
(SCOPE_VARFETCH('mydata', LEVEL=1))++
(SCOPE_VARFETCH('mydata', LEVEL=1)) += 57
(SCOPE_VARFETCH('mydata', LEVEL=1))[4] = 1000
```

To prevent IDL from making unwanted copies of the variable returned from `SCOPE_VARFETCH`, you should operate on the result of the `SCOPE_VARFETCH` function directly and not assign it to other variables. For example, consider the following code, which prints the value of a variable `mydata` from the main program, `$MAIN$`:

```
temp = SCOPE_VARFETCH('mydata', LEVEL=1)
PRINT, temp
```

This code will produce the desired result, but at a higher than necessary cost. Assigning the variable returned by `SCOPE_VARFETCH` to the variable `temp` causes IDL to allocate new memory for `temp` and to make a copy of the `mydata` variable from `$MAIN$` into `temp`. This process is slower, and will use twice as much memory as necessary, which can be a significant problem if the original `mydata` variable is very large. Instead, you should write the code this way:

```
PRINT, SCOPE_VARFETCH('mydata', LEVEL=1)
```

In cases where your code simply needs the value of a variable from another scope, assigning the result of `SCOPE_VARFETCH` to a local variable will use more memory and time, but is otherwise equivalent to using the direct result of the function. However, if your code wants to alter the original variable, using a local variable will produce the wrong answer. Consider the assignment code from above, modified to use a local variable:

```
temp = SCOPE_VARFETCH('mydata', LEVEL=1)
temp = FINDGEN(100)
temp++
temp += 57
temp[4] = 1000
```

This code alters the value of the local variable `temp`, but the original variable `mydata` remains unaltered. The first line makes a copy of `mydata`, the second line discards that copy, and the remaining lines operate on the local variable.

`SCOPE_VARFETCH` allows transparent access to variables from other scopes as long as you call it in every place where the variable is needed. Any assignment of the result from `SCOPE_VARFETCH` to another variable will create a copy. Altering the value of this copy will not alter the original.

## Examples

### Example 1: Creating a New Variable in the Main Level

The following creates a variable in the main program scope, named `newdata`. It sets the value using the `DIST` function, and then uses `SURFACE` to display it:

```
(SCOPE_VARFETCH('newdata', /ENTER, LEVEL=1)) = DIST(128)
SURFACE, SCOPE_VARFETCH('newdata', LEVEL=1)
```

## Example 2: Using the REF\_EXTRA Keyword

The following procedure will print the values of all keywords passed to it via the by-reference `_REF_EXTRA` keyword inheritance mechanism. In addition, it displays the name or names by which that variable is known in all currently active interpreter frames:

```

PRO example, _REF_EXTRA=ref
  FOR ridx = 0, N_ELEMENTS(ref)-1 DO BEGIN
    kw = ref[ridx]
    PRINT, 'Value of _REF_EXTRA keyword ', kw, ':'
    HELP, SCOPE_VARFETCH( kw, /REF_EXTRA )

    calls = SCOPE_TRACEBACK()
    FOR i=N_ELEMENTS(calls)-1, 0, -1 DO BEGIN
      name = SCOPE_VARNAME( SCOPE_VARFETCH(kw, /REF_EXTRA), $
        LEVEL=-i )
      cname = STREGEX( calls[i], '[^]*', /EXTRACT )
      PRINT, FORMAT='(%" _REF_EXTRA %s name in level %s: %s"', $
        kw, cname, name ? name : ''
    ENDFOR
  ENDFOR
END

```

Using this procedure, consider the output from the following IDL statements:

```

IDL> a = 1
IDL> b = 2
IDL> example, k_a=a, k_b=b
Value of _REF_EXTRA keyword K_A:
<No name>      INT      =      1
_REF_EXTRA K_A name in level EXAMPLE:
_REF_EXTRA K_A name in level $MAIN$: A
Value of _REF_EXTRA keyword K_B:
<No name>      INT      =      2
_REF_EXTRA K_B name in level EXAMPLE:
_REF_EXTRA K_B name in level $MAIN$: B

```

[ROUTINE\\_INFO](#)

# SCOPE\_VARNAME

The `SCOPE_VARNAME` function returns the names of variables outside the local scope of the currently running procedure or function. Given a variable within the local scope of the currently running routine, `SCOPE_VARNAME` can supply the name under which it is known in an earlier routine in the current chain of active routines. Similarly, given the positional index of a common block variable, `SCOPE_VARNAME` can report the name that the variable was given in the routine that first defined that common block within the current IDL session.

In normal IDL operation, routines are not allowed to see variables outside their own scope. This restriction is a fundamental and important property of structured modular programming. Code that accesses non-local scope to alter variables within other active routines can quickly become extremely difficult to understand and maintain. For this reason, RSI recommends against the use of the IDL scope routines.

Despite this warning, there is an important class of application that requires the functionality provided by these routines. Programs, usually with graphical user interfaces, that import and export data from the callers' scope need to be able to access the user's data variables directly, and without requiring them to explicitly pass those variables to the application as parameters. The `SCOPE_VARFETCH` function is used to access those variables, and `SCOPE_VARNAME` is used to obtain the correct names with which to refer to them. `SCOPE_LEVEL` returns the scope level of the currently executing routine. The IDL iTools and the ENVI image processing software are examples of programs that need to be able to perform these operations.

---

## Note

For more information, see [“Interpreter Frames, Level, and Variable Scope”](#) on page 2029.

---

## Syntax

```
Result = SCOPE_VARNAME( [Var1[, ..., Varn]] [, COMMON=string]
                        [, COUNT=variable] [, LEVEL=value] )
```

## Return Value

The value returned by `SCOPE_VARNAME` depends on whether or not the `COMMON` keyword is set, and whether or not plain arguments are provided in the call. In all cases, the result is of a scalar string or a string array of variable names.

## COMMON Keyword Not Set

### Arguments Present

The result is a string array, with each element giving the name of the corresponding argument variable within the scope of the routine specified by the [LEVEL](#) keyword. If an argument does not exist within the target scope, a scalar null string is returned.

### Arguments Not Present

The result is a string array containing the names of all known variables within the scope of the routine specified by the [LEVEL](#) keyword. If the specified scope has no variables, a scalar null string is returned.

See the description of the [LEVEL](#) keyword for additional information.

## COMMON Keyword Set

### Arguments Present

Each argument supplies the positional index of a variable within the common block. The result is a string array, with each element giving the name of the corresponding variable with that index within that common block.

### Arguments Not Present

The result is a string array containing the names of all known variables defined within a specified common block, given in the order in which they exist in the block.

## Arguments

### Var<sub>i</sub>

If the [COMMON](#) keyword is not set, the arguments to `SCOPE_VARNAME` are variables for which names are to be returned relative to the scope specified by the [LEVEL](#) keyword.

If the [COMMON](#) keyword is set, the arguments to `SCOPE_VARNAME` are integers, giving the positional index of variables within the specified common block for which names are to be returned.

## Keywords

### COMMON

Set this keyword to a string containing the name of a common block to cause `SCOPE_VARNAME` to return the names of variables contained within the specified block. If `COMMON` is set, the arguments to `SCOPE_VARNAME` are integers that give the positional index of variables within the specified common block for which names are to be returned.

#### Note

See “[COMMON Variable Names](#)” on page 2039 for more information on the names returned.

The `COMMON` keyword cannot be used in conjunction with the [LEVEL](#) keyword.

### COUNT

Set this keyword to a named variable that will contain the number of elements returned in the array value returned by `SCOPE_VARNAME`. If `SCOPE_VARNAME` returns a null string, a 0 is returned. This circumstance will occur if there are no arguments, the [COMMON](#) keyword is not set, and the specified scope has no variables.

### LEVEL

Set this keyword to an integer that specifies the scope within which the desired variable should be found. The level can be either an absolute value or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine. This is the default value.
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, <code>SCOPE_VARNAME</code> clips the value not to go past <code>\$MAIN\$</code> .

Table 3-114: LEVEL Values

Value	Meaning
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is \$MAIN\$, level 2 is the routine called from \$MAIN\$, and so forth. If you specify a level that is past the currently executing routine, SCOPE_VARNAME clips the value to the level of the current routine.

Table 3-114: LEVEL Values (Continued)

The LEVEL keyword cannot be used in conjunction with the **COMMON** keyword.

## COMMON Variable Names

Variables in IDL common blocks do not actually have names. Rather, IDL represents common blocks internally as an array of variables, and these variables are referenced by their positional index. Hence, the first variable is at position 0, the second at position 1, and so forth. When you specify a COMMON declaration in an IDL routine, you specify names to be used for these variables *within the scope of that routine*. In fact, different routines are allowed to use entirely different names to refer to a given variable. However, this can quickly become confusing, and most programmers use the same names in every case.

The first routine in which a COMMON block is defined is remembered by IDL as part of the state of that block. When another routine defines the same common block, it is allowed to omit the variable names. In this case, IDL uses the same names used in the original defining routine.

When the COMMON keyword is specified to the SCOPE\_VARNAME function, the names returned are the names that were defined by the originally defining routine. Because good programming practice dictates that the same names be used everywhere, this result usually causes no confusion. However, in an environment where different names are in use in different scopes, you should be aware of the difference. For example, execute the following COMMON statement at the IDL prompt:

```
COMMON DOGS, poodle, spaniel, retriever
```

Now execute the following IDL routine:

```
PRO dogs
```

```
COMMON DOGS, breed1, breed2, breed3
```

```
PRINT, 'In this scope: ', SCOPE_VARNAME(breed1, breed2, breed3)
```

```

PRINT, 'In $MAIN$: ', SCOPE_VARNAME(breed1, breed2, breed3, $
    LEVEL=-1)
PRINT, 'In COMMON: ', SCOPE_VARNAME(COMMON='dogs', 0, 1, 2)
END

```

The following output is produced when procedure DOGS is called:

```

In this scope: BREED1 BREED2 BREED3
In $MAIN$: POODLE SPANIEL RETRIEVER
In COMMON: POODLE SPANIEL RETRIEVER

```

If you do not specify the COMMON keyword, SCOPE\_VARNAME translates the names of all variables, common or regular, relative to the specified scope. Hence, the variables in the DOGS common block appear as POODLE, SPANIEL, and RETRIEVER in \$MAIN\$, and as BREED1, BREED2, and BREED3 within procedure DOGS, despite the fact that they refer to the same variables. When you direct SCOPE\_VARNAME to work from the common block instead of from an interpreter frame, the function uses the names from the scope of the routine that defined the common block, which in this example is \$MAIN\$.

Following this advice can minimize confusion:

- Use the same names for common block variables in all definitions. A convenient way to do so is to take advantage of the abbreviated form of the COMMON declaration, in which second and following declarations can leave off the variable names, and IDL will substitute the names from the initial definition.
- When possible, routines that use SCOPE\_VARNAME should not specify the COMMON keyword. Instead, translate their names relative to the caller's scope.

## Example

The following procedure outputs the names of all variables currently defined in the IDL main program, \$MAIN\$. It also prints the name of its argument, in its own scope, in that of its caller, and in that of \$MAIN\$.

```

PRO test_scope_varname, arg

PRINT, 'All variables in $MAIN$: ', SCOPE_VARNAME(LEVEL=1)
PRINT, 'Argument name in local scope: ', SCOPE_VARNAME(arg)
PRINT, 'Argument name in caller scope: ', SCOPE_VARNAME(arg, $
    LEVEL=-1)
PRINT, 'Argument name in $MAIN$ scope: ', SCOPE_VARNAME(arg, $
    LEVEL=1)

END

```

[ROUTINE\\_INFO](#)

# SEARCH2D

The SEARCH2D function finds “objects” or regions of similar data values within a two-dimensional array. Given a starting location and a range of values to search for, SEARCH2D finds all the cells within the array that are within the specified range and have some path of connectivity through these cells to the starting location. In addition to searching for cells within a global range of data values, SEARCH2D can also search for adjacent cells whose values deviate from their neighbors within specified tolerances.

This routine is written in the IDL language. Its source code can be found in the file `search2d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = SEARCH2D( Array, Xpos, Ypos, Min_Val, Max_Val [, DECREASE=value,  
INCREASE=value[, LPF_BAND=integer{≥3}]] [, /DIAGONAL] )
```

## Return Value

SEARCH2D returns a longword array that contains a list of the array subscripts that define the located object or region. The original X and Y indices of the array subscripts returned by SEARCH2D can be found with the following IDL code:

```
index_y = Result / (SIZE(Array)) [1]  
index_x = Result - (index_y * (SIZE(Array)) [1])
```

where *Result* is the array returned by SEARCH2D and *Array* is the original input array. The object within *Array* can be subscripted as *Array*(*Region*) or *Array*(*index\_x*, *index\_y*).

## Arguments

### Array

A two-dimensional array, of any data type, to be searched.

### Xpos

The X coordinate (dimension 0 of *Array*) of the starting location.

### Ypos

The Y coordinate (dimension 1 of *Array*) of the starting location.

## Min\_Val

The minimum data value for which to search. All array subscripts of all cells that are connected to the starting cell, and have a value between *Min\_Val* and *Max\_Val* (inclusive) are returned.

## Max\_Val

The maximum data value for which to search.

## Keywords

### DECREASE

This keyword and the INCREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. The search is limited to pixels for which the edge-enhanced gradient value lies between the DECREASE and INCREASE values. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min\_Val* and *Max\_Val*. The default for this keyword is 0.0 if INCREASE is specified.

### INCREASE

This keyword and the DECREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. The search is limited to pixels for which the edge-enhanced gradient value lies between the DECREASE and INCREASE values. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min\_Val* and *Max\_Val*. The default for this keyword is 0.0 if DECREASE is specified.

### LPF\_BAND

Set this keyword to an integer value of 3 or greater to perform low-pass filtering on the edge-enhanced array. The value of LPF\_BAND is used as the width of the smoothing window. This keyword is only effective when the DECREASE or INCREASE keywords are also specified. The default is no smoothing.

## DIAGONAL

Set this keyword to cause SEARCH2D to find cells meeting the search criteria whose surrounding squares share a common corner. Normally, cells are considered adjacent only when squares surrounding the cells share a common edge. Setting this option requires more memory and execution time.

## Examples

Find all the indices corresponding to an object in an image:

```
; Create an image with different valued regions:
img = FLTARR(512, 512)
img[3:503, 9:488] = 0.7
img[37:455, 18:438] = 0.5
img[144:388, 90:400] = 0.7
img[200:301, 1:255] = 1.0
img[155:193, 333:387] = 0.3
TVSCL, img ;Display the image.

; Search for an object starting at (175, 300) whose data values are
; between (0.6) and (0.8):
region = SEARCH2D(img, 175, 300, 0.6, 0.8, /DIAGONAL)

; Scale the background cells into the range 0 to 127:
img = BYTSCL(img, TOP=127B)

; Highlight the object region by setting it to 255:
img[region] = 255B

; Display the array with the highlighted object in it:
TVSCL, img
```

[SEARCH3D](#)

# SEARCH3D

The SEARCH3D function finds “objects” or regions of similar data values within a 3-D array of data. Given a starting location and a range of values to search for, SEARCH3D finds all the cells within the volume that are within the specified range of values and have some path of connectivity through these cells to the starting location. In addition to searching for cells within a global range of data values, SEARCH3D can also search for adjacent cells whose values deviate from their neighbors within specified tolerances.

This routine is written in the IDL language. Its source code can be found in the file `search3d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = SEARCH3D(Array, Xpos, Ypos, Zpos, Min_Val, Max_Val [, /DECREASE
, /INCREASE [, LPF_BAND=integer{≥3}] ] [, /DIAGONAL] )
```

## Return Value

SEARCH3D returns a longword array that contains a list of the array subscripts that define the selected object or region. The original X and Y indices of the array subscripts returned by SEARCH3D can be found with the following IDL code:

```
S = SIZE(Array)
index_z = Result / (S[1] * S[2])
index_y = (Result - (index_z * S[1] * S[2])) / S[1]
index_x = (Result - (index_z * S[1] * S[2])) - (index_y * S[1])
```

where *Result* is the array returned by SEARCH3D and *Array* is the original input volume. The object within *Array* can be subscripted as `Array[Region]` or `Array[index_x, index_y, index_z]`.

## Arguments

### Array

The three-dimensional array, of any data type except string, to be searched.

### Xpos

The X coordinate (dimension 0 or *Array*) of the starting location.

## Ypos

The Y coordinate (dimension 1 of *Array*) of the starting location.

## Zpos

The Z coordinate (dimension 2 of *Array*) of the starting location.

## Min\_Val

The minimum data value for which to search. All array subscripts of all the cells that are connected to the starting cell, and have a value between *Min\_Val* and *Max\_Val* (inclusive) are returned.

## Max\_Val

The maximum data value for which to search.

## Keywords

### DECREASE

This keyword and the INCREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min\_Val* and *Max\_Val*. The default for this keyword is 0.0 if INCREASE is specified.

### INCREASE

This keyword and the DECREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min\_Val* and *Max\_Val*. The default for this keyword is 0.0 if DECREASE is specified.

## LPF\_BAND

Set this keyword to an integer value of 3 or greater to perform low-pass filtering on the edge-enhanced array. The value of LPF\_BAND is used as the width of the smoothing window. This keyword is only effective when the DECREASE or INCREASE keywords are also specified. The default is no smoothing.

## DIAGONAL

Set this keyword to cause SEARCH3D to find cells meeting the search criteria whose surrounding cubes share a common corner or edge. Normally, cells are considered adjacent only when cubes surrounding the cells share a common edge. Setting this option requires more memory and execution time.

## Examples

Find all the indices corresponding to an object contained in a 3-D array:

```

; Create some data.
vol = RANDOMU(s, 40, 40, 40)
vol[3:13, 1:15, 17:33] = 1.3
vol[15:25, 5:25, 15:25] = 0.2
vol[5:30, 17:38, 7:28] = 1.3
vol[9:23, 16:27, 7:33] = 1.5

; Search for an object starting at (6, 22, 16) whose data values
; are between (1.2) and (1.4):
region = SEARCH3D(vol, 6, 22, 16, 1.2, 1.4, /DIAGONAL)

; Scale the background cells into the range 0 to 127:
vol = BYTSCL(vol, TOP=127B)

; Highlight the object region by setting it to 255:
vol[Region] = 255B
WINDOW, 0, XSIZE=640, YSIZE=512, RETAIN=2

; Set up a 3-D view:
CREATE_VIEW, XMAX=39, YMAX=39, ZMAX=39, AX=(-30), AZ=30, ZOOM=0.8

; Display the volume with the highlighted object in it:
TVSCL, PROJECT_VOL(vol, 64, 64, 40, DEPTH_Q=0.4)

```

[SEARCH2D](#)

# SET\_PLOT

The SET\_PLOT procedure sets the output device used by the [IDL Direct Graphics](#) procedures. Keyword parameters control how the color tables are transferred to the newly selected graphics device. SET\_PLOT performs the following actions:

- It sets the read-only system variable !D to reflect the configuration of the new device.
- It sets the default color !P.COLOR to the maximum color index minus one or, in the case of devices with white backgrounds, such as PostScript, to 0 (black).
- If the COPY keyword is set, the device color tables are copied directly from IDL's internal color tables. If the new device's color tables contain more indices than those of the old device, the new device's tables are not completely filled.
- If the INTERPOLATE keyword is set, the internal color tables are interpolated to fill the range of the new device.
- It sets the clipping rectangle to the entire device surface.

## Warning

---

After calling SET\_PLOT to change graphics devices, the scaling contained in the axis structures !X, !Y, and !Z is invalid. Any routines that rely on data coordinates should not be called until a new data coordinate system has been established. Be careful when switching devices as the number of color indices frequently differs between devices. When in doubt, reload the color table of the new device explicitly.

---

## Syntax

```
SET_PLOT, Device [, /COPY] [, /INTERPOLATE]
```

## Arguments

### Device

A scalar string containing the name of the device to use. The case of *Device* is ignored by IDL. See [Appendix A, "IDL Direct Graphics Devices"](#) for a list of device names.

## Keywords

### COPY

Set this keyword to copy the device's color table from the internal color table, preserving the current color mapping. The default is not to load the color table upon selection.

#### Warning

---

Unless this keyword is set, IDL's internal color tables will incorrectly reflect the state of the device's color tables until they are reloaded by TVLCT or the LOADCT procedure. Assuming that the previously-selected device's color table contains  $M$  elements, and the new device's color table contains  $N$  elements, then the minimum of  $M$  and  $N$  elements are loaded.

---

### INTERPOLATE

Set this keyword to indicate that the current contents of the internal color table should be interpolated to cover the range of the newly-selected device. Otherwise, the internal color tables are not changed.

## Examples

Change the IDL graphics device to PostScript by entering:

```
SET_PLOT, 'PS'
```

After changing the plotting device, all graphics commands are sent to that device until changed again by another use of the SET\_PLOT routine.

### Color Tables—Switching Between Devices

Use the SET\_PLOT procedure to direct the graphics output to different devices. Because devices have differing capabilities and not all are capable of representing the same number of colors, the treatment of color tables when switching devices is somewhat tricky.

After selecting a new graphics output device, SET\_PLOT will perform one of the following color-table actions depending upon which keyword parameters are specified:

- The default is to do nothing. The problem with this treatment is that the internal color tables incorrectly reflect the state of the device's color tables until TVLCT is called (usually via LOADCT).

- If the COPY keyword parameter is set, the internal color tables are copied into the device. This is straightforward if both devices have the same number of color indices. If the new device has more colors than the old device, some color indices will be invalid. If the new device has less colors than the old, not all the colors are saved. This is the preferred method if you are displaying graphics and each color index is explicitly loaded.
- When the INTERPOLATE keyword is set, the new device's table is loaded by interpolating the old color table to span the new number of color indices. This method works best when displaying images with continuous color ranges.

# SET\_SHADING

The SET\_SHADING procedure modifies the light source shading parameters that affect the output of SHADE\_SURF and POLYSHADE. Parameters can be changed to control the light-source direction, shading method, and the rejection of hidden surfaces. SET\_SHADING first resets the shading parameters to their default values. (Defaults are Gouraud interpolation, light-source direction [0, 0, 1], and rejection of hidden faces enabled.) The parameter values specified in the call then overwrite the default values. To reset all parameters to their default values, simply call this procedure with no parameters.

## Syntax

```
SET_SHADING [, /GOURAUD] [, LIGHT=[x, y, z]] [, /REJECT]  
[, VALUES=[darkest, brightest]]
```

## Arguments

None.

## Keywords

### GOURAUD

This keyword controls the method of shading the surface polygons by the POLYSHADE procedure. The SHADE\_SURF procedure always uses the Gouraud method. Set this keyword to a nonzero value (the default), to use Gouraud shading. Set this keyword to zero to shade each polygon with a constant intensity.

Gouraud shading interpolates intensities from each vertex along each edge. Then, when scan converting the polygons, the shading is interpolated along each scan line from the edge intensities. Gouraud shading is slower than constant shading but usually results in a more realistic appearance.

### LIGHT

A three-element vector that specifies the direction of the light source. The default light source vector is [0,0,1], with the light rays parallel to the Z axis.

## REJECT

Set this keyword (the default) to reject polygons as being hidden if their vertices are ordered in a clockwise direction as seen by the viewer. This keyword should always be set when rendering enclosed solids whose original vertex lists are in counterclockwise order. When rendering surfaces that are not closed or are not in counterclockwise order this keyword can be set to zero although shading anomalies at boundaries between visible and hidden surfaces may occur.

### Note

The REJECT keyword has no effect on the output of SHADE\_SURF—it is used only with solids.

## VALUES

A two-element array that specifies the range of pixel values (color indices) to use. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. For example, to render a shaded surface with the darkest shade set to pixel value 100 and the brightest value set to 150, use the commands:

```
SET_SHADING, VALUES=[100, 150]
SHADE_SURF, dataset
```

## Examples

Change the light source so that the light rays are parallel to the X axis:

```
SET_SHADING, LIGHT = [1, 0, 0]
```

### Note

[POLYSHADE](#), [SHADE\\_SURF](#)

# SETENV

The SETENV procedure adds or changes an environment string in the process environment.

## Syntax

SETENV, *Environment\_Expression*

## Arguments

### Environment\_Expression

A scalar string or string array containing an environment expressions to be added to the environment.

## Keywords

None.

## Examples

Change the current shell variable by entering:

```
SETENV, 'SHELL=/bin/sh'
```

Make sure to eliminate any whitespace around the equal sign:

```
; This is an incorrect usage--there are spaces around the equal
; sign:
SETENV, 'VAR = H:\rsi'
```

```
; This is correct--VAR is set to H:\rsi:
SETENV, 'VAR=H:\rsi'
```

[GETENV](#)

# SFIT

The SFIT function determines a polynomial fit to a surface and returns a fitted array. The function fitted is:

$$f(x, y) = \sum kx_{j,i} \cdot x^i \cdot y^j$$

This routine is written in the IDL language. Its source code can be found in the file `sfitt.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = SFIT( *Data*, *Degree* [, /IRREGULAR, KX=*variable*, /MAX\_DEGREE ] )

## Arguments

### Data

The two-dimensional array of data to fit. The sizes of the dimensions might be unequal, as indicated by the **IRREGULAR** keyword.

### Degree

The maximum degree of fit (in one dimension).

## Keywords

### IRREGULAR

If set, *Data* is a 3-by-*n* array containing the *x*, *y*, and *z* locations of *n* points sampled on the surface. If not set, *Data* is assumed to be sampled over a regular 2D grid, and should be in an *n*-by-*n* array, where the column and row subscripts implicitly contain the *x* and *y* location of the point.

### KX

Set this keyword to a named variable that will contain the array of coefficients for a polynomial function of *x* and *y* to fit data. If `MAX_DEGREE` is not set, this parameter is returned as a *Degree*+1 by *Degree*+1 array. If `MAX_DEGREE` is set, this parameter is returned as a *Degree*+1 by (*Degree*+2)/2 element vector.

## MAX\_DEGREE

If set, *Degree* represents the maximum degree of the fitting polynomial of all dimensions combined, rather than the maximum degree of the polynomial in a single variable.

For example, if *Degree* is 2 and MAX\_DEGREE is not set, then the terms returned are  $[[k, y, y^2], [x, xy, xy^2], [x^2, x^2y, x^2y^2]]$ . If MAX\_DEGREE is set, the terms returned are in a vector,  $[k, y, y^2, x, xy, x^2]$ , in which no terms has a power higher than two in x and y combined, and the powers of y vary the fastest.

## Examples

```

; Create a grid from zero to six radians in the X and Y directions:
X = (FINDGEN(61)/10) # REPLICATE(1,61)
Y = TRANSPOSE(X)

; Evaluate a function at each point:
F = -SIN(2*X) + COS(Y/2)

; Compute a sixth-degree polynomial fit to the function data:
result = SFIT(F, 6)

; Display the original function on the left and the fitted function
; on the right, using identical axis scaling:
WINDOW, XSIZE = 800, YSIZE = 400

; Set up side-by-side plots:
!P.MULTI = [0, 2, 1]

; Set background color to white:
!P.BACKGROUND = 255

; Set plot color to black:
!P.COLOR = 0

SURFACE, F, X, Y, ZRANGE = [-3, 3], ZSTYLE = 1
SURFACE, result, X, Y

```

The following figure shows the result of this example:

Figure 3-105: The Original Function (Left) and the Fitted Function (Right)

# SHADE\_SURF

The SHADE\_SURF procedure creates a shaded-surface representation of a regular or nearly-regular gridded surface with shading from either a light source model or from a user-specified array of intensities. Displays are easily constructed depicting the surface elevation of a variable shaded as a function of itself or another variable. This procedure and its parameters are similar to SURFACE, but it renders the visible surface as a shaded image rather than a mesh. Given a regular or near-regular grid of elevations it produces a shaded-surface representation of the data with hidden surfaces removed.

The [SET\\_SHADING](#) procedure can be used to control the direction of the light source and other shading parameters.

If the graphics output device has scalable pixels (e.g., PostScript), the output image is scaled so that its largest dimension is less than or equal to 512 (unless the PIXELS keyword is set to some other value). This default resolution may not be high enough for some datasets. If your output looks jagged or “stair-stepped”, try specifying a larger value with the PIXELS keyword.

When outputting to a device that prints black on a white background, (e.g., PostScript), pixels that contain the background color index of 0 are set to white.

---

## Note

See “[Polygon Shading Method](#)” in Chapter 8 of the *Using IDL* manual for information on how polygon shading is computed.

---

## Restrictions

If the  $(X, Y)$  grid is not regular or nearly regular, errors in hidden line removal will occur. If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the Z axis to a line parallel to the device Y axis, or errors will occur. The SHADE\_SURF\_IRR procedure can be used to render many datasets that do not meet these requirements. Irregularly-gridded data can also be made interpolated to a regular grid using the TRIGRID and TRIANGULATE routines.

## Syntax

```
SHADE_SURF, Z [, X, Y] [, AX=degrees] [, AZ=degrees] [, IMAGE=variable]
  [, MAX_VALUE=value] [, MIN_VALUE=value] [, PIXELS=pixels] [, /SAVE]
  [, SHADES=array] [, /XLOG] [, /YLOG]
```

**Graphics Keywords:** [, CHARSIZE=*value*] [, CHARTHICK=*integer*]  
 [, COLOR=*value*][, /DATA | , /DEVICE | , /NORMAL] [, FONT=*integer*]  
 [, /NODATA] [, POSITION=[ $X_0, Y_0, X_1, Y_1$ ]] [, SUBTITLE=*string*] [, /T3D]  
 [, THICK=*value*] [, TICKLEN=*value*] [, TITLE=*string*]  
 [, {X | Y | Z}CHARSIZE=*value*]  
 [, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}]  
 [, {X | Y | Z}MARGIN=[*left, right*]]  
 [, {X | Y | Z}MINOR=*integer*]  
 [, {X | Y | Z}RANGE=[*min, max*]]  
 [, {X | Y | Z}STYLE=*value*]  
 [, {X | Y | Z}THICK=*value*]  
 [, {X | Y | Z}TICKFORMAT=*string*]  
 [, {X | Y | Z}TICKINTERVAL= *value*]  
 [, {X | Y | Z}TICKLAYOUT=*scalar*]  
 [, {X | Y | Z}TICKLEN=*value*]  
 [, {X | Y | Z}TICKNAME=*string\_array*]  
 [, {X | Y | Z}TICKS=*integer*]  
 [, {X | Y | Z}TICKUNITS=*string*]  
 [, {X | Y | Z}TICKV=*array*]  
 [, {X | Y | Z}TICK\_GET=*variable*]  
 [, {X | Y | Z}TITLE=*string*]  
 [, ZVALUE=*value*{0 to 1}]

## Arguments

### Z

The two-dimensional array to be displayed. If  $X$  and  $Y$  are provided, the surface is plotted as a function of the  $(X, Y)$  locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of  $Z$ .

This argument is converted to double-precision floating-point before plotting. Plots created with SHADE\_SURF are limited to the range and precision of double-precision floating-point values.

### X

A vector or two-dimensional array specifying the  $X$  coordinates of the grid. If this argument is a vector, each element of  $X$  specifies the  $X$  coordinate for a column of  $Z$  (e.g.,  $X[0]$  specifies the  $X$  coordinate for  $Z[0, *]$ ). If  $X$  is a two-dimensional array, each element of  $X$  specifies the  $X$  coordinate of the corresponding point in  $Z$  ( $X_{ij}$  specifies the  $X$  coordinate for  $Z_{ij}$ ).

This argument is converted to double-precision floating-point before plotting.

## Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of *Y* specifies the Y coordinate for a row of *Z* (e.g., *Y*[0] specifies the Y coordinate for *Z*[\*, 0]). If *Y* is a two-dimensional array, each element of *Y* specifies the Y coordinate of the corresponding point in *Z* (*Y*<sub>*ij*</sub> specifies the Y coordinate for *Z*<sub>*ij*</sub>).

This argument is converted to double-precision floating-point before plotting.

## Keywords

### AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D and the T3D keyword are not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is contained in the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer (AX > 0), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

### AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

### IMAGE

A named variable into which an image containing the shaded surface is stored. If this keyword is omitted, the image is displayed but not saved.

### MAX\_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special](#)

[Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## MIN\_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## PIXELS

Set this keyword to a scalar value that specifies the maximum size of the image dimensions, in pixels. PIXELS only applies when the output device uses scalable pixels (e.g., the PostScript device). Use this keyword to increase the resolution of the output image if the default looks jagged or “stair-stepped”.

## SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SHADE\_SURF in the system variable field !P.T. Use this keyword when combining the output of SHADE\_SURF with the output of other routines in the same plot.

## SHADES

An array expression, of the same dimensions as Z, that contains the color index at each point. The shading of each pixel is interpolated from the surrounding SHADE values. If this parameter is omitted, light-source shading is used. For most displays, this parameter should be scaled into the range of bytes.

### Warning

---

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting DECOMPOSED=0 for [DEVICE](#).

---

## XLOG

Set this keyword to specify a logarithmic X axis.

## YLOG

Set this keyword to specify a logarithmic Y axis.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

CHARSIZE, CHARTHICK, COLOR, DATA, DEVICE, FONT, NODATA, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK\_GET, [XYZ]TITLE, ZVALUE

## Examples

### Note

Also see [“Mapping an Image onto Elevation Data”](#) in Chapter 3 of the *Image Processing in IDL* manual for additional examples.

```
; Create a simple dataset:
D = DIST(40)
; Display the dataset as a light-source shaded surface:
SHADE_SURF, D, TITLE = 'Shaded Surface'
```

Instead of light-source shading, an array of the same size as the elevation dataset can be used to color the surface. This technique creates four-dimensional displays.

```
; Create an array of shades to use:
S = SIN(D)

; Now create a new shaded surface that uses the array of shading
; values instead of the light source:
SHADE_SURF, D, SHADES = BYTSCL(S)
```

Note that the BYTSCL function is used to scale *S* into the range of bytes.

The following figure illustrates the application of SHADE\_SURF, with light-source shading, to the two-dimensional Gaussian (also drawn as a mesh in [Figure 3-122](#)). This figure was produced by the following statements.

```
; Create a 40-by-40 array in which each element
; is equal to the Euclidean distance from the center.
Z = SHIFT(DIST(40), 20, 20)
; Make Gaussian with a 1/e width of 10:
Z = EXP(-(Z/10)^2)
SHADE_SURF, Z
```

The right half of the following figure shows the use of an array of shades, which in this case is simply the surface elevation scaled into the range of bytes.

*Figure 3-106: Shaded Representations of a Two-Dimensional Gaussian*

The output of SURFACE is superimposed over the shaded image with the statements below.

```

; Show Gaussian with shades created by scaling
; elevation into the range of bytes.
SHADE_SURF, Z, SHADES=BYTSCL(Z, TOP = !D.TABLE_SIZE)
; Draw the mesh surface over the shaded figure.
; Suppress the axes:
SURFACE, Z, XST = 4, YST = 4, ZST = 4, /NOERASE

```

The next figure shows the Maroon Bells data as a light-source shaded surface (this data is also shown in the right half of [Figure 3-123](#)). It was produced by the following statements:

```

; Restore variables.
@cntour01
SHADE_SURF, elev, AZ=210, AX=45, XST=4, YST=4, ZST=4

```

The AX and AZ keywords specify the orientation. The axes are suppressed by the axis-style keyword parameters; as in this orientation, the axes are behind the surface.

*Figure 3-107: Maroon Bells Data Shown as a Shaded Surface*

# SHADE\_SURF\_IRR

The SHADE\_SURF\_IRR procedure creates a shaded surface representation of an irregularly gridded elevation dataset.

The data must be representable as an array of quadrilaterals. This routine should be used when the (X, Y, Z) arrays are too irregular to be drawn by SHADE\_SURF, but are still semi-regular.

This routine is written in the IDL language. Its source code can be found in the file `shade_surf_irr.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SHADE_SURF_IRR, Z, X, Y [, AX=degrees] [, AZ=degrees] [, IMAGE=variable]
  [, PLIST=variable] [, /T3D]
```

## Arguments

### Z

An  $n \times m$  array of elevations.

### X

An  $n \times m$  array containing the X location of each Z value.

### Y

An  $n \times m$  array containing the Y location of each Z value.

The grid described by X and Y must consist of quadrilaterals, must be semi-regular, and must be in “clockwise” order. Clockwise ordering means that:

```
  ;for all j
  x[i,j] <= x[i+1, j]
and
  ;for all i
  y[i,j] <= y[i, j+1]
```

## Keywords

### AX

The angle of rotation about the X axis. The default is 30 degrees.

### AZ

The angle of rotation about the Z axis. The default is 30 degrees.

### IMAGE

Set this keyword to a named variable that will contain the resulting shaded surface image. The variable is returned as a byte array of the same size as the currently selected graphics device.

### PLIST

Set this keyword to a named variable that will contain the polygon list on return. This feature is useful when you want to make a number of images from the same set of vertices and polygons.

### T3D

Set this keyword to indicate that the generalized transformation matrix in !P.T is to be used (in which case the keyword values for AX and AZ are ignored)

## Examples

The following example creates a semi-regular data set in the proper format and displays the resulting irregular surface.

```

; Create some elevation data:
z = DIST(10,10)*100.0
; Create arrays to hold X and Y data:
x = FLTARR(10,10) & y = FLTARR(10,10)
; Ensure that X and Y arrays are in "clockwise" order:
FOR i = 0,9 DO x[0:9,i] = FINDGEN(10)
FOR j = 0,9 DO y[j,0:9] = FINDGEN(10)
; Make X and Y arrays irregular:
x = x + RANDOMU(seed,10,10)*0.49
y = y + RANDOMU(seed,10,10)*0.49
; Display the irregular surface:
SHADE_SURF_IRR, z, x, y

```

# SHADE\_VOLUME

Given a 3-D volume and a contour value, SHADE\_VOLUME produces a list of vertices and polygons describing the contour surface. The polygons are described by a  $(3, n)$  array of vertices and a polygon list array that contains the vertices belonging to each polygon. Given a volume array with dimensions of  $(D_0, D_1, D_2)$ , the resulting vertex coordinates range between 0 and  $D_0 - 1$  in  $x$ , 0 and  $D_1 - 1$  in  $y$ , and 0 and  $D_2 - 1$  in  $z$ . This surface can then be displayed as a shaded surface by the POLYSHADE procedure. Shading is obtained from either a single light-source model or from user-specified values.

SHADE\_VOLUME computes the polygons that describe a three dimensional contour surface. Each volume element (voxel) is visited to find the polygons formed by the intersections of the contour surface and the voxel edges. The method used by SHADE\_VOLUME is that of Klemp, McIrvin and Boyd, 1990: "PolyPaint—A Three-Dimensional Rendering Package," *American Meteorology Society Proceedings, Sixth International Conference on Interactive Information and Processing Systems*. This method is similar to the marching cubes algorithm described by Lorensen and Cline, 1987: "Marching Cubes: A High Resolution 3D Surface Construction Algorithm," *Computer Graphics 21*, 163-169.

This routine is limited to processing datasets that will fit in memory.

## Syntax

```
SHADE_VOLUME, Volume, Value, Vertex, Poly [, /LOW] [, SHADES=array]
    [, /VERBOSE] [, XRANGE=vector] [, YRANGE=vector] [, ZRANGE=vector]
```

## Arguments

### Volume

A three-dimensional array that contains the dataset to be contoured. If the *Volume* array is dimensioned  $(D_0, D_1, D_2)$ , the resulting vertex coordinates are as follows:

$$0 < X < D_0 - 1; 0 < Y < D_1 - 1; 0 < Z < D_2 - 1.$$

If floating-point NaN values are present in *Volume*, then SHADE\_VOLUME may generate inconsistent surfaces and may return NaN values in the *Vertex* argument. The surfaces generated by SHADE\_VOLUME may also vary across platforms if NaN data is present in the *Volume* parameter.

## Value

The scalar contour value. This value specifies the constant-density surface (also called an isosurface) to be rendered.

## Vertex

The name of a variable to receive the vertex array. On output, this variable is set to a  $(3, n)$  floating-point array, suitable for input to POLYSHADE.

## Poly

A named variable to receive the polygon list, an  $n$ -element, longword array. This list describes the vertices of each polygon and is suitable for input to POLYSHADE. The vertices of each polygon are listed in counterclockwise order when observed from outside the surface. The vertex description of each polygon is a vector of the form:  $[n, i_0, i_1, \dots, i_{n-1}]$  and the *Poly* array is the concatenation of the lists of each polygon. For example, when rendering a pyramid consisting of four triangles, *Poly* would contain 16 elements, made by concatenating four, four-element vectors of the form  $[3, V_0, V_1, V_2]$ .  $V_0, V_1,$  and  $V_2$  are the indices of the vertices describing each triangle.

## Keywords

### LOW

Set this keyword to display the low side of the contour surface (i.e., the contour surfaces enclose high data values). If this keyword is omitted or is 0, the high side of the contour surface is displayed and the contour encloses low data values. If this parameter is incorrectly specified, errors in shading will result.

### SHADES

An optional array, converted to byte type before use, that contains the user-specified shading color index for each voxel. This array must have the same dimensions as *Volume*. On completion, SHADE\_VOLUME replaces this array with the interpolated shading for each vertex of the surface, contained in *Vertex*.

### Warning

---

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting DECOMPOSED=0 for [DEVICE](#).

---

## VERBOSE

Set this keyword to print a message indicating the number of polygons and vertices that are produced.

## XRANGE

An optional two-element vector that contains the limits, over the first dimension, of the sub-volume to be considered.

## YRANGE

An optional two-element vector that contains the limits, over the second dimension, of the sub-volume to be considered.

## ZRANGE

An optional two-element vector containing the limits, over the third dimension, of the sub-volume to be considered.

## Examples

The following procedure shades a volume passed as a parameter. It uses the SCALE3 procedure to establish the viewing transformation. It then calls SHADE\_VOLUME to produce the vertex and polygon lists, and POLYSHADE to draw the contour surface.

```

PRO SHOWVOLUME, vol, thresh, LOW = low
; Get the dimensions of the volume:
s = SIZE(vol)
; Error, must be a 3-D array:
IF s[0] NE 3 THEN MESSAGE, 'Error: vol must be a 3-D array'
; Establish the 3-D transformation and coordinate ranges:
SCALE3, XRANGE=[0, S[1]], YRANGE=[0, S[2]], ZRANGE=[0, S[3]]
; Default = view high side of contour surface:
IF N_ELEMENTS(low) EQ 0 THEN low = 0
; Produce vertices and polygons:
SHADE_VOLUME, vol, thresh, v, p, LOW = low
; Produce image of surface and display:
TV, POLYSHADE(v, p, /T3D)
END

```

## Creating an Isosurface Display

A common problem in data visualization is how to display a constant density surface (also known as an isosurface), given a three-dimensional grid of density

measurements. In medical imaging, stacking a series of two-dimensional images created by computed tomography or magnetic resonance creates a grid of density measurements that can be contoured to display the surfaces of anatomical structures. Atmospheric scientists create three-dimensional grids of water densities that can be contoured at the proper density level to show the surface of clouds. It is relatively easy to produce these surfaces using the `SHADE_VOLUME` procedure in conjunction with the `POLYSHADE` function.

## Cloud Example

This next figure, produced by the following IDL code, shows the three-dimensional contour surface of the precipitating region of a thunderstorm simulated by a three-dimensional cloud model.

*Figure 3-108: A 3-dimensional Contour Surface of a Cloud's Precipitating Region*

The data were provided by the National Center for Atmospheric Research. The original data are contained in an array called `clouds`, a (55, 55, 32) element floating-point array. Each array element contains the amount of water contained in the corresponding volume of air.

```

; Restore the data:
RESTORE, FILEPATH('clouds3d.dat', SUBDIR=['examples','data'])
; Create the contour surface polygons (v and p)
; at density 0.1, from clouds. Show the low side:
SHADE_VOLUME, clouds, 0.1, v, p, /LOW
; Obtain the dimensions of the volume.
; Variables S[1], S[2], and S[3] now contain
; the number of columns, rows, and slices in the volume:
s = SIZE(clouds)
; Use SCALE3 to establish the three-dimensional
; transformation matrix. Rotate 45 degrees about the z-axis:
SCALE3, X RANGE=[0,S[1]], Y RANGE=[0,S[2]], $
      Z RANGE=[0,S[3]], AX=0, AZ=45
; Render and display the polygons:
TV, POLYSHADE(v, p, /T3D)

```

### Example Code

---

If you prefer not to enter the IDL code by hand, run the batch file `clouds` with the following command at the IDL prompt:

```
@clouds
```

---

See “[Running the Example Code](#)” on page 40 if IDL does not find the referenced batch file.

## Rotating the Shaded Volume

The shaded volume can be viewed from different rotations by changing the three-dimensional transformation matrix, !P.T, and calling POLYSHADE for each view. The following code displays 20 views of the volume, each separated by 18 degrees.

```

; Define number of views:
nframes = 20
FOR i = 0, nframes - 1 DO BEGIN & $
  ; Translate the center of the (0, 1) unit cube
  ; to (0,0) and rotate about the x-axis:
  T3D, TR=[-.5, -.5, -.5], ROT=[0, 360./NFRAMES, 0] & $
  ; Translate the center back to (0.5, 0.5, 0.5):
  T3D, TR = [.5, .5, .5] & $
  ; Show the surface:
  TV, POLYSHADE(v, p, /T3D) & $
ENDFOR

```

The animation rate of the above loop will not be very fast, especially with a larger number of polygons. Each image could be saved for rapid replay by writing it to a disk file. Given enough memory and/or display resources, the XINTERANIMATE procedure could be used to animate the views.

# SHIFT

The SHIFT function shifts elements of vectors or arrays along any dimension by any number of elements. Positive shifts are to the right while left shifts are expressed as a negative number. All shifts are circular.

Elements shifted off one end wrap around and are shifted onto the other end. In the case of vectors the action of SHIFT can be expressed:

$$\text{Result}_{(i+s) \text{ modulation}} = \text{Array}_i \text{ for } (0 \leq i < n)$$

where  $s$  is the amount of the shift, and  $n$  is the number of elements in the array.

## Syntax

$$\text{Result} = \text{SHIFT}(\text{Array}, S_1, \dots, S_n)$$

## Return Value

The result is a vector or array of the same structure and type as *Array*.

## Arguments

### Array

The array to be shifted.

### $S_i$

The shift parameters. The  $S_i$  arguments can be either a single array containing the shift parameters for each dimension, or a sequence of up to eight scalar shift values. For arrays of more than one dimension, the parameter  $S_n$  specifies the shift applied to the  $n$ -th dimension.  $S_1$  specifies the shift along the first dimension and so on. If only one shift parameter is present and the parameter is an array, the array is treated as a vector (i.e., the array is treated as having one-dimensional subscripts).

A shift specification of 0 means that no shift is to be performed along that dimension.

## Keywords

None

## Examples

The following example demonstrates using SHIFT with a vector. by entering:

```
A = INDGEN(5)

; Print the original vector, the vector shifted one position to the
; right, and the vector shifted one position to the left:
PRINT, A, SHIFT(A, 1), SHIFT(A, -1)
```

IDL prints:

```
0  1  2  3  4
4  0  1  2  3
1  2  3  4  0
```

Notice how elements of the vector that shift off the end wrap around to the other end. This “wrap around” occurs when shifting arrays of any dimension.

---

### Note

# SHMDEBUG

The SHMDEBUG function enables a debugging mode in which IDL prints an informational message (including a traceback) every time a variable created with the SHMVAR function loses its reference to the underlying memory segment created by. There are many reasons why a such a variable might lose its reference; some reasons have to do with the internal implementation of the IDL interpreter and are not obvious or visible to the IDL user.

---

**Note**

The SHMDEBUG debugging mode should be used for problem solving only, and should not be part of production code.

---

## Syntax

*Result* = SHMDEBUG(*Enable*)

## Return Value

SHMDEBUG returns the previous setting of the debugging state.

## Arguments

### Enable

Set this argument equal to a non-zero value to enable debugging, or to zero to disable debugging.

## Keywords

None.

## Examples

Create a memory segment, tie a variable to it, enable debugging, and then cause the variable to lose the reference:

```
old_debug = SHMDEBUG(1) ; Enable debug mode
SHMMAP, 'A', 100 ; 100 element floating vector
z = SHMVAR('A') ; Variable tied to segment
z[0] = FINDGEN(100) ; Does not lose reference
```

```
z = FINDGEN(100) ; Loses reference
% Variable released shared memory segment: A
% Released at: $MAIN$
```

The assignment `z[0] = FINDGEN(100)` explicitly uses subscripting to assign the `FINDGEN` value to the array. Under normal circumstances, using subscripting in this way on the left hand side of an assignment is inefficient and not recommended. In this case, however, it has the desirable side effect of causing the variable `Z` to maintain its connection to its existing underlying memory. In contrast, the second (normally more desirable) assignment without the subscript causes IDL to allocate different memory for the variable `Z`, with the side effect of losing the connection to the shared memory segment.

[SHMMAP](#), [SHMUNMAP](#), [SHMVAR](#)

# SHMMAP

The SHMMAP procedure maps anonymous shared memory, or local disk files, into the memory address space of the currently executing IDL process. Mapped memory segments are associated with an IDL array specified by the user as part of the call to SHMMAP. The type and dimensions of the specified array determine the length of the memory segment.

The array can be of any type except pointer, object reference, or string. (Structure types are allowed as long as they do not contain any pointers, object references, or strings.) By default, the array type is single-precision floating-point; other types can be chosen by specifying the appropriate keyword.

Once such a memory segment exists, it can be tied to an actual IDL variable using the SHMVAR function, or unmapped using SHMUNMAP.

## Why Use Mapped Memory?

- Shared memory is often used for interprocess communication. Any process that has a shared memory segment mapped into its address space is able to “see” any changes made by any other process that has access to the same segment. Shared memory is the default for SHMMAP, unless the FILENAME keyword is specified.
- Memory-mapped files allow you to treat the contents of a local disk file as if it were simple memory. Reads and writes to such memory are automatically written to the file by the operating system using its standard virtual memory mechanisms. Access to mapped files has the potential to be faster than standard Input/Output using Read/Write system calls because it does not go through the expensive system call interface, and because it does not require the operating system to copy data between user and kernel memory buffers when performing the I/O. However, it is not as general or flexible as the standard I/O mechanisms, and is therefore not a replacement for them.

### Warning

---

Unlike most IDL functionality, incorrect use of SHMMAP can corrupt or even crash your IDL process. Proper use of these low level operating system features requires systems programming experience, and is not recommended for those without such experience. You should be familiar with the memory and file mapping features of your operating system and the terminology used to describe such features.

---

SHMMAP uses the facilities of the underlying operating system. Any of several alternatives may be used, as described in “Types Of Memory Segments” on page 2087. SHMMAP uses the following rules, in the specified order, to determine which method to use:

1. If the `FILENAME` keyword is present, SHMMAP creates a memory mapped file segment.
2. If the `SYSV` keyword is used under UNIX, a System V shared memory segment is created or attached. Use of the `SYSV` keyword under Windows will cause an error to be issued.
3. If none of the above options are specified, SHMMAP creates an anonymous shared memory segment. Under UNIX, this is done with Posix shared memory. Under Windows, the `CreateFileMapping()` system call is used.

## Syntax

```
SHMMAP [, SegmentName] [, D1, ..., D8] [, /BYTE] [, /COMPLEX]
  [, /DCOMPLEX] [, /DESTROY_SEGMENT] [, /DIMENSION=value]
  [, /DOUBLE] [, /FILENAME=value] [, /FLOAT] [, /GET_NAME=value]
  [, /GET_OS_HANDLE=value] [, /INTEGER] [, /L64] [, /LONG]
  [, /OFFSET=value] [, /OS_HANDLE=value] [, /PRIVATE] [, /SIZE=value]
  [, /SYSV] [, /TEMPLATE=value] [, /TYPE=value] [, /UINT] [, /UL64]
  [, /ULONG]
```

## Arguments

### SegmentName

A scalar string supplying the name by which IDL will refer to the shared memory segment. The *SegmentName* string must be constructed according to the same rules as an IDL variable name; see “Variable Names” in Chapter 13 of the *Building IDL Applications* manual for details. This name is only used by IDL, and does not necessarily correspond to the name used for the shared memory segment by the underlying operating system. See the discussion of the `OS_HANDLE` keyword for more information on the underlying operating system name. If *SegmentName* is not specified, IDL will generate a unique name. The *SegmentName* can be obtained using the `GET_NAME` keyword.

**$D_i$** 

The dimensions of the result. The  $D_i$  arguments can be either a single array containing the dimensions or a sequence of scalar dimensions. Up to eight dimensions can be specified.

## Keywords

### BYTE

Set this keyword to specify that the memory segment should be treated as a byte array.

### COMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, single-precision floating-point array.

### DCOMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, double-precision floating-point array.

### DESTROY\_SEGMENT

The UNIX anonymous shared memory mechanisms (Posix `shm_open()` and System V `shmget()`) create shared memory segments that are not removed from the operating system kernel until explicitly destroyed (or the system is rebooted). At any time, a client program can attach to such an existing segment, read or write to it, and then detach. This can be convenient in situations where the need for the shared memory is long lived, and programs that need it come and go. It also can create a problem, however, in that shared memory segments that are not explicitly destroyed can cause memory leaks in the operating system. Hence, it is important to properly destroy such segments when they are no longer required.

For UNIX anonymous shared memory (Posix or System V), the default behavior is for IDL to destroy any shared memory segments it created when the segments are unmapped, and not to destroy segments it did not create. The `DESTROY_SEGMENT` keyword is used to override this default: set `DESTROY_SEGMENT` to 1 (one) to indicate that IDL should destroy the segment when it is unmapped, or 0 (zero) to indicate that it should not destroy it. All such destruction occurs when the segment is unmapped (via the `SHMUNMAP` procedure) and not during the call to `SHMMAP`.

The `DESTROY_SEGMENT` keyword is ignored under the Windows operating system. Under UNIX, it is ignored for mapped files.

## DIMENSION

Set this keyword equal to a vector of 1 to 8 elements specifying the dimensions of the result. Setting this keyword is equivalent to specifying an array via the *D* argument.

## DOUBLE

Set this keyword to specify that the memory segment should be treated as a double-precision floating-point array.

## FILENAME

By default, `SHMMAP` maps anonymous shared memory. Set the `FILENAME` keyword equal to a string containing the path name of a file to be mapped to create a memory-mapped file. A shared mapped file can serve as shared memory between unrelated processes. The primary difference between anonymous shared memory and mapped files is that mapped files require a file of the specified size to exist in the filesystem, whereas anonymous shared memory has no user-visible representation in the filesystem.

By default, files are mapped as shared, meaning that all processes that map the file will see any changes made. All changes are written back to the file by the operating system and become permanent. You must have write access to the file in order to map it as shared.

To change the default behavior, set the `PRIVATE` keyword. When a file is mapped privately, changes made to the file are *not* written back to the file by the operating system, and are not visible to any other processes. You do not need write access to a file in order to map it privately — read access is sufficient.

### Note

---

The non-private form of file mapping corresponds to the `MAP_SHARED` flag to the UNIX `mmap()` function, or the `PAGE_READWRITE` to the Windows `CreateFileMapping()` system call.

---

## FLOAT

Set this keyword to specify that the memory segment should be treated as a single-precision floating-point array.

## GET\_NAME

If *SegmentName* is not specified in a call to SHMMAP, IDL automatically generates a name. Set this keyword equal to a named variable that will receive the name assigned by IDL to the memory segment.

## GET\_OS\_HANDLE

Set this keyword equal to a named variable that will receive the operating system name (or *handle*) for the memory segment. The meaning of the operating system handle depends on both the operating system and the type of memory segment used. See the description of the [OS\\_HANDLE](#) keyword for details.

## INTEGER

Set this keyword to specify that the memory segment should be treated as an integer array.

## L64

Set this keyword to specify that the memory segment should be treated as a 64-bit integer array.

## LONG

Set this keyword to specify that the memory segment should be treated as a longword integer array.

## OFFSET

If present and non-zero, this keyword specifies an offset (in bytes) from the start of the shared memory segment or memory mapped file that will be used as the base address for the IDL array associated with the memory segment.

---

### Note

Most computer hardware is not able to access arbitrary data types at arbitrary memory addresses. Data must be properly aligned for its type or the program will crash with an alignment error (often called a *bus error*) when the data is accessed. The specific rules differ between machines, but in many cases the address of a data object must be evenly divisible by the size of that object. IDL will issue an error if you specify an offset that is not valid for the array specified.

---

**Note**

The actual memory mapping primitives provided by the underlying operating system require such offsets to be integer multiples of the virtual memory pagesize (sometimes called the *allocation granularity*) for the system. This value is typically a power of two such as 8K or 64K. In contrast, IDL allows arbitrary offsets as long as they satisfy the alignment constraints of the data type. This is implemented by mapping the page that contains the specified offset, and then adjusting the memory address to point at the specified byte within that page. In rounding your offset request back to the nearest page boundary, IDL may map slightly more memory than your request would seem to require, but never more than a single page.

**OS\_HANDLE**

Set this keyword equal to the name (or *handle*) used by the underlying operating system for the memory segment. If you do not specify the OS\_HANDLE keyword, SHMMAP will under some circumstances provide a default value. The specific meaning and syntax of the OS\_HANDLE depends on both the operating system and the form of memory used. See the following sections for operating-system specific behavior, and “[Types Of Memory Segments](#)” on page 2087 for behavior differences based on the form of memory used.

**Posix (UNIX) Shared Memory**

Use the OS\_HANDLE keyword to supply a string value containing the system global name of the shared memory segment. Such names are expected to start with a slash (/) character, and not to contain any other slash characters. You can think of this as mimicking the syntax for a file in the root directory of the system, although no such file is created. See your system documentation for the `shm_open()` system call for specific details. If you do not supply the OS\_HANDLE keyword, SHMMAP will create one for you by prepending a slash character to the value given by the *SegmentName* argument.

**UNIX System V Shared Memory**

Use the OS\_HANDLE keyword to supply an integer value containing the system global identifier of an existing shared memory segment to attach to the process. If you do not supply the OS\_HANDLE keyword, then SHMMAP creates a new memory segment. The identifier for this segment is available via the [GET\\_OS\\_HANDLE](#) keyword.

## Windows Anonymous Shared Memory

Use the `OS_HANDLE` keyword to supply a global system name for the mapping object underlying the anonymous shared memory. If the `OS_HANDLE` keyword is not specified, `SHMMAP` uses the value of the *SegmentName* argument.

## UNIX Memory Mapped Files

The `OS_HANDLE` keyword has no meaning for UNIX memory mapped files and is quietly ignored.

## Windows Memory Mapped Files

Use the `OS_HANDLE` keyword to supply a global system name for the mapping object underlying the mapped file. Use of the `OS_HANDLE` will ensure that every process accessing the shared file will see a coherent view of its contents, and is thus recommended for Windows memory mapped files. However, if you do not supply the `OS_HANDLE` handle keyword for a memory mapped file, no global name is passed to the Windows operating system, and a unique mapping object for the file will be created.

## PRIVATE

Set this keyword to specify that a private file mapping is required. In a private file mapping, any changes written to the mapped memory are visible only to the process that makes them, and such changes are not written back to the file. This keyword is ignored unless the `FILENAME` keyword is also present.

Mapping a file as shared requires that you have write access to the file, but a private mapping requires only read access. Use `PRIVATE` to map files for which you do not have write access, or when you want to ensure that the original file will not be altered by your process.

### Note

---

Under UNIX, the private form of file mapping corresponds to the `MAP_PRIVATE` flag to the `mmap()` system call. Under Windows, the non-private form corresponds to the `PAGE_WRITECOPY` option to the Windows `CreateFileMapping()` system call. When your process alters data within a page of privately mapped memory, the operating system performs a *copy on write* operation in which the contents of that page are copied to a new memory page visible only to your process. This private memory usually comes from anonymous swap space or the system pagefile. Hence, private mapped files require more system resources than shared mappings.

It is possible for some processes to use private mappings to a given file while others use a public mapping to the same file. In such cases, the private mappings will see

changes made by the public processes up until the moment the private process itself makes a change to the page. The pagesize granularity and timing issues between such processes can make such scenarios very difficult to control. RSI does not recommend combining simultaneous shared and private mappings to the same file.

---

## SIZE

Set this keyword equal to a `size` vector specifying the type and dimensions to be associated with the memory segment. The format of a size vector is given in the description of the [SIZE](#) function.

## SYSV

Under UNIX, the default form of anonymous memory is Posix shared memory, (`shm_open()` and `shm_unlink()`). Specify the `SYSV` keyword to use System V shared memory (`shmget()`, `shmctl()`, and `shmdt()`) instead. On systems where it is available, Posix shared memory is more flexible and has fewer limitations. System V shared memory is available on all UNIX implementations, and serves as an alternative when Posix memory does not exist, or when interfacing to exiting non-IDL software that uses System V shared memory. See “[Types Of Memory Segments](#)” on page 2087 for a full discussion.

## TEMPLATE

Set this keyword equal to a variable of the type and dimensions to be associated with the memory segment.

## TYPE

Set this keyword to specify the type code for the memory segment. See the description of the [SIZE](#) function for a list of IDL type codes.

## UINT

Set this keyword to specify that the memory segment should be treated as a unsigned integer array.

## ULONG

Set this keyword to specify that the memory segment should be treated as a unsigned longword integer array.

## UL64

Set this keyword to specify that the memory segment should be treated as a unsigned 64-bit integer array.

## Types Of Memory Segments

SHMMAP is a relatively direct interface to the shared memory and file mapping primitives provided by the underlying operating system. The SHMMAP interface attempts to minimize the differences between these primitives, and for simple shared memory use, it may not be necessary to fully understand the underlying mechanisms. For most purposes, however, it is necessary to understand the operating system primitives in order to understand how to use SHMMAP properly.

## UNIX

In modern UNIX systems, the `mmap()` system call forms the primary basis for both file mapping and anonymous shared memory. The existence of System V shared memory, which is an older form of anonymous shared memory, adds some complexity to the situation.

### UNIX Memory Mapped Files

To memory map a file under UNIX, you open the file using the `open()` system call, and then map it using `mmap()`. Once the file is mapped, you can close the file, and the mapping remains in place until explicitly unmapped, or until the process exits or calls `exec()` to run a different program.

If more than one process maps a file at the same time using the `MAP_SHARED` flag to `mmap()`, then those processes will be able to see each others' changes. Hence, memory mapped files are one form of shared memory. Although the requirement for a scratch file large enough to satisfy the mapping is inconvenient, limitations in System V shared memory have led many UNIX programmers to use memory mapped files in this way.

### UNIX System V Shared Memory

Anonymous shared memory has traditionally been implemented via an API commonly referred to as System V IPC. The `shmget()` function is used to create a shared memory segment. The caller does not name the segment. Instead, the operating system assigns each such segment a unique integer ID when it is created. Once a shared memory segment exists, the `shmdt()` function can be used to map it into the address space of any process that knows the identifier. This segment persists in the OS kernel until it is explicitly destroyed via the `shmctl()` function, or until

the system is rebooted. This is true even if there are no processes currently mapped to the segment. This can be convenient in situations where the need for the shared memory is long lived, and programs that need it come and go. It also can create a problem, however, since shared memory segments that are not explicitly destroyed can cause memory leaks in the operating system. Hence, it is important to properly destroy such segments when they are no longer required.

System V shared memory has been part of UNIX for a long time. It is available on all UNIX platforms, and there is a large amount of existing code that uses it. There are, however, some limitations on its utility:

- Many systems place extremely small limits on the size allowed for such memory segments. These limits are often kernel parameters that can be adjusted by the system administrator. The details are highly system dependent. Consult your system documentation for details.
- The caller does not have the option of naming the shared memory segment. Instead, the operating system assigns an arbitrary number, which means that processes that want to map such a segment have to have a mechanism for finding the correct identifier to use before they can proceed. This, in turn, requires some additional form of interprocess communication.

RSI recommends the use of Posix shared memory instead of System V shared memory for those platforms that support it and applications that can use it. Under UNIX, SHMMAP defaults to Posix shared memory to implement anonymous shared memory. To use System V shared memory, you must specify the SYSV keyword. See the [Examples](#) section below for an example of using System V shared memory.

### Posix Shared Memory

Posix shared memory is a newer alternative for anonymous shared memory. It is part of the UNIX98 standard, and although not all current UNIX systems support it, it will in time be available on all UNIX systems. Posix shared memory uses the `shm_open()` and `ftruncate()` system calls to create a memory segment that can be accessed via a file descriptor. This descriptor is then used with the `mmap()` system call to map the memory segment in the usual manner. The primary difference between this, and simply using `mmap()` on a scratch file to implement shared memory is that no scratch file is required (the disk space comes from the system swap space). As with System V shared memory, Posix shared memory segments exist in the operating system until explicitly destroyed (using the `shm_unlink()` system call). Unlike System V shared memory, but like all the other forms, Posix shared memory allows the caller to supply the name of the segment. This simplifies the situation in which multiple processes want to map the same segment. One of them

creates it, and the others simply map it, all of them using the same name to reference it.

Posix shared memory is the default for SHMMAP on all UNIX platforms — even those that do not yet support it. (To use System V shared memory instead, you must specify the SYSV keyword.) There are several reasons for making Posix shared memory the default for all UNIX platforms:

- To remain UNIX compliant, all platforms will have to implement the UNIX98 standard. Most have, and the remainder are currently in the process of doing so. We believe that Posix shared memory will be available on all UNIX systems very soon.
- Having different defaults for different UNIX platforms would cause unnecessary confusion; the confusion would only increase as platforms added support for Posix shared memory, causing the platform's SHMMAP default to change with later IDL releases. Since in most cases you need to know the underlying mechanism in use, the default should be easy to determine, and should not change over time.
- In the long run, it is desirable for the best option to be the default.

### Microsoft Windows

Under Microsoft Windows, the `CreateFileMapping()` system call forms the basis for shared memory as well as memory mapped files. To map a file, you open the file and then pass the handle for that file to `CreateFileMapping()`. To create a region of anonymous mapped memory instead of a mapped file, you pass a special file handle (`0xffffffff`) to `CreateFileMapping()`. In this case, the disk space used to back the shared memory is taken from the system pagefile.

`CreateFileMapping()` accepts an optional parameter (`lpname`), which if present, is used to give the resulting memory mapping object a system global name. If you specify such a name, and a mapping object with that name already exists, you will receive a handle to the existing mapping object. Otherwise, `CreateFileMapping()` creates a new mapping object for the file. Hence, to create anonymous (no file) shared memory between unrelated processes, IDL calls `CreateFileMapping()` with the special `0xffffffff` file handle, and specifies a global name for it.

A global name (supplied via the `OS_HANDLE` keyword) is the only name by which an anonymous shared memory segment can be referenced within the system. Global names are not required for memory mapped files, because each process can create a separate mapping object and use it to refer to the same file. Although this does allow the unrelated processes to see each others' changes, their views of the file will not be *coherent* (that is, identical). With coherent access, all processes see exactly the same

memory at exactly the same time because they are all mapping the same physical page of memory. To get coherent access to a memory mapped file, every process should specify the `OS_HANDLE` keyword to ensure that they use the same mapping object. Coherence is only an issue when the contents of the file are altered; when using read-only access to a mapped file, you need not be concerned with this issue.

The Windows operating system automatically destroys a mapping object when the last process with an open handle to it closes that handle. Destruction of the mapping object may be the result of an explicit call to `CloseHandle()`, or may involve an implicit close that happens when the process exits. This differs from the UNIX behavior for anonymous shared memory, and consequently the benefits and disadvantages are reversed. The advantage is that it is not possible to forget to destroy a mapping object, and end up with the operating system holding memory that is no longer useful, but which cannot be freed. On the other hand, you must ensure that at least one open handle to the object is open at all times, or the system might free an object that you intended to use again.

---

**Note**

Under Windows, when attaching to an existing memory object by providing the global segment name, IDL is not able to verify that the memory segment returned by the operating system is large enough to satisfy the IDL array specified to `SHMMAP` for its type and size. If the segment is not large enough, the IDL program will crash with an illegal memory access exception when it attempts to access memory addresses beyond the end of the segment. Hence, the IDL user must ensure that such pre-existing memory segments are long enough for the specified IDL array.

---

## Reference Counts And Memory Segment Lifecycle

You can see a list of all current memory segments created with `SHMMAP` by issuing the statement

```
HELP, /SHARED_MEMORY
```

To access a current segment, it must be tied to an IDL variable using the `SHMVAR` function. IDL maintains a reference count of the number of variables currently accessing each memory segment, and does not allow a memory segment to be removed from the IDL process as long as variables that reference it still exist.

`SHMMAP` will not allow you to create a new memory segment with the same *SegmentName* as an existing segment. You should therefore be careful to pick unique segment names. One way to ensure that segment names are unique is to not provide the *SegmentName* argument when calling `SHMMAP`. In this case, `SHMMAP` will

automatically choose a unique name, which can be obtained using the `GET_NAME` keyword.

The `SHMUNMAP` procedure is used to remove a memory segment from the IDL session. In addition, it may remove the memory segment from the system. (Whether the memory segment is removed from the system depends on the type of segment, and on the arguments used with `SHMMAP` when the segment was initially attached.) If no variables from the current IDL session are accessing the segment (that is, if the IDL-maintained reference count is 0), the segment is removed immediately. If variables in the current IDL session are still referencing the segment, the segment is marked for removal when the last such variable drops its reference. Once `SHMMAP` is called on a memory segment, no additional calls to `SHMVAR` are allowed for it within the current IDL session; this means that a segment marked by `SHMUNMAP` as *UnmapPending* cannot be used for new variables within the current IDL session.

---

**Note**

IDL has no way to determine whether a process other than itself is accessing a shared memory segment. As a result, it is possible for IDL to destroy a memory segment that is in use by another process. The specific details depend on the type of memory segment, and the options used with `SHMMAP` when the segment was loaded. When creating applications that use shared memory, you should ensure that all applications that use the segment (be they instances of IDL or any other application) communicate regarding their use of the shared memory and act in a manner that avoids this pitfall.

---

## Examples

### Example 1

Create a shared memory segment of 1000000 double-precision data elements, and then fill it with a `DINDGEN` ramp:

```
SHMMAP, 'MYSEG', /DOUBLE, 1000000
z = SHMVAR('MYSEG')
z[0] = DINDGEN(1000000)
```

---

**Note**

When using shared memory, using the explicit subscript of the variable (`z`, in this case) maintains the variable's connection with the shared memory segment. When not using shared memory, assignment without subscripting is more efficient and is recommended.

---

## Example 2

Create the same shared memory segment as the previous example, but let IDL choose the segment name:

```
SHMMAP, /DOUBLE, DIMENSION=[1000000], GET_NAME=segname
z = SHMVAR(segname)
z[0] = DINDGEN(1000000)
```

## Example 3

Create the same shared memory segment as the previous example, but use a temporary file, mapped into IDL's address space, instead of anonymous shared memory. The file needs to be the correct length for the data we will be mapping onto it. We satisfy this need while simultaneously initializing it with the DINDGEN vector by writing the vector to the file. The use of the OS\_HANDLE keyword improves performance and correctness under Windows while being quietly ignored under UNIX:

```
filename = FILEPATH('idl_scratch', /TMP)
OPENW, unit, filename, /GET_LUN
WRITEU, unit, DINDGEN(1000000)
CLOSE, unit
SHMMAP, /DOUBLE, DIMENSION=[1000000], GET_NAME=segname, $
FILENAME=filename, OS_HANDLE='idl_scratch'
z = SHMVAR(segname)
```

## Example 4

Create an anonymous shared memory segment using UNIX System V shared memory. Use of System V shared memory differs from the other methods in two ways:

- The system identifier for the segment is a number chosen by the system instead of a name selected by the user.
- With SYSV memory, you have to explicitly indicate whether the operation is a create operation (no OS\_HANDLE keyword) or merely an attach to an existing segment (OS\_HANDLE is present). The other methods create the segment as needed, and will automatically attach to a memory segment with the desired operating system handle if it already exists. The SHMMAP call does not explicitly have to specify that the segment should be created.

In this example, we will use the type and size of the existing myvar variable to determine the size of the memory:

```
SHMMAP, TEMPLATE=myvar, GET_NAME=segname, /SYSV, $
GET_OS_HANDLE=oshandle
```

In this case, the `SYSV` keyword forces the use of System V shared memory. The absence of the `OS_HANDLE` keyword tells `SHMMAP` to create the segment, instead of simply mapping an existing one. In a different IDL session running on the same machine, if you knew the proper `OS_HANDLE` value for this segment, you could attach to the segment created above as follows:

```
SHMMAP, TEMPLATE=myvar, GET_NAME=segname, /SYSV, $  
      OS_HANDLE=oshandle
```

In this case, the `OS_HANDLE` keyword tells `SHMMAP` the identifier of the memory segment, causing it to attach to the existing segment instead of creating a new one.

# SHMUNMAP

The SHMUNMAP procedure is used to remove a memory segment previously created by SHMMAP from the IDL session. In addition, it may remove the memory segment from the system. (Whether the memory segment is removed from the system depends on the type of segment, and on the arguments used with SHMMAP when the segment was initially attached.) If no variables from the current IDL session are accessing the segment (that is, if the IDL-maintained reference count is 0), the segment is removed immediately. If variables in the current IDL session are still referencing the segment, the segment is marked for removal when the last such variable drops its reference.

During this *UnmapPending* phase:

- The segment still exists in the system, so attempts to use SHMMAP to create a new segment with the same *SegmentName* will fail.
- Additional calls to SHMVAR to attach new variables to this segment will fail.

## Note

---

IDL has no way to determine whether a process other than itself is accessing a shared memory segment. As a result, it is possible for IDL to destroy a memory segment that is in use by another process. The specific details depend on the type of memory segment, and the options used with SHMMAP when the segment was loaded. When creating applications that use shared memory, you should ensure that all applications that use the segment (be they instances of IDL or any other application) communicate regarding their use of the shared memory and act in a manner that avoids this pitfall.

---

## Syntax

SHMUNMAP, *SegmentName*

## Arguments

### SegmentName

A scalar string containing the IDL name for the shared memory segment, as assigned by SHMMAP.

## Keywords

None.

## Examples

To destroy a memory segment previously created by SHMMAP with the segment name `myseg`:

```
SHMUNMAP, 'myseg'
```

[SHMDEBUG](#), [SHMMAP](#), [SHMVAR](#)

# SHMVAR

The SHMVAR function creates an IDL array variable that uses the memory from a current mapped memory segment created by the SHMMAP procedure. Variables created by SHMVAR are used in much the same way as any other IDL variable, and provide the IDL user with the ability to alter the contents of anonymous shared memory or memory mapped files.

By default, the variable created by SHMVAR is given the type and dimensions that were specified to SHMMAP when the memory segment was created. However, this default can be changed by SHMVAR via a variety of keywords as well as via the  $D_i$  arguments. The created array can be of any type except for pointer, object reference, or string. Structure types are allowed as long as they do not contain any pointers, object references, or strings.

## Note

---

When assigning values to the returned array variable, explicitly make the assignment to the first element of the returned array. For example, the following creates a shared memory segment of 1000000 double-precision data elements, and then fills it with a DINDGEN ramp

```
SHMMAP, 'MYSEG', /DOUBLE, 1000000
z = SHMVAR('MYSEG')
z[0] = DINDGEN(1000000)
```

This technique maintains the array variable's connection with the shared memory segment.

---

## Syntax

```
Result = SHMVAR(SegmentName [,  $D_1$ , ...,  $D_8$ ] [, /BYTE] [, /COMPLEX]
[, /DCOMPLEX] [, DIMENSION=value] [, /DOUBLE] [, /FLOAT]
[, /INTEGER] [, /L64] [, /LONG] [, SIZE=value] [, TEMPLATE=value]
[, TYPE=value] [, /UINT] [, /UL64] [, /ULONG] )
```

## Return Value

An IDL array variable that uses memory from a the specified mapped memory segment.

## Arguments

### SegmentName

A scalar string supplying the IDL name for the shared memory segment, as assigned by SHMMAP.

### $D_i$

The dimensions of the result. The  $D_i$  arguments can be either a single array containing the dimensions or a sequence of scalar dimensions. Up to eight dimensions can be specified. If no dimensions are specified, the parameters specified to SHMMAP are used.

## Keywords

### BYTE

Set this keyword to specify that the memory segment should be treated as a byte array.

### COMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, single-precision floating-point array.

### DCOMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, double-precision floating-point array.

### DIMENSION

Set this keyword equal to a vector of 1 to 8 elements specifying the dimensions of the result. This is equivalent to the array form of the  $D_i$  plain arguments. If no dimensions are specified, the parameters specified to SHMMAP are used.

### DOUBLE

Set this keyword to specify that the memory segment should be treated as a double-precision floating-point array.

## FLOAT

Set this keyword to specify that the memory segment should be treated as a single-precision floating-point array.

## INTEGER

Set this keyword to specify that the memory segment should be treated as an integer array.

## L64

Set this keyword to specify that the memory segment should be treated as a 64-bit integer array.

## LONG

Set this keyword to specify that the memory segment should be treated as a longword integer array.

## SIZE

Set this keyword equal to a size vector specifying the type and dimensions to be associated with the memory segment. The format of a size vector is given in the description of the [SIZE](#) function. If no dimensions are specified, the parameters specified to SHMMAP are used.

## TEMPLATE

Set this keyword equal to a variable of the type and dimensions to be associated with the memory segment. If no dimensions are specified, the parameters specified to SHMMAP are used.

## TYPE

Set this keyword to specify the type code for the memory segment. See the description of the [SIZE](#) function for a list of IDL type codes.

## UINT

Set this keyword to specify that the memory segment should be treated as a unsigned integer array.

## ULONG

Set this keyword to specify that the memory segment should be treated as a unsigned longword integer array.

## UL64

Set this keyword to specify that the memory segment should be treated as a unsigned 64-bit integer array.

## Examples

See the examples given for the [SHMMAP](#) procedure.

# SHOW3

The SHOW3 procedure combines an image, a surface plot of the image data, and a contour plot of the images data in a single tri-level display.

This routine is written in the IDL language. Its source code can be found in the file `show3.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SHOW3, Image [, X, Y] [, /INTERP] [, E_CONTOUR=structure]  
      [, E_SURFACE=structure] [, SSCALE=scale]
```

## Arguments

### Image

The two-dimensional array to display.

### X

A vector containing the X values of each column of *Image*. If the X argument is omitted, columns have values 0, 1, ..., *n*columns-1.

### Y

A vector containing the Y values of each row of *Image*. If the Y argument is omitted, rows have values 0, 1, ..., *n*rows-1.

## Keywords

### INTERP

Set this keyword to use bilinear interpolation on the pixel display. This technique is slightly slower, but for small images, it makes a better display.

### E\_CONTOUR

Set this keyword equal to an anonymous structure containing additional keyword parameters that are passed to the CONTOUR procedure. Tag names in the structure should be valid keyword arguments to CONTOUR, and the values associated with each tag should be valid keyword values.

## E\_SURFACE

Set this keyword equal to an anonymous structure containing additional keyword parameters that are passed to the SURFACE procedure. Tag names in the structure should be valid keyword arguments to SURFACE, and the values associated with each tag should be valid keyword values.

## SSCALE

Reduction scale for surface. The default is 1. If this keyword is set to a value other than 1, the array size is reduced by this factor for the surface display. That is, the number of points used to draw the wire-mesh surface is reduced. If the array dimensions are not an integral multiple of SSCALE, the image is reduced to the next smaller multiple.

## Examples

```
; Create a dataset:
A = BESELJ(SHIFT(DIST(30,20), 15, 10)/2.,0)

; Show it with default display:
SHOW3, A

; Specify X axis proportional to square root of values:
SHOW3, A, SQRT(FINDGEN(30))

; Label CONTOUR lines with double size characters, and include
; downhill tick marks:
SHOW3, A, E_CONTOUR={C_CHARSIZE:2, DOWN:1}

; Draw a surface with a skirt and scale Z axis from -2 to 2:
SHOW3, A, E_SURFACE={SKIRT:-1, ZRANGE: [-2,2]}
```

## Combining Images with Three-Dimensional Graphics

Images are combined with three-dimensional graphics, as shown in the figure below, using the transformation techniques described above.

Figure 3-109: Using `SHOW3` to Overlay an Image, Surface Mesh, and Contour

The rectangular image must be transformed so that it fits underneath the mesh drawn by `SURFACE`. The general approach is as follows:

- Use `SURFACE` to establish the general scaling and geometrical transformation. Draw no data, as the graphics made by `SURFACE` will be over-written by the transformed image.
- For each of the four corners of the image, translate the data coordinate, which is simply the subscript of the corner, into a device coordinate. The data coordinates of the four corners of an  $(m, n)$  image are  $(0, 0)$ ,  $(m-1, 0)$ ,  $(0, n-1)$ , and  $(m-1, n-1)$ . Call this data coordinate system  $(x, y)$ . Using a procedure or function similar to `CVT_TO_2D` (see “[Three-Dimensional Direct Graphic Coordinate Conversion](#)” on page 356) convert to device coordinates, which in this discussion are called  $(U, V)$ .

- The image is transformed from the original  $xy$  coordinates to a new image in  $UV$  coordinates using the `POLY_2D` function. `POLY_2D` accepts an input image and the coefficients of a polynomial in  $UV$  giving the  $xy$  coordinates in the original image. The equations for  $x$  and  $y$  are below.

$$X = S_{0,0} + S_{1,0}U + S_{1,0}V + S_{1,1}UV$$

$$Y = T_{0,0} + T_{1,0}U + T_{1,0}V + T_{1,1}UV$$

We solve for the four unknown  $S$  coefficients using the four equations relating the  $x$  corner coordinates to their  $U$  coordinates. The  $T$  coefficients are similarly found using the  $y$  and  $V$  coordinates. This can be done using matrix operators and inversion or more simply, with the procedure `POLY_WARP`.

- The new image is a rectangle that encloses the quadrilateral described by the  $UV$  coordinates. Its size is specified in the formula below:

$$(\text{MAX}(U) - \text{MIN}(U) + 2, \text{MAX}(V) - \text{MIN}(V) + 1)$$

- `POLY_2D` is called to form the new image which is displayed at device coordinate  $(\text{MIN}(U), \text{MIN}(V))$ .
- `SURFACE` is called once again to display the mesh surface over the image.
- Finally, `CONTOUR` is called with `ZVALUE` set to 1.0, placing the contour above both the image and the surface.

The `SHOW3` procedure performs these operations. It should be examined for details of how images and graphics can be combined.

The following IDL commands were used to create the previous image:

```
; Restore variables:
@cntour01
; Reduce the size of elev array:
new = REBIN(elev, 360/5, 460/5)
; Create an array of levels for CONTOUR:
levs = (FINDGEN(10)*100)+3500
; Use SHOW3. Note the use of keywords E_SURFACE
; and E_CONTOUR to pass values to the SURFACE and
; CONTOUR routines used within SHOW3.
SHOW3, new, E_SURFACE={min:2000}, E_CONTOUR={levels:levs}
```

---

### Note

See “[Running the Example Code](#)” on page 40 if IDL does not find the referenced batch file.

# SHOWFONT

The SHOWFONT procedure displays a TrueType or vector-drawn font (from the file `hersh1.chr`, located in the `resource/fonts` subdirectory of the IDL distribution) on the current graphics device.

This routine is written in the IDL language. Its source code can be found in the file `showfont.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SHOWFONT, Font, Name [, /ENCAPSULATED] [, /TT_FONT]
```

## Arguments

### Font

The index number of the font (may range from 3 to 29) or, if the `TT_FONT` keyword is set, a string that contains the name of the TrueType font to display.

### Name

A string that contains the text of a title to appear at the top of the font display.

## Keywords

### ENCAPSULATED

Set this keyword, if the current graphics device is “PS”, to make encapsulated PostScript output.

### TT\_FONT

If this keyword is set, the specified font will be interpreted as a TrueType font.

## Examples

To create a display of the Helvetica italic TrueType font on the screen:

```
SHOWFONT, 'Helvetica Italic', 'Helvetica Italic', /TT_FONT
```

To create a display of Font 3 for PostScript:

```
; Set output to PostScript:
SET_PLOT, 'PS'

; Specify the output filename. If we didn't specify this, the file
; would be saved as idl.ps by default:
DEVICE, FILENAME='font3.ps'

;Display font 3:
SHOWFONT, 3, 'Simplex Roman'

; Close the new PS file:
DEVICE, /CLOSE
```

# SIMPLEX

The SIMPLEX function uses the simplex method to solve linear programming problems. Given a set of  $N$  independent variables  $X_i$ , where  $i = 0, \dots, N$ , the simplex method seeks to maximize the following function,

$$Z = a_1 X_1 + a_2 X_2 + \dots a_N X_N$$

with the assumption that  $X_i \geq 0$ . The  $X_i$  are further constrained by the following equations:

$$b_{j1} X_1 + b_{j2} X_2 + \dots b_{jN} X_N \leq c_j \quad j = 1, 2, \dots, M_1$$

$$b_{j1} X_1 + b_{j2} X_2 + \dots b_{jN} X_N \geq c_j \quad j = M_1 + 1, M_1 + 2, \dots, M_1 + M_2$$

$$b_{j1} X_1 + b_{j2} X_2 + \dots b_{jN} X_N = c_j \quad j = M_1 + M_2 + 1, M_1 + M_2 + 2, \dots, M$$

where  $M = M_1 + M_2 + M_3$  is the total number of equations, and the constraint values  $c_j$  must all be positive.

To solve the above problem using the SIMPLEX function, the  $Z$  equation is rewritten as a vector:

$$Z_{\text{equation}} = [a_1 \ a_2 \ \dots a_N]$$

The constraint equations are rewritten as a matrix with  $N+1$  columns and  $M$  rows, where all of the  $b$  coefficients have had their sign reversed:

$$\text{Constraints} = \begin{bmatrix} c_1 & -b_{11} & -b_{12} \dots -b_{1N} \\ c_2 & -b_{21} & -b_{22} \dots -b_{2N} \\ \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \\ c_M & -b_{M1} & -b_{M2} \dots -b_{MN} \end{bmatrix}$$

---

## Note

The constraint matrix must be organized so that the coefficients for the less-than (<) equations come first, followed by the coefficients of the greater-than (>) equations, and then the coefficients of the equal (=) equations.

---

The `SIMPLEX` function is based on the routine `simplex` described in section 10.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = SIMPLEX( Zequation, Constraints, M1, M2, M3
  [, Tableau [, Izrov [, Iposv] ] ] [, /DOUBLE] [, EPS = value]
  [, STATUS = variable] )
```

## Return Value

The *Result* is a vector of  $N+1$  elements containing the maximum  $Z$  value and the values of the  $N$  independent  $X$  variables (the optimal feasible vector):

$$\text{Result} = \left[ Z_{\max} \quad X_1 \quad X_2 \dots X_N \right]$$

## Arguments

### Zequation

A vector containing the  $N$  coefficients of the  $Z_{\text{equation}}$  to be maximized.

### Constraints

An array of  $N+1$  columns by  $M$  rows containing the constraint values and coefficients for the constraint equations.

### M1

An integer giving the number of less-than constraint equations contained in *Constraints*.  $M1$  may be zero, indicating that there are no less than constraints.

### M2

An integer giving the number of greater-than constraint equations contained in *Constraints*.  $M2$  may be zero, indicating that there are no greater than constraints.

### M3

An integer giving the number of equal-to constraint equations contained in *Constraints*.  $M3$  may be zero, indicating that there are no equal to constraints. The total of  $M1 + M2 + M3$  should equal  $M$ , the number of constraint equations.

## Tableau

Set this optional argument to a named variable in which to return the output array from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

## Izrov

Set this optional argument to a named variable in which to return the output izrov variable from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

## Iposv

Set this optional argument to a named variable in which to return the output iposv variable from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

## Keywords

### DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set DOUBLE to 0 to use single-precision for computations and to return a single-precision result. The default is /DOUBLE if any of the inputs are double-precision, otherwise the default is 0.

### EPS

Set this keyword to a number close to machine accuracy, which is used to test for convergence at each iteration. The default is  $10^{-6}$ .

### STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

Value	Description
0	Successful completion.
1	The objective function is unbounded.

Table 3-115: SIMPLEX Function Status Values

Value	Description
2	No solution satisfies the given constraints.
3	The routine did not converge.

Table 3-115: SIMPLEX Function Status Values (Continued)

## Examples

The following example is taken from *Numerical Recipes in C*.

Find the  $Z$  value which maximizes the equation  $Z = X_1 + X_2 + 3 X_3 - 0.5 X_4$ , with the following constraints:

$$X_1 + 2X_3 \leq 740$$

$$2X_2 - 7X_4 \leq 0$$

$$X_2 - X_3 + 2X_4 \geq 0.5$$

$$X_1 + X_2 + X_3 + X_4 = 9$$

To find the solution, enter the following code at the IDL command line:

```

; Set up the Zequation with the X coefficients.
Zequation = [1,1,3,-0.5]
; Set up the Constraints matrix.
Constraints = [ $
    [740, -1, 0, -2, 0], $
    [ 0, 0, -2, 0, 7], $
    [0.5, 0, -1, 1, -2], $
    [ 9, -1, -1, -1, -1] ]
; Number of less-than constraint equations.
m1 = 2
; Number of greater-than constraint equations.
m2 = 1
; Number of equal constraint equations.
m3 = 1
;
; Call the function.
result = SIMPLEX(Zequation, Constraints, m1, m2, m3)
;
; Print out the results.
PRINT, 'Maximum Z value is: ', result[0]
PRINT, 'X coefficients are: '
PRINT, result[1:*]

```

IDL prints:

```
Maximum Z value is:      17.0250
X coefficients are:
      0.000000      3.32500      4.72500      0.950000
```

Therefore, the optimal feasible vector is  $X_1 = 0.0$ ,  $X_2 = 3.325$ ,  $X_3 = 4.725$ , and  $X_4 = 0.95$ .

# SIN

The periodic function SIN returns the trigonometric sine of  $X$ .

## Syntax

$Result = SIN(X)$

## Return Value

Returns the double-precision floating-point, complex or single-precision floating-point value.

## Arguments

### $X$

The angle for which the sine is desired, specified in radians. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers:

$$SIN(x) = (EXP(i*x) + 1/EXP(i*x))/(2*i)$$

where  $i$  is defined as COMPLEX(0, 1).

If input argument  $X$  is an array, the result has the same structure, with each element containing the sine of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To find the sine of 0.5 radians and print the result, enter:

```
PRINT, SIN(0.5)
```

The following example plots the SIN function between 0 and  $2\pi$  with 100 intervals:

```
X = 2*!PI/100 * FINDGEN(100)
PLOT, X, SIN(X)
```

---

**Note**

!PI is a read-only system variable that contains the single-precision value for  $\pi$ .

---

# SINDGEN

The SINDGEN function returns a string array with the specified dimensions. Each element of the array is set to the string representation of the value of its one-dimensional subscript, using IDL's default formatting rules.

## Syntax

$$\text{Result} = \text{SINDGEN}(D_1 [, \dots, D_8])$$

## Return Value

Returns a string array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Examples

To create S, a six-element string vector with each element set to the string value of its subscript, enter:

```
S = SINDGEN(6)
```

# SINH

The SINH function returns the hyperbolic sine of  $X$ .

## Syntax

$Result = \text{SINH}(X)$

## Return Value

Returns the double-precision floating-point, complex or single-precision floating-point value.

## Arguments

### $X$

The angle for which the hyperbolic sine is desired, specified in radians. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. SINH is defined as:

$$\sinh x = (e^x - e^{-x}) / 2$$

If  $X$  is an array, the result has the same structure, with each element containing the hyperbolic sine of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To find the hyperbolic sine of each element in the array [.5, .2, .4] and print the result, enter:

```
PRINT, SINH([.5, .2, .4])
```

To plot the SINH function between 0 and  $2\pi$  with 100 intervals, enter:

```
X = 2*!PI/100 * FINDGEN(100)  
PLOT, X, SINH(X)
```

### Note

# SIZE

The `SIZE` function returns size and type information for its argument if no keywords are set. If a keyword is set, `SIZE` returns the specified quantity.

## Syntax

```
Result = SIZE( Expression [, /L64] [, /DIMENSIONS | , /FILE_LUN | ,
  /FILE_OFFSET | , /N_DIMENSIONS | , /N_ELEMENTS | , /SNAME, | ,
  /STRUCTURE | , /TNAME | , /TYPE] )
```

## Return Value

If no keywords are set, `SIZE` returns a vector of integer type. The first element is equal to the number of dimensions of *Expression*. This value is zero if *Expression* is scalar or undefined. The next elements contain the size of each dimension, one element per dimension (none if *Expression* is scalar or undefined). After the dimension sizes, the last two elements contain the type code (zero if undefined) and the number of elements in *Expression*, respectively. The type codes are listed below.

If a keyword is set, `SIZE` returns the specified information.

## IDL Type Codes and Names

The following table lists the IDL type codes and type names returned by the `SIZE` function:

Type Code	Type Name	Data Type
0	UNDEFINED	Undefined
1	BYTE	Byte
2	INT	Integer
3	LONG	Longword integer
4	FLOAT	Floating point
5	DOUBLE	Double-precision floating
6	COMPLEX	Complex floating

Table 3-116: IDL Type Codes and Names

Type Code	Type Name	Data Type
7	STRING	String
8	STRUCT	Structure
9	DCOMPLEX	Double-precision complex
10	POINTER	Pointer
11	OBJREF	Object reference
12	UINT	Unsigned Integer
13	ULONG	Unsigned Longword Integer
14	LONG64	64-bit Integer
15	ULONG64	Unsigned 64-bit Integer

Table 3-116: IDL Type Codes and Names (Continued)

## Arguments

### Expression

The expression for which size information is requested.

## Keywords

With the exception of L64, the following keywords determine the return value of the SIZE function and are mutually exclusive — specify at most one of the following.

### DIMENSIONS

Set this keyword to return the dimensions of *Expression*. If *Expression* is scalar, the result is a scalar containing a 0. For arrays, the result is an array containing the array dimensions. The result is a 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. If *Expression* is undefined, IDL reports eight dimensions.

### FILE\_LUN

Set this keyword to return the file unit to which *Expression* is associated, if it is an IDL file variable, as created with the ASSOC function. If *Expression* is not a file variable, 0 is returned (0 is not a valid file unit for ASSOC).

## FILE\_OFFSET

Set this keyword to return the ASSOC file offset for *Expression*. In the case of ASSOC file variables, this is the value of the *Offset* argument specified to ASSOC when the variable was created. In the case of regular non-file variables, 0 is returned. The result will be 32-bit integer when possible, and 64-bit integer if the size of the offset requires it. Set [L64](#) to force a 64-bit integer to be returned in all cases.

## L64

By default, the result of SIZE is 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. In addition to affecting the default result, L64 also affects the output from the [DIMENSIONS](#), [FILE\\_OFFSET](#), [N\\_ELEMENTS](#), and [STRUCTURE](#) keywords.

### Note

---

Only 64-bit versions of IDL are capable of creating variables requiring 64-bit SIZE output. Check the value of !VERSION.MEMORY\_BITS to see if your IDL is 64-bit or not.

---

## N\_DIMENSIONS

Set this keyword to return the number of dimension in *Expression*, if it is an array. If *Expression* is scalar or undefined, 0 is returned.

## N\_ELEMENTS

Set this keyword to return the number of data elements in *Expression*. Setting this keyword is equivalent to using the N\_ELEMENTS function. The result will be 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. If *Expression* is undefined, 0 is returned.

## SNAME

Set this keyword to return the name of the structure definition for *Expression*, if *Expression* is a named structure. If *Expression* is not a named structure, a null string is returned. The string returned by this keyword is the same as that returned by TAG\_NAMES(/STRUCTURE\_NAME).

## STRUCTURE

Set this keyword to return all available information about *Expression* in a structure.

**Note**

Since the structure is a named structure, the size of its fields is fixed. The result is an IDL\_SIZE (32-bit) structure when possible, and an IDL\_SIZE64 structure otherwise. Set [L64](#) to force an IDL\_SIZE64 structure to be returned in all cases.

The following are descriptions of the fields in the returned structure:

Field	Description
TYPE_NAME	Name of IDL type of <i>Expression</i>
STRUCTURE_NAME	If <i>Expression</i> is a named (not anonymous) structure, the name of the structure definition; otherwise, a null string
TYPE	Type code of <i>Expression</i>
FILE_LUN	If <i>Expression</i> is an IDL file variable, as created with the ASSOC function, the file unit to which it is associated; otherwise, 0
FILE_OFFSET	If <i>Expression</i> is an IDL file variable, as created with the ASSOC function, the offset specified to ASSOC when the variable was created; otherwise, 0
N_ELEMENTS	Number of data elements in <i>Expression</i>
N_DIMENSIONS	If <i>Expression</i> is an array, the number of dimensions; otherwise, 0
DIMENSIONS	An 8-element array containing the dimensions of <i>Expression</i>

Table 3-117: Structure Fields

**TNAME**

Set this keyword to return the IDL type of *Expression* as a string. See [“IDL Type Codes and Names”](#) on page 2118 for details.

**TYPE**

Set this keyword to return the IDL type code for *Expression*. See [“IDL Type Codes and Names”](#) on page 2118 for details. For an example illustrating how to determine

the type code of an expression, see [“Example: Returning the IDL Type Code of an Expression”](#) on page 2122.

## Examples

Print the size information for a 10 by 20 floating-point array by entering:

```
PRINT, SIZE(FINDGEN(10, 20))
```

IDL prints:

```
2 10 20 4 200
```

This IDL output indicates the array has 2 dimensions, equal to 10 and 20, a type code of 4, and 200 elements total. Similarly, to print only the number of dimensions of the same array:

```
PRINT, SIZE(FINDGEN(10, 20), /N_DIMENSIONS)
```

IDL prints:

```
2
```

### Example: Returning the IDL Type Code of an Expression

The following example illustrates two ways in which to determine the type code of the input expression (see [“IDL Type Codes and Names”](#) on page 2118 for a list). The type code is always the next to last element in the result returned by the `SIZE` function. Using this information, and the `N_ELEMENTS` procedure, you can quickly access the data’s type code. For example:

```
array = [[1,2,3], [4,5,6], [7,8,9]]

; A more flexible method:
sz = SIZE(array)
n = N_ELEMENTS(sz)
type = sz[n-2]
```

The second method involves using the `TYPE` keyword to `SIZE`. In this case, the value returned by the `SIZE` function contains only the type code of the input expression. You can use the `TNAME` keyword to return the type name. Select any image file and the pixel data type will be printed in the Output window.

```
; Select an image file.
result = DIALOG_READ_IMAGE(FILE=selectedFile, IMAGE=image)
type = SIZE(image, /TYPE)
typeName = SIZE(image, /TNAME)
PRINT, "Type code = ", type, " type code name = ", typeName
```

## Example: Returning Array Dimension Information

Assume A is an integer array with dimensions of (3,4,5). The statements:

```
arr = INDGEN(3,4,5)
S = SIZE(arr)
```

assign to the variable S a six-element vector containing:

Element	Value	Description
$S_0$	3	Three dimensions
$S_1$	3	First dimension
$S_2$	4	Second dimension
$S_3$	5	Third dimension
$S_4$	2	Integer type
$S_5$	60	Number of elements = 3*4*5

*Table 3-118: SIZE Values*

The following code segment checks to see if the variable arr is two-dimensional and extracts the dimensions:

```
;Create a variable.
arr = [[1,2,3],[4,5,6]]

;Get size vector.
S = SIZE(arr)

;Check if two dimensional.
IF S[0] NE 2 THEN $
    ;Print error message.
    MESSAGE, 'Variable a is not two dimensional.'

;Get number of columns and rows.
NX = S[1] & NY = S[2]

PRINT, 'Array is ', NX, ' columns by ', NY, ' rows.'
```

IDL prints:

```
Array is      3 columns by      2 rows.
```

**Note**

Also see “[Padding Images](#)” in Chapter 2 of the *Image Processing in IDL* manual for an example that uses `SIZE` to add pixels around the edges of an image. The padding provides space for annotations or acts as a boundary when using advanced filtering techniques.

## Version History

Original	Introduced
6.1	Added <code>FILE_OFFSET</code> and <code>SNAME</code> keywords Added <code>FILE_OFFSET</code> and <code>STRUCTURE_NAME</code> fields to <code>STRUCTURE</code>

# SKEWNESS

The SKEWNESS function computes the statistical skewness of an  $n$ -element vector. Skewness determines whether a distribution is symmetric about its maximum. Positive skewness indicates the distribution is skewed to the right, with a longer tail to the right of the distribution maximum. Negative skewness indicates the distribution is skewed to the left, with a longer tail to the left of the distribution maximum.

SKEWNESS calls the IDL function MOMENT.

## Syntax

```
Result = SKEWNESS( X [, /DOUBLE] [, /NAN] )
```

## Return Value

Returns the floating point or double precision statistical skewness. If the variance of the vector is zero, the skewness is not defined, and SKEWNESS returns !VALUES.F\_NAN as the result.

## Arguments

### X

A numeric vector.

## Keywords

### DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]
; Compute the skewness:
result = SKEWNESS(x)
PRINT, 'Skewness = ', result
```

IDL prints:

```
Skewness =      -0.0942851
```

## Version History

5.1	Introduced

# SKIP\_LUN

The SKIP\_LUN procedure reads data in an open file and moves the file pointer. It is useful in situations where it is necessary to skip over a known amount of data in a file without the requirement of having the data available in an IDL variable. SKIP\_LUN can skip over a fixed amount of data, specified in bytes or lines of text, or can skip over the remainder of the input file from the current position to end of file. Since SKIP\_LUN actually performs an input operation to advance the file pointer, it is not as efficient as POINT\_LUN for skipping over a fixed number of bytes in a disk file. For that reason, use of POINT\_LUN is preferred when possible. SKIP\_LUN is especially useful in situations such as:

- Skipping over a fixed number of lines of text. Since lines of text can have variable length, it can be difficult to use POINT\_LUN to skip them.
- Skipping data from a file that is not a regular disk file (for example, data from an internet socket).

## Syntax

```
SKIP_LUN, FromUnit, [, Num] [, /EOF] [, /LINES]  
[, /TRANSFER_COUNT=variable]
```

## Arguments

### FromUnit

An integer that specifies the file unit for the file in which the file pointer is to be moved. Data in *FromUnit* is skipped, starting at the current position of the file pointer. The file pointer is advanced as data is read and skipped. The file specified by *FromUnit* must be open, and must not have been opened with the RAWIO keyword to OPEN.

### Num

The amount of data to skip. This value is specified in bytes, unless the LINES keyword is specified, in which case it is taken to be the number of text lines. If *Num* is not specified, SKIP\_LUN acts as if the EOF keyword has been set, and skips all data in *FromUnit* (the source file) from the current position of the file pointer to the end of the file.

If *Num* is specified and the source file comes to end of file before the specified amount of data is skipped, `SKIP_LUN` issues an end-of-file error. The `EOF` keyword alters this behavior.

## Keywords

### EOF

Set this keyword to ignore the value given by *Num* (if present) and instead skip all data from the current position of the file pointer in *FromUnit* and the end of the file.

#### Note

If `EOF` is set, no end-of-file error is issued even if the amount of data skipped does not match the amount specified by *Num*. The `TRANSFER_COUNT` keyword can be used with `EOF` to determine how much data was skipped.

### LINES

Set this keyword to indicate that the *Num* argument specifies the number of lines of text to be skipped. By default, the *Num* argument specifies the number of bytes of data to skip.

### TRANSFER\_COUNT

Set this keyword equal to a named variable that will contain the amount of data skipped. If `LINES` is specified, this value is the number of lines of text. Otherwise, it is the number of bytes. `TRANSFER_COUNT` is primarily useful in conjunction with the `EOF` keyword. If `EOF` is not specified, `TRANSFER_COUNT` will be the same as the value specified for *Num*.

## Examples

Skip the next 8 lines of text from a file:

```
SKIP_LUN, FromUnit, 8, /LINES
```

Skip the remainder of the data in a file, and use the `TRANSFER_COUNT` keyword to determine how much data was skipped:

```
SKIP_LUN, FromUnit, /EOF, TRANSFER_COUNT=n
```

Skip the remainder of the text lines in a file, and use the `TRANSFER_COUNT` keyword to determine how many lines were skipped:

```
SKIP_LUN, FromUnit, /EOF, /LINES, TRANSFER_COUNT=n
```

# SLICER3

The IDL SLICER3 is a widget-based application to visualize three-dimensional datasets. This program supersedes the SLICER program.

This routine is written in the IDL language. Its source code can be found in the file  `slicer3.pro`  in the  `lib`  subdirectory of the IDL distribution.

---

## Note

See [“The SLICER3 Graphical User Interface”](#) on page 2132 for details on working with volumetric data within this application.

---

## Syntax

```
SLICER3 [, hData3D] [, DATA_NAMES=string/string_array] [, /DETACH]
      [, GROUP=widget_id] [, /MODAL]
```

## Arguments

### *hData3D*

A pointer to a three-dimensional data array, or an array of pointers to multiple three-dimensional arrays. If multiple arrays are specified, they all must have the same X, Y, and Z dimensions. If *hData3D* is not specified, SLICER3 creates a 2 x 2 x 2 array of byte data using the IDL BYTARR function. You can also load data interactively via the File menu of the SLICER3 application (see [“Examples”](#) on page 2146 for details).

---

## Note

If data are loaded in this fashion, any data passed to SLICER3 via a pointer (or pointers) is deleted, and the pointers become invalid.

---

## Keywords

### DATA\_NAMES

Set this keyword equal to a string array of names for the data. The names appear on the droplist widget for the current data. If the number of elements of DATA\_NAMES is less than the number of elements in *hData3D* then default names will be generated for the unnamed data.

## DETACH

Set this keyword to place the drawing area in a window that is detached from the SLICER3 control panel. The drawing area can only be detached if SLICER3 is not run as a modal application.

## GROUP

Set this keyword equal to the Widget ID of an existing widget that serves as the “group leader” for the SLICER3 graphical user interface. When a group leader is destroyed, all widgets in the group are also destroyed. If SLICER3 is started from a widget application, then GROUP should *always* be specified.

## MODAL

Set this keyword to block user interaction with all other widgets (and block the command line) until the SLICER3 exits. If SLICER3 is started from some other widget-based application, then it is usually advisable to run SLICER3 with the MODAL keyword set.

### Note

---

SLICER3 modifies the current color table, as well as various elements of the plotting system (i.e., the “!X”, “!Y”, “!Z”, and “!P” system variables). If the MODAL keyword is set (recommended), then SLICER3 will, upon exit, restore these system variables (and the color tables) to the values they had when SLICER3 was started.

---

## The SLICER3 Graphical User Interface

Figure 3-110: SLICER3 Graphical User Interface

The following options are available via SLICER3's graphical user interface.

### File Menu

#### Load

Select this menu option to choose a file containing a 3-D array (or arrays) to load into SLICER3. The file must have been written in the format specified in the following table. For each data array in the file, the following values must be included. Note that the first six values are returned by the IDL SIZE function; see “Examples” on page 2146 for an example of how to create a data file suitable for SLICER3 with just a few IDL commands.

Data item	Data Type	Number of Bytes
Number of dimension in array. <b>Note</b> - This is always 3 for valid SLICER3 data.	long	4

Table 3-119: SLICER3 Data File Structure

Data item	Data Type	Number of Bytes
Size of first dimension.	long	4
Size of second dimension.	long	4
Size of third dimension.	long	4
Data type (Must be type 1 through 5. See <a href="#">“SIZE”</a> on page 2118 for a list of data types.)	long	4
Total number of elements (dimX, dimY, dimZ).	long	4
Number of characters in data name. (See <a href="#">“STRLEN”</a> on page 2227 for the easiest way to determine this number.)	long	4
Data name	byte	strlen()
3-D data array.	varies	varies

*Table 3-119: SLICER3 Data File Structure (Continued)*

If multiple arrays are present in the file, they must all have the same dimensions.

**Note**

Files saved by the “Save Subset” operation (see below) are suitable for input via the “Load” operation.

Data files that are moved from one platform to another may not load as expected, due to byte ordering differences. See the [BYTEORDER](#) and [SWAP\\_ENDIAN](#) for details.

**Save/Save Subset**

SLICER3 must be in BLOCK mode to for this option to be available.

Select this menu option to save a subset of the 3-D data enclosed in the current block to the specified file. Subsets saved in this fashion are suitable for loading via the “Load” menu option. If multiple 3-D arrays are available when this option is selected, multiple subsets are saved to the file.

**Save/Save Tiff Image**

Select this menu option to save the contents of the current SLICER3 image window as a TIFF image in the specified file. When running in 8-bit mode, a “Class P” palette

color TIFF file is created. In 24-bit mode, a “Class R” (interleaved by image) TIFF file is created.

### **Quit**

Select this menu option to exit SLICER3.

## **Tools Menu**

### **Erase**

Select this menu option to erase the display window and delete all the objects in the display list.

### **Delete/...**

As graphical objects are created, they are added to the display list. Select this menu option to delete a specific object from the list. When an object is deleted, the screen is redrawn with the remaining objects.

### **Colors/Reset Colors**

Select this menu option to restore the original color scheme.

### **Colors/Differential Shading**

Use this menu option to change the percentage of differential shading applied to the X, Y, and Z slices.

### **Colors/Slice/Block**

Use this menu option to launch the XLOADCT application to modify the colors used for slices and blocks

### **Colors/Surface**

Use this menu option to launch the XLOADCT application to modify the colors used for isosurfaces.

### **Colors/Projection**

Use this menu option to launch the XLOADCT application to modify the colors used for projections.

### **Note**

---

On some platforms, the selected colors may not become visible until after you exit the “XLOADCT” application.

---

## Options

Select this menu option to display a panel that allows you to set:

- The axis visibility.
- The wire-frame cube visibility.
- The display window size.

## Main Draw Window

Operations available in the Main Draw Window are dependent on the mode selected in the Mode pulldown menu. In general, when coordinate input is required from the user, it is performed by clicking a mouse button on the “surface” of the wire-frame cube that surrounds the data. This 3-D location is then used as the basis for whatever input is needed. In most cases, the “front” side of the cube is used. In a few cases, the coordinate input is on the “back” side of the cube.

## Data Pulldown Menu

If multiple datasets are currently available in SLICER3, this menu allows you to select which data will be displayed in the Main Draw Window. Slices, blocks, iso-surfaces, etc. are created from the currently selected data. If only one dataset is loaded, this menu is inactive.

## Mode Pulldown Menu

This menu is used to select the current mode of operation.

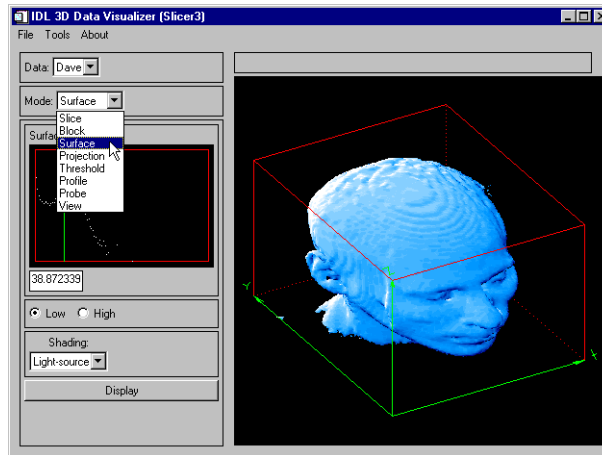

Figure 3-111: Mode Pulldown Menu

### Slice Mode

To display a slice, click and drag the left mouse button on the wire-frame cube. When the button is released, a slice through the data will be drawn at that location.

### Draw Radio Button

When in Draw mode, new slices will be merged into the current Z-buffer contents.

### Expose Radio Button

When in Expose mode, new slices will be drawn in front of everything else.

### Orthogonal Radio Button

When in Orthogonal mode, use the left mouse button in the main draw window to position and draw an orthogonal slicing plane. Clicking the right mouse button in the main draw window (or any mouse button in the small window) will toggle the slicing plane orientation.

## **X/Y/Z Radio Buttons**

- X: This sets the orthogonal slicing plane orientation to be perpendicular to the X axis.
- Y: This sets the orthogonal slicing plane orientation to be perpendicular to the Y axis.
- Z: This sets the orthogonal slicing plane orientation to be perpendicular to the Z axis.

## **Oblique Radio Button**

Clicking any mouse button in the small window will reset the oblique slicing plane to its default orientation.

## **Normal Radio Button**

When in this mode, click and drag the left mouse button in the big window to set the surface normal for the oblique slicing plane.

## **Center Radio Button**

When in this mode, click and drag the left mouse button in the big window to set the center point for the surface normal.

## **Display Button**

Clicking this button will cause an oblique slicing plane to be drawn.

## Block Mode

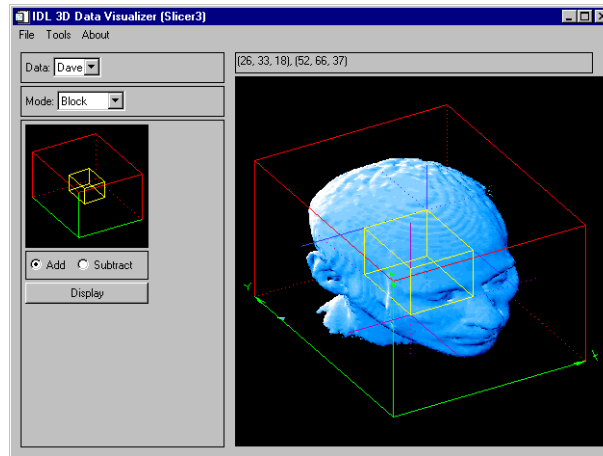

Figure 3-112: Block Mode

When in Block mode, use the left mouse button in the main draw window to set the location for the “purple” corner of the block. Use the right mouse button to locate the opposite “blue” corner of the block. When in Block mode, the “Save Subset” operation under the main “File” menu is available.

### Add

When in this mode, the block will be “added” to the current Z-buffer contents.

### Subtract

When in this mode, the block will be “subtracted” from the current Z-buffer contents. Subtract mode is only effective when the block intersects some other object in the display (such as an iso-surface).

### Display Button

Clicking this button will cause the block to be drawn.

## Surface Mode

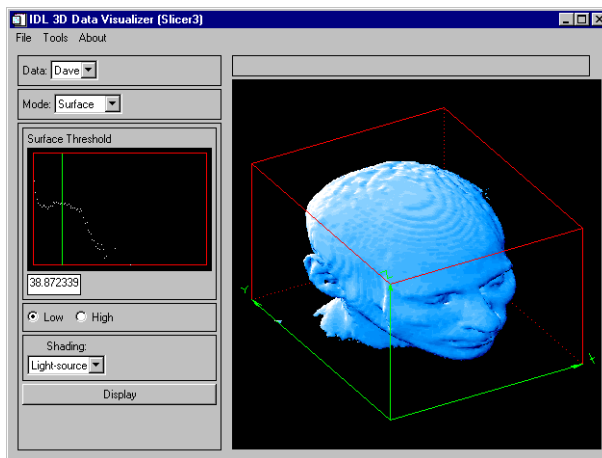

Figure 3-113: Surface Mode

An iso-surface is like a contour line on a contour map. On one side of the line, the elevation is higher than the contour level, and on the other side of the line, the elevation is lower than the contour level. An iso-surface, however, is a 3-D surface that passes through the data such that the data values on one side of the surface are higher than the threshold value, and on the other side of the surface, the data values are lower than the threshold value.

When in Surface mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag a mouse button on this plot to set the iso-surface threshold value. This value is also shown in the text widget below the plot. The threshold value may also be set by typing a new value in this text widget. The histogram plot is affected by the current threshold settings. (See Threshold mode, below).

### Low

Selecting this mode will cause the iso-surface polygon facing to face towards the lower data values. Usually, this is the mode to use when the iso-surface is desired to surround high data values.

## High

Selecting this mode will cause the iso-surface polygon facing to face towards the higher data values. Usually, this is the mode to use when the iso-surface is desired to surround low data values.

## Shading pulldown menu

Iso-surfaces are normally rendered with light-source shading. If multiple datasets are currently loaded, then this menu allows the selection of a different 3-D array for the source of the iso-surface shading values. If only one dataset is currently loaded, then this menu is inactive.

## Display Button

Clicking this button will cause the iso-surface to be created and drawn. Iso-surfaces often consist of tens of thousands of polygons, and can sometimes take considerable time to create and render.

## Projection Mode

Figure 3-114: Projection Mode

A “voxel” projection of a 3-D array is the projection of the data values within that array onto a viewing plane. This is similar to taking an X-ray image of a 3-D object.

**Max**

Select this mode for a Maximum intensity projection.

**Avg**

Select this mode for an Average intensity projection.

**Low**

Select this mode for a Low resolution projection.

**Med**

Select this mode for a Medium resolution projection.

**High**

Select this mode for a High resolution projection.

**Depth Queue % Slider**

Use the slider to set the depth queue percent. A value of 50, for example, indicates that the farthest part of the projection will be 50% as bright as the closest part of the projection.

**Display Button**

Clicking this button will cause the projection to be calculated and drawn. Projections can sometimes take considerable time to display. Higher resolution projections take more computation time.

## Threshold Mode

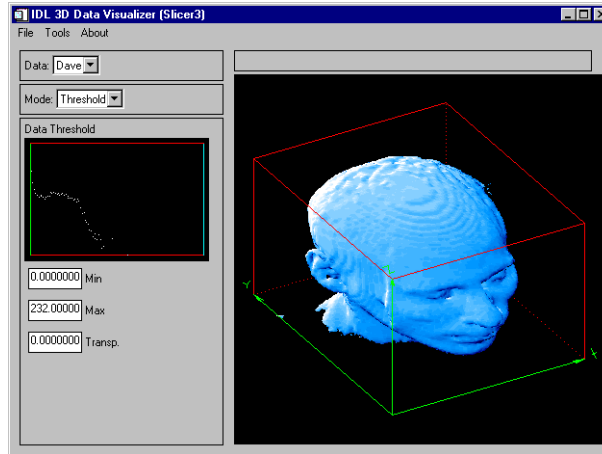

Figure 3-115: Threshold Mode

When in Threshold mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag the left mouse button on this plot to set the minimum and maximum threshold values. To expand a narrow range of data values into the full range of available colors, set the threshold range before displaying slices, blocks, or projections. The threshold settings also affect the histogram plot in “Surface” mode. The minimum and maximum threshold values are also shown in the text widgets below the histogram plot.

Click and drag the right mouse button on the histogram plot to set the transparency threshold. Portions of any slice, block, or projection that are less than the transparency value are not drawn (clear). Iso-surfaces are not affected by the transparency threshold. The transparency threshold value is also shown in a text widget below the histogram plot.

### Min

In this text widget, a minimum threshold value can be entered.

### Max

In this text widget, a maximum threshold value can be entered.

## Transp.

In this text widget, a transparency threshold value can be entered.

## Profile Mode

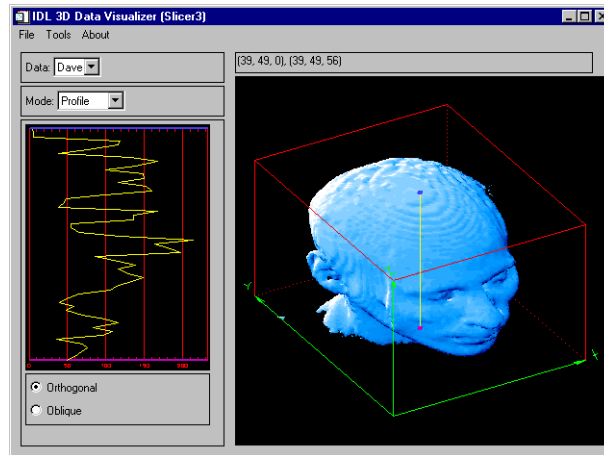

Figure 3-116: Profile Mode

In Profile mode, a plot is displayed showing the data values along a line. This line is also shown superimposed on the data in the main draw window. The bottom of the plot corresponds to the “purple” end of the line, and the top of the plot corresponds to the “blue” end of the line.

### Orthogonal

Click and drag the left mouse button to position the profile line, based upon a point on the “front” faces of the wire-frame cube. Click and drag the right mouse button to position the profile line, based upon a point on the “back” faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

### Oblique

Click and drag the left mouse button to position the “purple” end of the profile line on one of the “front” faces of the wire-frame cube. Click and drag the right mouse button to position the “blue” end of the profile line on one of the “back” faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

## Probe Mode

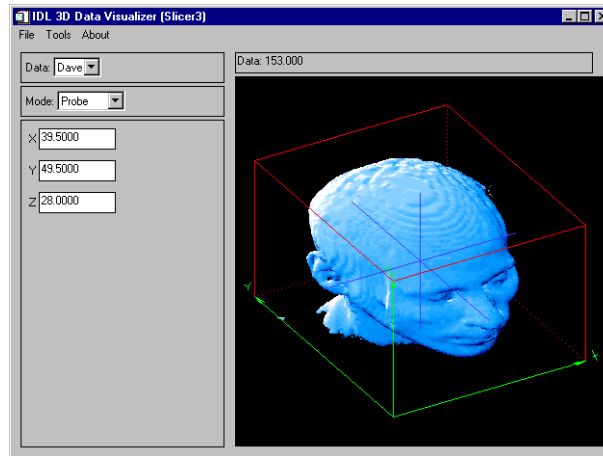

Figure 3-117: Probe Mode

In Probe mode, click and drag a mouse button over an object in the main draw window. The actual X-Y-Z location within the data volume is displayed in the three text widgets. Also, the data value at that 3-D location is displayed in the status window, above the main draw window. If the cursor is inside the wire-frame cube, but not on any object, then the status window displays “No data value”, and the three text widgets are empty. If the cursor is outside the wire-frame cube, then the status window and text widgets are empty.

### **X**

Use this text widget to enter the X coordinate for the probe.

### **Y**

Use this text widget to enter the Y coordinate for the probe.

### **Z**

Use this text widget to enter the Z coordinate for the probe.

## View Mode

Figure 3-118: View Mode

In view mode, a small window shows the orientation of the data cube in the current view. As view parameters are changed, this window is dynamically updated. The main draw window is then updated when the user clicks on “Display”, or exits View mode.

### Display

Clicking on this button will cause the objects in the main view window to be drawn in the new view. If any view parameters have been changed since the last time the main view was updated, the main view will be automatically redrawn when the user exits View mode.

### 1st Rotation

Use this slider to set the angle of the first view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

### 2nd Rotation

Use this slider to set the angle of the second view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

### Zoom % Slider

Use this slider to set the zoom factor percent. Depending upon the view rotations, SLICER3 may override this setting to ensure that all eight corners of the data cube are within the window.

### Z % Slider

Use this slider to set a scale factor for the Z axis (to compensate for the data's aspect ratio).

## Operational Details

The SLICER3 procedure has the following side effects:

- SLICER3 sets the position for the light source and enables back-facing polygons to be drawn (see the IDL “SET\_SHADING” command).
- SLICER3 overwrites the existing contents of the Z-buffer. Upon exiting SLICER3, the Z-buffer contents are the same as what was last displayed by SLICER3.
- On 24-bit displays, SLICER3 sets the device to non-decomposed color mode (DEVICE, DECOMPOSED=0).
- SLICER3 overwrites the existing color table. Upon exiting SLICER3, the color table (as displayed in another window, such as PLOT) is the same as what was last displayed by SLICER3.

On 24-bit displays, you can often improve performance by running SLICER3 in 8-bit mode. This can be accomplished (on some platforms) by entering the following command at the start of the IDL session (before any windows are created):

```
Device, Pseudo_Color=8
```

## Examples

### Note

---

Also see “[Planar Slicing of Volumetric Data](#)” in Chapter 2 of the *Image Processing in IDL* manual for additional examples.

---

The following IDL commands open a data file from the IDL distribution and load it into SLICER3:

```
; Choose a data file:
file=FILEPATH('head.dat', SUBDIR=['examples', 'data'])
```

```

; Open the data file:
OPENR, UNIT, file, /GET_LUN

; Create an array to hold the data:
data = BYTARR(80, 100, 57, /NOZERO)

; Read the data into the array:
READU, UNIT, data

; Close the data file:
CLOSE, UNIT

; Create a pointer to the data array:
hData = PTR_NEW(data, /NO_COPY)

; Load the data into SLICER3:
SLICER3, hdata, DATA_NAMES='Dave'

```

**Note**

---

If data are loaded via the File menu after SLICER3 is launched with a pointer argument (as shown above), the pointer becomes invalid. You can use an IDL statement like the following to “clean up” after calling SLICER3 in this fashion:

```
if PTR_VALID(hdata) then PTR_FREE, hdata
```

---

Because we did not launch SLICER3 with the MODAL keyword, the last contents of the main draw window still reside in IDL’s Z-buffer. To retrieve this image after exiting SLICER3, use the following IDL statements:

```

; Save the current graphics device:
current_device = !D.Name

; Change to the Z-buffer device:
SET_PLOT, 'Z'

; Read the image from the Z-buffer:
image_buffer = TVRD()

; Return to the original graphics device:
SET_PLOT, current_device

; Display the image:
TV, image_buffer

```

The following IDL commands manually create a data save file suitable for dynamic loading into SLICER3. Note that if you load data into SLICER3 as shown above, you

can also create save files by switching to **BLOCK** mode and using the Save Subset menu option.

```

; Store some 3-D data in a variable called data_1:
data_1 = INDGEN(20,30,40)

; Store some 3-D data in a variable called data_2:
data_2 = FINDGEN(20,30,40)

; Define the names for the datasets. Their names will appear in the
; "Data" pulldown menu in SLICER3:
data_1_name = 'Test Data 1'
data_2_name = 'Data 2'

; Select a data file name:
dataFile = DIALOG_PICKFILE()

; Write the file:
GET_LUN, lun
OPENW, lun, dataFile
WRITEU, lun, SIZE(data_1)
WRITEU, lun, STRLEN(data_1_name)
WRITEU, lun, BYTE(data_1_name)
WRITEU, lun, data_1
WRITEU, lun, SIZE(data_2)
WRITEU, lun, STRLEN(data_2_name)
WRITEU, lun, BYTE(data_2_name)
WRITEU, lun, data_2
CLOSE, lun
FREE_LUN, lun

```

# SLIDE\_IMAGE

The SLIDE\_IMAGE procedure creates a scrolling graphics window for examining large images. By default, 2 draw widgets are used. The draw widget on the left shows a reduced version of the complete image, while the draw widget on the right displays the actual image with scrollbars that allow sliding the visible window.

This routine is written in the IDL language. Its source code can be found in the file `slide_image.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SLIDE_IMAGE [, Image] [, /BLOCK] [, CONGRID=0]
  [, FULL_WINDOW=variable] [, GROUP=widget_id] [, /ORDER]
  [, /REGISTER] [, RETAIN={0 | 1 | 2}] [, SLIDE_WINDOW=variable]
  [, SHOW_FULL=0] [, TITLE=string] [, TOP_ID=variable] [, XSIZE=width]
  [, XVISIBLE=width] [, YSIZE=height] [, YVISIBLE=height]
```

## Arguments

### Image

A 2-D image array to be displayed. If this argument is not specified, no image is displayed. The FULL\_WINDOW and SCROLL\_WINDOW keywords can be used to obtain the window numbers of the two draw widgets so they can be drawn into at a later time.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO\_BLOCK keyword to XMANAGER.

**Note**

---

Only the outermost call to XMANAGER can block. Therefore, to have SLIDE\_IMAGE block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

**CONGRID**

Normally, the image is processed with the CONGRID procedure before it is written to the fully visible window on the left. Specifying CONGRID=0 will force the image to be drawn as is.

**FULL\_WINDOW**

Set this keyword to a named variable that will contain the IDL window number of the fully visible window. This window number can be used with the WSET procedure to draw to the scrolling window at a later point.

**GROUP**

Set this keyword to the widget ID of the widget that calls SLIDE\_IMAGE. If set, the death of the caller results in the death of SLIDE\_IMAGE.

**ORDER**

This keyword is passed directly to the TV procedure to control the order in which the images are drawn. Usually, images are drawn from the bottom up. Set this keyword to a non-zero value to draw images from the top down.

**REGISTER**

Set this keyword to create a “Done” button for SLIDE\_IMAGE and register the widgets with the XMANAGER procedure.

The basic widgets used in this procedure do not generate widget events, so it is not necessary to process events in an event loop. The default is therefore to simply create the widgets and return. Hence, when REGISTER is not set, SLIDE\_IMAGE can be displayed and the user can still type commands at the IDL command prompt.

## RETAIN

This keyword is passed directly to the `WIDGET_DRAW` function. `RETAIN` specifies how backing store should be handled for the window. Valid values are:

- 0 — Specifies no backing store. In this case, it is recommended that the `REGISTER` keyword be set so that expose and scroll events are handled.
- 1 — Requests that the server or window system provide backing store. This is the default if `RETAIN` is not specified.
- 2 — Specifies that IDL provide backing store directly.

See “[Backing Store](#)” on page 4728 for details.

## SLIDE\_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the sliding window. This window number can be used with the `WSET` procedure to draw to the scrolling window at a later time.

## SHOW\_FULL

Set this keyword to zero to show the entire image at full resolution in one scrolling graphics window. By default, `SHOW_FULL` is set, displaying two draw widgets.

## TITLE

Set this keyword to the title to be used for the `SLIDE_IMAGE` widget. If this keyword is not specified, “Slide Image” is used.

## TOP\_ID

Set this keyword to a named variable that will contain the top widget ID of the `SLIDE_IMAGE` hierarchy. This ID can be used to kill the hierarchy as shown below:

```
SLIDE_IMAGE, TOP_ID=base, ...  
WIDGET_CONTROL, /DESTROY, base
```

## XSIZE

Set this keyword to the maximum width of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the `XVISIBLE` keyword. If `XSIZE` is not specified, the width of *Image* is used. If *Image* is not specified, 256 is used.

## XVISIBLE

Set this keyword to the width of the viewport on the scrolling window. If this keyword is not specified, 256 is used.

## YSIZE

Set this keyword to the maximum height of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the YVISIBLE keyword. If YSIZE is not present the height of *Image* is used. If *Image* is not specified, 256 is used.

## YVISIBLE

Set this keyword to the height of the viewport on the scrolling window. If this keyword is not present, 256 is used.

## Examples

The following example imports a grayscale image from the `nyny.dat` binary file. This grayscale image is an aerial view of New York City. The image contains byte data values and is 768 pixels by 512 pixels. You can use the `SLIDE_IMAGE` procedure to zoom in on the image and pan over it.

### Example Code

---

See `panning_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

---

1. Determine the path to the `nyny.dat` file:

```
file = FILEPATH('nyny.dat', $
  SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
imageSize = [768, 512]
```

3. Import the image from the file:

```
image = READ_BINARY(file, DATA_DIMS = imageSize)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Load a grayscale color table:

```
LOADCT, 0
```

6. Display the image with the `SLIDE_IMAGE` procedure:

```
SLIDE_IMAGE, image
```

Use the sliders in the display on the right side to pan over the image.

The following figure shows a possible display within the `SLIDE_IMAGE` application.

Figure 3-119: The `SLIDE_IMAGE` Application Displaying an Image of New York

[IMAGE](#), [TV](#), [TVSCL](#), [WIDGET\\_DRAW](#), [WINDOW](#)

# SMOOTH

The SMOOTH function returns a copy of *Array* smoothed with a boxcar average of the specified width. The result has the same type and dimensions as *Array*. The algorithm used by SMOOTH is:

$$R_i = \begin{cases} \frac{1}{w} \sum_{j=0}^{w-1} A_{i+j-w/2}, & i = \frac{(w-1)}{2}, \dots, N - \frac{(w+1)}{2} \\ A_i, & \text{otherwise} \end{cases}$$

where  $N$  is the number of elements in  $A$ .

## Syntax

*Result* = SMOOTH(*Array*, *Width* [, /EDGE\_TRUNCATE] [, MISSING=*value*] [, /NAN])

## Return Value

Returns the smoothed array, which has the same dimensions as the input array.

## Arguments

### Array

The array to be smoothed. *Array* can have any number of dimensions.

### Width

The width of the smoothing window. *Width* can either be a scalar or a vector with length equal to the number of dimensions of *Array*. If *Width* is a scalar then the same width is applied for each dimension that has length greater than 1 (dimensions of length 1 are skipped). If *Width* is a vector, then each element of *Width* is used to specify the smoothing width for each dimension of *Array*. Values for *Width* must be smaller than the corresponding *Array* dimension. If a *Width* value is even, then  $Width+1$  will be used instead. The value of *Width* does not affect the running time of SMOOTH to a great extent.

---

**Note**

A Width value of zero or 1 implies no smoothing. However, if the NAN keyword is set, then any NaN values within the Array will be treated as missing data and will be replaced.

---

**Tip**

For a multi-dimensional array, set widths to 1 within the Width vector for dimensions that you don't want smoothed.

---

## Keywords

### EDGE\_TRUNCATE

Set this keyword to apply the smoothing function to all points. If the neighborhood around a point includes a point outside the array, the nearest edge point is used to compute the smoothed result. If EDGE\_TRUNCATE is not set, the end points are copied from the original array to the result with no smoothing.

For example, when smoothing an  $n$ -element vector with a three point wide smoothing window, the first point of the result  $R_0$  is equal to  $A_0$  if EDGE\_TRUNCATE is not set, but is equal to  $(A_0+A_0+A_1)/3$  if the keyword is set. In the same manner, point  $R_{n-1}$  is set to  $A_{n-1}$  if EDGE\_TRUNCATE is not set, or to  $(A_{n-2}+A_{n-1}+A_{n-1})/3$  if it is.

---

**Note**

Normally, two-dimensional floating-point arrays are smoothed in one pass. If the EDGE\_TRUNCATE keyword is specified for a two-dimensional floating-point array, the result is obtained in two passes, first for all of the rows, and second for all of the columns. Therefore, the results for points in the interior of the array may differ slightly when the EDGE\_TRUNCATE keyword is set. This difference will be most pronounced if the array contains NaN values.

---

### MISSING

The value to return for elements that contain no valid points within the kernel. The default is the IEEE floating-point value NaN. This keyword is only used if the NAN keyword is set.

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 8 of the

*Building IDL Applications* manual for more information on IEEE floating-point values.) In the *Result*, missing elements are replaced by the smoothed value of all other valid points within the smoothing window. If all points within the window are missing, then the result at that point is given by the MISSING keyword.

---

**Note**

SMOOTH should never be called without the NAN keyword if the input array may possibly contain *NaN* values.

---

## Examples

---

**Note**

Also see “[Smoothing an Image](#)” in Chapter 8 of the *Image Processing in IDL* manual.

---

Create and display a simple image by entering:

```
WINDOW, XSIZE=800, YSIZE=400
D = SIN(DIST(256)/3)
TVSCL, D
```

Now display the same dataset smoothed with a width of 9 in each dimension by entering:

```
TVSCL, SMOOTH(D, 9), 256, 0
```

Now smooth only in the vertical direction with a width of 15:

```
TVSCL, SMOOTH(D, [1, 15]), 512, 0
```

This example shows the use of SMOOTH with the multidimensional width argument on an RGB image.

```
; Determine the path to the file.
file = FILEPATH('rose.jpg', $
  SUBDIRECTORY = ['examples', 'data'])
; Import in the RGB image from the file.
image = READ_IMAGE(file)
; Initialize the image size parameter.
imageSize = SIZE(image, /DIMENSIONS)
; Initialize the display.
DEVICE, DECOMPOSED = 1
WINDOW, 0, XSIZE = imageSize[1], YSIZE = imageSize[2], $
  TITLE = 'Original Rose Image'
; Display the original image on the left side.
TV, image, TRUE = 1
```

```

; Initialize another display.
WINDOW, 1, XSIZE = 3*imageSize[1], YSIZE = imageSize[2], $
    TITLE = 'Vertically Smoothed (left), Horizontally ' + $
    'Smoothed (middle), and Both (right)'
; Smooth the RGB image in just the width dimension.
smoothed = SMOOTH(image, [1, 1, 21])
; Display the results.
TV, smoothed, 0, TRUE = 1
; Smooth the RGB image in just the height dimension.
smoothed = SMOOTH(image, [1, 21, 1])
; Display the results.
TV, smoothed, 1, TRUE = 1
; Smooth the RGB image in just the width and height dimensions.
smoothed = SMOOTH(image, [1, 5, 5])
; Display the results.
TV, smoothed, 2, TRUE = 1

```

# SOBEL

The SOBEL function returns an approximation to the Sobel edge enhancement operator for images,

$$G_{jk} = |G_x| + |G_y|$$

$$G_Y = F_{j-1,k-1} + 2F_{j,k-1} + F_{j+1,k-1} - (F_{j-1,k+1} + 2F_{j,k+1} + F_{j+1,k+1})$$

$$G_X = F_{j+1,k+1} + 2F_{j+1,k} + F_{j+1,k-1} - (F_{j-1,k+1} + 2F_{j-1,k} + F_{j-1,k-1})$$

where  $(j, k)$  are the coordinates of each pixel  $F_{jk}$  in the *Image*. This is equivalent to a convolution using the masks,

$$\text{X mask} = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \qquad \text{Y mask} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}$$

*Figure 3-120: Masks*

All of the edge points in the result are set to zero.

## Syntax

*Result* = SOBEL(*Image*)

## Return Value

SOBEL returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer then the result is of integer type, otherwise the result is of the same type as *Image*.

---

**Note**

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

---

## Arguments

### Image

The two-dimensional array containing the image to which edge enhancement is applied.

## Keywords

None.

## Examples

If the variable `myimage` contains a two-dimensional image array, a Sobel sharpened version of `myimage` can be displayed with the command:

```
TVSCL, SOBEL(myimage)
```

---

**Note**

Also see “[Detecting Edges](#)” in Chapter 8 of the *Image Processing in IDL* manual.

[ROBERTS](#)

# SOCKET

The SOCKET procedure, supported on UNIX and Microsoft Windows platforms, opens a client-side TCP/IP Internet socket as an IDL file unit. Such files can be used in the standard manner with any of IDL's Input/Output routines.

## Tip

RSI recommends that you don't use the EOF procedure as a way to check to see if a socket is empty. It is recommended that you structure your communication across the socket so that using EOF is not necessary to know when the communication is complete.

## Syntax

```
SOCKET, Unit, Host, Port [, CONNECT_TIMEOUT=value] [, ERROR=variable]
    [, /GET_LUN] [, /RAWIO] [, READ_TIMEOUT=value] [, /SWAP_ENDIAN]
    [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN]
    [, WIDTH=value] [, WRITE_TIMEOUT=value]
```

**UNIX-Only Keywords:** [, /STDIO]

## Arguments

### Unit

The unit number to associate with the opened socket.

### Host

The name of the host to which the socket is connected. This can be either a standard Internet host name (e.g. ftp.RSInc.com) or a dot-separated numeric address (e.g. 192.5.156.21).

### Port

The port to which the socket is connected on the remote machine. If this is a well-known port (as contained in the /etc/services file on a UNIX host), then you can specify its name (e.g. daytime); otherwise, specify a number.

## Keywords

### CONNECT\_TIMEOUT

Set this keyword to the number of seconds to wait before giving up and issuing an error to shorten the connect timeout from the system-supplied default. Most experts recommend that you not specify an explicit timeout, and instead use your operating system defaults.

---

#### Note

Although you can use `CONNECT_TIMEOUT` to shorten the timeout, you cannot increase it past the system-supplied default.

---

### ERROR

A named variable in which to place the error status. If an error occurs in the attempt to open File, IDL normally takes the error handling action defined by the `ON_ERROR` and/or `ON_IOERROR` procedures. `SOCKET` always returns to the caller without generating an error message when `ERROR` is present. A nonzero error status indicates that an error occurred. The error message can then be found in the system variable `!ERROR_STATE.MSG`.

### GET\_LUN

Set this keyword to use the `GET_LUN` procedure to set the value of *Unit* before the file is opened. Instead of using the two statements:

```
GET_LUN, Unit
OPENR, Unit, 'data.dat'
```

you can use the single statement:

```
OPENR, Unit, 'data.dat', /GET LUN
```

### RAWIO

Set this keyword to disable all use of the standard operating system I/O for the file, in favor of direct calls to the operating system. This allows direct access to devices, such as tape drives, that are difficult or impossible to use effectively through the standard I/O. Using this keyword has the following implications:

- No formatted or associated (`ASSOC`) I/O is allowed on the file. Only `READU` and `WRITEU` are allowed.

- Normally, attempting to read more data than is available from a file causes the unfilled space to be set to zero and an error to be issued. This does not happen with files opened with RAWIO. When using RAWIO, the programmer must check the transfer count, either via the TRANSFER\_COUNT keywords to READU and WRITEU, or the FSTAT function.
- The EOF and POINT\_LUN functions cannot be used with a file opened with RAWIO.
- Each call to READU or WRITEU maps directly to UNIX read(2) and write(2) system calls. The programmer must read the UNIX system documentation for these calls and documentation on the target device to determine if there are any special rules for I/O to that device. For example, the size of data that can be transferred to many cartridge tape drives is often forced to be a multiple of 512 bytes.

## READ\_TIMEOUT

Set this keyword to the number of seconds to wait for data to arrive before giving up and issuing an error. By default, IDL blocks indefinitely until the data arrives. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

## STDIO

*This keyword is only available on UNIX platforms.*

Under UNIX, forces the file to be opened via the standard C I/O library (stdio) rather than any other more native OS API that might usually be used. This is primarily of interest to those who intend to access the file from external code, and is not necessary for most uses.

### Note

---

Under Windows, the STDIO feature is not possible. Requesting it causes IDL to throw an error.

---

## SWAP\_ENDIAN

Set this keyword to swap byte ordering for multi-byte data when performing binary I/O on the specified file. This is useful when accessing files also used by another system with byte ordering different than that of the current host.

## SWAP\_IF\_BIG\_ENDIAN

Setting this keyword is equivalent to setting `SWAP_ENDIAN`; it only takes effect if the current system has big endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## SWAP\_IF\_LITTLE\_ENDIAN

Setting this keyword is equivalent to setting `SWAP_ENDIAN`; it only takes effect if the current system has little endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## WIDTH

The desired output width. When using the defaults for formatted output, IDL uses the following rules to determine where to break lines:

- If the output file is a terminal, the terminal width is used.
- Otherwise, a default of 80 columns is used.

The `WIDTH` keyword allows the user to override this default.

## WRITE\_TIMEOUT

Set this keyword to the number of seconds to wait to send data before giving up and issuing an error. By default, IDL blocks indefinitely until it is possible to send the data. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

## Examples

Most UNIX systems maintain a daytime server on the daytime port (port 13). These servers send a 1 line response when connected to, containing the current time of day.

```
; To obtain the current time from the host bullwinkle:
SOCKET, 1, 'bullwinkle', 'daytime'
date=' '
READF, 1, date
CLOSE, 1
PRINT, date
```

IDL prints:

```
Wed Sep 15 17:20:27 1999
```

## Version History

5.3	Introduced
5.6	Added SWAP_IF_BIG_ENDIAN and SWAP_IF_LITTLE_ENDIAN keywords

# SORT

The SORT function returns a vector of subscripts that allow access to the elements of *Array* in ascending order.

## Syntax

*Result* = SORT(*Array* [, /L64] )

## Return Value

The result is always a vector of integer type with the same number of elements as *Array*.

---

**Note**

If *Array* contains any identical elements, the order in which the identical elements are sorted is arbitrary and may vary between operating systems.

---

## Arguments

### Array

The array to be sorted. *Array* can be any basic type of vector or array. String arrays are sorted using the ASCII collating sequence. Complex arrays are sorted by their magnitude. Array values which are Not A Number (NaN) are moved to the end of the resulting array.

## Keywords

### L64

By default, the result of SORT is 32-bit integer when possible, and 64-bit integer if the number of elements being sorted requires it. Set L64 to force 64-bit integers to be returned in all cases.

---

**Note**

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit sort. Check the value of !VERSION.MEMORY\_BITS to see if your IDL is 64-bit or not.

---

## Examples

### Example 1

```
A = [4, 3, 7, 1, 2]
PRINT, 'SORT(A) = ', SORT(A)

; Display the elements of A in sorted order:
PRINT, 'Elements of A in sorted order: ', A[SORT(A)]

; Display the elements of A in descending order:
PRINT, 'Elements of A in descending order: ', A[REVERSE(SORT(A))]
```

IDL prints:

```
SORT(A) = 3 4 1 0 2
Elements of A in sorted order: 1 2 3 4 7
Elements of A in descending order: 7 4 3 2 1
```

SORT(A) returns “3 4 1 0 2” because:

$$A[3] < A[4] < A[1] < A[0] < A[2]$$

### Example 2

#### Sorting NaN Values

When sorting data including Not A Number (NaN) values, the NaN entries are moved to the end of the resulting array. For example:

```
values = [ 500, !VALUES.F_NAN, -500 ]
PRINT, SORT(values)
```

IDL prints:

```
2          0          1
```

# SPAWN

The SPAWN procedure spawns a child process to execute a command or series of commands. The result of calling SPAWN depends on the platform on which it is being used:

- Under UNIX, the shell used (if any) is obtained from the SHELL environment variable. The NOSHELL keyword can be used to execute a command directly as a child process without starting a shell process.
- Under Windows, a Command Shell is opened. The NOSHELL keyword can be used to execute the specified command directly without starting an intermediate command interpreter shell.

---

## Note

See [“Using SPAWN Without a Shell Under UNIX”](#) on page 2173 for notes on executing commands without using a shell process under UNIX. See [“Execution Directory under Microsoft Windows”](#) on page 2174 for a caution regarding Windows network paths.

---

If SPAWN is called without arguments, an interactive command interpreter process is started, in which you can enter one or more operating system commands.

By default, IDL waits for the child process started by SPAWN to finish before it continues. It is possible to have IDL instead continue execution in parallel with the child process. The syntax for this depends on the operating system on your system:

- Under UNIX, include an ampersand (&) at the end of your shell command.
- Under Windows, specify the NOWAIT keyword to SPAWN.

---

## Note

For more information on using SPAWN, see the *External Development Guide*.

---

## Syntax

SPAWN [, *Command* [, *Result*] [, *ErrResult*] ]

**Keywords (all platforms):** [, [COUNT=variable](#)] [, [EXIT\\_STATUS=variable](#)] [, [/NOSHELL](#)] [, [/NULL\\_STDIN](#)] [, [PID=variable](#)] [, [/STDERR](#)]

**UNIX-Only Keywords:** [, [/NOTTYRESET](#)] [, [/SH](#)] [, [UNIT=variable](#) { *Command* required, *Result* and *ErrResult* not allowed }]

**Windows-Only Keywords:** [, /HIDE] [, /LOG\_OUTPUT] [, /NOWAIT]

## Arguments

### Command

A string containing the commands to be executed.

If *Command* is present, it must be specified as follows:

- On UNIX, *Command* is expected to be scalar unless used in conjunction with the NOSHELL keyword, in which case *Command* is expected to be a string array where each element is passed to the child process as a separate argument.
- On Windows, *Command* can be a scalar string or string array. If it is a string array, SPAWN glues together each element of the string array, with each element separated by whitespace.

If *Command* is not present, SPAWN starts an interactive command interpreter process, which you can use to enter one or more operating system commands. While you use the command interpreter process, IDL is suspended. Under Windows, an interactive command shell window is created for this purpose. UNIX spawn does not create a separate window, but simply runs on the user's current tty, using the default shell (as specified by the SHELL environment variable). The SH keyword can be used to force use of the Bourne shell (/bin/sh).

---

#### Note

Using SPAWN in this manner is equivalent to using the IDL \$ command. The difference between these two is that \$ can only be used interactively while SPAWN can be used interactively or in IDL programs

---

### Result

A named variable in which to place the output from the child process. Each line of output becomes a single array element. If *Result* is not present, the output from the child shell process goes to the standard output (usually the terminal).

---

#### Note

*Result* will be a null string if the NOWAIT keyword is specified (Windows) or if *Command* ends in an ampersand (&) (UNIX).

---

## ErrResult

A named variable in which to place the error output (stderr) from the child process. Each line of output becomes a single array element. If *ErrResult* is not present, the error output from the child shell process goes to the standard error file.

---

**Note**

See the [STDERR](#) keyword for another error stream option.

---

---

**Note**

*ErrResult* will be a null string if the NOWAIT keyword is specified (Windows). If *Command* ends in an ampersand (&) (UNIX), *ErrResult* may contain an error string generated by the shell.

---

## Keywords

### COUNT

If *Result* is present and this keyword is also specified, COUNT specifies a named variable into which the number of lines of output is placed. This value gives the number of elements placed into *Result*.

### EXIT\_STATUS

Set this keyword to a named variable in which the exit status for the child process is returned. The meaning of this value is operating system dependent:

- Under UNIX, it is the value passed by the child to `exit(2)`, and is analogous to the value returned by  `$?`  under most UNIX shells. If the UNIT keyword is used, this keyword always returns 0. In this case, use the EXIT\_STATUS keyword to FREE\_LUN or CLOSE to determine the final exit status of the process.
- Under Windows, it is the value returned by the Win32 `GetExitCodeProcess()` system function. If the NOWAIT keyword is set, EXIT\_STATUS returns 0.

### HIDE

*This keyword is only available on Windows platforms.*

If HIDE is set, the command interpreter shell window is minimized to prevent the user from seeing it.

## LOG\_OUTPUT

*This keyword is only available on Windows platforms.*

Normally, IDL starts a command interpreter shell, and output from the child process is displayed in the command interpreter's window. If LOG\_OUTPUT is set, the command interpreter window is minimized (as with HIDE) and all output is diverted to the IDLDE log window. If the *Result* or *ErrResult* arguments are present, they take precedence over LOG\_OUTPUT.

## NOSHELL

Set this keyword to specify that *Command* should execute directly as a child process without an intervening shell process.

- UNIX – When using the NOSHELL keyword under UNIX, you must specify *Command* as a string array in which the first element is the name of the command to execute and the following arguments are the arguments to be passed to the command. See [“Using SPAWN Without a Shell Under UNIX”](#) on page 2173 for notes on executing commands without using a shell process.
- Windows – Use this keyword to start the specified *Command* directly, without the use of an intervening command shell. This is useful for Windows programs that do not require a console, such as Notepad.

Many common DOS commands (e.g. DIR) are not distinct programs, and are instead implemented as part of the command interpreter. Specifying NOSHELL with such commands results in the command not being found. In such cases, the HIDE keyword might be useful.

## NOTTYRESET

*This keyword is only available on UNIX platforms.*

Some UNIX systems drop characters when the tty mode is switched between normal and raw modes. IDL switches between these modes when reading command input and when using the GET\_KBRD function. On such systems, IDL avoids losing characters by delaying the switch back to normal mode until it is truly needed. This method has the benefit of avoiding the large number of mode changes that would otherwise be necessary. Routines that cause output to be sent to the standard output (e.g., I/O operations, user interaction and SPAWN) ensure that the tty is in its normal mode before performing their operations.

If the NOTTYRESET keyword is set, SPAWN does not switch the tty back to normal mode before launching the child process assuming instead that the child will not send

output to the tty. Use this keyword to avoid characters being dropped in a loop of the form:

```
WHILE (GET_KBRD(0) NE 'q') SPAWN, command
```

This keyword has no effect on systems that don't suffer from dropped characters.

## NOWAIT

*This keyword is only available on Windows platforms.*

If this keyword is set, the IDL process continues executing in parallel with the subprocess. Normally, the IDL process suspends execution until the subprocess completes.

## NULL\_STDIN

If set, the null device is connected to the standard input of the child process. The null device is either `/dev/null` (under UNIX) or `NUL` (under Windows).

## PID

A named variable into which the Process Identification number of the child process is stored.

## SH

*This keyword is only available on UNIX platforms.*

Set this keyword to force the use of the Bourne shell (`/bin/sh`). Usually, the shell used is determined by the `SHELL` environment variable.

## STDERR

If set, the child's error output (`stderr`) is combined with the standard output and returned in *Result*. `STDERR` and the *ErrResult* argument are mutually exclusive. You should use one or the other, but not both.

## UNIT

*This keyword is only available on UNIX platforms.*

If `UNIT` is present, `SPAWN` creates a child process in the usual manner, but instead of waiting for the specified command to finish, it attaches a bidirectional pipe between the child process and IDL. From the IDL session, the pipe appears as a logical file unit. The other end of the pipe is attached to the child process standard

input and output. The `UNIT` keyword specifies a named variable into which the number of the file unit is stored.

Once the child process is started, the IDL session can communicate with it through the usual input/output facilities. After the child process has done its task, the `CLOSE` procedure can be used to kill the process and close the pipe. Since `SPAWN` uses `GET_LUN` to allocate the file unit, `FREE_LUN` should be used to free the unit.

If `UNIT` is present, `Command` must be present, and neither `Result` or `ErrResult` are allowed.

## Using SPAWN Without a Shell Under UNIX

When a Unix program is run, its name and arguments are provided to it as an array of strings, one string per argument. The first string is the name of the program, and the remainder (if any) are the arguments. C programmers will recognize this as the standard (`argc`, `argv`) arguments passed to the `main()` function when the program is run. When you execute a command via a Unix shell, one of the operations that the shell carries out for you is to split the command and arguments apart on whitespace boundaries (blanks and tabs) to create this array of arguments. It then runs the program for you, using one of the Unix system `exec()` functions.

By default, `SPAWN` creates a shell process and passes the command to this shell instead of simply creating a child process to directly execute the command. Use of a shell is the default because the shell provides useful facilities such as wildcard expansion and argument processing (described above). Although this is usually desirable, it has the drawback of being slower than necessary, and of using an additional process for the shell.

When `SPAWN` is called with the `NOSHELL` keyword set, the command is executed as a direct child process, avoiding the extra overhead of starting a shell. This is faster, but since there is no shell, you must specify the arguments in the standard form required by Unix programs. When you specify the `NOSHELL` keyword, the `Command` argument should be a string array. The first element of the array is the name of the command to use, and the following elements contain the arguments.

For example, consider the command,

```
SPAWN, 'ps ax'
```

that uses the UNIX `ps` command to show running processes on the computer. To issue this command without a shell, you would write it as follows:

```
SPAWN, ['ps', 'ax'], /NOSHELL
```

## Execution Directory under Microsoft Windows

SPAWN attempts to use IDL's current working directory as the current directory for the spawned process. However, Microsoft Windows does not support the specification of a UNC path as the current directory for a Command Shell. Issuing a SPAWN command when IDL's current working directory is set to a UNC path will cause Windows to generate an error that looks something like:

```
CMD.EXE was started with '\\host\dir' as the current directory
path. UNC paths are not supported. Defaulting to Windows
directory.
```

If your application requires that you be able to use SPAWN when IDL's current working directory is set to a directory on a Windows network, consider mapping the UNC path to a Windows drive letter and setting that to be IDL's working directory.

## Examples

### Example 1: Interactive use of SPAWN

To simply spawn a shell process from within IDL, enter the command:

```
SPAWN
```

To execute the UNIX `ls` command and return to the IDL prompt, enter:

```
SPAWN, 'ls'
```

To execute the UNIX `ls` command and store the result in the IDL string variable `listing`, enter:

```
SPAWN, 'ls', listing
```

### Example 2: Noninteractive use of SPAWN

It is sometimes useful to create a temporary scratch file, removing the file when it is no longer needed. SPAWN could be used as shown below to manage the removal of the scratch file.

```
OPENW, UNIT, 'scratch.dat', /GET_LUN

;...IDL commands go here.

;Deallocate the file unit and close the file.
FREE_LUN, UNIT

;Use the !VERSION system variable to determine the proper file
;deletion command for the current operating system.
```

```

CASE !VERSION.OS OF
  'Windows': CMD = 'DEL'
  ELSE: CMD = 'rm'
ENDCASE

;Delete the file using SPAWN.
SPAWN, CMD + ' scratch.dat'

END

```

**Note**

---

The DELETE keyword to the [OPENR/OPENU/OPENW](#) procedure or the [FILE\\_DELETE](#) procedure more efficiently handles this job. The above example should serve only to demonstrate use of the SPAWN procedure.

# SPH\_4PNT

Given four 3-dimensional points, the SPH\_4PNT procedure returns the center and radius necessary to define the unique sphere passing through those points.

This routine is written in the IDL language. Its source code can be found in the file `sph_4pnt.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SPH_4PNT, X, Y, Z, Xc, Yc, Zc, R [, /DOUBLE]
```

## Arguments

### X, Y, Z

4-element floating-point or double-precision vectors containing the X, Y, and Z coordinates of the points.

### Xc, Yc, Zc

Named variables that will contain the sphere's center X, Y, and Z coordinates.

### R

A named variable that will contain the sphere's radius.

## Keywords

### DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

## Examples

Find the center and radius of the unique sphere passing through the points: (1, 1, 0), (2, 1, 2), (1, 0, 3), (1, 0, 1):

```
; Define the floating-point vectors containing the x, y and z
; coordinates of the points:
X = [1, 2, 1, 1] + 0.0
Y = [1, 1, 0, 0] + 0.0
Z = [0, 2, 3, 1] + 0.0
```

```
; Compute sphere's center and radius:  
SPH_4PNT, X, Y, Z, Xc, Yc, Zc, R  
  
; Print the results:  
PRINT, Xc, Yc, Zc, R
```

IDL prints:

```
-0.500000      2.00000      2.00000      2.69258
```

# SPH\_SCAT

The SPH\_SCAT function performs spherical gridding. Scattered samples on the surface of a sphere are interpolated to a regular grid. This routine is a convenient interface to the spherical gridding and interpolation provided by TRIANGULATE and TRIGRID.

This routine is written in the IDL language. Its source code can be found in the file `sph_scat.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = SPH_SCAT( Lon, Lat, F [, BOUNDS=[lonmin, latmin, lonmax, latmax]]  
  [, BOUT=variable] [, GOUT=variable] [, GS=[lonspacing, latspacing]]  
  [, NLON=value] [, NLAT=value] )
```

## Return Value

Returns a regularly-interpolated grid of the function.

## Arguments

### Lon

A vector of sample longitudes, in degrees.

### Note

---

*Lon*, *Lat*, and *F* must all have the same number of points.

---

### Lat

A vector of sample latitudes, in degrees.

### F

A vector of data values which are functions of Lon and Lat.  $F_i$  represents a value at  $(Lon_i, Lat_i)$ .

## Keywords

### BOUNDS

Set this keyword to a four-element vector containing the grid limits in longitude and latitude of the output grid. The four elements are: [ $Lon_{min}$ ,  $Lat_{min}$ ,  $Lon_{max}$ ,  $Lat_{max}$ ]. If this keyword is not set, the grid limits are set to the extent of  $Lon$  and  $Lat$ .

---

**Note**

To cover all longitudes, you must explicitly specify the values for the BOUNDS keyword.

---

### BOUT

Set this keyword to a named variable that, on return, contains a four-element vector (similar to BOUNDS) that describes the actual extent of the regular grid.

### GOUT

Set this keyword to a named variable that, on return, contains a two-element vector (similar to GS) that describes the actual grid spacing.

### GS

Set this keyword to a two-element vector that specifies the spacing between grid points in longitude (the first element) and latitude (the second element).

If this keyword is not set, the default value is based on the extents of  $Lon$  and  $Lat$ . The default longitude spacing is  $(Lon_{max} - Lon_{min}) / (NLON - 1)$ . The default latitude spacing is  $(Lat_{max} - Lat_{min}) / (NLAT - 1)$ . If NLON and NLAT are not set, the default grid size of 26 by 26 is used for NLON and NLAT.

### NLON

The output grid size in the longitude direction. The default value is 26.

---

**Note**

NLON need not be specified if the size can be inferred from GS and BOUNDS.

---

### NLAT

The output grid size in the latitude direction. The default value is 26.

**Note**

---

NLAT need not be specified if the size can be inferred from GS and BOUNDS.

---

## Examples

```

; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. -180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. -90.

; Make a function to fit:
z = SIN(lat*!DTOR)
c = COS(lat*!DTOR)
x = COS(lon*!DTOR) * c
y = SIN(lon*!DTOR) * c

; The finished dependent variable:
f = SIN(x+y) * SIN(x*z)
; Interpolate the data and return the result in variable r:
r = SPH_SCAT(lon, lat, f, BOUNDS=[0, -90, 350, 85], GS=[10,5])

```

# SPHER\_HARM

The SPHER\_HARM function returns the value of the spherical harmonic  $Y_{lm}(\theta, \phi)$ ,  $-l \leq m \leq l$ ,  $l \geq 0$ , which is a function of two coordinates on a spherical surface.

The spherical harmonics are related to the associated Legendre polynomial by:

$$Y_{lm}(\theta, \phi) = \sqrt{\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!}} P_l^m(\cos \theta) e^{im\phi}$$

For negative  $m$  the following relation is used:

$$Y_{l,-m}(\theta, \phi) = (-1)^m Y_{lm}^*(\theta, \phi)$$

where \* represents the complex conjugate.

This routine is written in the IDL language. Its source code can be found in the file `spher_harm.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = SPHER\_HARM(*Theta*, *Phi*, *L*, *M*, [, /DOUBLE] )

## Return Value

SPHER\_HARM returns a complex scalar or array containing the value of the spherical harmonic function. The return value has the same dimensions as the input arguments *Theta* and *Phi*. If one argument (*Theta* or *Phi*) is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If either *Theta* or *Phi* are double-precision or if the DOUBLE keyword is set, the result is double-precision complex, otherwise the result is single-precision complex.

## Arguments

### Theta

The value of the polar (colatitudinal) coordinate  $\theta$  at which  $Y_{lm}(\theta, \phi)$  is evaluated. *Theta* can be either a scalar or an array.

## Phi

The value of the azimuthal (longitudinal) coordinate  $\phi$  at which  $Y_{lm}(\theta, \phi)$  is evaluated. *Phi* can be either a scalar or an array.

## L

A scalar integer,  $L \geq 0$ , specifying the order  $l$  of  $Y_{lm}(\theta, \phi)$ . If  $L$  is of type float, it will be truncated.

## M

A scalar integer,  $-L \leq M \leq L$ , specifying the azimuthal order  $m$  of  $Y_{lm}(\theta, \phi)$ . If  $M$  is of type float, it will be truncated.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

This example visualizes the electron probability density for the hydrogen atom in state 3d0. (Feynman, Leighton, and Sands, 1965: The Feynman Lectures on Physics, Calif. Inst. Tech, Ch. 19):

```

; Define a data cube (N x N x N)
n = 41L
a = 60*FINDGEN(n)/(n-1) - 29.999 ; [-1,+1]
x = REBIN(a, n, n, n) ; X-coordinates of cube
y = REBIN(REFORM(a,1,n), n, n, n) ; Y-coordinates
z = REBIN(REFORM(a,1,1,n), n, n, n); Z-coordinates

; Convert from rectangular (x,y,z) to spherical (phi, theta, r)
spherCoord = CV_COORD(FROM_RECT= $
  TRANSPOSE([[x[*]], [y[*]], [z[*]]]), /TO_SPHERE)
phi = REFORM(spherCoord[0,*], n, n, n)
theta = REFORM(!PI/2 - spherCoord[1,*], n, n, n)
r = REFORM(spherCoord[2,*], n, n, n)

; Find electron probability density for hydrogen atom in state 3d0
; Angular component
L = 2 ; state "d" is electron spin L=2
M = 0 ; Z-component of spin is zero
angularState = SPHER_HARM(theta, phi, L, M)

```

```

; Radial component for state n=3, L=2
radialFunction = EXP(-r/2)*(r^2)
waveFunction = angularState*radialFunction
probabilityDensity = ABS(waveFunction)^2

SHADE_VOLUME, probabilityDensity, $
0.1*MEAN(probabilityDensity), vertex, poly
oPolygon = OBJ_NEW('IDLgrPolygon', vertex, $
POLYGON=poly, COLOR=[180,180,180])
XOBJVIEW, oPolygon

```

The results are shown in the following figure (rotated in XOBJVIEW for clarity):

Figure 3-121: SPHER\_HARM Example of Hydrogen Atom  
(object rotated in XOBJVIEW for clarity)

# SPL\_INIT

The SPL\_INIT function is called to establish the type of interpolating spline for a tabulated set of functional values  $X_i$ ,  $Y_i = F(X_i)$ .

It is important to realize that SPL\_INIT should be called only *once* to process an entire tabulated function in arrays  $X$  and  $Y$ . Once this has been done, values of the interpolated function for any value of  $X$  can be obtained by calls (as many as desired) to the separate function SPL\_INTERP.

SPL\_INIT is based on the routine spline described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = SPL_INIT( X, Y [, /DOUBLE] [, YP0=value] [, YPN_1=value] )
```

## Return Value

Returns the values of the 2nd derivative of the interpolating function at the points  $X_i$ .

## Arguments

### X

An  $n$ -element input vector that specifies the tabulate points in ascending order.

### Y

An  $n$ -element input vector that specifies the values of the tabulated function  $F(X_i)$  corresponding to  $X_i$ .

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### YP0

The first derivative of the interpolating function at the point  $X_0$ . If YP0 is omitted, the second derivative at the boundary is set to zero, resulting in a “natural spline.”

## YPN\_1

The first derivative of the interpolating function at the point  $X_{n-1}$ . If YPN\_1 is omitted, the second derivative at the boundary is set to zero, resulting in a “natural spline.”

## Examples

### Example 1

```
X = (FINDGEN(21)/20.) * 2.0*!PI
Y = SIN(X)
PRINT, SPL_INIT(X, Y, YP0 = -1.1, YPN_1 = 0.0)
```

IDL Prints:

```
23.1552    -6.51599    1.06983    -1.26115    -0.839544    -1.04023
-0.950336  -0.817987   -0.592022  -0.311726   2.31192e-05  0.311634
 0.592347   0.816783   0.954825   1.02348    0.902068    1.02781
-0.198994   3.26597   -11.0260
```

### Example 2

```
PRINT, SPL_INIT(X, Y, YP0 = -1.1)
```

IDL prints:

```
23.1552    -6.51599    1.06983    -1.26115    -0.839544    -1.04023
-0.950336  -0.817988   -0.592020  -0.311732   4.41521e-05  0.311555

# SPL\_INTERP

Given the arrays  $X$  and  $Y$ , which tabulate a function (with the  $X_i$  in ascending order), and given the array  $Y_2$ , which is the output from SPL\_INIT, and given an input value of  $X_2$ , the SPL\_INTERP function returns a cubic-spline interpolated value for the given value of  $X_1$ .

SPL\_INTERP is based on the routine `splint` described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = SPL_INTERP( X, Y, Y2, X2 [, /DOUBLE] )
```

## Return Value

Returns either single- or double-precision floating result of the same structure as  $X_2$ .

## Arguments

### X

An input array that specifies the tabulated points in ascending order.

### Y

An input array that specifies the values of the tabulate function corresponding to  $X_1$ .

### Y2

The output from SPL\_INIT for the specified  $X$  and  $Y$ .

### X2

The input value for which an interpolated value is desired.  $X$  can be scalar or an array of values. The result of SPL\_INTERP will have the same structure.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To create a spline interpolation over a tabulated set of data,  $[X_i, Y_i]$ , first create the tabulated data. In this example,  $X_i$  will be in the range  $[0.0, 2\pi]$  and  $Y_i$  in the range  $[\sin(0.0), \sin(2\pi)]$ .

```
X = (FINDGEN(21)/20.0) * 2.0 * !PI
Y = SIN(X)

; Calculate interpolating cubic spline:
Y2 = SPL_INIT(X, Y)

; Define the X values P at which we desire interpolated Y values:
X2= FINDGEN(11)/11.0 * !PI

; Calculate the interpolated Y values corresponding to X2[i]:
result = SPL_INTERP(X, Y, Y2, X2)

PRINT, result
```

IDL prints:

```
0.00000 0.281733 0.540638 0.755739 0.909613 0.989796
0.989796 0.909613 0.755739 0.540638 0.281733
```

The exact solution vector is  $\sin(X_2)$ .

To interpolate a line in the XY plane, see [SPLINE\\_P](#).

[SPL\\_INIT](#), [SPLINE](#), [SPLINE\\_P](#)

# SPLINE

The SPLINE function performs cubic spline interpolation. It accepts single- or double-precision input.

This routine is written in the IDL language. Its source code can be found in the file `spline.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

$Result = \text{SPLINE}( X, Y, T [, Sigma] [, /DOUBLE] )$

## Return Value

Returns the result of the cubic spline interpolation. If  $X$ ,  $Y$ , or  $T$  are of type double precision, then the computations will be done using double precision, and a double-precision result will be returned. Otherwise, single precision will be used, and a single-precision result will be returned.

## Arguments

### X

The abscissa vector. Values *must* be monotonically increasing.  $X$  must have three or more points.

### Y

The vector of ordinate values corresponding to  $X$ .  $Y$  should have the same number of elements as  $X$ .

### T

The vector of abscissa values for which the ordinate is desired. The values of  $T$  *must* be monotonically increasing.

### Sigma

The amount of “tension” that is applied to the curve. The default value is 1.0. If sigma is close to 0, (e.g., .01), then effectively there is a cubic spline fit. If sigma is large, (e.g., greater than 10), then the fit will be like a polynomial interpolation.

## Keywords

### DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result.

## Examples

The commands below show a typical use of SPLINE:

```
; X values of original function:  
X = [2.,3.,4.]  
  
; Make a quadratic  
Y = (X-3)^2  
;Values for interpolated points:  
T = FINDGEN(20)/10.+2  
  
; Do the interpolation:  
Z = SPLINE(X,Y,T)
```

## Version History

6.1	Added DOUBLE keyword

## See Also

[SPL\\_INIT](#), [SPLINE\\_P](#)

# SPLINE\_P

The `SPLINE_P` procedure performs parametric cubic spline interpolation with relaxed or clamped end conditions.

This routine is both more general and faster than the `SPLINE` function. One call to `SPLINE_P` is equivalent to two calls to `SPLINE`, as both the X and Y are interpolated with splines. It is suited for interpolating between randomly placed points, and the abscissa values need not be monotonic. In addition, the end conditions may be optionally specified via tangents.

This routine is written in the IDL language. Its source code can be found in the file `spline_p.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SPLINE_P, X, Y, Xr, Yr [, /DOUBLE] [, INTERVAL=value] [, TANO=[X0, Y0]]
      [, TANI=[Xn-1, Yn-1]]
```

## Arguments

### X

The abscissa vector. *X* should be floating-point or double-precision.

### Y

The vector of ordinate values corresponding to *X*. *Y* should be floating-point or double-precision.

Neither *X* or *Y* need be monotonic.

### Xr

A named variable that will contain the abscissa values of the interpolated function. If *X* or *Y* is double-precision, then the computations will be done using double-precision and a double-precision result will be returned. Otherwise, single-precision will be used.

### Yr

A named variable that will contain the ordinate values of the interpolated function. If *X* or *Y* is double-precision, then the computations will be done using double-

precision and a double-precision result will be returned. Otherwise, single-precision will be used.

## Keywords

### DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result.

### INTERVAL

Set this keyword equal to the desired interval in XY space between interpolants. If omitted, approximately 8 interpolants per XY segment will result.

### TAN0

The tangent to the spline curve at  $X[0]$ ,  $Y[0]$ . If omitted, the tangent is calculated to make the curvature of the result zero at the beginning. TAN0 is a two element vector, containing the X and Y components of the tangent.

### TAN1

The tangent to the spline curve at  $X[n-1]$ ,  $Y[n-1]$ . If omitted, the tangent is calculated to make the curvature of the result zero at the end. TAN1 is a two element vector, containing the X and Y components of the tangent.

## Examples

The commands below show a typical use of `SPLINE_P`:

```
; Abscissas for square with a vertical diagonal:
X = [0.,1,0,-1,0]

; Ordinates:
Y = [0.,1,2,1,0]

; Interpolate with relaxed end conditions:
SPLINE_P, X, Y, XR, YR

; Show it:
PLOT, XR, YR
```

As above, but with setting both the beginning and end tangents:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0]
```

This yields approximately 32 interpolants.

As above, but with setting the interval to 0.05, making more interpolants, closer together:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0], INTERVAL=0.05
```

This yields 116 interpolants and looks close to a circle.

# SPRSAB

The SPRSAB function performs matrix multiplication on two row-indexed sparse arrays created by SPRSIN. The routine computes all components of the matrix products, but only stores those values whose absolute magnitude exceeds the threshold value.

SPRSAB is based on the routine `sprstm` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission. The difference between the two routines is that SPRSAB performs the matrix multiplication  $A*B$  rather than  $A*B^T$ .

## Syntax

*Result* = SPRSAB( *A*, *B* [, /DOUBLE] [, THRESHOLD=*value*] )

## Return Value

The result is a row-indexed sparse array.

## Arguments

### A, B

Row-indexed sparse arrays created by the SPRSIN function.

### Note

---

If SPRSAB is complex then only the real part is used for the computation.

---

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the

default value is  $1.0 \times 10^{-7}$ . For double-precision calculations, the default is  $1.0 \times 10^{-14}$ .

## Examples

```

; Begin by creating two arrays:
A = [[ 5.0,  0.0,  0.0,  1.0], $
      [ 3.0, -2.0,  0.0,  1.0], $
      [ 4.0, -1.0,  0.0,  2.0], $
      [ 0.0,  3.0,  3.0,  1.0]]
B = [[ 1.0,  2.0,  3.0,  1.0], $
      [ 3.0, -3.0,  0.0,  1.0], $
      [-1.0,  3.0,  1.0,  2.0], $
      [ 0.0,  3.0,  3.0,  1.0]]

; Convert the arrays to sparse array format before multiplying.
; The variable SPARSE holds the result in sparse array form:
sparse = SPRSAB(SPRSIN(A), SPRSIN(B))

; Restore the sparse array structure to full storage mode:
result = FULSTR(sparse)

; Print the result:
PRINT, 'result:'
PRINT, result

; Check this result by multiplying the original arrays:
exact = B # A
PRINT, 'exact:'
PRINT, exact

```

IDL prints:

```

result:
  5.00000    13.0000    18.0000    6.00000
 -3.00000    15.0000    12.0000    2.00000
  1.00000    17.0000    18.0000    5.00000
  6.00000     3.00000    6.00000    10.0000
exact:
  5.00000    13.0000    18.0000    6.00000
 -3.00000    15.0000    12.0000    2.00000
  1.00000    17.0000    18.0000    5.00000
  6.00000     3.00000    6.00000    10.0000

# SPRSAX

The SPRSAX function takes a row-indexed sparse array created by the SPRSIN function and multiplies it by an  $n$ -element vector to its right.

SPRSAX is based on the routine `spr sax` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SPRSAX( *A*, *X* [, /DOUBLE] )

## Return Value

Returns a  $n$ -element vector.

## Arguments

### A

A row-indexed sparse array created by the SPRSIN function.

### Note

---

If SPRSAX is complex then only the real part is used for the computation.

---

### X

An  $n$ -element right hand vector.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Begin by creating an array A:  
A = [[ 5.0,  0.0, 0.0], $  
      [ 3.0, -2.0, 0.0], $  
      [ 4.0, -1.0, 0.0]]
```

```
; Define the right-hand vector:  
X = [1.0, 2.0, -1.0]  
  
; Convert to sparse format, then multiply by X:  
result = SPRSAX(SPRSIN(A),X)  
  
; Print the result:  
PRINT, result
```

IDL prints:

```
5.00000      -1.00000      2.00000

[FULSTR](#), [LINBCG](#), [SPRSAB](#), [SPRSIN](#), [SPRSTP](#), [READ\\_SPR](#), [WRITE\\_SPR](#)

# SPRSIN

The SPRSIN function converts an array, or list of subscripts and values, into a row-index sparse storage mode, retaining only elements with an absolute magnitude greater than or equal to the specified threshold. The list form is much more efficient than the array form if the density of the matrix is low.

SPRSIN is based on the routine `sprsin` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = SPRSIN( A [, /COLUMN] [, /DOUBLE] [, THRESHOLD=value] )
```

or

```
Result = SPRSIN(Columns, Rows, Values, N [, /DOUBLE] [, THRESHOLD=value])
```

## Return Value

The result is a row-indexed sparse array contained in structure form. The structure consists of two linear sparse storage vectors: SA, a vector of array values, and IJA, a vector of subscripts to the SA vector. The length of these vectors is equal to 1 plus the number of diagonal elements of the array, plus the number of off-diagonal elements with an absolute magnitude greater than or equal to the threshold value. Diagonal elements of the array are always retained even if their absolute magnitude is less than the specified threshold.

## Arguments

### A

An  $n$  by  $n$  array of any type except string or complex.

### Columns

A vector containing the column subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

## Rows

A vector, of the same length as Column, containing the row subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

## Values

A vector, of the same length as Column, containing the values of the non-zero elements.

## N

The size of the resulting sparse matrix.

## Keywords

### COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors). This keyword is not allowed in the list form of the call.

### DOUBLE

Set this keyword to convert the sparse array to double-precision.

### THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the default value is  $1.0 \times 10^{-7}$ . For double-precision values, the default is  $1.0 \times 10^{-14}$ .

## Examples

### Example1

Suppose we wish to convert the following array to sparse storage format:

```
A = [[ 5.0, -0.2, 0.1], $
      [ 3.0, -2.0, 0.3], $
      [ 4.0, -1.0, 0.0]]
```

```
; Convert to sparse storage mode. All elements of the array A that
; have absolute values less than THRESH are set to zero.
sparse = SPRSIN(A, THRESH = 0.5)
```

The variable SPARSE now contains a representation of A in structure form. See the description of FULSTR for an example that restores such a structure to full storage mode.

## Example2

This example demonstrates how to use the list form of the call to SPRSIN. The following line of code creates a sparse matrix, equivalent to a 100 by 100 identity matrix, i.e. all diagonal elements are set to 1, all other elements are zero:

```
I100 = SPRSIN(LINDGEN(100), LINDGEN(100), REPLICATE(1.0,100), 100)
```

## Version History

4.0	Introduced

[FULSTR](#), [LINBCG](#), [SPRSAB](#), [SPRSAX](#), [SPRSTP](#), [READ\\_SPR](#), [WRITE\\_SPR](#)

# SPRSTP

The SPRSTP function constructs the transpose of a sparse matrix.

## Syntax

*Result* = SPRSTP(*A*)

## Return Value

Returns the sparse matrix of the given sparse array.

## Arguments

### A

A row-indexed sparse array created by the SPRSIN function.

## Keywords

None

## Examples

This example creates a 100 by 100 pseudo-random sparse matrix, with 1000 non-zero elements, and then computes the product of the matrix and its transpose:

```
n = 100                                ;Dimensions of matrix
m = 1000                               ;Number of non-zero elements
a = SPRSIN(RANDOMU(seed, m)*n, RANDOMU(seed, m)*n, $
          RANDOMU(seed, m),n)
b = SPRSAB(a, SPRSTP(a)) ;Transpose and create the product
```

# SQRT

The SQRT function computes the square root of  $X$ .

## Syntax

$Result = \text{SQRT}(X)$

## Return Value

Returns the square root of  $X$ .

## Arguments

### $X$

The value for which the square root is desired. If  $X$  is double-precision floating-point or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers,  $z = x+iy$ :

$$z^{1/2} = \left[ \frac{1}{2}(r + x) \right]^{1/2} \pm i \left[ \frac{1}{2}(r - x) \right]^{1/2}$$

$$r = \sqrt{x^2 + y^2}$$

The ambiguous sign is taken to be the same as the sign of  $y$ . The result has the same structure as  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To find the square root of 145 and store the result in variable S, enter:

```
S = SQRT(145)
```

# STANDARDIZE

The STANDARDIZE function computes standardized variables from an array of  $m$  variables (columns) and  $n$  observations (rows).

This routine is written in the IDL language. Its source code can be found in the file `standardize.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = STANDARDIZE( A [, /DOUBLE] )
```

## Return Value

The result is an  $m$ -column,  $n$ -row array where all columns have a mean of zero and a variance of one.

## Arguments

### A

An  $m$ -column,  $n$ -row single- or double-precision floating-point array.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an array with 4 variables and 20 observations:
array = $
      [[19.5, 43.1, 29.1, 11.9], $
       [24.7, 49.8, 28.2, 22.8], $
       [30.7, 51.9, 37.0, 18.7], $

[MOMENT](#)

# STDDEV

The STDDEV function computes the standard deviation of an  $n$ -element vector.

## Syntax

$$\text{Result} = \text{STDDEV}(X [, /\text{DOUBLE}] [, /\text{NAN}])$$

## Return Value

The result is the standard deviation of the given vector.

## Arguments

### X

A numeric vector.

## Keywords

### DOUBLE

If this keyword is set, computations are performed in double precision arithmetic.

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]

; Compute the standard deviation:
result = STDDEV(x)

PRINT, result
```

IDL prints:

2.65832

# STOP

The STOP procedure stops the execution of a running program or batch file. Control reverts to the interactive mode.

## Syntax

```
STOP [, Expr1, ..., Exprn]
```

## Arguments

### Expr<sub>*i*</sub>

One or more expressions whose value is printed. If no parameters are present, a brief message describing where the STOP was encountered is printed.

## Keywords

None.

## Examples

Suppose that you want to stop the execution of a procedure and print the values of the variables A, B, C and NUM. At the appropriate location in your procedure include the command:

```
STOP, A, B, C, NUM
```

To continue execution of the procedure (if possible) enter the IDL executive command:

```
.CONT
```

# STRARR

The STRARR function returns a string array containing zero-length strings.

## Syntax

$$Result = STRARR(D_1 [, \dots, D_8])$$

## Return Value

The result is a string array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Examples

To create S, a 20-element string vector, enter:

```
S = STRARR(20)
```

## Version History

Original	Introduced
----------	------------

# STRCMP

The STRCMP function performs string comparisons between its two String arguments, returning True (1) for those that match and False (0) for those that do not. Normally, the IDL equality operator (EQ) is used for such comparisons, but STRCMP can optionally perform case-insensitive comparisons and can be limited to compare only the first N characters of the two strings, both of which require extra steps using the EQ operator.

## Syntax

*Result* = STRCMP( *String1*, *String2* [, *N*] [, /FOLD\_CASE] )

## Return Value

If all of the arguments are scalar, the result is scalar. If one of the arguments is an array, the result is an integer with the same structure. If more than one argument is an array, the result has the structure of the smallest array. Each element of the result contains True (1) if the corresponding elements of String1 and String2 are the same, and False (0) otherwise.

## Arguments

### String1, String2

The strings to be compared.

### N

Normally String1 and String2 are compared in their entirety. If N is specified, the comparison is made on at most the first N characters of each string.

## Keywords

### FOLD\_CASE

String comparison is normally a case sensitive operation. Set FOLD\_CASE to perform case insensitive comparisons instead.

## Examples

Compare two strings in a case-insensitive manner, considering only the first 3 characters:

```
Result = STRCMP('Moose', 'moo', 3, /FOLD_CASE)
PRINT, Result
```

IDL prints:

1

“[Non-Printing Characters](#)” in Chapter 14 of the *Building IDL Applications* manual

# STRCOMPRESS

The STRCOMPRESS function returns a copy of *String* with all whitespace (blanks and tabs) compressed to a single space or completely removed.

## Syntax

```
Result = STRCOMPRESS( String [, /REMOVE_ALL ] )
```

## Return Value

The result is a compressed string.

## Arguments

### String

The string to be compressed. If not of type string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a compressed copy of the corresponding element of *String*.

## Keywords

### REMOVE\_ALL

Set this keyword to remove *all* whitespace. Normally, all whitespace is compressed to a *single* space.

## Examples

```
; Create a string variable S:  
S = 'This is a string with spaces in it.'  
  
; Print S with all of the whitespace removed:  
PRINT, STRCOMPRESS(S, /REMOVE_ALL)
```

### IDL Output

```
Thisisastringwithspacesinit.
```

## Version History

[STRTRIM](#)

# STREAMLINE

The STREAMLINE procedure generates the visualization graphics from a path. The output is a polygonal ribbon which is tangent to a vector field along its length. The ribbon is generated by placing a line at each vertex in the direction specified by each normal value multiplied by the anisotropy factor. The input normal array is not normalized before use, making it possible to vary the ribbon width as well.

## Syntax

```
STREAMLINE, Verts, Conn, Normals, Outverts, Outconn [, ANISOTROPY=array]  
[, SIZE=vector] [, PROFILE=array]
```

## Arguments

### Verts

Input array of path vertices ( $[3, n]$  array).

### Conn

Input path connectivity array in IDLgrPolyline POLYLINES keyword format. There is one set of line segments in this array for each streamline.

### Normals

Normal estimate at each input vertex ( $[3, n]$  array).

### Outverts

Output vertices ( $[3 \times n]$  float array). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

### Outconn

Output polygonal connectivity array to match the output vertices.

## Keywords

### ANISOTROPY

Set this input keyword to a three-element array describing the distance between grid points in each dimension. The default value is  $[1.0, 1.0, 1.0]$

## SIZE

Set this keyword to a vector of values (one for each path point). These values are used to specify the width of the ribbon or the size of profile at each point along its path. This keyword is generally used to convey additional data parameters along the streamline.

## PROFILE

Set this keyword to an array of two-dimensional points which are treated as the cross section of the ribbon instead of a line segment. If the first and last points in the array are the same, a closed profile is generated. The profile is placed at each path vertex in the plane perpendicular to the line connecting each path vertex with the vertex normal defining the up direction. This allows for the generation of streamtubes and other geometries.

## Version History

5.3	Introduced
-----	------------

# STREGEX

The STREGEX function performs regular expression matching against the strings contained in StringExpression. STREGEX can perform either a simple boolean True/False evaluation of whether a match occurred, or it can return the position and offset within the strings for each match. The regular expressions accepted by this routine, which correspond to “Posix Extended Regular Expressions”, are similar to those used by such UNIX tools as egrep, lex, awk, and Perl.

For more information about regular expressions, see “[Learning About Regular Expressions](#)” in Chapter 14 of the *Building IDL Applications* manual.

STREGEX is based on the regex package written by Henry Spencer, modified by RSI only to the extent required to integrate it into IDL. This package is freely available at <ftp://zoo.toronto.edu/pub/regex.shar>.

## Syntax

```
Result = STREGEX( StringExpression, RegularExpression [, /BOOLEAN |  
                , /EXTRACT | , LENGTH=variable [, /SUBEXPR]] [, /FOLD_CASE] )
```

## Return Value

By default, STREGEX returns the position and length of the matched string within StringExpression. If no match is found, -1 is returned for both of these. Optionally, it can return a Boolean True/False result of the match, or the matched strings.

## Arguments

### StringExpression

String to be matched.

### RegularExpression

A scalar string containing the regular expression to match. See “[Learning About Regular Expressions](#)” in Chapter 14 of the *Building IDL Applications* manual for a description of the meta characters that can be used in a regular expression.

## Keywords

### BOOLEAN

Normally, STREGEX returns the position of the first character in StringExpression that matches RegularExpression. Setting BOOLEAN modifies this behavior to simply return a True/False value indicating if a match occurred or not.

### EXTRACT

Normally, STREGEX returns the position of the first character in StringExpression that matches RegularExpression. Setting EXTRACT modifies this behavior to simply return the matched substrings. The EXTRACT keyword cannot be used with either BOOLEAN or LENGTH.

### FOLD\_CASE

Regular expression matching is normally a case-sensitive operation. Set FOLD\_CASE to perform case-insensitive matching instead.

### LENGTH

If present, specifies a variable to receive the lengths of the matches. Together with this result of this function, which contains the starting points of the matches in StringExpression, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with either BOOLEAN or EXTRACT.

### SUBEXPR

By default, STREGEX only reports the overall match. Setting SUBEXPR causes it to report the overall match as well as any subexpression matches. A subexpression is any part of a regular expression written within parentheses. For example, the regular expression '(a)(b)(c+)' has 3 subexpressions, whereas the functionally equivalent 'abc+' has none. The SUBEXPR keyword cannot be used with BOOLEAN.

If a subexpression participated in the match several times, the reported substring is the last one it matched. Note, as an example in particular, that when the regular expression '(b\*)+' matches 'bbb', the parenthesized subexpression matches the three 'b's and then an infinite number of empty strings following the last 'b', so the reported substring is one of the empties. This occurs because the '\*' matches *zero or more* instances of the character that precedes it.

In order to return multiple positions and lengths for each input, the result from SUBEXPR has a new first dimension added compared to StringExpression.

## Examples

### Example 1

To match a string starting with an “a”, followed by a “b”, followed by 1 or more “c”:

```
pos = STREGEX('aaabccc', 'abc+', length=len)
PRINT, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc
```

To perform the same match, and also find the locations of the three parts:

```
pos = STREGEX('aaabccc', '(a)(b)(c+)', length=len, /SUBEXPR)
print, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc a b ccc
```

Or more simply:

```
print, STREGEX('aaabccc', '(a)(b)(c+)', /SUBEXPR, /EXTRACT)
```

IDL Prints:

```
abccc a b ccc
```

### Example 2

This example searches a string array for words of any length beginning with “f” and ending with “t” without the letter “o” in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'affluent']
PRINT, STREGEX(str, '^f[^o]*t$', /EXTRACT, /FOLD_CASE)
```

This statement results in:

```
Feet FAST ferret
```

Note the following about this example:

- Unlike the \* wildcard character used by STRMATCH, the \* meta character used by STREGEX applies to the item directly on its left, which in this case is [^o], meaning “any character except the letter ‘o’”. Therefore, [^o]\* means

“zero or more characters that are not ‘o’ ”, whereas the following statement would find only words whose second character is not “o”:

```
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

- The anchors (^ and \$) tell STREGEX to find only words that begin with “f” and end with “t”. If we left out the ^ anchor in the above example, STREGEX would also return “ffluent” (a substring of “affluent”). Similarly, if we left out the \$ anchor, STREGEX would also return “fat” (a substring of “fate”).

# STRETCH

The STRETCH procedure stretches the image display color tables so the full range runs from one color index to another. The modified colortable is loaded, but the COLORS common block is not changed. The original colortable can be restored by calling STRETCH with no arguments. A colortable must be loaded before STRETCH can be called.

This routine is written in the IDL language. Its source code can be found in the file `stretch.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
STRETCH [, Low, High [, Gamma]] [, /CHOP]
```

## Arguments

### Low

The lowest pixel value to use. If this parameter is omitted, 0 is assumed. Appropriate values range from 0 to the number of available colors-1. If no parameters are supplied, the original color tables are restored.

### High

The highest pixel value to use. If this parameter is omitted, the number of colors-1 is assumed. Appropriate values range from 0 to the number of available colors-1.

### Gamma

An optional Gamma correction factor. If this value is omitted, 1.0 is assumed. Gamma correction works by raising the color indices to the *Gamma* power, assuming they are scaled into the range 0 to 1.

## Keywords

### CHOP

Set this keyword to set color indices above the upper threshold to color index 0. Normally, values above the upper threshold are set to the maximum color index.

## Examples

Load the STD GAMMA-II color table by entering:

```
LOADCT, 5
```

Create and display an image by entering:

```
TVSCL, DIST(300)
```

Now adjust the color table with `STRETCH`. Make the entire color table fit in the range 0 to 70 by entering:

```
STRETCH, 0, 70
```

Notice that pixel values above 70 are now colored white. Restore the original color table by entering:

```
STRETCH
```

---

**Note**

The window-oriented procedures will not work without a window system.

# STRING

The STRING function returns its arguments converted to string type. It is similar to the PRINT procedure, except that its output is placed in a string rather than being output to the terminal. The case in which a single expression of type byte is specified without the FORMAT keyword is special—see the “[Differences Between STRING and PRINT](#)” on page 2223 for details.

---

## Note

Applying the STRING function to a byte array containing a null (zero) value will result in the resulting string being truncated at that position.

---

## Syntax

```
Result = STRING( Expression1, ..., Expressionn [, AM_PM=[string, string]]
  [, DAYS_OF_WEEK=string_array{7 names}] [, FORMAT=value]
  [, MONTHS=string_array{12 names}] [, /PRINT] )
```

## Return Value

Returns a string containing the specified expression.

## Arguments

### Expression<sub>n</sub>

The expressions to be converted to string type.

---

## Note

If you supply a comma-separated list of expressions without specifying a FORMAT, and the combined length of the expressions is greater than the current width of your tty or command log window, STRING will create a string array with one element for each expression, rather than concatenating all expressions into a single string. In this case, you can either specify a FORMAT, or use the string concatenation operator, “+”.

---

## Keywords

### AM\_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

### DAYS\_OF\_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

### FORMAT

A format string to be used in formatting the expressions. See [“Using Explicitly Formatted Input/Output”](#) in Chapter 18 of the *Building IDL Applications* manual.

### MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

### PRINT

Set this keyword to specify that any special case processing should be ignored and that STRING should behave exactly as the PRINT procedure would.

## Differences Between STRING and PRINT

The behavior of STRING differs from the behavior of the PRINT procedure in the following ways (unless the PRINT keyword is set):

- When called with a single non-byte argument and no format specification, STRING returns a result that has the same dimensions as the original argument. For example, the statement:

```
HELP, STRING(INDGEN(5))
```

gives the result:

```
<Expression> STRING = Array[5]
```

while:

```
HELP, STRING(INDGEN(5), /PRINT)
```

results in:

```
<Expression> STRING = ' 0 1 2 3 4'
```

- If called with a single argument of byte type and the **FORMAT** keyword is not used, **STRING** simply stores the unmodified values of each byte element in the result. This result is a string containing the byte values from the original argument. Thus, the result has one less dimension than the original argument. For example, a 2-dimensional byte array becomes a vector of strings, a byte vector becomes a scalar string. However, a byte scalar also becomes a string scalar. For example, the statement:

```
PRINT, STRING([72B, 101B, 108B, 108B, 111B])
```

produces the output `Hello` because the argument to **STRING**, is a byte vector. Its first element is a 72B which is the ASCII code for “H”, the second is 101B which is an ASCII “e”, and so forth.

- If both the **FORMAT** and **PRINT** keywords are not present and **STRING** is called with more than one argument, and the last argument is a scalar string starting with the characters “\$(” or “(”, this final argument is taken to be the format specification, just as if it had been specified via the **FORMAT** keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

## Examples

To convert the contents of variable **A** to string type and store the result in variable **B**, enter:

```
B = STRING(A)
```

# STRJOIN

The STRJOIN function collapses a one-dimensional string array into a single merged string or two-dimensional string array into a one-dimensional array of merged strings. The strings in the removed first dimension are concatenated into a single string using the string in *Delimiter* to separate them.

## Syntax

```
Result = STRJOIN( String [, Delimiter] [, /SINGLE] )
```

## Return Value

Returns the merged strings.

## Arguments

### String

A string array to be collapsed into merged strings.

### Delimiter

The separator string to use between the joined strings. If Delimiter is not specified, an empty string is used.

## Keywords

### SINGLE

If SINGLE is set, the entire String is joined into a single scalar string result.

## Examples

Replace all the blanks in a sentence with colons:

```
str = 'Out, damned spot! Out I say!'
print, (STRJOIN(STRSPLIT(str, /EXTRACT), ':'))
```

IDL prints:

```
Out, :damned:spot!:Out:I:say!
```

# STRLEN

The STRLEN function returns the length of its string-type argument. If the argument is not a string, it is first converted to string type.

## Syntax

*Result* = STRLEN(*Expression*)

## Return Value

Returns the string length.

## Arguments

### Expression

The expression for which the string length is desired. If this parameter is not a string, it is converted using IDL's default formatting rules in order to determine the length. The result is a long integer. If *Expression* is an array, the result is a long integer array with the same structure, where each element contains the length of the corresponding *Expression* element.

## Keywords

None.

## Examples

To find the length of the string "IDL is fun" and print the result, enter:

```
PRINT, STRLEN('IDL is fun')
```

IDL prints:

```
10
```

## Version History

Original	Introduced
----------	------------

# STRLOWCASE

The STRLOWCASE function returns a copy of *String* converted to lowercase characters. Only uppercase characters are modified—lowercase and non-alphabetic characters are copied without change.

## Syntax

*Result* = STRLOWCASE(*String*)

## Return Value

Returns a string composed of lowercase characters.

## Arguments

### String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a lower case copy of the corresponding element of *String*.

## Keywords

None.

## Examples

To convert the string “IDL is fun” to all lowercase characters and print the result, enter:

```
PRINT, STRLOWCASE('IDL is fun')
```

IDL prints:

```
idl is fun
```

## Version History

Original	Introduced
----------	------------

[STRUPCASE](#)

# STRMATCH

The STRMATCH function compares its search string, which can contain wildcard characters, against the input string expression. The result is an array with the same structure as the input string expression. Those elements that match the corresponding input string are set to True (1), and those that do not match are set to False (0).

The wildcards understood by STRMATCH are similar to those used by the standard UNIX shell:

Wildcard Character	Description
*	Matches any string, including the null string.
?	Matches any single character.
[...]	Matches any one of the enclosed characters. A pair of characters separated by “-” matches any character lexically between the pair, inclusive. If the first character following the opening [ is a !, any character not enclosed is matched.

To prevent one of these characters from acting as a wildcard, precede it with a backslash character (e.g. "\\*" matches the asterisk character). Quoting any other (non-wildcard) character (including \ itself) is equivalent to the character (e.g. "\a" is the same as "a").

Table 3-120: Wildcard Characters used by STRMATCH

## Syntax

*Result* = STRMATCH( *String*, *SearchString* [, /**FOLD\_CASE**] )

## Return Value

Returns 1 if the pattern specified by *SearchString* exists in *String*, or 0 otherwise. If the *String* argument contains an array of strings, the result is an array of 1s and 0s with the same number of elements as *String*, indicating which elements contain *SearchString*.

## Arguments

### String

A scalar string or string array to be searched.

### SearchString

A scalar string containing the pattern to search for in *String*. The pattern string can contain wildcard characters as discussed above.

## Keywords

### FOLD\_CASE

The comparison is usually case sensitive. Setting the FOLD\_CASE keyword causes a case insensitive match to be done instead.

## Examples

### Example 1

Find all 4-letter words in a string array that begin with “f” or “F” and end with “t” or “T”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f??t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST fort
```

### Example 2

Find words of any length that begin with “f” and end with “t”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST ferret fort
```

### Example 3

Find 4-letter words beginning with “f” and ending with “t”, with any combination of “o” and “e” in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[eo][eo]t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet
```

### Example 4

Find all words beginning with “f” and ending with “t” whose second character is not the letter “o”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
Feet FAST ferret
```

“Non-Printing Characters” in Chapter 14 of the *Building IDL Applications* manual

# STRMESSAGE

The STRMESSAGE function returns the text of the error message specified by *Err*. This function is especially useful in conjunction with the CODE field of the !ERROR\_STATE system variable which always contains the error number of the last error. The MSG field of the !ERROR\_STATE system variable contains the text of the last error message.

## Syntax

*Result* = STRMESSAGE( *Err* [, /BLOCK | , /CODE | , /NAME] )

## Return Value

Returns the error message text.

## Arguments

### Err

The error number or text. Programs must not make the assumption that certain error numbers are always related to certain error messages—the actual correspondence changes over time as IDL is modified.

## Keywords

### BLOCK

Set this keyword to return the name of the message block that defines *Err*. If this keyword is specified, *Err* must be an error code.

### CODE

Set this keyword to return the error code for the error message specified in *Err*. If this keyword is specified, *Err* must be an error name.

### NAME

Set this keyword to return a string containing the error message that goes with *Err*. If this keyword is specified, *Err* must be an error code.

## Examples

Print the error message associated with error number 4 by entering:

```
PRINT, STRMESSAGE(4)
```

## Version History

Original	Introduced

[MESSAGE](#)

# STRMID

The STRMID function extracts one or more substrings from a string expression. Each extracted string is the result of removing characters.

## Syntax

*Result* = STRMID(*Expression*, *First\_Character* [, *Length*] [, /REVERSE\_OFFSET])

## Return Value

The result of the function is a string of *Length* characters taken from *Expression*, starting at character position *First\_Character*.

The form of *First\_Character* and *Length* control how they are applied to *Expression*. Either argument can be a scalar or an array:

- If a scalar value is supplied for *First\_Character* and *Length*, then those values are applied to all elements of *Expression*. The result has the same structure and number of elements as *Expression*.

If *First\_Character* or *Length* is an array, the size of their first dimension determines how many substrings are extracted from each element of *Expression*. We call this the “stride”. If both are arrays, they must have the same stride. If *First\_Character* or *Length* do not contain enough elements to process *Expression*, STRMID automatically loops back to the beginning as necessary. Excess values are ignored. If the stride is 1, the result will have the same structure and number of elements as *Expression*. If it is greater than 1, the result will have an additional dimension, with the new first dimension having the same size as the stride.

## Arguments

### Expression

The expression from which the substrings are to be extracted. If this argument is not a string, it is converted using IDL's default formatting rules.

### First\_Character

The starting position within *Expression* at which the substring starts. The first character position is 0.

## Length

The length of the substring. If there are not enough characters left in the main string to obtain *Length* characters, the substring is truncated. If *Length* is not supplied, STRMID extracts all characters from the specified start position to the end of the string.

## Keywords

### REVERSE\_OFFSET

Specifies that *First\_Character* should be counted from the end of the string backwards. This allows simple extraction of strings from the end.

## Examples

If the variable B contains the string “IDL is fun”, the substring “is” can be extracted and stored in the variable C with the command:

```
C = STRMID(B, 4, 2)
```

## Version History

Original	Introduced
----------	------------

## See Also

[STRPOS](#), [STRPUT](#), [STRTRIM](#)

# STRPOS

The STRPOS function finds the first occurrence of a substring within an object string.

## Syntax

```
Result = STRPOS( Expression, Search_String [, Pos] [, /REVERSE_OFFSET]  
                [, /REVERSE_SEARCH] )
```

## Return Value

If *Search\_String* occurs in *Expression*, STRPOS returns the character position of the match, otherwise it returns -1.

## Arguments

### Expression

The expression in which to search for the substring. If this argument is not a string, it is converted using IDL's default formatting rules. If *Expression* is an array, the result is an array with the same structure, where each element contains the position of the substring within the corresponding element *Expression*. If *Expression* is the null string, STRPOS returns the value -1.

### Search\_String

The substring to be searched for within *Expression*. If this argument is not a string, it is converted using IDL's default formatting rules. If *Search\_String* is the null string, STRPOS returns the smaller of *Pos* or one less than the length of *Expression*.

### Pos

The character position at which the search is begun. If *Pos* is omitted and the REVERSE\_SEARCH keyword is not set, the search begins at the first character (character position 0). If REVERSE\_SEARCH is set, the default is to start at the last character in the string. If *Pos* is less than zero, zero is used for the starting position.

## Keywords

### REVERSE\_OFFSET

Normally, the value of *Pos* is used as an offset from the beginning of the expression towards the end. Set `REVERSE_OFFSET` to use it as an offset from the last character of the string moving towards the beginning. This keyword makes it easy to position the starting point of the search at a fixed offset from the end of the string.

### REVERSE\_SEARCH

`STRPOS` usually starts at *Pos* and moves toward the end of the string looking for a match. If `REVERSE_SEARCH` is set, the search instead moves towards the beginning of the string.

## Examples

### Example 1

Find the position of the string “fun” within the string “IDL is fun” and print the result by entering:

```
PRINT, STRPOS('IDL is fun', 'fun')
```

IDL prints:

```
7
```

### Example 2

The `REVERSE_SEARCH` keyword to the `STRPOS` function makes it easy to find the last occurrence of a substring within a string. In the following example, we search for the last occurrence of the letter “I” (or “i”) in a sentence:

```
sentence = 'IDL is fun.'
sentence = STRUPCASE(sentence)
lasti = STRPOS(sentence, 'I', /REVERSE_SEARCH)
PRINT, lasti
```

This results in:

```
4
```

Note that although `REVERSE_SEARCH` tells `STRPOS` to begin searching from the end of the string, the `STRPOS` function still returns the position of the search string from the beginning of the string (where 0 is the position of the first character).

[STRMID](#), [STRPUT](#), [STRTRIM](#)

“[Non-Printing Characters](#)” in Chapter 14 of the *Building IDL Applications* manual

# STRPUT

The STRPUT procedure inserts the contents of one string into another. The source string, *Source*, is inserted into the destination string, *Destination*, starting at the given position, *Position*. Characters in *Destination* before the starting position and after the starting position plus the length of *Source* remain unchanged. The length of the destination string is not changed. If the insertion extends past the end of the destination, it is clipped at the end.

## Syntax

```
STRPUT, Destination, Source [, Position]
```

## Arguments

### Destination

The named string variable into which *Source* is inserted. *Destination* must be a named variable of type string. If it is an array, *Source* is inserted into every element of the array.

### Source

A scalar string to be inserted into *Destination*. If this argument is not a string, it is converted using IDL's default formatting rules.

### Position

The character position at which the insertion is begun. If *Position* is omitted, the insertion begins at the first character (character position 0). If *Position* is less than zero, zero is used for the initial position.

## Keywords

None.

## Examples

If the variable A contains the string "IBM is fun", the substring "IBM" can be overwritten with the string "IDL" by entering:

```
STRPUT, A, 'IDL', 0
```

The following commands demonstrate the clipping of output that extends past the end of the destination string:

```
STRPUT, A, 'FUNNY', 7  
PRINT, A
```

IDL prints:

```
IDL is FUN
```

[STRMID](#), [STRPOS](#), [STRTRIM](#)

# STRSPLIT

The STRSPLIT function splits its input *String* argument into separate substrings, according to the specified delimiter or regular expression. By default, the position of the substrings is returned. The EXTRACT keyword can be used to cause STRSPLIT to return an array containing the substrings.

## Syntax

```
Result = STRSPLIT( String [, Pattern] [, COUNT=variable] [, ESCAPE=string |
, /REGEX [, /FOLD_CASE]] [, /EXTRACT | , LENGTH=variable]
[, /PRESERVE_NULL] )
```

## Return Value

Returns an array containing either the positions of the substrings or the substrings themselves (if the EXTRACT keyword is specified).

## Arguments

### String

A scalar string to be split into substrings.

### Pattern

A scalar string that can contain one of two types of information:

- One or more *single characters*, each of which is considered to be a separator. *String* will be split when any of the characters is detected. For example, if *Pattern* is " , " *String* will be split whenever *either* a space or a comma is detected. In this case, IDL performs a simple string search for the specified characters. This method is simple and fast.
- If the REGEX keyword is specified, *Pattern* is considered to be a single regular expression (as implemented by the [STREGEX](#) function). This method is slower and more complex, but can handle extremely complicated *Pattern* strings.

In either case, if the EXTRACT keyword is specified, the separator characters are *not* included in the result.

**Note**

*Pattern* is an optional argument. If it is not specified, STRSPLIT defaults to splitting on spans of whitespace (space or tab characters) in *String*.

## Keywords

### COUNT

Set this keyword to a named variable that will contain the number of matched substrings returned by STRSPLIT. This value will be 0 if either of the *String* or *Pattern* arguments is null. Otherwise, it will contain the number of elements in the *Result* array.

### ESCAPE

When doing simple pattern matching, the ESCAPE keyword can be used to specify any characters that should be considered to be “escape” characters. Preceding any character with an escape character prevents STRSPLIT from treating it as a separator character even if it is found in *Pattern*.

Note that if the EXTRACT keyword is set, STRSPLIT will automatically remove the escape characters from the resulting substrings. If EXTRACT is not specified, STRSPLIT cannot perform this editing, and the returned position and offsets will include the escape characters.

For example:

```
print, STRSPLIT('a\b,c', ' ', ESCAPE='\', /EXTRACT)
```

IDL prints:

```
a,b c
```

ESCAPE cannot be specified with the FOLD\_CASE or REGEX keywords.

### EXTRACT

By default, STRSPLIT returns an array of character offsets into *String* that indicate where the substrings are located. These offsets, along with the lengths available from the LENGTH keyword can be used later with STRMID to extract the substrings. Set EXTRACT to bypass this step, and cause STRSPLIT to return the substrings. EXTRACT cannot be specified with the LENGTH keyword.

## FOLD\_CASE

Indicates that the regular expression matching should be done in a case-insensitive fashion. FOLD\_CASE can only be specified if the REGEX keyword is set, and cannot be used with the ESCAPE keyword.

## LENGTH

Set this keyword to a named variable to receive the lengths of the substrings. Together with this result of this function, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with the EXTRACT keyword.

## PRESERVE\_NULL

Normally, STRSPLIT will not return null length substrings unless there are no non-null values to report, in which case STRSPLIT will return a single null string. Set PRESERVE\_NULL to cause all null substrings to be returned.

## REGEX

For complex splitting tasks, the REGEX keyword can be specified. In this case, *Pattern* is taken to be a regular expression to be matched against *String* to locate the separators. If REGEX is specified and *Pattern* is not, the default *Pattern* is the regular expression:

```
' [ ' + STRING(9B) + ' ] +'
```

which means “any series of one or more space or tab characters” (9B is the byte value of the ASCII TAB character).

Note that the default *Pattern* contains a space after the [ character.

The REGEX keyword cannot be used with the ESCAPE keyword.

### Note

---

If *Pattern* specifies a single multi-character separator pattern (as contrasted with a string of two or more individual separator characters), you *must* specify the REGEX keyword.

---

## Examples

### Example 1

To split a string on spans of whitespace and replace them with hyphens:

```
Str = 'STRSPLIT chops up strings.'
print, STRJOIN(STRSPLIT(Str, /EXTRACT), '-')
```

IDL prints:

```
STRSPLIT-chops-up-strings.
```

### Example 2

As an example of a more complex splitting task that can be handled with the simple character-matching mode of STRSPLIT, consider a sentence describing different colored ampersand characters. For unknown reasons, the author used commas to separate all the words, and used ampersands or backslashes to escape the commas that actually appear in the sentence (which therefore should not be treated as separators). The unprocessed string looks like:

```
Str = 'There,was,a,red,&&&,a,yellow,&&\,,and,a,blue,\&.'
```

We use STRSPLIT to break this line apart, and STRJOIN to reassemble it as a standard blank-separated sentence:

```
S = STRSPLIT(Str, ',', ESCAPE='&\', /EXTRACT)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
There was a red &, a yellow &, and a blue &.
```

### Example 3

Strings separated by multi-character delimiters cannot be split using the simple character matching mode of STRSPLIT. Such delimiters require the use of a regular expression. For instance, consider splitting the following string on double ampersand boundaries.

```
str = 'red&&blue&&yellow&&odds&ends'
```

The desired result of such splitting would be four strings, with the values 'red', 'blue', 'yellow', and 'odds&ends'. You might be tempted to use STRSPLIT as follows:

```
PRINT, STRSPLIT(str, '&&', /EXTRACT)
```

which causes IDL to print:

```
red blue yellow odds ends
```

IDL split the string on single ampersand boundaries, yielding 5 strings instead of the desired 4. When using the simple character matching mode of STRSPLIT, the characters in the Pattern argument specify a set of possible single character delimiters. The order of these characters is unimportant, and specifying a character more than once has no effect (the extras are ignored).

To properly split the above string using a regular expression:

```
print, strsplit(str, '&&', /EXTRACT, /REGEX)
```

producing the desired IDL output:

```
red blue yellow odds&ends
```

## Example 4

Finally, suppose you had a complicated string, in which every token was preceded by the count of characters in that token, with the count enclosed in angle brackets:

```
str = '<4>What<1>a<7>tangled<3>web<2>we<6>weave.'
```

This is too complex to handle with simple character matching, but can be easily handled using the regular expression '<[0-9]+>' to match the separators. This regular expression can be read as “an opening angle bracket, followed by one or more numeric characters between 0 and 9, followed by a closing angle bracket.” The STRJOIN function is used to glue the resulting substrings back together:

```
S = STRSPLIT(str, '<[0-9]+>', /EXTRACT, /REGEX)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
What a tangled web we weave.
```

## Version History

5.3	Introduced
6.0	Added COUNT keyword

## See Also

# STRTRIM

The STRTRIM function removes leading and/or trailing blank from the input *String*.

## Syntax

```
Result = STRTRIM( String [, Flag] )
```

## Return Value

Returns a copy of string with the specified blank spaces removed.

## Arguments

### String

The string to have leading and/or trailing blanks removed. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains a trimmed copy of the corresponding element of *String*.

### Flag

A value that controls the action of STRTRIM. If *Flag* is zero or not present, trailing blanks are removed. Leading blanks are removed if it is equal to 1. Both are removed if it is equal to 2.

## Examples

Converting variables to string type often results in undesirable leading blanks. For example, the following command converts the integer 56 to string type:

```
C = STRING(56)
```

Entering the command:

```
HELP, C
```

IDL prints:

```
C          STRING = '      56'
```

which shows that there are six leading spaces before the characters 5 and 6. To remove these leading blanks, enter the command:

```
C = STRTRIM(C, 1)
```

To confirm that the blanks were removed, enter:

```
HELP, C
```

IDL prints:

```
C          STRING = '56'
```

[STRMID](#), [STRPOS](#), [STRPUT](#), [STRSPLIT](#)

# STRUCT\_ASSIGN

The IDL “=” operator is unable to assign a structure value to a structure of a different type. The `STRUCT_ASSIGN` procedure performs “relaxed structure assignment,” which is a field-by-field copy of a structure to another structure. Fields are copied according to the following rules:

1. Any fields found in the destination structure that are not found in the source structure are “zeroed” (set to zero, the empty string, or a null pointer or object reference depending on the type of field).
2. Any fields in the source structure that are not found in the destination structure are quietly ignored.
3. Any fields that are found in both the source and destination structures are copied one at a time. If necessary, type conversion is done to make their types agree. If a field in the source structure has fewer data elements than the corresponding field in the destination structure, then the “extra” elements in the field in the destination structure are zeroed. If a field in the source structure has more elements than the corresponding field in the destination structure, the extra elements are quietly ignored.

Relaxed structure assignment is especially useful when restoring structures from disk files into an environment where the structure definition has changed. See the description of the `RELAXED_STRUCTURE_ASSIGNMENT` keyword to the `RESTORE` procedure for additional details. “[Relaxed Structure Assignment](#)” in Chapter 16 of the *Building IDL Applications* manual provides a more in-depth discussion of the structure-definition process.

## Syntax

```
STRUCT_ASSIGN, Source, Destination [, /NOZERO] [, /VERBOSE]
```

## Arguments

### Source

A named variable or element of an array containing a structure, the contents of which will be assigned to the structure specified by the *Destination* argument. *Source* can be an object reference if `STRUCT_ASSIGN` is called inside an object method.

## Destination

A named variable containing a structure into which the contents of the structure specified by the *Source* argument will be inserted. *Destination* can be an object reference if `STRUCT_ASSIGN` is called inside an object method.

## Keywords

### NOZERO

Normally, any fields found in the destination structure that are not found in the source structure are zeroed. Set `NOZERO` to prevent this action and leave the original contents of such fields unchanged.

### VERBOSE

Set this keyword to cause `STRUCT_ASSIGN` to issue informational messages about any incompatibilities that prevent data from being copied.

## Examples

The following example creates two anonymous structures, then uses `STRUCT_ASSIGN` to insert the contents of the first into the second:

```
source = { a: FINDGEN(4), b: 12 }
dest = { a: INDGEN(2), c: 20 }
STRUCT_ASSIGN, /VERBOSE, source, dest
```

IDL prints:

```
% STRUCT_ASSIGN: <Anonymous> tag A is longer than destination.
                  The end will be clipped.
% STRUCT_ASSIGN: Destination lacks <Anonymous> tag B. Not copied.
```

After assignment, `dest` contains a two-element integer array [0, 1] in its field A and the integer 0 in its field C. Since `dest` does not have a field B, field B from `source` is not copied.

## Version History

5.1	Introduced
-----	------------

# STRUCT\_HIDE

The IDL HELP procedure displays information on all known structures or object classes when used with the STRUCTURES or OBJECTS keywords. Although this is usually the desired behavior, authors of large vertical applications or library routines may wish to prevent IDL from displaying information on structures or objects that are not part of their public interface, but which exist solely in support of the internal implementation. The STRUCT\_HIDE procedure is used to mark such structures or objects as hidden. Items so marked are not displayed by HELP, /STRUCTURE unless the user sets the FULL keyword, but are otherwise unaltered.

---

**Note**

STRUCT\_HIDE is primarily intended for use with named structures or objects. Although it can be safely used with anonymous structures, there is no visible benefit to doing so as anonymous structures are hidden by default.

---

---

**Tip**

Authors of objects will often place a call to STRUCT\_HIDE in the \_\_DEFINE procedure that defines the structure.

---

## Syntax

```
STRUCT_HIDE, Arg1 [, Arg2, ..., Argn]
```

## Arguments

### Arg<sub>1</sub>, ..., Arg<sub>n</sub>

If an argument is a variable of one of the following types, its underlying structure and/or object definition is marked as being hidden from the HELP procedure's default output:

- Structure
- Pointer that refers to a heap variable of structure type
- Object Reference

Any arguments that are not one of these types are quietly ignored. No change is made to the value of any argument.

## Keywords

None

## Examples

This example shows how a structure can be hidden if an application designer doesn't want end-users to be able to see it, but variables are not hidden. To create a named structure called `bullwinkle` and prevent it from appearing in the `HELP` procedure's default output, do the following.

```

; Define a variable containing the named structure:
tmp = { bullwinkle, moose:1, squirrel:0 }
; IDL returns BULLWINKLE in addition to the other system variables.
HELP, /STRUCTURE, /BRIEF
; Next, specifically hide the structure using
; the STRUCT_HIDE procedure.
STRUCT_HIDE, tmp
; This time IDL returns the system variables but
; not the BULLWINKLE structure.
HELP, /STRUCTURE, /BRIEF
; IDL returns the variable tmp showing that it is
; a named structure called BULLWINKLE.
HELP, tmp

```

[COMPILE\\_OPT](#)

# STRUPCASE

The STRUPCASE function returns a copy of *String* converted to upper case. Only lowercase characters are modified—uppercase and non-alphabetic characters are copied without change.

## Syntax

*Result* = STRUPCASE(*String*)

## Return Value

Returns a string composed of uppercase characters.

## Arguments

### String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains an uppercase copy of the corresponding element of *String*.

## Keywords

None.

## Examples

To print an uppercase version of the string “IDL is fun”, enter:

```
PRINT, STRUPCASE('IDL is fun')
```

IDL prints:

```
IDL IS FUN
```

## Version History

[STRLOWCASE](#)

# SURFACE

The SURFACE procedure draws a wire-mesh representation of a two-dimensional array projected into two dimensions, with hidden lines removed. SURFACE accepts a two-dimensional array of  $z$  (elevation) values, and optionally  $x$  and  $y$  parameters indicating the location of each  $z$  element. SURFACE depicts the surface created by interpreting each element value as an elevation. These three-dimensional, wire-mesh surface plots can have almost any rotation about the  $x$ - and  $z$ -axes (the data  $z$ -axis must project parallel to the device's  $y$ -axis).

SURFACE projects the three-dimensional array of points into two dimensions after rotating about the  $z$ - and then the  $x$ -axes. Each point is connected to its neighbors by lines. Hidden lines are suppressed. The rotation about the  $x$ - and  $z$ -axes can be specified with keywords or a complete three-dimensional transformation matrix can be stored in the field !P.T for use by SURFACE. Details concerning the mechanics of three-dimensional projection and rotation are covered in “[Coordinates of 3-D Graphics](#)” in Chapter 8 of the *Using IDL* manual.

## Restrictions

If the  $(X, Y)$  grid is not regular or nearly regular, errors in hidden line removal occur. The TRIGRID and TRIANGULATE routines can be used to interpolate irregularly-gridded data points to a regular grid before plotting.

If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the  $Z$  axis to a line parallel to the device  $Y$  axis, or errors will occur.

The surface lines may blend together when drawing large arrays, especially on low or medium resolution displays. Use the REBIN or CONGRID procedure to resample the array to a lower resolution before plotting.

## Syntax

```
SURFACE, Z [, X, Y] [, AX=degrees] [, AZ=degrees] [, BOTTOM=index]
  [, /HORIZONTAL] [, /LEGO] [, /LOWER_ONLY | /UPPER_ONLY]
  [, MAX_VALUE=value] [, MIN_VALUE=value] [, /SAVE] [, SHADES=array]
  [, SKIRT=value] [, /XLOG] [, /YLOG] [, ZAXIS={1 | 2 | 3 | 4}] [, /ZLOG]
```

**Graphics Keywords:** Accepts all graphics keywords accepted by PLOT except for: PSYM, SYMSIZE. See “[Graphics Keywords Accepted](#)” on page 2260.

**Note**

Many of the graphic keyword parameters correspond directly to fields in the system variables !P, !X, !Y, or !Z. When specifying a keyword parameter name and value in a call that value affects only the current call, the corresponding system-variable field is not changed. Changing the value of a system-variable field changes the default for that particular parameter and remains in effect until explicitly changed. The system variables involving graphics and their corresponding keywords are detailed in “!P” in Appendix D.

## Arguments

### Z

The two-dimensional array to be displayed. If  $X$  and  $Y$  are provided, the surface is plotted as a function of the  $(X, Y)$  locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of  $Z$ .

This argument is converted to double-precision floating-point before plotting. Plots created with SURFACE are limited to the range and precision of double-precision floating-point values.

### X

A vector or two-dimensional array specifying the  $X$  coordinates of the grid. If this argument is a vector, each element of  $X$  specifies the  $X$  coordinate for a column of  $Z$  (e.g.,  $X[0]$  specifies the  $X$  coordinate for  $Z[0, *]$ ). If  $X$  is a two-dimensional array, each element of  $X$  specifies the  $X$  coordinate of the corresponding point in  $Z$  ( $X_{ij}$  specifies the  $X$  coordinate for  $Z_{ij}$ ).

This argument is converted to double-precision floating-point before plotting.

### Y

A vector or two-dimensional array specifying the  $Y$  coordinates of the grid. If this argument is a vector, each element of  $Y$  specifies the  $Y$  coordinate for a row of  $Z$  (e.g.,  $Y[0]$  specifies the  $Y$  coordinate for  $Z[* , 0]$ ). If  $Y$  is a two-dimensional array, each element of  $Y$  specifies the  $Y$  coordinate of the corresponding point in  $Z$  ( $Y_{ij}$  specifies the  $Y$  coordinate for  $Z_{ij}$ ).

This argument is converted to double-precision floating-point before plotting.

## Keywords

### AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D is not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is taken from the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer ( $AX > 0$ ), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted and !P.T3D is 0.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

### AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

### BOTTOM

The color index used to draw the bottom surface. If not specified, the bottom is drawn with the same color as the top.

### HORIZONTAL

A keyword flag which if set causes SURFACE to only draw lines across the plot perpendicular to the line of sight. The default is for SURFACE to draw both across the plot and from front to back.

### LEGO

Set this keyword to produce stacked histogram-style plots. Each data value is rendered as a box covering the XY extent of the cell and with a height proportional to the Z value.

If the X and Y arguments are specified, only  $N_x-1$  columns and  $N_y-1$  rows are drawn. (This means that the last row and column of array data are not displayed.) The rectangular area covered by  $Z[i, j]$  is given by  $X[i]$ ,  $X[i+1]$ ,  $Y[j]$ , and  $Y[j+1]$ .

## LOWER\_ONLY

Set this keyword to draw only the lower surface of the object. By default, both surfaces are drawn.

## MAX\_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## MIN\_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN\_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SURFACE in the system variable field !P.T. Use this keyword when combining the output of SURFACE with additional output from other routines in the same plot.

When used with AXIS, the SAVE keyword parameter saves the scaling parameters established by the call in the appropriate axis system variable, !X, !Y, or !Z. This causes subsequent overplots to be scaled to the new axis.

For example, to display a two-dimensional array using SURFACE, and to then superimpose contours over the surface (this example assumes that !P.T3D is zero, its default value.), enter the following commands:

```
; Make a surface plot and save the transformation:
SURFACE, Z, /SAVE
```

```
; Make contours, don't erase, use the 3-D to 2-D transform placed
; in !P.T by SURFACE:
CONTOUR, Z, /NOERASE, /T3D
```

To display a surface and to then display a flat contour plot, registered above the surface:

```
; Make the surface, save transform:
SURFACE, Z, /SAVE
```

```

; Now display a flat contour plot, at the maximum Z value
; (normalized coordinates):
CONTOUR, Z, /NOERASE, /T3D, ZVALUE=1.0

```

You can display the contour plot below the surface with by using a *ZVALUE* of 0.0.

## SHADES

This keyword allows user-specified coloring of the mesh surfaces. Set this keyword to an array that specifies the color index of the lines emanating from each data point toward the top and right.

### Warning

---

When using the **SHADES** keyword on True Color devices, we recommend that decomposed color support be turned off, by setting `DEVICE, DECOMPOSED=0`. See “**DEVICE**” on page 582 and “**DECOMPOSED**” on page 4698.

---

## SKIRT

This keyword represents a *Z*-value at which to draw a skirt around the array. The *Z* value is expressed in data units. The default is no skirt.

If the skirt is drawn, each point on the four edges of the surface is connected to a point on the skirt which has the given *Z* value, and the same *X* and *Y* values as the edge point. In addition, each point on the skirt is connected to its neighbor.

## UPPER\_ONLY

Set this keyword to draw only the upper surface of the object. By default, both surfaces are drawn.

## XLOG

Set this keyword to specify a logarithmic *X* axis.

## YLOG

Set this keyword to specify a logarithmic *Y* axis.

## ZAXIS

This keyword specifies the placement of the *Z* axis for the **SURFACE** plot.

By default, **SURFACE** draws the *Z* axis at the upper left corner of the axis box. To suppress the *Z* axis, use `ZAXIS=-1` in the call. The position of the *Z* axis is

determined from the value of ZAXIS as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

## ZLOG

Set this keyword to specify a logarithmic Z axis.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, LINSTYLE, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK\_GET, [XYZ]TITLE, ZVALUE

## Examples

### Note

---

Also see the PLOT routine [“Examples”](#) on page 1663 for examples that control plot position, configure axes and position multiple plots on a page.

---

## Surface of a Gaussian Function

The following IDL code illustrates the most basic call to SURFACE. ; Create a 40 by 40 array in which each element is

```

; equal to the Euclidean distance from the center:
Z = SHIFT(DIST(40), 20, 20)
; Make Gaussian with a 1/e width of 10:
Z = EXP(-(Z/10)^2)
; Call SURFACE to display plot:
SURFACE, Z

```

In the example above, the `DIST` function creates an  $(n, n)$  array in which each element is set to its Euclidean distance from the origin. It produces a two-dimensional Gaussian function, then calls `SURFACE` to produce the figure below.

*Figure 3-122: Simple SURFACE Plot of a Gaussian*

Another simple example is created with the following statements:

```
; Create a simple dataset to display:
D = DIST(30)

; Plot a simple wire-mesh surface representation of D:
SURFACE, D

; Create a wire-mesh plot of D with a title and a "skirt" around
; the edges of the dataset at Z=0:
SURFACE, D, SKIRT=0.0, TITLE = 'Surface Plot', CHAR.SIZE = 2
```

## Surface of Elevation Data

The figures below illustrate the application of the `SURFACE` procedure to the Maroon Bells elevation data. As with `CONTOUR`, it is often useful to reduce the number of individual data values, so that the surface is not obscured by excessive detail.

Figure 3-123: Maroon Bells Surface Plots

The left illustration in the figure above was produced by the following statements:

```

; Restore variables.
@cntour01
; Resize the original data into a 72 x 92 array, setting
; all data values which are less than 2650 (the lowest
; elevation we wish to show) to 2650.
surf = REBIN(elev > 2650, 360/5, 460/5)
; Display the surface, drawing a skirt down to 2650 meters:
SURFACE, surf, X, Y, SKIRT = 2650

```

### Example Code

Alternatively, run the batch file `surf01` with the following command at the IDL prompt:

```
@surf01
```

See “[Running the Example Code](#)” on page 40 if IDL does not find the batch file.

The right illustration in the figure shows the Maroon Peaks area looking from the back row to the front row (north to the south) of the Maroon Peaks area. This perspective on the data is created by setting the angle of rotation around the  $z$ -axis to 210 degrees (setting `AZ = 210`), and increasing the azimuth from the default 30 degrees to 45 (setting `AX = 45`). Also, only the horizontal lines are drawn because the `/HORIZONTAL` keyword is present in the following call:

```
SURFACE, surf, X, Y, SKIRT = 2650, /HORIZ, AZ = 210, AX = 45
```

Because the axes are rotated 210 degrees about the original  $z$ -axis, the annotation is reversed and the  $x$ -axis is behind and obscured by the surface. This undesirable effect

can be eliminated by reversing the minimum and maximum values of the X and Y ranges used when drawing the surface:

```
; As above, but reverse the data rather than the axes:
SURFACE, surf, X, Y, SKIRT = 2650, /HORIZONTAL, AX = 45, $
  YRANGE = [MAX(Y), MIN(Y)], XRANGE=[MAX(X), MIN(X)]
```

## Transformation Created by SURFACE

The SURFACE procedure creates a transformation matrix from its keyword parameters AX and AZ as follows:

1. Starting with the identity transformation, SURFACE translates the center of the normalized cube to the origin.
2. SURFACE rotates 90 degrees about the  $x$ -axis to make the  $+z$ -axis of the data the  $+y$  axis of the display. The  $+y$  data axis extends from the front of the display to the rear.
3. SURFACE rotates AZ degrees about the  $y$ -axis. This rotates the result counter-clockwise, as seen from above the page.
4. SURFACE rotates AX degrees about the  $x$ -axis, tilting the data towards the viewer.
5. The procedure then removes the translation applied in the first step and scales the data so that the data are still contained within the normal coordinate unit cube after transformation.

These transformations can be created using [T3D](#) as shown below. The [SCALE3](#) procedure, mimics the transformation matrix created by SURFACE using the following method:

```
; Translate to move center of cube to origin.
T3D, /RESET, TRANSLATE = [-.5, -.5, -.5]
; Rotate 90 degrees about x-axis, so +z axis is now +y.
; Then rotate AZ degrees about y-axis.
T3D, ROTATE = [-90, AZ, 0]
; Rotate AX about x axis:
T3D, ROTATE = [AX, 0, 0]
; Restore origin.
T3D, TRANSLATE = [0.5, 0.5, 0.5]
```

The SCALE3 procedure, scales the unit cube by a fixed factor,  $1/\text{SQRT}(3)$  to ensure that the corners of the rotated cube fit within the drawing area. If requested, it also will set the data scaling. Animations involving rotations or the SURFACE procedure should have their scaling and viewing transformation set by SCALE3 rather than the obsolete SURFR procedure, so that the scaling does not vary between frames.

## Combining CONTOUR and SURFACE

It is easy to combine the results of SURFACE with the other IDL graphics procedures. The keyword parameter SAVE causes SURFACE to save the graphic transformation it used in !P.T. Then, when either CONTOUR or PLOT is called with the keyword parameter T3D, its output is transformed with the same projection. For example, the figure below illustrates how SURFACE and CONTOUR can be combined. In essence, this is a combination of figures from 2 previous sections.

Figure 3-124: Combining CONTOUR with SURFACE, Maroon Bells Data

Using the same variables as in the earlier sections of this section, the figure was produced with the following statements:

```

; Restore variables.
@cntour01

; Resize the original data into a 72 x 92 array,
; setting all data values which are less than
; 2650 (the lowest elevation we wish to show) to 2650.
surf = REBIN(elev > 2650, 360/5, 460/5)

; Make the mesh.
SURFACE, surf, X, Y, SKIRT=2650, /SAVE

```

```
; Specify T3D to align with SURFACE, at ZVALUE of 1.0.  
; Suppress clipping as the plot is outside the normal plot window.  
CONTOUR, surf, X, Y, /T3D, /NOERASE, TITLE = 'Contour Plot', $  
    MAX_VAL = 5000., ZVALUE = 1.0, /NOCLIP, $  
    LEVELS = 2750. + FINDGEN(6) * 250
```

[CONTOUR](#), [ISURFACE](#), [SHADE\\_SURF](#)

# SURFR

The SURFR procedure sets up 3-D transformations. This procedure duplicates the rotation, translation, and scaling features of the SURFACE routine, but does not display any data. The resulting transformations are stored in the !P.T system variable.

This routine is written in the IDL language. Its source code can be found in the file `surfr.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SURFR [, AX=degrees] [, AZ=degrees]
```

## Arguments

None.

## Keywords

### AX

This keyword specifies the angle of rotation about the X axis in degrees towards the viewer. The default is 30 degrees.

First rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer ( $AX > 0$ ), or away from the viewer.

### AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. The default is 30 degrees.

# SVDC

The SVDC procedure computes the Singular Value Decomposition (SVD) of a square ( $n \times n$ ) or non-square ( $n \times m$ ) array as the product of orthogonal and diagonal arrays. SVD is a very powerful tool for the solution of linear systems, and is often used when a solution cannot be determined by other numerical algorithms.

The SVD of an ( $n \times m$ ) non-square array  $A$  is computed as the product of an ( $n \times m$ ) column orthogonal array  $U$ , an ( $n \times n$ ) diagonal array  $SV$ , composed of the singular values, and the transpose of an ( $n \times n$ ) orthogonal array  $V$ :  $A = U \, SV \, V^T$

SVDC is based on the routine `svdcmp` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

## Note

If you are working with complex inputs, use the `LA_SVD` procedure instead.

---

## Syntax

SVDC,  $A$ ,  $W$ ,  $U$ ,  $V$  [, /COLUMN] [, /DOUBLE] [, ITMAX=*value*]

## Arguments

### A

The square ( $n \times n$ ) or non-square ( $n \times m$ ) single- or double-precision floating-point array to decompose.

### W

On output,  $W$  is an  $n$ -element output vector containing the “singular values.”

### U

On output,  $U$  is an  $n$ -column,  $m$ -row orthogonal array used in the decomposition of  $A$ .

### V

On output,  $V$  is an  $n$ -column,  $n$ -row orthogonal array used in the decomposition of  $A$ .

## Keywords

### COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 30.

## Examples

To find the singular values of an array *A*:

```

; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
      [1.5, 3.3, -0.5, 2.0], $
      [3.1, 0.7, 2.2, 0.0], $
      [0.0, 0.3, -2.0, 5.3], $
      [2.1, 1.0, 4.3, 2.2], $
      [0.0, 5.5, 3.8, 0.2]]

; Compute the Singular Value Decomposition:
SVDC, A, W, U, V

; Print the singular values:
PRINT, W

```

IDL prints:

```

8.81973      2.65502      4.30598      6.84484

```

To verify the decomposition, use the relationship  $A = U \## SV \## \text{TRANSPPOSE}(V)$ , where *SV* is a diagonal array created from the output vector *W*:

```

sv = FLTARR(4, 4)
FOR K = 0, 3 DO sv[K,K] = W[K]
result = U ## sv ## TRANSPPOSE(V)
PRINT, result

```

IDL prints:

```
      1.00000      2.00000      -1.00000      2.50000
      1.50000      3.30000     -0.500001      2.00000
      3.10000      0.700000      2.20000      0.00000
      2.23517e-08  0.300000     -2.00000      5.30000
      2.10000      0.999999      4.30000      2.20000
     -3.91155e-07  5.50000      3.80000      0.200000
```

This is the input array, to within machine precision.

# SVDFIT

The SVDFIT function performs a least squares fit with optional error estimates. Either a user-supplied function written in the IDL language or a built-in polynomial can be used to fit the data.

SVDFIT is based on the routine `svdfit` described in section 15.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = SVDFIT( X, Y [, M] [, A=vector] [, CHISQ=variable] [, COVAR=variable]
  [, /DOUBLE] [, FUNCTION_NAME=string] [, /LEGENDRE]
  [, MEASURE_ERRORS=vector] [, SIGMA=variable]
  [, SING_VALUES=variable] [, SINGULAR=variable] [, STATUS=variable]
  [, TOL=value] [, VARIANCE=variable] [, YFIT=variable] )
```

## Return Value

Returns a vector of coefficients.

## Arguments

### X

An n-element vector of independent variables.

### Y

A vector of dependent variables, the same length as X.

### M

The number of coefficients in the fitting function. For polynomials, *M* is equal to the degree of the polynomial + 1. If the *M* argument is not specified, you must supply initial coefficient estimates using the *A* keyword. In this case, *M* is set equal to the number of elements of the array specified by the *A* keyword.

## Keywords

### A

This keyword is both an input and output keyword. Set this keyword equal to a variable containing a vector of initial estimates for the fitted function parameters. On exit, SVDFIT returns in this variable a vector of coefficients that are improvements of the initial estimates. If A is supplied, the *M* argument will be set equal to the number of elements in the vector specified by A.

### CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit.

### COVAR

Set this keyword equal to a named variable that will contain the covariance matrix of the fitted coefficients.

#### Note

---

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE\_ERRORS. The values do not depend upon Y. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

---

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### FUNCTION\_NAME

Set this keyword equal to a string containing the name of a user-supplied IDL basis function with *M* coefficients. If this keyword is omitted, and the LEGENDRE keyword is not set, IDL assumes that the IDL procedure SVDFUNCT, found in the file `svdfunct.pro`, located in the `lib` subdirectory of the IDL distribution, is to be used. SVDFUNCT uses the basis functions for the fitting polynomial:

$$y = \sum_{i=0}^M A(i)x^i$$

The function to be fit must be written as an IDL function and compiled prior to calling SVDFIT. The function must accept values of  $X$  (a scalar), and  $M$  (a scalar). It must return an  $M$ -element vector containing the basis functions.

See the “[Examples](#)” section below for an example function.

## LEGENDRE

Set this keyword to use Legendre polynomials instead of the function specified by the FUNCTION\_NAME keyword. If the LEGENDRE keyword is set, the IDL uses the function SVDLEG found in the file `svdleg.pro`, located in the `lib` subdirectory of the IDL distribution.

## MEASURE\_ERRORS

Set this keyword to a vector containing standard measurement errors for each point  $Y[i]$ . This vector must be the same length as  $X$  and  $Y$ .

---

### Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE\_ERRORS should be set to the standard deviations of each point in  $Y$ . For Poisson or statistical weighting, MEASURE\_ERRORS should be set to  $\text{SQRT}(Y)$ .

---

## SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

---

### Note

If MEASURE\_ERRORS is omitted, then you are assuming that the polynomial (or your user-supplied model) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by  $\text{SQRT}(\text{CHISQ}/(N-M))$ , where  $N$  is the number of points in  $X$ , and  $M$  is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

---

## SING\_VALUES

Set this keyword to a named variable in which to return the singular values from the SVD. Singular values which have been removed will be set to zero.

## SINGULAR

Set this keyword equal to a named variable that will contain the number of singular values returned. This value should be 0. If not, the basis functions do not accurately characterize the data.

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- **STATUS = 0:** The computation was successful.
- **STATUS > 0:** Singular values were found and were removed. STATUS contains the number of singular values.

---

**Note**

If STATUS is not specified, any error messages will be output to the screen.

---

## TOL

Set this keyword to the tolerance used when removing singular values. The default is  $10^{-5}$  for single precision, and  $2 \times 10^{-12}$  for double precision (these defaults are approximately 100 and 10000 times the machine precisions for single and double precision, respectively).

Setting TOL to a larger value may remove coefficients that do not contribute to the solution, which may reduce the errors on the remaining coefficients.

## VARIANCE

Set this keyword equal to a named variable that will contain the variance (sigma squared) of each coefficient  $M$ .

## YFIT

Set this keyword equal to a named variable that will contain the vector of calculated  $Y$  values.

## Examples

This example fits a function of the following form:

$$F(x) = A(0) + A(1) \sin \frac{(2x)}{x} + A(2) \cos(4x)^2$$

First, create the function in IDL, then create a procedure to perform the fit. Create the following file called `example_svdfit.pro`:

```

PRO example_svdfit

; Provide an array of coefficients:
C = [7.77, 8.88, -9.99]
X = FINDGEN(100)/15.0 + 0.1
Y = C[0] + C[1] * SIN(2*X)/X + C[2] * COS(4.*X)^2.

; Set uncertainties to 5%:
measure_errors = 0.05 * Y

; Provide an initial guess:
A=[1,1,1]
result_a = SVDFIT(X, Y, A=A, MEASURE_ERRORS=measure_errors, $
    FUNCTION_NAME='myfuncnt', SIGMA=SIGMA, YFIT=YFIT)

; Plot the results:
PLOT, X, YFIT
FOR I = 0, N_ELEMENTS(A)-1 DO $
    PRINT, I, result_a[I], SIGMA[I], C[I], $
    FORMAT = $
    ' (" result_a ( ", I1, " ) = ", F7.4, " +- ", F7.4, " VS. ", F7.4 ) '
END

FUNCTION myfuncnt, X, M
    RETURN, [ [1.0], [SIN(2*X)/X], [COS(4.*X)^2.] ]
END

```

Place the file `example_svdfit.pro` in a directory in the IDL search path, and enter `example_svdfit` at the command prompt to create the plot.

*Figure 3-125: Example Plot*

In addition to creating the above plot, IDL prints:

```
result_a ( 0 ) = 7.7700 +- 0.0390 VS. 7.7700
result_a ( 1 ) = 8.8800 +- 0.0468 VS. 8.8800
result_a ( 2 ) = -9.9900 +- 0.0506 VS. -9.9900
```

## Version History

# SVSOL

The SVSOL function uses “back-substitution” to solve a set of simultaneous linear equations  $Ax = b$ , given the  $U$ ,  $W$ , and  $V$  arrays returned by the SVDC procedure. None of the input arguments are modified, making it possible to call SVSOL multiple times with different right hand vectors,  $B$ .

SVSOL is based on the routine `svbksb` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = SVSOL( U, W, V, B [, /COLUMN] [, /DOUBLE] )
```

## Return Value

Returns the solution to the linear system using decomposition and back substitution.

## Arguments

### U

An  $n$ -column,  $m$ -row orthogonal array used in the decomposition of  $A$ . Normally,  $U$  is returned from the SVDC procedure.

### W

An  $n$ -element vector containing “singular values.” Normally,  $W$  is returned from the SVDC procedure. Small values (close to machine floating-point precision) should be set to zero prior to calling SVSOL.

### V

An  $n$ -column,  $n$ -row orthogonal array used in the decomposition of  $A$ . Normally,  $V$  is returned from the SVDC procedure.

### B

An  $m$ -element vector containing the right hand side of the linear system  $Ax = b$ .

## Keywords

### COLUMN

Set this keyword if the input arrays  $U$  and  $V$  are in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To solve the linear system  $Ax = b$  using Singular-value decomposition and back substitution, begin with an array  $A$  which serves as the coefficient array:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7, 2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0, 4.3, 2.2], $
     [0.0, 5.5, 3.8, 0.2]]

; Define the right-hand side vector B:
B = [0.0, 1.0, 5.3, -2.0, 6.3, 3.8]

; Decompose A:
SVDC, A, W, U, V

; Compute the solution and print the result:
PRINT, SVSOL(U, W, V, B)
```

IDL prints:

```
1.00095    0.00881170    0.984176    -0.0100954
```

This is the correct solution.

# SWAP\_ENDIAN

The `SWAP_ENDIAN` function reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

---

**Note**

The `BYTEORDER` procedure can be used to reverse the byte ordering of *scalars and arrays* (`SWAP_ENDIAN` also allows structures).

---

This routine is written in the IDL language. Its source code can be found in the file `swap_endian.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = SWAP_ENDIAN(Variable [, /SWAP_IF_BIG_ENDIAN]  
                    [, /SWAP_IF_LITTLE_ENDIAN])
```

## Return Value

`SWAP_ENDIAN` returns values of the same type and structure as the input value, with the pertinent bytes reversed.

## Arguments

### Variable

The named variable—scalar, array, or structure—to be swapped.

## Keywords

### SWAP\_IF\_BIG\_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the `SWAP_ENDIAN` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

### SWAP\_IF\_LITTLE\_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the

SWAP\_ENDIAN request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## Examples

```
; Reverse the byte order of A:  
A = SWAP_ENDIAN(A)
```

## Version History

Pre-4.0	Introduced
5.6	Added SWAP_IF_BIG_ENDIAN and SWAP_IF_LITTLE_ENDIAN keywords

## See Also

[BYTEORDER](#), [SWAP\\_ENDIAN\\_INPLACE](#)

# SWAP\_ENDIAN\_INPLACE

The `SWAP_ENDIAN_INPLACE` procedure reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

## Note

---

The `BYTEORDER` procedure can be used to reverse the byte ordering of *scalars and arrays* (`SWAP_ENDIAN_INPLACE` also allows structures).

---

`SWAP_ENDIAN_INPLACE` differs from the `SWAP_ENDIAN` function in that it alters the input data in place rather than making a copy as does `SWAP_ENDIAN`. `SWAP_ENDIAN_INPLACE` can therefore be more efficient, if a copy of the data is not needed. The pertinent bytes in the input variable are reversed.

This routine is written in the IDL language. Its source code can be found in the file `swap_endian_inplace.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
SWAP_ENDIAN_INPLACE, Variable [, /SWAP_IF_BIG_ENDIAN]  
                        [, /SWAP_IF_LITTLE_ENDIAN]
```

## Arguments

### Variable

The named variable—scalar, array, or structure—to be swapped.

## Keywords

### SWAP\_IF\_BIG\_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the `SWAP_ENDIAN_INPLACE` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## SWAP\_IF\_LITTLE\_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the `SWAP_ENDIAN_INPLACE` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## Examples

Reverse the byte order of A:

```
SWAP_ENDIAN_INPLACE, A
```

## Version History

5.6	Introduced

# SWITCH

The SWITCH statement is used to select one statement for execution from multiple choices, depending upon the value of the expression following the word SWITCH.

Each statement that is part of a SWITCH statement is preceded by an expression that is compared to the value of the SWITCH expression. SWITCH executes by comparing the SWITCH expression with each selector expression in the order written. If a match is found, program execution jumps to that statement and execution continues from that point. Whereas CASE executes at most one statement within the CASE block, SWITCH executes the first matching statement and any following statements in the SWITCH block. Once a match is found in the SWITCH block, execution falls through to any remaining statements. For this reason, the BREAK statement is commonly used within SWITCH statements to force an immediate exit from the SWITCH block.

The ELSE clause of the SWITCH statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the switch statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, program execution continues immediately below the SWITCH without executing any of the SWITCH statements.

SWITCH is similar to the CASE statement. For more information on using SWITCH and other IDL program control statements, as well as the differences between SWITCH and CASE, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

## Syntax

```
SWITCH expression OF
    expression: statement
    ...
    expression: statement
ELSE: statement
ENDSWITCH
```

## Examples

This example illustrates how, unlike CASE, SWITCH executes the first matching statement and any following statements in the SWITCH block:

```
x=2

SWITCH x OF
  1: PRINT, 'one'
  2: PRINT, 'two'
  3: PRINT, 'three'
  4: PRINT, 'four'
ENDSWITCH
```

IDL Prints:

```
two
three
four
```

## Version History

[CASE](#)

# SYSTIME

The SYSTIME function returns the current time as either a date/time string, as the number of seconds elapsed since 1 January 1970, or as a Julian date/time value.

## Syntax

*String* = SYSTIME( [0 [, *ElapsedSeconds*]] [, /UTC] )

or

*Seconds* = SYSTIME( 1 | /SECONDS )

or

*Julian* = SYSTIME( /JULIAN [, /UTC] )

## Return Value

Returns the specified time.

## Arguments

### SecondsFlag

If *SecondsFlag* is present and nonzero, the number of seconds elapsed since 1 January 1970 UTC is returned as a double-precision, floating-point value.

Otherwise, if *SecondsFlag* is not present or zero, a scalar string containing the date/time is returned in standard 24-character system format as follows:

```
DOW MON DD HH:MM:SS YEAR
```

where DOW is the day of the week, MON is the month, DD is the day of the month, HH is the hour, MM is the minute, SS is the second, and YEAR is the year. By default, the date/time string is adjusted for the local time zone; use the UTC keyword to override this default.

### Note

---

If the JULIAN or SECONDS keyword is set, the *SecondsFlag* argument is ignored.

---

### ElapsedSeconds

If the *SecondsFlag* argument is zero, the *ElapsedSeconds* argument may be set to the number of seconds past 1 January 1970 UTC. In this case, SYSTIME returns the

corresponding date/time string (rather than the string for the current time). The returned date/time string is adjusted for the local time zone, unless the UTC keyword is set. If this argument is present, the JULIAN keyword is not allowed.

## Keywords

### JULIAN

Set this keyword to specify that the current time is to be returned as a double precision floating value containing the current Julian date/time. By default, the current time is adjusted for the local time zone; use the UTC keyword to override this default. This keyword is not allowed if the *ElapsedSeconds* argument is present.

#### Note

---

If the JULIAN keyword is set, a small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, and seconds. This offset is given by the larger of EPS and EPS\*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR. For typical Julian dates, this offset is approximately  $6 \times 10^{-10}$  (which corresponds to  $5 \times 10^{-5}$  seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

---

### SECONDS

Set this keyword to specify that the current time is to be returned as the number of seconds elapsed since 1 January 1970 UTC. This option is equivalent to setting the *SecondsFlag* argument to a non-zero value.

### UTC

Set this keyword to specify that the value returned by SYSTIME is to be returned in Universal Time Coordinated (UTC) rather than being adjusted for the current time zone. UTC time is defined as Greenwich Mean Time updated with leap seconds.

## Examples

Print today's date as a string:

```
PRINT, SYSTIME()
```

Print today's date as a string in UTC (rather than local time zone):

```
PRINT, SYSTIME(/UTC)
```

Print today's date as a Julian date/time value in UTC:

```
PRINT, SYSTIME(/JULIAN, /UTC), FORMAT='(f12.2)'
```

Compute the seconds elapsed since 1 January 1970 UTC:

```
seconds = SYSTIME(1) ; or seconds = SYSTIME(/SECONDS)
```

Verify that the seconds from the previous example are correct:

```
PRINT, SYSTIME(0, seconds)
```

Print the day of the week:

```
PRINT, STRMID(SYSTIME(0), 0, 3)
```

Compute the time required to perform a 16,384 point FFT:

```
T = SYSTIME(1)
A = FFT(FINDGEN(16384), -1)
PRINT, SYSTIME(1) - T, 'Seconds'
```

# T\_CVF

The `T_CVF` function computes the cutoff value  $V$  in a Student's  $t$  distribution with  $Df$  degrees of freedom such that the probability that a random variable  $X$  is greater than  $V$  is equal to a user-supplied probability  $P$ .

---

**Note**

`T_CVF` computes the cutoff value using the one-tailed probability. The cutoff value for the two-tailed probability, which is the probability that the absolute value of  $X$  is greater than  $V$ , can be computed as `T_CVF(P/2, Df)`.

---

This routine is written in the IDL language. Its source code can be found in the file `t_cvf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = `T_CVF(P, Df)`

## Return Value

Returns the cutoff value.

## Arguments

### P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

### Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the Student's  $t$  distribution.

## Keywords

None

## Examples

Use the following command to compute the cutoff value in a Student's *t* distribution with five degrees of freedom such that the probability that a random variable *X* is greater than the cutoff value is 0.025.

```
result = T_CVF(0.025, 5)
PRINT, result
```

IDL prints:

```
2.57058
```

## Version History

# T\_PDF

The T\_PDF function computes the probability  $P$  that, in a Student's t distribution with  $Df$  degrees of freedom, a random variable  $X$  is less than or equal to a user-specified cutoff value  $V$ .

---

**Note**

T\_PDF computes the one-tailed probability. The two-tailed probability, which is the probability that the absolute value of  $X$  is less than or equal to  $V$ , can be computed as  $1 - 2 \times (1 - T\_PDF(V, Df))$ .

---

This routine is written in the IDL language. Its source code can be found in the file `t_pdf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = T\_PDF(*V*, *Df*)

## Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of  $V$  and  $Df$ , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

## Arguments

### **V**

A scalar or array that specifies the cutoff value(s).

### **Df**

A scalar or array that specifies the number of degrees of freedom of the Student's t distribution.

## Keywords

None.

## Examples

Use the following command to compute the probability that a random variable  $X$ , from the Student's  $t$  distribution with 15 degrees of freedom, is less than or equal to 0.691:

```
PRINT, T_PDF(0.691, 15)
```

IDL prints:

```
0.749940
```

# T3D

The T3D procedure implements three-dimensional transforms.

This routine accumulates one or more sequences of translation, scaling, rotation, perspective, and oblique transformations and stores the result in !P.T, the 3D transformation system variable. All the IDL graphic routines use this (4,4) matrix for output. Note that !P.T3D is *not* set, so for the transformations to have effect you must set !P.T3D = 1 (or set the T3D keyword in subsequent calls to graphics routines).

This procedure is based on that of Foley & Van Dam, Chapter 8, “Viewing in Three Dimensions” (Foley, J.D., and A. Van Dam (1982), *Fundamentals of Interactive Computer Graphics*, Addison-Wesley Publishing Co.). The matrix notation is reversed from the normal IDL sense, i.e., here, the first subscript is the column, the second is the row, in order to conform with this reference.

Transformations are applied in the order of the following keywords: 1) **RESET**, 2) **TRANSLATE**, 3) **SCALE**, 4) **ROTATE**, 5) **PERSPECTIVE**, 6) **OBLIQUE**, 7) **XYEXCH**, 8) **XZEXCH**, 9) **YZEXCH**.

A right-handed system is used. Positive rotations are counterclockwise when looking from a positive axis position towards the origin.

This routine is written in the IDL language. Its source code can be found in the file `t3d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
T3D [, Array][, /RESET] [, MATRIX=variable] [, OBLIQUE=vector]
  [, PERSPECTIVE=p{eye at (0,0,p)}] [, ROTATE={x, y, z}] [, SCALE={x, y, z}]
  [, TRANSLATE={x, y, z}] [, /XYEXCH | , /XZEXCH | , /YZEXCH]
```

## Arguments

### Array

An optional 4 x 4 matrix used as the starting transformation. If *Array* is missing, the current !P.T transformation is used. *Array* is ignored if /RESET is set.

## Keywords

The transformation specified by each keyword is performed in the order of their descriptions below (e.g., if both TRANSLATE and SCALE are specified, the translation is done first).

### MATRIX

Set this keyword to a named variable that will contain the result. If this keyword is specified, !P.T is not modified.

### OBLIQUE

A two-element vector of oblique projection parameters. Points are projected onto the XY plane at Z=0 as follows:

$$\begin{aligned}x' &= x + z(d * \cos(a)) \\y' &= y + z(d * \sin(a))\end{aligned}$$

where OBLIQUE[0] = d and OBLIQUE[1] = a. An oblique projection is a parallel projection in which the normal to the projection plane is the z-axis, and the unit vector (0, 0, 1) is projected to  $(d \cos \alpha, d \sin \alpha)$  where  $\alpha$  is expressed in degrees.

### PERSPECTIVE

Perspective transformation. This parameter is a scalar (p) that indicates the Z distance of the center of the projection. Objects are projected into the XY plane at Z=0, and the “eye” is at point (0,0,p).

### RESET

Set this keyword to reset the transformation to the default identity matrix. Set this keyword to begin a new accumulation of transformations. If this keyword is not present, the current transformation matrix !P.T is post-multiplied by the new transformation. The final transformation matrix is always stored back in !P.T. If this keyword is set, the *Array* argument is ignored.

### ROTATE

A three-element vector of the rotations, in DEGREES, about the X, Y, and Z axes. The viewing area is rotated about each axis by the amount  $[\theta_x, \theta_y, \theta_z]$ , in degrees. Rotations are performed in the order of X, Y, and then Z.

## SCALE

A three-element vector of scale factors for the X, Y, and Z axes. The viewing area is scaled by factor  $[S_x, S_y, S_z]$ .

## TRANSLATE

A three-element vector of the translations in the X, Y, and Z directions. The viewpoint is translated by the three-element vector  $[T_x, T_y, T_z]$ .

## XYEXCH

Set this keyword to exchange the X and Y axes.

## XZEXCH

Set this keyword to exchange the X and Z axes.

## YZEXCH

Set this keyword to exchange the Y and Z axes.

## Examples

To reset the transformation, rotate 30 degs about the X axis and do perspective transformation with the center of the projection at  $Z = -1$ ,  $X=0$ , and  $Y=0$ , enter:

```
T3D, /RESET, ROT = [ 30,0,0], PERS = 1.
```

Transformations may be cascaded, for example:

```
T3D, /RESET, TRANS = [-.5,-.5,0], ROT = [0,0,45]
T3D, TRANS = [.5,.5,0]
```

The first command resets, translates the point  $(.5,.5,0)$  to the center of the viewport, then rotates 45 degrees counterclockwise about the Z axis. The second call to T3D moves the origin back to the center of the viewport.

Also see [“Transformation Created by SURFACE”](#) on page 2263.

## Establishing a Three-Dimensional Coordinate System

Usually, scaling parameters for coordinate conversion are set up by the higher-level procedures. To set up your own three-dimensional coordinate system with a given transformation matrix and  $x$ ,  $y$ ,  $z$  data range, follow these steps:

- Establish the scaling from your data coordinates to normalized coordinates—the (0, 1) cube. Assuming your data are contained in the range ( $X_{min}$ ,  $Y_{min}$ ,  $Z_{min}$ ) to ( $X_{max}$ ,  $Y_{max}$ ,  $Z_{max}$ ), set the data scaling system variables as follows:
 
$$\begin{aligned} !X.S &= [ -X_{min}, 1 ] / (X_{max} - X_{min}) \\ !Y.S &= [ -Y_{min}, 1 ] / (Y_{max} - Y_{min}) \\ !Z.S &= [ -Z_{min}, 1 ] / (Z_{max} - Z_{min}) \end{aligned}$$
- Establish the transformation matrix that determines the view of the unit cube. This can be done by either calling T3D, as explained above or by directly manipulating !P.T yourself. If you wish to simply mimic the rotations provided by the SURFACE procedure, call the SCALE3 procedure (which can also be used to perform the previous step).

### House Example

This example draws four views of a simple house. The procedure HOUSE defines the coordinates of the front and back faces of the house. The data-to-normal coordinate scaling is set, as shown above, to a volume about 25 percent larger than that enclosing the house. The PLOTS procedure is called to draw lines describing and connecting the front and back faces. XYOUTS is called to label the front and back faces.

The commands shown after the definition of the HOUSE procedure contain four sequences of calls to T3D to establish the coordinate transformation, each followed by a call to HOUSE.

### Example Code

If you prefer not to enter the IDL code by hand, run the batch file `showhaus` with the following command at the IDL prompt:

```
@showhaus
```

See [“Running the Example Code”](#) on page 40 if IDL does not find the batch file.

```
PRO HOUSE
  ; X coordinates of 10 vertices. First 5 are front face,
  ; second 5 are back face. The range is 0 to 16.
  house_x = [0, 16, 16, 8, 0, 0, 16, 16, 8, 0]
  ; The corresponding y values range from 0 to 16.
  house_y = [0, 0, 10, 16, 10, 0, 0, 10, 16, 10]
  ; The z values range from 30 to 54.
```

```

house_z = [54, 54, 54, 54, 54, 30, 30, 30, 30, 30]
; Define max and min xy values to scale.
; Slightly larger than data range.
min_x = -4 & max_x = 20.
; Set x data scale to range from -4 to 20.
!X.S = [ -(-4), 1. ] / (20 - (-4))
; Same for y.
!Y.S = !X.S
; The z range is from 10 to 70.
!Z.S = [-10, 1.] / (70 - 10)
; Indices of front face.
face = [INDGEN(5), 0]
; Draw front face.
PLOTS, house_x[face], house_y[face], $
      house_z[face], /T3D, /DATA
; Draw back face.
PLOTS, house_x[face + 5], house_y[face + 5], $
      house_z[face + 5], /T3D, /DATA
; Connecting lines from front to back.
FOR I = 0, 4 DO PLOTS, [house_x[i], house_x[i + 5]], $
      [house_y[i], house_y[i + 5]], $
      [house_z[i], house_z[i + 5]], /T3D, /DATA
; Annotate front peak.
XYOUTS, house_x[3], house_y[3], Z = house_z[3], 'Front', $
      /T3D, /DATA, SIZE = 2
; Annotate back.
XYOUTS, house_x[8], house_y[8], Z = house_z[8], 'Back', $
      /T3D, /DATA, SIZE = 2
END

```

The HOUSE procedure could be called from the IDL command line to produce a number of different plots. For example:

```

; Set up no rotation, scale, and draw house.
T3D, /RESET & HOUSE
; Create a handy constant.
H = [0.5, 0.5, 0.5]
; Straight projection after rotating 30 degrees about x and y axes.
T3D, /RESET, TRANS = -H, ROT = [30, 30, 0] & $
      T3D, TR = H & HOUSE
; No rotation, oblique projection, z factor = 0.5, angle = 45.
T3D, /RESET, TRANS = -H, ROT=[0, 0, 0], OBLIQUE=[.5, -45] & $
      T3D, TR = H & HOUSE
; Rotate 6 degrees about x and y, then apply perspective.
T3D, /RESET, TR=-H, ROT=[-6, 6, 0], PERS=4 & $
      T3D, TR=H & HOUSE

```

*Figure 3-126: Illustration of Different Three-Dimensional Transformations*

The figure illustrates the different transformations. The four rotations are:

- Upper left: no rotation, plain projection
- Upper right: oblique projection, factor = 0.5, angle =  $-45$
- Bottom left: rotation of 30 degrees about both the  $x$ - and  $y$ -axes, plain projection
- Bottom right: rotation of  $-6$  degrees about the  $x$ -axis and  $+6$  degrees about the  $y$ -axis, and perspective projection with the eye at 4.

See “[Rotating the Shaded Volume](#)” on page 2073 for another T3D example.

## Rotating the House

A common procedure for visualizing three-dimensional data is to animate the data by rotating it about one or more axes. To make an animation of the house in the preceding example (“[House Example](#)” on page 2295), use the [XINTERANIMATE](#) procedure as follows:

```

; Initialize animation: set frame size and number of frames.
sizx = 300
sizy = 300

```

```

nframes = 16
XINTERANIMATE, SET=[sizx, sizy, nframes]
; Rotate about the z axis. Draw the house. Save the window.
FOR i = 0, nframes - 1 DO BEGIN $
    SCALE3, AX = 75, AZ = i * 360. / nframes & $
    ERASE & $
    HOUSE & $
    SCALE3, AX = 75, AZ = i * 360. / nframes & $
    XINTERANIMATE, FRAME=i, WINDOW=!D.WINDOW & $
ENDFOR
; Show the animation.
XINTERANIMATE

```

In the above example, [SCALE3](#) rather than `SCALE3D` is used to maintain the same scaling in all rotations.

### Example Code

---

If you prefer not to enter the IDL code by hand, run the batch file `animhaus` with the following command at the IDL prompt:

```
@animhaus
```

---

See [“Running the Example Code”](#) on page 40 if IDL does not find the batch file.

## Positioning Contours and Plots Three-Dimensions

The `CONTOUR` and `PLOT` procedures output their results using the three-dimensional coordinate transformation contained in `!P.T` when the keyword `T3D` is specified. Note that `!P.T` must contain a valid transformation matrix prior to using the `T3D` keyword.

`PLOT` and its variants output graphs in the  $xy$ -plane at the normal coordinate  $z$  value given by the keyword `ZVALUE`. If this keyword is not specified, the plot is drawn at the bottom of the unit cube at  $z = 0$ .

`CONTOUR` draws its axes at  $z = 0$  and its contours at their  $z$  data value if `ZVALUE` is not specified. If `ZVALUE` is present, `CONTOUR` draws both the axes and contours in the  $xy$ -plane at the given  $z$  value. See the following for examples:

- [“Combining CONTOUR and SURFACE”](#) on page 2264
- [“SCALE3 and More Complicated Transformations”](#) on page 2021
- [“Combining Images with Three-Dimensional Graphics”](#) on page 2102

# TAG\_NAMES

The TAG\_NAMES function returns a string array containing the names of the tags in a structure expression. It can also be used to determine the expression's structure name (if the structure has a name).

## Syntax

*Result* = TAG\_NAMES( *Expression* [, /STRUCTURE\_NAME] )

## Return Value

Returns structure tag names or the expression's structure name.

## Arguments

### Expression

The structure expression for which the tag names are returned. This argument must be of structure type. TAG\_NAMES does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the names of tags in the outermost structure are returned.

## Keywords

### STRUCTURE\_NAME

Set this keyword to return a scalar string that contains the name of the structure instead of the names of the tags in the structure. If the structure is “anonymous”, a null string is returned.

## Examples

Print the names of the tags in the system variable !P by entering:

```
PRINT, TAG_NAMES(!P)
```

IDL prints:

```
BACKGROUND CHARSIZE CHARTHICK CLIP COLOR FONT LINSTYLE MULTI  
NOCLIP NOERASE NSUM POSITION PSYM REGION SUBTITLE SYMSIZE T  
T3D THICK TITLE TICKLEN CHANNEL
```

Print the name of the structure in the system variable !P:

```
PRINT, TAG_NAMES (!P, /STRUCTURE_NAME)
```

IDL prints:

```
!PLT
```

# TAN

The TAN function computes the tangent of  $X$ .

## Syntax

$Result = \text{TAN}(X)$

## Return Value

Returns the tangent of the specified angle.

## Arguments

### X

The angle for which the tangent is desired, specified in radians. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If  $X$  is an array, the result has the same structure, with each element containing the tangent of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

```
; Find the tangent of 0.5 radians and store the result in  
; the variable T:  
T = TAN(0.5)
```

## Version History

Original	Introduced
----------	------------

## See Also

[ATAN](#), [TANH](#)

# TANH

The TANH function returns the hyperbolic tangent of  $X$ .

## Syntax

*Result* = TANH( $X$ )

## Return Value

Returns the single- or double-precision hyperbolic tangent.

## Arguments

### $X$

The value for which the hyperbolic tangent is desired, specified in radians. If  $X$  is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. TANH is defined as:

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

If  $X$  is an array, the result has the same structure, with each element containing the hyperbolic tangent of the corresponding element of  $X$ .

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

```
; Find the hyperbolic tangent of 1 radian and print the result:  
PRINT, TANH(1)  
  
; Plot the hyperbolic tangent from -5 to +5 with an increment  
; of 0.1:  
PLOT, TANH(FINDGEN(101)/10. - 5)
```

# TEK\_COLOR

The TEK\_COLOR procedure loads a 32-color colortable similar to the default Tektronix 4115 colortable. This colortable is useful because of its distinct colors.

By default, this palette consists of 32 colors. The first 9 colors are: Index 0=black, 1=white, 2=red, 3=green, 4=blue, 5=cyan, 6=magenta, 8=orange.

## Syntax

```
TEK_COLOR [, Start_Index, Colors]
```

## Arguments

### Start\_Index

An optional starting index for the palette. The default is 0. If this argument is included, the colors are loaded into the current colortable starting at the specified index.

### Colors

The number of colors to load. The default is 32, which is also the maximum.

## Keywords

None.

## Version History

Pre-4.0	Introduced
---------	------------

## See Also

[LOADCT](#), [XLOADCT](#)

# TEMPORARY

The TEMPORARY function returns a temporary copy of a variable, and sets the original variable to “undefined”. This function can be used to conserve memory when performing operations on large arrays, as it avoids making a new copy of results that are only temporary. In general, the TEMPORARY routine can be used to advantage whenever a variable containing an array on the left hand side of an assignment statement is also referenced on the right hand side.

## Syntax

*Result* = TEMPORARY(*Variable*)

## Return Value

Returns a copy of a specified variable.

## Arguments

### Variable

The variable to be referenced and deleted.

## Keywords

None.

## Examples

Assume the variable `A` is a large array of integers. The statement:

```
A = A + 1
```

creates a new array for the result of the addition, places the sum into the new array, assigns it to `A`, and then frees the old allocation of `A`. Total storage required is twice the size of `A`. The statement:

```
A = TEMPORARY(A) + 1
```

requires no additional space.

**Note**

---

If the operation performed on *Variable* requires that *Variable* be converted to another data type, there is no benefit to using TEMPORARY. For instance, if the array *A* in the above example contained byte data rather than integer data, the array would have to be converted to integer type before the addition could be performed. In such a case, memory could not be re-used.

---

[DELVAR](#)

# TETRA\_CLIP

The TETRA\_CLIP function clips a tetrahedral mesh to an arbitrary plane in space and returns a tetrahedral mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex (the trailing array dimension must match the number of vertices in the Vertsin array).

A tetrahedral connectivity array consists of groups of four vertex index values. Each set of four index values specifies four vertices which define a single tetrahedron.

## Syntax

```
Result = TETRA_CLIP ( Plane, Vertsin, Connin, Vertsout, Connout  
    [, AUXDATA_IN=array, AUXDATA_OUT=variable]  
    [, CUT_VERTS=variable] )
```

## Return Value

The return value is the number of tetrahedra returned.

## Arguments

### Plane

Input four-element array describing the equation of the plane to be clipped to. The elements are the coefficients  $(a,b,c,d)$  of the equation  $ax+by+cz+d=0$ .

### Vertsin

Input array of tetrahedral vertices  $[3, n]$ .

### Connin

Input tetrahedral mesh connectivity array.

### Vertsout

Output array of tetrahedral vertices  $[3, n]$ .

### Connout

Output tetrahedral mesh connectivity array.

## Keywords

### AUXDATA\_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA\_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

### AUXDATA\_OUT

Set this keyword to a named variable to contain an output array of interpolated auxiliary data.

### CUT\_VERTS

Set this keyword to a named variable to contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be 'on' the clipped surface.

## Version History

5.5	Introduced
-----	------------

# TETRA\_SURFACE

The TETRA\_SURFACE function extracts a polygonal mesh as the exterior surface of a tetrahedral mesh. The output of this function is a polygonal mesh connectivity array that can be used with the input Verts array to display the outer surface of the tetrahedral mesh.

## Syntax

*Result* = TETRA\_SURFACE (*Verts*, *Connin*)

## Return Value

Returns a polygonal mesh connectivity array. When used with the input vertex array, this function yields the exposed tetrahedral mesh surface.

## Arguments

### Verts

Array of vertices [3, *n*].

### Connin

Tetrahedral connectivity array.

## Keywords

None.

## Version History

5.5	Introduced
-----	------------

# TETRA\_VOLUME

The TETRA\_VOLUME function computes properties of a tetrahedral mesh array. The basic property is the volume. An auxiliary data array may be supplied which specifies weights at each vertex which are interpolated through the volume during integration. Higher order moments (with respect to the X, Y, and Z axis) may be computed as well (with or without weights).

## Syntax

```
Result = TETRA_VOLUME ( Verts, Conn [, AUXDATA=array]  
[, MOMENT=variable] )
```

## Return Value

Returns the cumulative (weighted) volume of the tetrahedrons in the mesh.

## Arguments

### Verts

Array of vertices [3, *n*].

### Conn

Tetrahedral connectivity array.

## Keywords

### AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex. The volume area integral will linearly interpolate these values. The volume integral will linearly interpolate these values within each tetrahedra. The default weight is 1.0 which results in a basic volume.

## MOMENT

Set this keyword to a named variable that will contain a three-element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} = \sum_{ntetras} v_i \vec{c}_i$$

where  $v$  is the (weighted) volume of the tetrahedron and  $c$  is the centroid of the tetrahedron, thus

$$\vec{m}/volume$$

yields the (weighted) centroid of the tetrahedral mesh.

# THIN

The THIN function returns the “skeleton” of a bi-level image. The skeleton of an object in an image is a set of lines that reflect the shape of the object. The set of skeletal pixels can be considered to be the medial axis of the object. For a much more extensive discussion of skeletons and thinning algorithms, see *Algorithms for Graphics and Image Processing*, Theo Pavlidis, Computer Science Press, 1982. The THIN function is adapted from Algorithm 9.1 (the classical thinning algorithm).

On input, the bi-level image is a rectangular array in which pixels that compose the object have a nonzero value. All other pixels are zero. The result is a byte type image in which skeletal pixels are set to 2 and all other pixels are zero.

## Syntax

*Result* = THIN( *Image* [, /NEIGHBOR\_COUNT] [, /PRUNE] )

## Return Value

Returns the thinned, two-dimensional byte array.

## Arguments

### Image

The two-dimensional image (array) to be thinned.

## Keywords

### NEIGHBOR\_COUNT

Set this keyword to select an alternate form of output. In this form, output pixel values count the number of neighbors an individual skeletal pixel has (including itself). For example, a pixel that is part of a line will have the value 3 (two neighbors and itself). Terminal pixels will have the value 2, while isolated pixels have the value 1.

### PRUNE

If the PRUNE keyword is set, pixels with single neighbors are removed iteratively until only pixels with 2 or more neighbors exist. This effectively removes (or “prunes”) skeleton branches, leaving only closed paths.

## Examples

The following commands display the “thinned” edges of a Sobel filtered image:

```
; Open a file for reading:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])

; Create a byte array in which to store the image:
A = BYTARR(192, 192)

; Read first 192 by 192 image:
READU, 1, A

; Close the file:
CLOSE, 1

; Display the image:
TV, A, 0

; Apply the Sobel filter, threshold the image at value 75, and
; display the thinned edges:
TVSCL, THIN(SOBEL(A) GT 75), 1
```

# THREED

The THREED procedure plots a 2-D array as a pseudo 3-D plot. The orientation of the data is fixed. This routine is written in the IDL language. Its source code can be found in the file `threed.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
THREED, A [, Sp] [, TITLE=string] [, XTITLE=string] [, YTITLE=string]
```

## Arguments

### A

The two-dimensional array to plot.

### Sp

The spacing between plot lines. If *Sp* is omitted, the spacing is set to:  $(\text{MAX}(A) - \text{MIN}(A)) / \text{ROWS}$ . If *Sp* is negative, hidden lines are not removed.

## Keywords

### TITLE

Set this keyword to the main plot title.

### XTITLE

Set this keyword to the X axis title.

### YTITLE

Set this keyword to the Y axis title.

## Examples

```
; Create a 2-D dataset:
A = -SHIFT(DIST(30), 15, 15)
; Make a THREED plot:
THREED, A
; Compare to SURFACE:
SURFACE, A
```

# TIME\_TEST2

The TIME\_TEST2 procedure is a general-purpose IDL benchmark program that performs approximately 20 common operations and prints the time required.

This routine is written in the IDL language. Its source code can be found in the file `time_test.pro` in the `lib` subdirectory of the IDL distribution. This file also contains the procedure GRAPHICS\_TIMES, used to time graphical operations.

## Syntax

```
TIME_TEST2 [, Filename]
```

## Arguments

### Filename

An optional string that contains the name of output file for the results of the time test.

## Keywords

None.

## Examples

```
; Run the computational tests:  
TIME_TEST2  
  
; Run the graphics tests. Note that TIME_TEST2 must be compiled  
; before GRAPHICS_TIMES will run:  
GRAPHICS_TIMES
```

# TIMEGEN

The TIMEGEN function returns an array, with specified dimensions, of double-precision floating-point values that represent times in terms of Julian dates.

The Julian date is the number of days elapsed since Jan. 1, 4713 B.C.E., plus the time expressed as a day fraction. Following the astronomical convention, the day is defined to start at 12 PM (noon). Julian date 0.0d is therefore Jan. 1, 4713 B.C.E. at 12:00:00.

The first value of the returned array corresponds to a Julian date start time, and each subsequent value corresponds to the next Julian date in the sequence. The sequence is determined by specifying the time unit (such as months or seconds) and the step size, or spacing, between the units. You can also construct more complicated arrays by including smaller time units within each major time interval.

A small offset is added to each Julian date to eliminate roundoff errors when calculating the day fraction from the hour, minute, second. This offset is given by the larger of EPS and EPS\*Julian, where Julian is the integer portion of the Julian date and EPS is the double-precision floating-point precision parameter from [MACHAR](#). For typical Julian dates the offset is approximately  $6 \times 10^{-10}$  (which corresponds to  $5 \times 10^{-5}$  seconds). This offset ensures that when the Julian date is converted back to the hour, minute, and second, the hour, minute, and second will have the same integer values.

---

## Tip

Because of the large magnitude of the Julian date (1 Jan 2000 is Julian day 2451545), the precision of most Julian dates is limited to 1 millisecond (0.001 seconds). If you are not interested in the date itself, you can improve the precision by subtracting a large offset or setting the START keyword to zero.

---

---

## Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

---

## Syntax

```
Result = TIMEGEN( [D1,...,Dg] [, FINAL=value] [, DAYS=vector]
  [, HOURS=vector] [, MINUTES=vector] [, MONTHS=vector]
  [, SECONDS=vector] [, START=value] [, STEP_SIZE=value] [, UNITS=string]
  [, YEAR=value] )
```

## Return Value

Returns the specified time values.

## Arguments

$D_i$

The dimensions of the result. The dimension parameters may be any scalar expression. Up to eight dimensions may be specified. If the dimension arguments are not integer values, IDL will truncate them to integer values before creating the new array. The dimension arguments are required unless keyword `FINAL` is set, in which case they are ignored.

## Keywords

### DAYS

Set this keyword to a scalar or a vector giving the day values that should be included within each month. This keyword is ignored if the `UNITS` keyword is set to “Days”, “Hours”, “Minutes”, or “Seconds”.

---

**Note**

Day values that are beyond the end of the month will be set equal to the last day for that month. For example, setting `DAY= [31]` will automatically return the last day in each month.

---

### FINAL

Set this keyword to a double-precision value representing the Julian date/time to use as the last value in the returned array. In this case, the dimension arguments are ignored and *Result* is a one-dimensional array, with the number of elements depending upon the step size. The `FINAL` time may be less than the `START` time, in which case `STEP_SIZE` should be negative.

---

**Note**

If the step size is not an integer then the last element may not be equal to the `FINAL` time. In this case, `TIMEGEN` will return enough elements such that the last element is less than or equal to `FINAL`.

---

## HOURS

Set this keyword to a scalar or a vector giving the hour values that should be included within each day. This keyword is ignored if UNITS is set to “Hours”, “Minutes”, or “Seconds”.

## MINUTES

Set this keyword to a scalar or a vector giving the minute values that should be included within each hour. This keyword is ignored if UNITS is set to “Minutes” or “Seconds”.

## MONTHS

Set this keyword to a scalar or a vector giving the month values that should be included within each year. This keyword is ignored if UNITS is set to “Months”, “Days”, “Hours”, “Minutes”, or “Seconds”.

## SECONDS

Set this keyword to a scalar or a vector giving the second values that should be included within each minute. This keyword is ignored if UNITS is set to “Seconds”.

## START

Set this keyword to a double-precision value representing the Julian date/time to use as the first value in the returned array. The default is 0.0d [corresponding to January 1, 4713 B.C.E. at 12 pm (noon)].

---

### Note

If subintervals are provided by MONTHS, DAYS, HOURS, MINUTES, or SECONDS, then the first element may not be equal to the START time. In this case the first element in the returned array will be greater than or equal to START.

---

---

### Tip

Other array generation routines in IDL (such as FINDGEN) do not allow you to specify a starting value because the resulting array can be added to a scalar representing the start value. For TIMEGEN it is correct to add a scalar to the array if the units are days, hours, minutes, seconds, or sub-seconds. For example:

```
MyTimes = TIMEGEN(365, UNITS="Days") + SYSTIME (/JULIAN)
```

However, if the units are months or years, the start value is necessary because the number of days in a month or year can vary depending upon the year in which they

fall (for instance, consider leap years). For example:

```
MyTimes = TIMEGEN(12, UNITS="Months", START=JULDAY(1,1,2000))
```

---

## STEP\_SIZE

Set this keyword to a scalar value representing the step size between the major intervals of the returned array. The step size may be negative. The default step size is 1. When the UNITS keyword is set to “Years” or “Months”, the STEP\_SIZE value is rounded to the nearest integer.

## UNITS

Set this keyword to a scalar string indicating the time units to be used for the major intervals for the generated array. Valid values include:

- “Years” or “Y”
- “Months” or “M”
- “Days” or “D”
- “Hours” or “H”
- “Minutes” or “T”
- “Seconds” or “S”

The case (upper or lower) is ignored. If this keyword is not specified, then the default for UNITS is the time unit that is larger than the largest keyword present:

Largest Keyword Present	Default UNITS
SECONDS= <i>vector</i>	“Minutes”
MINUTES= <i>vector</i>	“Hours”
HOURS= <i>vector</i>	“Days”
DAYS= <i>vector</i>	“Months”
MONTHS= <i>vector</i>	“Years”
YEAR= <i>value</i>	“Years”

Table 3-121: Defaults for the UNITS keyword

If none of the above keywords are present, the default is UNITS="Days".

## YEAR

Set this keyword to a scalar giving the starting year. If YEAR is specified then the starting year from START is ignored.

## Examples

Generate an array of 366 time values that are one day apart starting with January 1, 2000:

```
MyDates = TIMEGEN(366, START=JULDAY(1,1,2000))
```

Generate an array of 20 time values that are 12 hours apart starting with the current time:

```
MyTimes = TIMEGEN(20, UNITS='Hours', STEP_SIZE=12, $
  START=SYSTIME(/JULIAN))
```

Generate an array of time values that are 1 hour apart from 1 January 2000 until the current time:

```
MyTimes = TIMEGEN(START=JULDAY(1,1,2000), $
  FINAL=SYSTIME(/JULIAN), UNITS='Hours')
```

Generate an array of time values composed of seconds, minutes, and hours that start from the current hour:

```
MyTimes = TIMEGEN(60, 60, 24, $
  START=FLOOR(SYSTIME(/JULIAN)*24)/24d, UNITS='S')
```

Generate an array of 24 time values with monthly intervals, but with subintervals at 5 PM on the first and fifteenth of each month:

```
MyTimes = TIMEGEN(24, START=FLOOR(SYSTIME(/JULIAN)), $
  DAYS=[1,15], HOURS=17)
```

# TM\_TEST

The `TM_TEST` function computes the Student's T-statistic and the probability that two sample populations  $X$  and  $Y$  have significantly different means.  $X$  and  $Y$  may be of different lengths. The default assumption is that the data is drawn from populations with the same true variance. This type of test is often referred to as the t-means test.

The T-statistic for sample populations  $x$  and  $y$  with means  $\bar{x}$  and  $\bar{y}$  is defined as:

$$T = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{\sum_{i=0}^{N-1} (x_i - \bar{x})^2 + \sum_{i=0}^{M-1} (y_i - \bar{y})^2}{(N + M - 2)} \left( \frac{1}{N} + \frac{1}{M} \right)}}$$

where  $x = (x_0, x_1, x_2, \dots, x_{N-1})$  and  $y = (y_0, y_1, y_2, \dots, y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `tm_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = `TM_TEST`(  $X$ ,  $Y$  [, `/PAIRED`] [, `/UNEQUAL`] )

## Return Value

The result is a two-element vector containing the T-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that  $X$  and  $Y$  have significantly different means.

## Arguments

### X

An  $n$ -element integer, single-, or double-precision floating-point vector.

### Y

An  $m$ -element integer, single-, or double-precision floating-point vector. If the `PAIRED` keyword is set,  $X$  and  $Y$  must have the same number of elements.

## Keywords

### PAIRED

If this keyword is set,  $X$  and  $Y$  are assumed to be paired samples and must have the same number of elements.

### UNEQUAL

If this keyword is set,  $X$  and  $Y$  are assumed to be from populations with unequal variances.

## Examples

```

; Define two n-element sample populations.
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the Student's t-statistic and its significance assuming
; that X and Y belong to populations with the same true variance:
PRINT, TM_TEST(X, Y)

```

IDL prints:

```
5.52839  2.52455e-06
```

The result indicates that  $X$  and  $Y$  have significantly different means.

# TOTAL

The TOTAL function returns the sum of the elements of *Array*. The sum of the array elements over a given dimension is returned if the *Dimension* argument is present.

## Syntax

```
Result = TOTAL( Array [, Dimension] [, /CUMULATIVE] [, /DOUBLE]
               [, /INTEGER] [, /NAN] [, /PRESERVE_TYPE] )
```

## Return Value

Returns the array sum for the specified dimensions.

## Arguments

### Array

The array to be summed. This array can be of any basic type except string. If *Array* is double-precision floating-point, complex, or double-precision complex, the result is of the same type. Otherwise, the result is single-precision floating-point.

### Dimension

The dimension over which to sum, starting at one. If this argument is not present or zero, the scalar sum of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*. For example, if the dimensions of *Array* are  $N_1, N_2, N_3$ , and *Dimension* is 2, the dimensions of the result are  $(N_1, N_3)$ , and element  $(i, j)$  of the result contains the sum:

$$\sum_{k=0}^{N_2-1} A_{i, k, j}$$

## Keywords

### CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element,  $i$ , containing the sum of the input array elements 0 to  $i$ . This keyword also works with the *Dimension* parameter, in which case the sum is performed over the given dimension.

**Tip**

---

If the input array is a temporary variable or an expression, and the result type matches the input type (for example by using the `PRESERVE_TYPE` keyword), then `TOTAL` will perform the cumulative sum in place and no additional memory will be used.

---

**DOUBLE**

Set this keyword to force the summation to be done using double-precision arithmetic. By default, if the input is of type `DOUBLE`, `DCOMPLEX`, `LONG64`, or `ULONG64`, IDL does the summation using double precision; otherwise IDL does the summation using single precision. If this keyword is set to zero, IDL still does the summation using the default precision, but the result is converted to single precision before returning.

**INTEGER**

Set this keyword to perform the `TOTAL` using integer arithmetic, and to return an integer result. If *Array* is of type `ULONG64` then unsigned 64-bit integers are used for the computation and the Result is of type `ULONG64`, otherwise signed 64-bit integers are used and the Result is of type `LONG64`. If *Array* is complex and `INTEGER` is set, then only the real part of each value is used for the computation. The `DOUBLE` keyword is ignored if `INTEGER` is set.

**Note**

---

If *Array* has a large number of values or the values themselves are large, then the `TOTAL` with the `INTEGER` keyword may easily overflow the largest 64-bit integer and return an incorrect result. In this case you may want to avoid using the `INTEGER` keyword.

---

**NAN**

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

**Note**

---

Since the value `NaN` is treated as missing data, if *Array* contains only `NaN` values the `TOTAL` routine will return 0.

---

## PRESERVE\_TYPE

Set this keyword to perform the TOTAL using the input type, and to return a result of the same type. The DOUBLE and INTEGER keywords are ignored if PRESERVE\_TYPE is set.

### Note

---

For byte or integer data the TOTAL with PRESERVE\_TYPE may easily overflow the largest value for that type. The PRESERVE\_TYPE keyword is only useful if you know that your values will not overflow, or you want to exploit the overflow, for example in computing a checksum. Otherwise, you may want to use the INTEGER keyword instead.

---

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

The thread pool is used for non-cumulative sums, and is not used if the CUMULATIVE keyword is specified. In a cumulative sum, each result value depends on all of the previous results, so overlapped execution is not possible.

You should be aware that when summing a large number of values, the result from TOTAL can depend heavily upon the order in which the numbers are added. Since the thread pool will add values in a different order, you may obtain a different — but equally correct — result than that obtained using the standard non-threaded implementation. This effect occurs because TOTAL uses floating point arithmetic, and the mantissa of a floating point value has a fixed number of significant digits. The effect is especially obvious when using single precision arithmetic, but can also affect double precision computations. Such differences do not mean that the sums are incorrect. Rather, they mean that they are equal within the ability of the floating point representation used to represent them. For more information on floating-point numbers, see [“Accuracy and Floating Point Operations”](#) in Chapter 13 of the *Building IDL Applications* manual.

It is also worth noting that this effect, while illustrated by the use of the thread pool, is not caused by the use of threading. It is simply caused by the different order in which the numbers are summed, as can be illustrated by the following non-threaded example:

```
vec = FINDGEN(100000)
PRINT, TOTAL(vec, /TPOOL_NO) - TOTAL(REVERSE(vec), /TPOOL_NO)
```

IDL prints:

```
-96768.0
```

As you can see, the small floating-point errors can accumulate across the sum of a large number of values.

---

### Note

The computation above was done on a Sun Sparc workstation. Your result will depend on the architecture of your CPU; it may be slightly different, and in the notable case of Intel-compatible X86 CPUs may actually be zero due to the use of internal 80-bit floating point registers on that CPU which give it better than double precision accuracy for some computations. Nonetheless, you should be aware of the fact that the order of operations can influence the result.

---

## Examples

### Example 1

This example sums the elements of a one-dimensional array:

```
; Define a one-dimensional array:
A = [20, 10, 5, 5, 3]

; Sum the elements of the array:
SUMA = TOTAL([20, 10, 5, 5, 3])

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of A = ', SUMA
```

IDL prints:

```
A =   20   10   5   5   3
Sum of A =   43.0000
```

## Example 2

The results are different when a multi-dimensional array is used:

```

; Define a multi-dimensional array:
A = FINDGEN(5,5)

; Sum each of the rows in A:
SUMROWS = TOTAL(A, 1)

; Sum each of the columns in A:
SUMCOLS = TOTAL(A, 2)

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of each row:', SUMROWS
PRINT, 'Sum of each column:', SUMCOLS

```

IDL prints:

```

A = 0.000000  1.00000  2.00000  3.00000  4.00000
      5.00000  6.00000  7.00000  8.00000  9.00000
      10.0000  11.0000  12.0000  13.0000  14.0000
      15.0000  16.0000  17.0000  18.0000  19.0000
      20.0000  21.0000  22.0000  23.0000  24.0000

Sum of each row:  10.0000  35.0000  60.0000  85.0000  110.000

Sum of each column:  50.0000  55.0000  60.0000  65.0000  70.0000

```

# TRACE

The TRACE function computes the trace of an  $n$  by  $n$  array.

This routine is written in the IDL language. Its source code can be found in the file `trace.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = TRACE( A [, /DOUBLE] )
```

## Return Value

Returns the sum of the values along the array diagonal.

## Arguments

### A

An  $n$  by  $n$  real or complex array.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an array:
A = [[ 2.0,1.0, 1.0, 1.5], $
      [ 4.0, -6.0, 0.0, 0.0], $
      [-2.0, 7.0, 2.0, 2.5], $
      [ 1.0, 0.5, 0.0, 5.0]]

; Compute the trace of A:
result = TRACE(A)

;Print the result:
PRINT, 'TRACE(A) = ', result
```

IDL prints:

```
TRACE(A) = 3.00000
```

# TrackBall Object

See [“TrackBall”](#) on page 4670.

# TRANSPOSE

The TRANSPOSE function returns the transpose of *Array*. If an optional permutation vector is provided, the dimensions of *Array* are rearranged as well.

## Syntax

*Result* = TRANSPOSE( *Array* [, *P*] )

## Return Value

Returns the reflection of the array along a diagonal.

## Arguments

### Array

The array to be transposed.

### P

A vector specifying how the dimensions of *Array* will be permuted. The elements of *P* correspond to the dimensions of *Array*; the *i*th dimension of the output array is dimension *P*[*i*] of the input array. Each element of the vector *P* must be unique. Dimensions start at zero and can not be repeated.

If *P* is not present, the order of the dimensions of *Array* is reversed.

## Keywords

None.

## Examples

### Note

---

Also see “[Transposing Images](#)” in Chapter 2 of the *Image Processing in IDL* manual for a more extensive example.

---

## Example 1

Print a simple array and its transpose by entering:

```

; Create an array:
A = INDGEN(3,3)
TRANSA = TRANSPOSE(A)

; Print the array and its transpose:
PRINT, 'A:'
PRINT, A
PRINT, 'Transpose of A:'
PRINT, TRANSA

```

IDL prints:

```

A:
  0  1  2
  3  4  5
  6  7  8

Transpose of A:
  0  3  6
  1  4  7
  2  5  8

```

## Example 2

This example demonstrates multi-dimensional transposition:

```

; Create the array:
A = INDGEN(2, 3, 4)

; Take the transpose, reversing the order of the indices:
B = TRANSPOSE(A)

; Re-order the dimensions of A, so that the second dimension
; becomes the first, the third becomes the second, and the first
; becomes the third:
C = TRANSPOSE(A, [1, 2, 0])

; View the sizes of the three arrays:
HELP, A, B, C

```

IDL prints:

```

A  INT  = Array[2, 3, 4]
B  INT  = Array[4, 3, 2]
C  INT  = Array[3, 4, 2]

```

# TRI\_SURF

The TRI\_SURF function interpolates a regularly- or irregularly-gridded set of points with a smooth quintic surface.

TRI\_SURF is similar to MIN\_CURVE\_SURF but the surface fitted is a smooth surface, not a minimum curvature surface. TRI\_SURF has the advantage of being much more efficient for larger numbers of points.

---

## Note

The TRI\_SURF function is designed to interpolate low resolution data. Large arrays may cause TRI\_SURF to issue the following error message:

Partial Derivative Approximation Failed to Converge”

In such cases, interpolation is most likely unnecessary.

---

This routine is written in the IDL language. Its source code can be found in the file `tri_surf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = TRI_SURF( Z [, X, Y] [, /EXTRAPOLATE] [, /LINEAR]
  [, MISSING=value] [, /REGULAR] [, XGRID=[xstart, xspacing] |
  [, XVALUES=array]] [, YGRID=[yxstart, yspacing] | [, YVALUES=array]]
  [, GS=[xspacing, yspacing]] [, BOUNDS=[xmin, ymin, xmax, ymax]]
  [, NX=value] [, NY=value] )
```

## Return Value

The result is a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

## Arguments

### X, Y, Z

arrays containing the X, Y, and Z coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

## Keywords

### EXTRAPOLATE

Set this keyword to cause TRI\_SURF to extrapolate the surface to points outside the convex hull of input points. This keyword has no effect if the input points are regularly gridded.

### LINEAR

Set this keyword to use linear interpolation, without gradient estimates, instead of quintic interpolation. Linear interpolation does not extrapolate, although it is faster and more numerically stable.

### MISSING

Set this keyword equal to the value to which points outside the convex hull of input points should be set. The default is 0. This keyword has no effect if the input points are regularly gridded.

#### Input Grid Description:

### REGULAR

If set, the  $Z$  parameter is a two-dimensional array of dimensions  $(n,m)$ , containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter,  $Z$ . If REGULAR is set, and no grid specifications are present, the grid is set to  $(0, 1, 2, \dots)$ .

### XGRID

A two-element array,  $[xstart, xspacing]$ , defining the input grid in the  $x$  direction. Do not specify both XGRID and XVALUES.

### XVALUES

An  $n$ -element array defining the  $x$  locations of  $Z[i,j]$ . Do not specify both XGRID and XVALUES.

### YGRID

A two-element array,  $[ystart, yspacing]$ , defining the input grid in the  $y$  direction. Do not specify both YGRID and YVALUES.

## YVALUES

An  $n$ -element array defining the  $y$  locations of  $Z[i,j]$ . Do not specify both YGRID and YVALUES.

### Output Grid Description:

#### Note

---

The output grid must enclose the convex hull of the input points.

---

## GS

The output grid spacing. If present, GS must be a two-element vector  $[xs, ys]$ , where  $xs$  is the horizontal spacing between grid points and  $ys$  is the vertical spacing. The default is based on the extents of  $x$  and  $y$ . If the grid starts at  $x$  value  $xmin$  and ends at  $xmax$ , then the default horizontal spacing is  $(xmax - xmin)/(NX-1)$ . YS is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

## BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in  $x$  and  $y$  of the output grid:  $[xmin, ymin, xmax, ymax]$ . If not specified, the grid limits are set to the extent of  $x$  and  $y$ .

## NX

The output grid size in the  $x$  direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

## NY

The output grid size in the  $y$  direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

## Examples

### Example 1

Regularly gridded case:

```
; Make some random data
Z = randomu(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, TRI_SURF(Z, /REGULAR)
```

## Example 2

Irregularly gridded case:

```

; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Use a 26 by 26 grid over the rectangle bounding x and y.
; Get the surface:
R = TRI_SURF(Z, X, Y)

; Alternatively, get a surface over the unit square, with spacing
; of 0.05:
R = TRI_SURF(z, x, y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])

; Alternatively, get a 10 by 10 surface over the rectangle bounding
; x and y:
R = TRI_SURF(z, x, y, NX=10, NY=10)

```

# TRIANGULATE

The TRIANGULATE procedure constructs a Delaunay triangulation of a planar set of points. Delaunay triangulations are very useful for the interpolation, analysis, and visual display of irregularly-gridded data. In most applications, after the irregularly gridded data points have been triangulated, the function TRIGRID is invoked to interpolate surface values to a regular grid. TRIANGULATE uses double precision for all computations.

Since Delaunay triangulations have the property that the circumcircle of any triangle in the triangulation contains no other vertices in its interior, interpolated values are only computed from nearby points.

TRIANGULATE can, optionally, return the adjacency list that describes, for each node, the adjacent nodes in the Delaunay triangulation. With this list, the Voronoi polygon (the polygon described by the set of points which are closer to that node than to any other node) can be computed for each node. This polygon contains the area influenced by its associated node. Tiling of the region in this manner is also called Dirichlet, Wigner-Seitz, or Thiessen tessellation.

The grid returned by the TRIGRID function can be input to various routines such as SURFACE, TV, and CONTOUR. See the description of TRIGRID for an example.

TRIANGULATE and TRIDGRID can also be used to perform gridding and interpolation over the surface of a sphere. The interpolation is  $C_1$  continuous, meaning that the result is continuous over both the function value and its first derivative. This feature is ideal for interpolating an irregularly-sampled dataset over part or all of the surface of the earth (or other (spherical) celestial bodies). Extrapolation outside the convex hull of sample points is also supported. To perform spherical gridding, you must include the FVALUE and SPHERE keywords described below. The spherical gridding technique used in IDL is based on the paper "Interpolation of Data on the Surface of a Sphere", R. Renka, *Oak Ridge National Laboratory Report ORNL/CSD-108*, 1982.

The TRIANGULATE procedure uses the divide-and-conquer method described in "Two Algorithms for Constructing a Delaunay Triangulation," D.T. Lee and B.J. Schachter, *Int. J. of Computer and Information Sci.*, Vol. 9, 1980, pp. 219-242.

## Syntax

```
TRIANGULATE, X, Y, Triangles [, B] [, CONNECTIVITY=variable]
    [, SPHERE=variable [, /DEGREES]] [, FVALUE=variable]
    [, REPEATS=variable] [, TOLERANCE=value]
```

## Arguments

### X

An array that contains the X coordinates of the points to be triangulated.

### Y

An array that contains the Y coordinates of the points to be triangulated. Parameters X and Y must have the same number of elements.

### Triangles

A named variable that, on exit, contains the list of triangles in the Delaunay triangulation of the points specified by the X and Y arguments. Triangles is a longword array dimensioned (3, *number of triangles*), where Triangles[0, i], Triangles[1, i], and Triangles[2, i] contain the indices of the vertices of the *i*-th triangle (i.e., X[Tr[\* , i]] and Y[Triangles[\* , i]] are the X and Y coordinates of the vertices of the *i*-th triangle).

### B

An optional, named variable that, upon return, contains a list of the indices of the boundary points in counterclockwise order.

## Keywords

### CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the  $N$  nodes (xy point) is returned. The list has the following form:

Each element  $i$ ,  $0 \leq i < N$ , contains the starting index of the connectivity list for node  $i$  within the list array. To obtain the adjacency list for node  $i$ , extract the list elements from LIST[ $i$ ] to LIST[ $i+1$ ]-1.

The adjacency list is ordered in the counter-clockwise direction. The first item on the list of boundary nodes is the subscript of the node itself. For interior nodes, the list contains the subscripts of the adjacent nodes in counter-clockwise order.

For example, the call:

```
TRIANGULATE, X, Y, CONNECTIVITY = LIST
```

returns the adjacency list in the variable LIST.

The subscripts of the nodes adjacent to  $X[i]$  and  $Y[i]$  are contained in the array:

```
LIST[LIST[i] : LIST[i+1] - 1]
```

## DEGREES

Set this keyword to indicate that the  $X$  and  $Y$  arguments contain longitude and latitude coordinates specified in degrees. This keyword is only effective if the `SPHERE` keyword is specified. If `DEGREES` is not set,  $X$  and  $Y$  are assumed to be specified in radians when a spherical triangulation is performed.

## FVALUE

Set this keyword to a named variable that contains sample values for each longitude/latitude point in a spherical triangulation. On output, the elements of `FVALUE` are rearranged to correspond to the new ordering of  $X$  and  $Y$  (as described in the `SPHERE` keyword, below). This reordered array can be passed to `TRIGRID` to complete the interpolation.

## REPEATS

Set this keyword to a named variable to return a  $(2, n)$  list of the indices of duplicated points. That is, for each  $i$ ,

```
X[REPEATS[0, i]] = X[REPEATS[1, i]]
```

and

```
Y[REPEATS[0, i]] = Y[REPEATS[1, i]]
```

### Note

---

Use the `GRID_INPUT` procedure to handle repeated points (duplicate locations).

---

## SPHERE

Set this keyword to a named variable in which the results from a spherical triangulation are returned. This result is a structure that can be passed to `TRIGRID` to perform spherical gridding. The structure contains the 3D Cartesian locations sample points and the adjacency list that describes the triangulation.

When spherical triangulation is performed,  $X$  and  $Y$  are interpreted as longitude and latitude, in either degrees or radians (see the `DEGREES` keyword, above). The  $X$  and  $Y$  parameters are converted to double precision and are rearranged to match the spherical triangulation.

## TOLERANCE

Set this keyword to the tolerance to be used when determining whether points are colinear. If  $X$  and  $Y$  are double-precision values, the default is  $10^{-12} * \text{Max}(X, Y)$ ; otherwise the default is  $10^{-6} * \text{Max}(X, Y)$ , where  $\text{Max}(X, Y)$  is the maximum absolute value of the  $X$  and  $Y$  arrays. If three points are colinear within the given tolerance, a triangle will not be constructed for those points. The default is zero, which assumes that none of the points are colinear.

### Tip

TRIANGULATE is typically used for irregular grids, where none of the points are colinear. For regular or semi-regular grids, you can use the TOLERANCE value to avoid creating artificial triangles along the boundary, and to triangulate the appropriate points within the grid. In this case, an appropriate tolerance value might be  $10^{-6} * \text{Max}(X, Y)$ , where  $\text{Max}(X, Y)$  is the maximum absolute value of the  $X$  and  $Y$  arrays.

## Examples

For some examples using the TRIANGULATE routine, see the [TRIGRID](#) function.

# TRIGRID

For non-spherical data, given data points defined by the parameters  $X$ ,  $Y$ , and  $Z$  and a triangulation of the planar set of points determined by  $X$  and  $Y$ , the TRIGRID function returns a regular grid of interpolated  $Z$  values. Linear or smooth quintic polynomial interpolation can be selected. Extrapolation for gridpoints outside of the triangulation area is also an option. An input triangulation can be constructed using the procedure [TRIANGULATE](#). TRIGRID uses double precision for all computations.

For spherical data, given the data values  $F$  and the spherical triangulation, the TRIGRID function returns a regular grid of interpolated  $F$  values using quadratic polynomial interpolation.

## Syntax

*Result* = TRIGRID(  $X$ ,  $Y$ ,  $Z$ , *Triangles* [, *GS*, *Limits*] )

For spherical gridding:

*Result* = TRIGRID(  $F$ , *GS*, *Limits*, [SPHERE](#)= $S$  )

**Keywords:** [, [/DEGREES](#)] [, [EXTRAPOLATE](#)=array] [, [INPUT](#)=variable]  
 [, [MAX\\_VALUE](#)=value] [, [MIN\\_VALUE](#)=value] [, [MISSING](#)=value]  
 [, [NX](#)=value] [, [NY](#)=value] [, [/QUINTIC](#)] [, [SPHERE](#)=variable]  
 [, [XGRID](#)=variable] [, [XOUT](#)=vector] [, [YGRID](#)=variable] [, [YOUT](#)=vector]

## Return Value

If any of  $X$ ,  $Y$ , or  $Z$  are double precision, *Result* is double precision; otherwise, *Result* is single precision. If [SPHERE](#) is present, *Result* is always double precision.

## Arguments

### $X$ , $Y$ , $Z$

Input arrays of  $X$ ,  $Y$ , and  $Z$  coordinates of data points. Integer, long, double-precision and floating-point values are allowed. In addition,  $Z$  can be a complex array. All three arrays must have the same number of elements.

## F

When performing a spherical gridding, this argument should be the named variable that contains the rearranged sample values that were returned by TRIANGULATE's FVALUE keyword.

## Triangles

A longword array of the form output by TRIANGULATE. That is, *Triangles* has the dimensions (3, *number of triangles*) and, for each *i*, `Triangles[0, i]`, `Triangles[1, i]`, and `Triangles[2, i]` are the indices of the vertices of the *i*-th triangle.

## GS

If present, *GS* should be a two-element vector [*XS*, *YS*], where *XS* is the horizontal spacing between grid points and *YS* is the vertical spacing. The default is based on the extents of *X* and *Y*. If the grid starts at *X* value  $x_0$  and ends at  $x_1$ , then the horizontal spacing is

$$(x_1 - x_0)/50$$

The default for *YS* is computed in the same way. Since the default grid spacing divides each axis into 50 intervals and produces 51 samples, TRIGRID returns a grid with dimensions (51, 51).

If the *NX* or *NY* keywords are set to specify the output grid dimensions, either or both of the values of *GS* may be set to 0. In this case, the grid spacing is computed as the respective range divided by the dimension minus one:

$$(x_1 - x_0)/(NX-1) \text{ and } (y_1 - y_0)/(NY-1)$$

For spherical gridding, *GS* is assumed to be specified in radians, unless the DEGREES keyword is set.

## Limits

If present, *Limits* should be a four-element vector [ $x_0$ ,  $y_0$ ,  $x_1$ ,  $y_1$ ] that specifies the data range to be gridded ( $x_0$  and  $y_0$  are the lower X and Y data limits, and  $x_1$  and  $y_1$  are the upper limits). The default for *Limits* is:

$$[\text{MIN}(X), \text{MIN}(Y), \text{MAX}(X), \text{MAX}(Y)]$$

If the *NX* or *NY* keywords are not specified, the size of the grid produced is specified by the value of *Limits*. If the *NX* or *NY* keywords are set to specify the output grid dimensions, a grid of the specified size will be used regardless of the value of *Limits*.

## Keywords

### DEGREES

For a spherical gridding, set this keyword to indicate that the grid spacing (the *GS* argument) is specified in degrees rather than radians.

### EXTRAPOLATE

Set this keyword equal to an array of boundary node indices (as returned by the optional parameter *B* of the [TRIANGULATE](#) procedure) to extrapolate to grid points outside the triangulation. The extrapolation is not smooth, but should give acceptable results in most cases.

Setting this keyword sets the quintic interpolation mode, as if the *QUINTIC* keyword has been specified.

This keyword is ignored for spherical gridding.

### INPUT

Set this keyword to a named variable (which must be an array of the appropriate size to hold the output from *TRIGRID*) in which the results of the gridding are returned. This keyword is provided to make it easy and memory-efficient to perform multiple calls to *TRIGRID*. The interpolates within each triangle overwrite the array and the array is not initialized.

### MAX\_VALUE

Set this keyword to a value that represents the maximum *Z* value to be gridded. Data larger than this value are treated as missing data and are not gridded.

This keyword is ignored for spherical gridding.

### MIN\_VALUE

Set this keyword to a value that represents the minimum *Z* value to be gridded. Data smaller than this value are treated as missing data and are not gridded.

This keyword is ignored for spherical gridding.

### MISSING

The *Z* value to be used for grid points that lie outside the triangles in *Triangles*. The default is 0. This keyword also applies to data points outside the range specified by *MIN\_VALUE* and *MAX\_VALUE*.

**Note**

Letting MISSING default to 0 does not always produce the same result as explicitly setting it to 0. For example, if you specify INPUT and not EXTRAPOLATE, letting MISSING default to 0 will result in the INPUT values being used for data outside the Triangles; explicitly setting MISSING to 0 will result in 0 being used for the data outside the Triangles.

**NX**

The output grid size in the  $x$  direction. The default value is 51.

**NY**

The output grid size in the  $y$  direction. The default value is 51.

**QUINTIC**

If QUINTIC is set, smooth interpolation is performed using Akima's quintic polynomials from "A Method of Bivariate Interpolation and Smooth Surface Fitting for Irregularly Distributed Data Points" in *ACM Transactions on Mathematical Software*, 4, 148-159. For non-spherical data, the default method is linear interpolation. For spherical data, the default method is quadratic interpolation, and the QUINTIC keyword is ignored.

Derivatives are estimated by Renka's global method in "A Triangle-Based C1 Interpolation Method" in *Rocky Mountain Journal of Mathematics*, vol. 14, no. 1, 1984.

QUINTIC is not available for complex data values. Setting the EXTRAPOLATE keyword implies the use of quintic interpolation; it is not necessary to specify both.

**SPHERE**

For a spherical gridding, set this keyword to the named variable that contains the results of the spherical triangulation returned by TRIANGULATE's SPHERE keyword.

**XGRID**

Set this keyword to a named variable that will contain a vector of  $X$  values for the output grid.

## XOUT

Set this keyword to a vector specifying the output grid *X* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. If keyword NX is also supplied then only the first NX points of XOUT will be used.

---

### Note

The XOUT keyword cannot be used with the SPHERE keyword.

---

## YGRID

Set this keyword to a named variable that will contain a vector of *Y* values for the output grid.

## YOUT

Set this keyword to a vector specifying the output grid *Y* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If keyword NY is also supplied then only the first NY points of YOUT will be used.

The following table shows the interrelationships between the keywords EXATRAPOLATE, INPUT, MAX\_VALUE, MIN\_VALUE, MISSING, and QUINTIC.

---

### Note

The YOUT keyword cannot be used with the SPHERE keyword.

---

INPUT	EXTRAPOLATE	MISSING	Not in Triangles	Beyond MIN_VALUE, MAX_VALUE

## Examples

### Example 1

This example creates and displays a 50 point random normal distribution. The random points are then triangulated, with the triangulation displayed. Next, the interpolated surface is computed and displayed using linear and quintic interpolation. Finally, the smooth extrapolated surface is generated and shown.

```

PRO TrigridExample

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)

; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1
in=' '
READ,"Press enter",in

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

; Show the triangles:
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN & $
    ; Subscripts of vertices [0,1,2,0]:
    t = [tr[*],i], tr[0,i] & $
    ; Connect triangles:
    PLOTS, x[t], y[t] & $
ENDFOR

```

```

; Show linear surface:
SURFACE, TRIGRID(x, y, z, tr)
in=' '
READ,"Press enter",in

; Show smooth quintic surface:
SURFACE, TRIGRID(x, y, z, tr, /QUINTIC)
in=' '
READ,"Press enter",in

; Show smooth extrapolated surface:
SURFACE, TRIGRID(x, y, z, tr, EXTRA = b)
in=' '
READ,"Press enter",in

; Output grid size is 12 x 24:
SURFACE, TRIGRID(X, Y, Z, Tr, NX=12, NY=24)
in=' '
READ,"Press enter",in

; Output grid size is 20 x 11. The X grid is
; [0, .1, .2, ..., 19 * .1 = 1.9]. The Y grid goes from 0 to 1:
SURFACE, TRIGRID(X, Y, Z, Tr, [.1, .1], NX=20)
in=' '
READ,"Press enter",in

; Output size is 20 x 40. The range of the grid in X and Y is
; specified by the Limits parameter. Grid spacing in X is
; [5-0]/(20-1) = 0.263. Grid spacing in Y is (4-0)/(40-1) = 0.128:
SURFACE, TRIGRID(X, Y, Z, Tr, [0,0], [0,0,5,4],NX=20, NY=40)
in=' '
READ,"Press enter",in

WDELETE

END

```

## Example 2

This example shows how to perform spherical gridding:

```

PRO SphericalGrid
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. - 180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. - 90.

```

```

; Make a fake function value to be passed to FVALUE. The system
; variable !DTOR contains the conversion value for degrees to
; radians.
f = SIN(lon * !DTOR)^2 * COS(lat * !DTOR)

; Perform a spherical triangulation:
TRIANGULATE, lon, lat, tr, $
    SPHERE=s, FVALUE=f, /DEGREES

; Perform a spherical triangulation using the values returned from
; TRIANGULATE. The result, r, is a 180 by 91 element array:
r=TRIGRID(f, SPHERE=s, [2.,2.],$
    [-180.,-90.,178.,90.], /DEGREES)

; Display the surface
SURFACE, r
END

```

### Example 3

This example demonstrates the use of the INPUT keyword:

```

PRO TrigridInputKeyword

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)

; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

; Show the triangles.
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN $
    ; Subscripts of vertices [0,1,2,0]:
    t = [tr[*],i], tr[0,i] & $
    ; Connect triangles:
    PLOTS, x[t], y[t]
ENDFOR

; The default size for the return value of trigrid. xtemp should be
; the same type as Z. xtemp provides temporary space for trigrid:
xtemp=FLTARR(51,51)
xtemp = TRIGRID(x, y, z, INPUT = xtemp, tr)

```

```

; Show linear surface:
SURFACE, xtemp, TITLE='Linear surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, /QUINTIC)

; Show smooth quintic surface:
SURFACE, xtemp, TITLE='Smooth Quintic surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, EXTRA = b)

; Show smooth extrapolated surface:
SURFACE, xtemp, TITLE='Smooth Extrapolated surface', CHARSIZE=2
in=' '
READ,"Press enter",in
END

```

## Example 4

The XOUT and YOUT keywords allow you to obtain an irregular interval from the TRIGRID routine. This example creates an irregularly-gridded dataset of a Gaussian surface. A grid is formed from these points with the TRIANGULATE and TRIGRID routines. The inputs to the XOUT and YOUT keywords are determined at random to produce an irregular interval. These inputs are sorted before setting them to XOUT and YOUT because these keywords require monotonically ascending or descending values. The lines of the resulting surface are spaced at the irregular intervals provided by the settings of the XOUT and YOUT keywords.

```

PRO GriddingIrregularIntervals

; Make 100 normal x, y points:
x = RANDOMN(seed, 100)
y = RANDOMN(seed, 100)
PRINT, MIN(x), MAX(x)
PRINT, MIN(y), MAX(y)

; Make a Gaussian surface:
z = EXP(-(x^2 + y^2))

; Obtain triangulation:
TRIANGULATE, x, y, triangles, boundary

; Create random x values. These values will be used to
; form the x locations of the resulting grid.
gridX = RANDOMN(seed, 30)
; Sort x values. Sorted values are required for the XOUT

```

```

; keyword.
sortX = UNIQ(gridX, SORT(gridX))
gridX = gridX[sortX]
; Output sorted x values to be used with the XOUT
; keyword.
PRINT, 'gridX:'
PRINT, gridX

; Create random y values. These values will be used to
; form the y locations of the resulting grid.
gridY = RANDOMN(seed, 30)
; Sort y values. Sorted values are required for the YOUT
; keyword.
sortY = UNIQ(gridY, SORT(gridY))
gridY = gridY[sortY]
; Output sorted y values to be used with the YOUT
; keyword.
PRINT, 'gridY:'
PRINT, gridY

; Derive grid of initial values. The location of the
; resulting grid points are the inputs to the XOUT and
; YOUT keywords.
grid = TRIGRID(x, y, z, triangles, XOUT = gridX, $
              YOUT = gridY, EXTRAPOLATE = boundary)

; Display resulting grid. The grid lines are not
; at regular intervals because of the randomness of the
; inputs to the XOUT and YOUT keywords.
SURFACE, grid, gridX, gridY, /XSTYLE, /YSTYLE

# TRIQL

The TRIQL procedure uses the QL algorithm with implicit shifts to determine the eigenvalues and eigenvectors of a real, symmetric, tridiagonal array. The routine TRIRED can be used to reduce a real, symmetric array to the tridiagonal form suitable for input to this procedure.

TRIQL is based on the routine `tqli` described in section 11.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the LA\_TRIQL procedure instead.

---

## Syntax

TRIQL, *D*, *E*, *A* [, /DOUBLE]

## Arguments

### D

On input, this argument should be an  $n$ -element vector containing the diagonal elements of the array being analyzed. On output,  $D$  contains the eigenvalues.

### E

An  $n$ -element vector containing the off-diagonal elements of the array.  $E_0$  is arbitrary. On output, this parameter is destroyed.

### A

A named variable that returns the  $n$  eigenvectors. If the eigenvectors of a tridiagonal array are desired,  $A$  should be input as an identity array. If the eigenvectors of an array that has been reduced by TRIRED are desired,  $A$  is input as the array  $Q$  output by TRIRED.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

To compute eigenvalues and eigenvectors of a real, symmetric, tridiagonal array, begin with an array A representing a symmetric array:

```

; Create the array A:
A = [[ 3.0,  1.0, -4.0], $
      [ 1.0,  3.0, -4.0], $
      [-4.0, -4.0,  8.0]]

; Compute the tridiagonal form of A:
TRIRED, A, D, E

; Compute the eigenvalues (returned in vector D) and the
; eigenvectors (returned in the rows of the array A):
TRIQL, D, E, A

; Print eigenvalues:
PRINT, 'Eigenvalues:'
PRINT, D

; Print eigenvectors:
PRINT, 'Eigenvectors:'
PRINT, A

```

IDL prints:

```

Eigenvalues:
  2.00000  4.76837e-7  12.0000

Eigenvectors:
  0.707107  -0.707107  0.00000
 -0.577350  -0.577350  -0.577350
 -0.408248  -0.408248  0.816497

```

The exact eigenvalues are:

```
[2.0, 0.0, 12.0]
```

The exact eigenvectors are:

```

[ 1.0/sqrt(2.0), -1.0/sqrt(2.0), 0.0/sqrt(2.0)],
[-1.0/sqrt(3.0), -1.0/sqrt(3.0), -1.0/sqrt(3.0)],
[-1.0/sqrt(6.0), -1.0/sqrt(6.0), 2.0/sqrt(6.0)]

```

# TRIRED

The TRIRED procedure uses Householder's method to reduce a real, symmetric array to tridiagonal form.

TRIRED is based on the routine `tred2` described in section 11.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the `LA_TRIRED` procedure instead.

---

## Syntax

TRIRED, A, D, E [, /DOUBLE]

## Arguments

### A

An  $n$  by  $n$  real, symmetric array that is replaced, on exit, by the orthogonal array  $Q$  effecting the transformation. The routine `TRIQL` can use this result to find the eigenvectors of the array  $A$ .

### D

An  $n$ -element output vector containing the diagonal elements of the tridiagonal array.

### E

An  $n$ -element output vector containing the off-diagonal elements.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

See the description of `TRIQL` for an example using this function.

# TRISOL

The TRISOL function solves tridiagonal systems of linear equations that have the form:  $A^T U = R$

---

**Note**

Because IDL subscripts are in column-row order, the equation above is written  $A^T U = R$  rather than  $AU = R$ . The result  $U$  is a vector of length  $n$  whose type is identical to  $A$ .

---

TRISOL is based on the routine `tridag` described in section 2.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

---

**Note**

If you are working with complex inputs, use the `LA_TRISOL` procedure instead.

---

## Syntax

*Result* = TRISOL( *A*, *B*, *C*, *R* [, /DOUBLE] )

## Return Value

Returns a vector containing the solutions.

## Arguments

**A**

A vector of length  $n$  containing the  $n-1$  sub-diagonal elements of  $A^T$ . The first element of  $A$ ,  $A_0$ , is ignored.

**B**

An  $n$ -element vector containing the main diagonal elements of  $A^T$ .

**C**

An  $n$ -element vector containing the  $n-1$  super-diagonal elements of  $A^T$ . The last element of  $C$ ,  $C_{n-1}$ , is ignored.

**R**

An  $n$ -element vector containing the right hand side of the linear system  
 $A^T U = R$ .

**Keywords****DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

**Example**

To solve a tridiagonal linear system, begin with an array representing a real tridiagonal linear system. (Note that only three vectors need be specified; there is no need to enter the entire array shown.)

$$\begin{bmatrix} -4.0 & 1.0 & 0.0 & 0.0 \\ 2.0 & -4.0 & 1.0 & 0.0 \\ 0.0 & 2.0 & -4.0 & 1.0 \\ 0.0 & 0.0 & 2.0 & -4.0 \end{bmatrix}$$

```

; Define a vector A containing the sub-diagonal elements with a
; leading 0.0 element:
A = [0.0, 2.0, 2.0, 2.0]

; Define B containing the main diagonal elements:
B = [-4.0, -4.0, -4.0, -4.0]

; Define C containing the super-diagonal elements with a trailing
; 0.0 element:
C = [1.0, 1.0, 1.0, 0.0]

; Define the right-hand side vector:
R = [6.0, -8.0, -5.0, 8.0]

; Compute the solution and print:
result = TRISOL(A, B, C, R)
PRINT, result

```

IDL prints:

```
-1.00000  2.00000  2.00000  -1.00000
```

The exact solution vector is [-1.0, 2.0, 2.0, -1.0].

# TRUNCATE\_LUN

The TRUNCATE\_LUN procedure truncates the contents of a file (which must be open for write access) at the current position of the file pointer. After this operation, all data before the current file pointer remains intact, and all data following the file pointer are gone. The position of the current file pointer is not altered.

## Syntax

```
TRUNCATE_LUN, Unit1, ..., Unitn
```

## Arguments

### Unit<sub>n</sub>

Scalar or array variables containing the logical file unit numbers of the open files to be truncated.

## Keywords

None.

## Examples

### Example 1

Truncate the entire contents of an existing file:

```
OPENU, unit, 'baddata.dat', /GET_LUN
TRUNCATE_LUN, unit
FREE_LUN, unit
```

### Example 2

Given an existing file of 10,000 bytes, throw away the final 5,000 bytes, and then write an additional 2,000 byte array in their place. The resulting file will be 7,000 bytes in length.

```
OPENU, unit, 'mydata.dat', /GET_LUN
POINT_LUN, unit, 5000
TRUNCATE_LUN, unit
WRITEU, unit, BYTARR(2000)
FREE_LUN, unit
```

# TS\_COEF

The `TS_COEF` function computes the coefficients  $\phi_1, \phi_2, \dots, \phi_P$  used in a  $P$ -th order autoregressive time-series forecasting model. This routine is written in the IDL language. Its source code can be found in the file `ts_coef.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = `TS_COEF`( *X*, *P* [, `/DOUBLE`] [, `MSE=variable`] )

## Return Value

Returns a  $P$ -element vector whose type is identical to  $X$ .

## Arguments

### **X**

An  $n$ -element single- or double-precision floating-point vector containing time-series samples.

### **P**

An integer or long integer scalar that specifies the number of coefficients to be computed.

## Keywords

### **DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

### **MSE**

Set this keyword to a named variable that will contain the mean square error of the  $P$ -th order autoregressive model.

## Examples

```
; Define an n-element vector of time-series samples:  
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $  
      5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $  
      5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]  
; Compute the coefficients of a 5th order autoregressive model:  
PRINT, TS_COEF(X, 5)
```

IDL prints:

```
1.30168      -0.111783      -0.224527      0.267629      -0.233363
```

[TS\\_FCAST](#)

# TS\_DIFF

The `TS_DIFF` function recursively computes the forward differences of an  $n$ -element time-series  $k$  times. This routine is written in the IDL language. Its source code can be found in the file `ts_diff.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = `TS_DIFF( X, K [, /DOUBLE] )`

## Return Value

The result is an  $n$ -element differenced time-series with its last  $k$  elements as zeros.

## Arguments

### X

An  $n$ -element integer, single- or double-precision floating-point vector containing time-series samples.

### K

A positive integer or long integer scalar that specifies the number of times  $X$  is to be differenced.  $K$  must be in the interval  $[1, N\_ELEMENTS(X) - 1]$ .

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```

; Define an n-element vector of time-series samples:
X = [389, 345, 303, 362, 412, 356, 325, 375, $
     410, 350, 310, 388, 399, 362, 325, 382, $
     399, 382, 318, 385, 437, 357, 310, 391]
; Compute the second forward differences of X:
PRINT, TS_DIFF(X, 2)

```

IDL prints:

```
    2  101   -9 -106   25   81  -15  -95   20
  118  -67  -48    0   94  -40  -34  -47  131
  -15 -132   33  128    0    0
```

## Version History

[SMOOTH](#), [TS\\_FCAST](#)

# TS\_FCAST

The TS\_FCAST function computes future or past values of a stationary time-series using a  $P$ -th order autoregressive model.

A  $P$ -th order autoregressive model relates a forecasted value  $x_t$  of the time series  $X = [x_0, x_1, x_2, \dots, x_{t-1}]$ , as a linear combination of  $P$  past values.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \dots + \phi_P x_{t-P} + w_t$$

The coefficients  $\phi_1, \phi_2, \dots, \phi_P$  are calculated such that they minimize the uncorrelated random error terms,  $w_t$ .

This routine is written in the IDL language. Its source code can be found in the file `ts_fcast.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TS\_FCAST( *X*, *P*, *Nvalues* [, /BACKCAST] [, /DOUBLE] )

## Return Value

The result is an *Nvalues*-element vector whose type is identical to *X*.

## Arguments

### **X**

An  $n$ -element single- or double-precision floating-point vector containing time-series samples.

### **P**

An integer or long integer scalar that specifies the number of actual time-series values to be used in the forecast. In general, a larger number of values results in a more accurate forecast.

### **Nvalues**

An integer or long integer scalar that specifies the number of future or past values to be computed.

## Keywords

### BACKCAST

Set this keyword to produce past values (backward forecasts or “backcasts”)

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute and print five future values of the time-series using ten
; time-series values:
PRINT, TS_FCAST(X, 10, 5)

; Compute five past values of the time-series using ten time-series
; values:
PRINT, TS_FCAST(X, 10, 5, /BACKCAST)
```

IDL prints:

```
4.65870      4.58380      4.50030      4.48828      4.46971
6.94862      6.91103      6.86297      6.77826      6.70282
```

[A\\_CORRELATE](#), [COMFIT](#), [CURVEFIT](#), [SMOOTH](#), [TS\\_COEF](#), [TS\\_DIFF](#)

# TS\_SMOOTH

The `TS_SMOOTH` function computes central, backward, or forward moving averages of an  $n$ -element time-series. Autoregressive forecasting and backcasting are used to extrapolate the time-series and compute a moving average for each point.

---

**Note**

Central moving averages require  $Nvalues/2$  forecasts and  $Nvalues/2$  backcasts. Backward moving averages require  $Nvalues-1$  backcasts. Forward moving averages require  $Nvalues-1$  forecasts.

---

This routine is written in the IDL language. Its source code can be found in the file `ts_smooth.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = TS_SMOOTH( X, Nvalues [, /BACKWARD] [, /DOUBLE] [, /FORWARD]
                  [, ORDER=value] )
```

## Return Value

The result is an  $n$ -element vector of the same data type as the input vector.

## Arguments

### X

An  $n$ -element single- or double-precision floating-point vector containing time-series samples. Note that  $n$  must be greater than or equal to 11.

### Nvalues

A scalar of type integer or long integer that specifies the number of time-series values used to compute each moving-average. If central-moving averages are computed (the default), this parameter must be an odd integer greater than or equal to three.

## Keywords

### BACKWARD

Set this keyword to compute backward-moving averages. If BACKWARD is set, the *Nvalues* argument must be an integer greater than one.

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### FORWARD

Set this keyword to compute forward-moving averages. If FORWARD is set, the *Nvalues* argument must be an integer greater than one.

### ORDER

An integer or long-integer scalar that specifies the order of the autoregressive model used to compute the forecasts and backcasts of the time-series. By default, a time-series with a length between 11 and 219 elements will use an autoregressive model with an order of 10. A time-series with a length greater than 219 will use an autoregressive model with an order equal to 5% of its length. The ORDER keyword is used to override this default.

## Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99,$
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31,$
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute the 11-point central-moving-averages of the time-series:
PRINT, TS_SMOOTH(X, 11)
```

IDL prints:

```
6.65761 6.60592 6.54673 6.47646 6.40480 6.33364
6.27000 6.20091 6.14273 6.09364 6.04455 5.99000
5.92273 5.85455 5.78364 5.72636 5.65818 5.58000
5.50182 5.42727 5.34182 5.24545 5.15273 5.07000
5.00182 4.94261 4.87205 4.81116 4.75828 4.71280
```

[SMOOTH](#), [TS\\_DIFF](#), [TS\\_FCAST](#)

# TV

The TV procedure displays images in a Direct Graphics window without scaling the intensity. To display an image with scaling, use the TVSCL procedure.

## Note

The TV procedure displays an image in its original form. The TVSCL procedure displays an image scaled to range from 0 up to 255 depending on the colors available to IDL.

RGB images are displayed with the TV procedure. To display a TrueColor image (an image with 16, 24, or 32 bits per pixel) you must use the TRUE keyword.

While the TV procedure does not *scale* the intensity of an image, it does convert the input image data to byte type. Values outside the range [0,255] are “wrapped” during the conversion. In addition, for displays with less than 256 colors, elements of the input image with values between !D.TABLE\_SIZE and 255 will be displayed using the color index !D.TABLE\_SIZE-1.

If no optional parameters are present, IMAGE is output to the display with its lower-left corner at coordinate (0, 0). The optional parameters can be used to specify the screen position of the image in a variety of ways.

## Syntax

```
TV, Image [, Position] [, /CENTIMETERS | , /INCHES] [, /ORDER]
    [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=value] [, YSIZE=value]
```

or

```
TV, Image [, X, Y [, Channel]] [, /CENTIMETERS | , /INCHES] [, /ORDER]
    [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=value] [, YSIZE=value]
```

**Graphics Keywords:** [, CHANNEL=value] [, /DATA | , /DEVICE | , /NORMAL]
 [, /T3D | Z=value]

## Arguments

### Image

A vector or two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

## X, Y

If  $X$  and  $Y$  are present, they specify the lower-left coordinate of the displayed image, relative to the lower-left corner of the screen.

## Position

An integer specifying the position for *Image* within the graphics window. Image positions run from the top left of the screen to the bottom right. If a position number is used instead of  $X$  and  $Y$ , the position of the image is calculated from the dimensions of the image as follows (integer arithmetic is used).

$Xsize, Ysize =$  Size of display or window

$Xdim, Ydim =$  Dimensions of image to be displayed

$$N_x = \frac{Xsize}{Xdim} = \text{Images across screen}$$

$$X = Xdim \text{Position}_{\text{modulo}N_x} = \text{Starting } X$$

$$Y = Ysize - Ydim \left[ 1 + \frac{\text{Position}}{N_x} \right] = \text{Starting } Y$$

For example, when displaying 128 by 128 images on a 512 by 512 display, the position numbers run from 0 to 15 as follows:

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

---

### Note

When using a device with scalable pixels (e.g., PostScript), the `XSIZE` and `YSIZE` keywords should also be used.

---

## Channel

Some image display devices are capable of storing more than a single image or can combine three single color images to form a TrueColor image. `CHANNEL` specifies

the memory channel to be written. It is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel. The *Channel* argument is identical to the CHANNEL graphics keyword.

## Keywords

### CENTIMETERS

Set this keyword to indicate that the *X*, *Y*, *Xsize*, *Ysize*, and *Z* arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

### INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

### ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

### TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of  $(3, m, n)$ . Specify 2 for row-interleaved images, of size  $(m, 3, n)$ , and 3 for band-interleaved images of the form  $(m, n, 3)$ .

See “[TrueColor Images](#)” on page 4746 for an example using this keyword to write 24-bit images to the PostScript device.

### WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the

*Image* parameter is converted to short integer type, if necessary, and then written to the display.

## XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

## YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[CHANNEL](#), [DATA](#), [DEVICE](#), [NORMAL](#), [T3D](#), [Z](#)

## Examples

In addition to the following basic example, this section also includes :

- [“Positioning Multiple Images in Direct Graphics”](#) on page 2379
- [“Displaying RGB Images with Direct Graphics”](#) on page 2382
- [“Displaying RGB Images and Converting to Grayscale”](#) on page 2385

```
; Create and display a simple image:
D = BYTSCL(DIST(256)) & TV, D

; Erase the screen:
ERASE

; Use the position parameter to display a number of images in the
; same window.
; Display the image in the upper left corner.
TV, D, 0
```

```

; Display another copy of the image in the next position:
TV, D, 1

```

## Positioning Multiple Images in Direct Graphics

The following example imports an RGB image from the `rose.jpg` image file. This RGB image is a close-up photograph of a red rose and is pixel interleaved. This example extracts the three color channels of this image, and displays them as grayscale images in various locations within the same window. Complete the following steps for a detailed description of the process.

### Example Code

---

See `displaymultiples_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

---

1. Determine the path to the `rose.jpg` file:

```

file = FILEPATH('rose.jpg', $
SUBDIRECTORY = ['examples', 'data'])

```

2. Use `QUERY_IMAGE` to query the file to determine image parameters:

```

queryStatus = QUERY_IMAGE(file, imageInfo)

```

3. Set the image size parameter from the query information:

```

imageSize = imageInfo.dimensions

```

4. Use `READ_IMAGE` to import the image from the file:

```

image = READ_IMAGE(file)

```

5. Extract the channels (as images) from the pixel interleaved RGB image:

```

redChannel = REFORM(image[0, *, *])
greenChannel = REFORM(image[1, *, *])
blueChannel = REFORM(image[2, *, *])

```

- If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

- Since the channels are grayscale images, load a grayscale color table:

```
LOADCT, 0
```

The `TV` procedure can be used to display the channels (grayscale images). The `TV` procedure has two different location input arguments. One argument is *position*. This argument arranges the image in a calculated location based on the size of the display and the dimension sizes of the image.

- Create a window and horizontally display the three channels with the *position* argument:

```
WINDOW, 0, XSIZE = 3*imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'The Channels of an RGB Image'
TV, redChannel, 0
TV, greenChannel, 1
TV, blueChannel, 2
```

The following figure shows the resulting grayscale images.

*Figure 3-127: Horizontal Display of RGB Channels in Direct Graphics*

The `TV` procedure can also be used with its *x* and *y* input arguments. These arguments define the location of the lower left corner of the image. The values of these arguments are in device coordinates by default. However, you can provide data or normalized coordinates when the `DATA` or `NORMAL` keyword is set.

9. Create a window and vertically display the three channels with the  $x$  and  $y$  arguments:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = 3*imageSize[1], $
      TITLE = 'The Channels of an RGB Image'
TV, redChannel, 0, 0
TV, greenChannel, 0, imageSize[1]
TV, blueChannel, 0, 2*imageSize[1]
```

The following figure shows the resulting grayscale images.

*Figure 3-128: Vertical Display of RGB Channels in Direct Graphics*

The  $x$  and  $y$  arguments can also be used to create a display of overlapping images. When overlapping images in Direct Graphics, you must remember the last image placed in the window will be in front of the previous images. So if you want to bring a display from the back of the window to the front, you must redisplay it after all the other displays.

10. Create another window:

```
WINDOW, 2, XSIZE = 2*imageSize[0], YSIZE = 2*imageSize[1], $
      TITLE = 'The Channels of an RGB Image'
```

11. Make a white background to distinguish the edges of the images:

```
ERASE, !P.COLOR
```

12. Diagonally display the three channels with the  $x$  and  $y$  arguments:

```
TV, redChannel, 0, 0
TV, greenChannel, imageSize[0]/2, imageSize[1]/2
TV, blueChannel, imageSize[0], imageSize[1]
```

The following figure shows the resulting grayscale images.

*Figure 3-129: Diagonal Display of RGB Channels in Direct Graphics*

## Displaying RGB Images with Direct Graphics

RGB images are three-dimensional arrays made up of width, height, and three channels of color information. In Direct Graphics, these images are displayed with the TV procedure. The TRUE keyword to TV is set according to the interleaving of the RGB image. With RGB images, the interleaving, or arrangement of the channels within the image file, dictates the setting of the TRUE keyword. If the image is:

- pixel interleaved (3, w, h), TRUE is set to 1.
- line interleaved (w, 3, h), TRUE is set to 2.
- planar interleaved (w, h, 3), TRUE is set to 3.

You can determine if an image file contains an RGB image by querying the file. The CHANNELS tag of the resulting query structure will equal 3 if the file's image is RGB. The query does not determine which interleaving is used in the image, but the array returned in DIMENSIONS tag of the query structure can be used to determine the type of interleaving.

If you are using a PseudoColor display, your RGB images must be converted to indexed images to be displayed within IDL.

The following example queries and imports a pixel-interleaved RGB image from the `rose.jpg` image file. This pixel interleaved RGB image is a close-up photograph of a red rose. Complete the following steps for a detailed description of the process.

### Example Code

See `displayrgbimage_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `rose.jpg` file:

```
file = FILEPATH('rose.jpg', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Use `QUERY_IMAGE` to query the file to determine image parameters:

```
queryStatus = QUERY_IMAGE(file, imageInfo)
```

3. Output the results of the file query:

```
PRINT, 'Query Status = ', queryStatus
HELP, imageInfo, /STRUCTURE
```

The following text appears in the Output Log:

```
Query Status =          1
** Structure <14055f0>, 7 tags, length=36, refs=1:
  CHANNELS      LONG      3
  DIMENSIONS    LONG      Array[2]
  HAS_PALETTE   INT       0
  IMAGE_INDEX   LONG      0
  NUM_IMAGES    LONG      1
  PIXEL_TYPE    INT       1
  TYPE          STRING    'JPEG'
```

The `CHANNELS` tag has a value of 3. Thus, the image is an RGB image.

4. Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

The type of interleaving can be determined from the image size parameter and actual size of each dimension of the image. To determine the size of each dimension, you must first import the image.

5. Use `READ_IMAGE` to import the image from the file:

```
image = READ_IMAGE(file)
```

6. Determine the size of each dimension within the image:

```
imageDims = SIZE(image, /DIMENSIONS)
```

7. Determine the type of interleaving by comparing the dimension sizes to the image size parameter from the file query:

```
interleaving = WHERE((imageDims NE imageSize[0]) AND $
    (imageDims NE imageSize[1])) + 1
```

8. Output the results of the interleaving computation:

```
PRINT, 'Type of Interleaving = ', interleaving
```

The following text appears in the Output Log:

```
Type of Interleaving = 1
```

The image is pixel interleaved. If the resulting value was 2, the image would have been line interleaved. If the resulting value was 3, the image would have been planar interleaved.

9. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to one before your first RGB image is displayed within an IDL session or program.

```
DEVICE, DECOMPOSED = 1
```

10. Create a window and display the image with the `TV` procedure:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
    TITLE = 'An RGB Image'
TV, image, TRUE = interleaving[0]
```

The following figure shows the resulting RGB image display.

*Figure 3-130: RGB Image in Direct Graphics*

## Displaying RGB Images and Converting to Grayscale

The following example displays an RGB image, extracts the three channels contained in the `glowing_gas.jpg` file, which is in the `examples/data` directory. This file is provided by the Hubble Heritage Team, which is made of AURA, STScI, and NASA.

The channels are extracted as grayscale (intensity) images. These images are converted to floating-point data and then added together to form a single image, which is a grayscale version of the original RGB image. Complete the following steps for a detailed description of the process.

### Example Code

---

See `rgbtograyscale.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

---

1. Determine the path to the file:

```
file = FILEPATH('glowing_gas.jpg', $
  SUBDIRECTORY = ['examples', 'data'])
```

2. Query the file to determine the image parameters:

```
queryStatus = QUERY_JPEG(file, imageInfo)
```

3. Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

4. Import the image from the file:

```
READ_JPEG, file, image
```

5. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to one before your first RGB image is displayed within an IDL session or program.

```
DEVICE, DECOMPOSED = 1
```

6. Create a window and display the image:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'Glowing Gas RGB Image'
TV, image, TRUE = 1
```

The following figure shows the original RGB image.

*Figure 3-131: The Glowing Gas RGB Image*

7. Extract the channels (as images) from the RGB image:

```
redChannel = REFORM(image[0, *, *])
greenChannel = REFORM(image[1, *, *])
blueChannel = REFORM(image[2, *, *])
```

8. Initialize the grayscale display:

```
DEVICE, DECOMPOSED = 0
LOADCT, 0
```

9. Create another window and display each channel of the RGB image:

```
WINDOW, 1, XSIZE = 3*imageSize[0], YSIZE = imageSize[1], $
  TITLE = 'Red (left), Green (middle), ' + $
  'and Blue (right) Channels of the RGB Image'
TV, redChannel, 0
TV, greenChannel, 1
TV, blueChannel, 2
```

The following figure shows the RGB channels. The red channel is on the left, the green channel is in the middle, and the blue channel is on the right.

*Figure 3-132: The Channels of the Glowing Gas RGB Image*

10. Convert the channels into a single grayscale image.

```
grayscaleImage = BYTE(0.299*FLOAT(redChannel) + $
    0.587*FLOAT(redChannel) + 0.114*FLOAT(blueChannel))
```

The pixel values of the channels are converted from byte values to floating-point values because byte values cannot exceed 255. The adjustment factors (0.299, 0.587, and 0.114) are used to enhance visual perception and to scale the results to a range from 0 to 255. The BYTE function is used to restore the pixel values back to their original data type.

11. Create another window and display the grayscale image:

```
WINDOW, 2, XSIZE = 2*imageSize[0], YSIZE = imageSize[1], $
    TITLE = 'Resulting Grayscale Image' + $
    TV, grayscaleImage
```

The following figure shows the result of creating a grayscale image from the individual channels of an RGB image.

*Figure 3-133: Resulting Grayscale Image*

# TVCRS

The TVCRS procedure manipulates the display device cursor. The initial state of the cursor is device dependent. Call TVCRS with one argument to enable or disable the cursor. Call TVCRS with two parameters to enable the cursor and place it on pixel location (X, Y).

## Syntax

```
TVCRS [, ON_OFF] [, /CENTIMETERS | , /INCHES] [, /HIDE_CURSOR]
```

or

```
TVCRS [, X, Y] [, /CENTIMETERS | , /INCHES] [, /HIDE_CURSOR]
```

**Graphics Keywords:** [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=value]

## Arguments

### ON\_OFF

This argument specifies whether the cursor should be on or off. If this argument is present and nonzero, the cursor is enabled. If *ON\_OFF* is zero or no parameters are specified, the cursor is turned off.

### X

The column to which the cursor is set.

### Y

The row to which the cursor is set.

## Keywords

### CENTIMETERS

Set this keyword to cause X and Y to be interpreted as centimeters, based on the current device resolution.

### INCHES

Set this keyword to cause X and Y to be interpreted as inches, based on the current device resolution.

## HIDE\_CURSOR

By default, disabling the cursor works differently for window systems than for other devices. For window systems, the cursor is restored to the standard cursor used for non-IDL windows (and remains visible), while for other devices it is completely blanked out. If the HIDE keyword is set, disabling the cursor causes it to always be blanked out.

### Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[DATA](#), [DEVICE](#), [NORMAL](#), [T3D](#), [Z](#)

## Examples

To enable the graphics cursor and position it at device coordinate (100, 100), enter:

```
TVCRS, 100, 100
```

To position the cursor at data coordinate (0.5, 3.2), enter:

```
TVCRS, 0.5, 3.2, /DATA
```

[CURSOR](#), [RDPIX](#)

# TVLCT

The TVLCT procedure loads the display color translation tables from the specified variables. Although IDL uses the RGB color system internally, color tables can be specified to TVLCT using any of the following color systems: RGB (Red, Green, Blue), HLS (Hue, Lightness, Saturation), and HSV (Hue, Saturation, Value). Alpha values may also be used when using the second form of the command. The type and meaning of each argument is dependent upon the color system selected, as described below. Color arguments can be either scalar or vector expressions. If no color-system keywords are present, the RGB color system is used.

## Syntax

```
TVLCT, V1, V2, V3 [, Start] [, /GET] [, /HLS | , /HSV]
```

or

```
TVLCT, V [, Start] [, /GET] [, /HLS | , /HSV]
```

## Arguments

TVLCT will accept either three  $n$ -element vectors ( $V_1$ ,  $V_2$ , and  $V_3$ ) or a single  $n$ -by-3 array ( $V$ ) as an argument. The vectors (or rows of the array) have different meanings depending on the color system chosen. If an array  $V$  is specified,  $V[* , 0]$  is the same as  $V_1$ ,  $V[* , 1]$  is the same as  $V_2$ ,  $V[* , 2]$  is the same as  $V_3$ . In the description below, we assume that three vectors,  $V_1$ ,  $V_2$ , and  $V_3$  are specified.

### $V_1$ , $V_2$ , and $V_3$

The  $V_1$ ,  $V_2$ , and  $V_3$  arguments have different meanings depending upon which color system they represent.

If the **GET** keyword is specified,  $V_1$ ,  $V_2$ , and  $V_3$  should be set to named variables.

### **R, G, B Color System**

The parameters  $V_1$ ,  $V_2$ , and  $V_3$  contain the red, green, and blue values, respectively. Values are interpreted as integers in the range 0 (lowest intensity) to 255 (highest intensity). The parameters can be scalars or vectors of up to 256 elements. By default, the three arguments are assumed to be R, G, and B values.

## H, L, S Color System

Parameters  $V_1$ ,  $V_2$ , and  $V_3$  contain the Hue, Lightness, and Saturation values respectively. All parameters are floating-point. Hue is expressed in degrees and is reduced modulo 360.  $V_2$  (lightness) and  $V_3$  (saturation) and can range from 0 to 1.0. Set the HLS keyword to have the arguments interpreted this way.

## H, S, V Color System

Parameters  $V_1$ ,  $V_2$ , and  $V_3$  contain values for Hue, Saturation, and Value (similar to intensity). All parameters are floating-point. Hue is in degrees. The Saturation and Value can range from 0 to 1.0. Set the HSV keyword to have the arguments interpreted this way.

## Start

An integer value that specifies the starting point in the color translation table into which the color intensities ( $V_1$ ,  $V_2$ , and  $V_3$ ) are loaded. If this argument is not specified, a value of zero is used, causing the tables to be loaded starting at the first element of the translation tables. The *Start* argument can be used to change only part of the color table.

## Keywords

### GET

Set this keyword to return the RGB values from the internal color tables into the  $V_1$ ,  $V_2$ , and  $V_3$  parameters. For example, the statements:

```
TVLCT, H, S, V, /HSV
TVLCT, R, G, B, /GET
```

load a color table based in the HSV system, and then read the equivalent RGB values into the variables R, G, and B.

If GET is specified,  $V_1$ ,  $V_2$ , and  $V_3$  must be set to named variables. A single  $V$  argument can be used with this keyword only if  $V$  is an array.

### HLS

Set this keyword to indicate that the parameters specify color using the HLS color system. The plain argument parameters are in the order H-L-S. Hue is expressed in degrees, and the lightness and saturation range from 0 to 1.

## HSV

Set this keyword to indicate that the parameters specify color using the HSV color system. The plain argument parameters are in the order H-S-V. As above, hue is in degrees, and the saturation and value range from 0 to 1.

## Examples

This section includes the following simple example as well as the following, more extensive examples:

- [“Highlighting Features with Color in Direct Graphics”](#) on page 2393
- [“Converting Indexed Images to RGB Images”](#) on page 2396

```
; Initialize display.
DEVICE, DECOMPOSED = 0

; Create a set of R, G, and B colormap vectors:
R = BYTSCL(SIN(FINDGEN(256)))
G = BYTSCL(COS(FINDGEN(256)))
B = BINDGEN(256)

; Load these vectors into the color table:
TVLCT, R, G, B

; Display an image to see the effect of the new color table:
TVSCL, DIST(400)
```

## Highlighting Features with Color in Direct Graphics

The data in the `mineral.png` file in the `examples/data` directory comes with its own color table. The following example will apply this related color table, then a pre-defined color table, and finally derive a new color table to highlight specific features. Complete the following steps for a detailed description of the process.

### Example Code

---

See `highlightfeatures_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

---

1. Determine the path to the `mineral.png` file:

```
mineralFile = FILEPATH('mineral.png', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image from the `mineral.png` file into IDL:

```
mineralImage = READ_PNG(mineralFile, red, green, blue)
```

The image's associated color table is contained within the resulting red, green, and blue vectors.

- Determine the size of the imported image:

```
mineralSize = SIZE(mineralImage, /DIMENSIONS)
```

- If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

- Load the image's associated color table with the `TVLCT` routine:

```
TVLCT, red, green, blue
```

- Initialize the display:

```
WINDOW, 0, XSIZE = mineralSize[0], YSIZE = mineralSize[1], $  
      TITLE = 'mineral.png'
```

- Display the imported image:

```
TV, mineralImage
```

This scanning electron microscope image shows mineral deposits in a sample of polished granite and gneiss. The associated color table is a reverse grayscale.

The following figure shows that the associated color table highlights the gneiss very well, but the other features are not very clear. The other features can be defined with IDL's pre-defined color table, `RAINBOW`.

Figure 3-134: Mineral Image and Default Color Table (Direct Graphics)

8. Load the RAINBOW color table and redisplay the image in another window:

```
LOADCT, 13
WINDOW, 1, XSIZE = mineralSize[0], YSIZE = mineralSize[1], $
    TITLE = 'RAINBOW Color'
TV, mineralImage
```

The following figure shows that the yellow, cyan, and red sections are now apparent, but the cracks are no longer visible. Details within the yellow areas and the green background are also difficult to distinguish. These features can be highlighted by designing your own color table.

*Figure 3-135: Mineral Image and RAINBOW Color Table (Direct Graphics)*

The features within the image are at specific ranges in between 0 and 255. Instead of a progressive color table, specific colors can be defined to be constant over these ranges. Any contrasting colors can be used, but it is easiest to derive the additive and subtractive primary colors used in the previous section.

9. Define the colors for a new color table:

```
colorLevel = [[0, 0, 0], $ ; black
              [255, 0, 0], $ ; red
              [255, 255, 0], $ ; yellow
              [0, 255, 0], $ ; green
              [0, 255, 255], $ ; cyan
              [0, 0, 255], $ ; blue
              [255, 0, 255], $ ; magenta
              [255, 255, 255]] ; white
```

10. Create a new color table that contains eight levels, including the highest end boundary by first deriving levels for each color in the new color table:

```
numberOfLevels = CEIL(!D.TABLE_SIZE/8.)
level = INDGEN(!D.TABLE_SIZE)/numberOfLevels
```

11. Place each color level into its appropriate range.

```
newRed = colorLevel[0, level]
newGreen = colorLevel[1, level]
newBlue = colorLevel[2, level]
```

12. Include the last color in the last level:

```
newRed[!D.TABLE_SIZE - 1] = 255
newGreen[!D.TABLE_SIZE - 1] = 255
newBlue[!D.TABLE_SIZE - 1] = 255
```

13. Make the new color table current:

```
TVLCT, newRed, newGreen, newBlue
```

14. Display the image with this new color table in another window:

```
WINDOW, 2, XSIZE = mineralSize[0], $
      YSIZE = mineralSize[1], TITLE = 'Cube Corner Colors'
TV, mineralImage
```

The following figure shows that each feature is now highlighted including the cracks. The color table also highlights at least three different types of cracks.

Figure 3-136: Mineral Image and Derived Color Table (Direct Graphics)

## Converting Indexed Images to RGB Images

The `convec.dat` file is a binary file that contains an indexed image (a two-dimensional image and its associated color table) of the convection of the earth's mantle. This file does not contain a related color table. The following example applies a color table to this image and then converts the image and table to an RGB image (which contains its own color information) and writes it to a JPEG file. Complete the following steps for a detailed description of the process.

**Example Code**

See `indexedtorgb.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `convec.dat` binary file:

```
convecFile = FILEPATH('convec.dat', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
convecSize = [248, 248]
```

3. Import the image from the file:

```
convecImage = READ_BINARY(convecFile, $
    DATA_DIMS = convecSize)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Load the EOS B color table (index number 27) to highlight the image's features and initialize the display:

```
LOADCT, 27
WINDOW, 0, TITLE = 'convec.dat', $
    XSIZE = convecSize[0], YSIZE = convecSize[1]
```

6. Now display the image with this color table.

```
TV, convecImage
```

Figure 3-137: Example of an Indexed Image With Associated Color Table

A color table is formed from three vectors (the red vector, the green vector, and the blue vector). The same element of each vector together form an RGB triplet to create a color. For example, the  $i$ -th element of the red vector may be 255, the  $i$ th element of the green vector may be 255, and the  $i$ th element of the blue vector maybe 0. The RGB triplet of the  $i$ th element would then be (255, 255, 0), which is the color yellow. Since a color table contains 256 indices, its three vectors have 256 elements each. You can access these vectors with the TVLCT routine using the GET keyword.

---

**Note**

On some PseudoColor displays, fewer than 256 entries will be available.

---

7. Access the values of the color table by setting the GET keyword to the TVLCT routine.

```
TVLCT, red, green, blue, /GET
```

This color table (color information) can be stored within the image by converting it to an RGB image. For this example, the RGB image will be pixel interleaved in order to be exported to a JPEG file.

---

**Tip**

If the original indexed image contains values of a data type other than byte, you should byte-scale the image (with the BYTSCL routine) before using the following method.

---

8. Before converting the indexed image into an RGB image, the resulting three-dimensional array must be initialized. Initialize the data type and the dimensions of the resulting RGB image:

```
imageRGB = BYTARR(3, convecSize[0], convecSize[1])
```

9. Use the red, green, and blue vectors of the color table and the original indexed image to form a single image composed of these channels:

```
imageRGB[0, *, *] = red[convecImage]
imageRGB[1, *, *] = green[convecImage]
imageRGB[2, *, *] = blue[convecImage]
```

10. Export the resulting RGB image to a JPEG file:

```
WRITE_JPEG, 'convecImage.jpg', imageRGB, TRUE = 1, $
QUALITY = 100.
```

The TRUE keyword is set to 1 because the resulting RGB image is pixel interleaved. See [WRITE\\_JPEG](#) for more information.

# TVRD

The TVRD function returns the contents of the specified rectangular portion of the current Direct Graphics window or device.  $(X_0, Y_0)$  is the coordinate of the lower left corner of the area to be read and  $N_x, N_y$  is the size of the rectangle in columns and rows. The result is a byte array of dimensions  $N_x$  by  $N_y$ . All parameters are optional. If no arguments are supplied, the entire display device area is read.

## Important Note about TVRD and Backing Store

On some systems, when backing store is provided by the window system (the RETAIN keyword to DEVICE or WINDOW is set to 1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (set the RETAIN keyword to 2) ensures that the window contents will be read properly. More detailed notes about TVRD and the X Window system can be found below in [“Unexpected Results Using TVRD with X Windows”](#) on page 2402.

## Syntax

```
Result = TVRD( [X0 [, Y0 [, Nx [, Ny [, Channel]]]]] [, CHANNEL=value]
              [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS] )
```

## Return Value

Returns a byte array of the specified dimensions.

## Arguments

**X<sub>0</sub>**

The starting column of data to read. The default is 0.

**Y<sub>0</sub>**

The starting row of data to read. The default is 0.

**N<sub>x</sub>**

The number of columns to read. The default is the width of the display device or window less  $X_0$ .

## **$N_y$**

The number of rows to read. The default is the height of the display device or window less  $Y_0$ .

## **Channel**

The memory channel to be read. If not specified, this argument is assumed to be zero. This parameter is ignored on display systems that have only one memory channel.

## **Keywords**

### **CHANNEL**

The memory channel to be read. The CHANNEL keyword is identical to the optional *Channel* argument.

#### **Note**

---

If the display is a 24-bit display, and both the CHANNEL and TRUE parameters are absent, the maximum RGB value in each pixel is returned.

---

### **ORDER**

Set this keyword to override the current setting of the !ORDER system variable for the current image only. If set, it causes the image to be read from the top down instead of the normal bottom up.

### **TRUE**

If this keyword is present, it indicates that a TrueColor image is to be read, if the display is capable. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The result is an  $(3, n_x, n_y)$  pixel-interleaved array if TRUE is 1; or an  $(n_x, 3, n_y)$  line-interleaved array if TRUE is 2; or an  $(n_x, n_y, 3)$  image-interleaved array if TRUE is 3.

### **WORDS**

Set this keyword to indicate that words are to be transferred from the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the function result is an integer array.

## Unexpected Results Using TVRD with X Windows

When using TVRD with the X Windows graphics device, there are two unexpected behaviors that can be confusing to users:

- When reading from a window that is obscured by another window (i.e., the target window has another window “on top” or “in front” of it), TVRD may return the contents of the window in front as part of the image contained in the target window.
- When reading from an iconified window, the X server may return a stream of “BadMatch” protocol events.

IDL uses the Xlib function `XGetSubImage()` to implement TVRD. The following quote is from the documentation for `XGetSubImage()` found in *The X Window System* by Robert W. Scheifler and James Gettys, Second Edition, page 174. It explains the reasons for the behaviors described above:

“If the drawable is a window, the window must be viewable, and it must be the case that if there were no... overlapping windows, the specified rectangle of the window would be fully visible on the screen, ... or a BadMatch error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured... If the window does not have backing-store, the returned contents of such obscured regions are undefined.”

Hence, the first behavior is caused by attempting to use TVRD on an obscured window that does not have backing store provided by the X server. The result in this case is undefined, meaning that the different servers can produce entirely different results. Many servers simply return the image of the obscuring window.

The second behavior is caused by attempting to read from a non-viewable (i.e., unmapped) window. Although IDL could refuse to allow TVRD to work with unmapped windows, some X servers return valid and useful results. Therefore, TVRD is allowed to attempt to read from unmapped windows.

Both of these behavior problems can be solved by using one of the following methods:

- Always make sure that your target window is mapped and is not obscured before using TVRD on it. The following IDL command can be used:  

```
WSET, Window_Index
```
- Make IDL provide backing store (rather than the window system) by setting the `RETAIN` keyword to `DEVICE` or `WINDOW` equal to 2.

For a full description of backing store, see “[Backing Store](#)” on page 4728. Note that under X Windows, backing store is a request that may or may not be honored by the X server. Many servers will honor backing store for 8-bit visuals but ignore them for 24-bit visuals because they require three times as much memory.

## Examples

```
; Read the entire contents of the current display device into the
; variable T:
T = TVRD()
```

To read from the display to an IDL variable or expression, use the TVRD function with either the CHANNEL parameter or TRUE keyword parameter. The calling sequence for TVRD is:

$$\text{Result} = \text{TVRD}([X_0, Y_0, N_x, N_y, \text{Channel}])$$

where  $(X_0, Y_0)$  specifies the window coordinate of the lower-left corner of the rectangle to be read, and  $(N_x, N_y)$  contains the number of columns and rows to read. Note that all parameters to TVRD are optional. If no arguments are supplied, the entire area of the display device is returned.

When used without the TRUE parameter, TVRD returns an  $(N_x, N_y)$  byte image read from the indicated channel. If the channel number is not specified or is zero, the maximum RGB value of each pixel is returned, approximating the luminance.

If present and nonzero, the TRUE keyword indicates that a TrueColor image is to be read and specifies the index of the dimension over which color is interleaved. The result is a  $(3, N_x, N_y)$  pixel interleaved array if TRUE is 1; or an  $(N_x, 3, N_y)$  line interleaved array if TRUE is 2; or an  $(N_x, N_y, 3)$  image interleaved array if TRUE is 3.

Some examples of TVRD follow.

```
; Read a 512 × 512 image, starting at (0, 0),
; from the red channel into R:
R = TVRD(0, 0, 512, 512, 1)
; Read a TrueColor 512 × 512, line interleaved image,
; starting at (0, 0) into T. The variable T is
; now dimensioned (512, 3, 512):
T = TVRD(0, 0, 512, 512, TRUE = 2)
; Read the maximum RGB value of each pixel into L:
L = TVRD(0, 0, 512, 512)
```

# TVSCL

The TVSCL procedure scales the intensity values of *Image* into the range of the Direct Graphics image display device and outputs the data to the image display at the specified location. The array is scaled so the minimum data value becomes 0 and the maximum value becomes the maximum number of available colors (held in the system variable !D.TABLE\_SIZE) as follows:

$$\text{Output} = (!\text{D.TABLE\_SIZE} - 1) \frac{\text{Data} - \text{Data}_{\min}}{\text{Data}_{\max} - \text{Data}_{\min}}$$

where the maximum and minimum are found by scanning the array. The parameters and keywords of the TVSCL procedure are identical to those accepted by the TV procedure. For additional information about each parameter, consult the description of TV.

## Syntax

```
TVSCL, Image [, Position] [, /CENTIMETERS] [, /INCHES] [, /ORDER]
    [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=value] [, YSIZE=value]
```

or

```
TVSCL, Image [, X, Y [, Channel] [, /CENTIMETERS] [, /INCHES] [, /NAN]
    [, /ORDER] [, TOP=value] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=value]
    [, YSIZE=value]]
```

**Graphics Keywords:** [, CHANNEL=value] [, /DATA | /DEVICE | /NORMAL]
 [, /T3D | Z=value]

## Arguments

### Image

A two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

### X, Y

If *X* and *Y* are present, they specify the lower left coordinate of the displayed image.

## Position

Image position. See the discussion of “[Position](#)” on page 2376 under [TV](#) for a full description.

## Channel

Some image display devices are capable of storing more than a single image or can combine three single color images to form a TrueColor image. *Channel* specifies the memory channel to be written. It is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel.

## Keywords

### CENTIMETERS

Set this keyword to indicate that the *X*, *Y*, *Xsize*, *Ysize*, and *Z* arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

### INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

### NAN

Set this keyword to cause TVSCL to treat elements of *Image* that are not numbers (that is, elements that have the special IEEE floating-point values *Infinity* or *NaN*) as missing data, and display them using color index 0 (zero). Note that color index 0 is also used to display elements that have the minimum value in the *Image* array. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

### ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

## TOP

The maximum value of the scaled result. If TOP is not specified, !D.TABLE\_SIZE-1 is used. Note that the minimum value of the scaled result is always 0.

## TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of  $(3, m, n)$ . Specify 2 for row-interleaved images, of size  $(m, 3, n)$ , and 3 for band-interleaved images of the form  $(m, n, 3)$ .

See [“TrueColor Images”](#) on page 4746 for an example using this keyword to write 24-bit images to the PostScript device.

## WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the *Image* parameter is converted to short integer type, if necessary, and then written to the display.

## XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image’s aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

## YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image’s aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[CHANNEL](#), [DATA](#), [DEVICE](#), [NORMAL](#), [T3D](#), [Z](#)

## Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

Display a floating-point array as an image using the TV command:

```
TV, DIST(200)
```

Note that the image is not easily visible because the values in the array have not been scaled into the full range of display values. Now display the image with the TVSCL command by entering:

```
TVSCL, DIST(200)
```

Notice how much brighter the image appears.

# UINDGEN

The UINDGEN function creates an unsigned integer array. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$\text{Result} = \text{UINDGEN}(D_1 [, \dots, D_8])$$

## Return Value

Returns an unsigned integer array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

To create UI, a 10-element by 10-element 16-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
UI = UINDGEN(10, 10)
```

## Version History

# UINT

The `UINT` function returns a result equal to *Expression* converted to unsigned integer type.

## Syntax

$$\text{Result} = \text{UINT}(\text{Expression}[, \text{Offset} [, D_1 [, \dots, D_8]]])$$

## Return Value

Returns the specified dimensions of the given expression as an unsigned integer type.

## Arguments

### Expression

The expression to be converted to unsigned integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned integer data. See the description in [Chapter 13, “Working with Data in IDL”](#) in the *Building IDL Applications* manual for details.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The `ON_IOERROR` procedure can be used to establish a statement to be jumped to in case of such errors.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

## Examples

If A contains the floating-point value 32000.0, it can be converted to an unsigned integer and stored in the variable B by entering:

```
B = UINT(A)
```

# UINTARR

The `UINTARR` function creates an unsigned integer vector or array.

## Syntax

$$Result = \text{UINTARR}(D_1 [, \dots, D_8] [, \text{NOZERO}] )$$

## Return Value

Returns an unsigned integer vector or array of the specified dimensions.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

**NOZERO**

Normally, `UINTARR` sets every element of the result to zero. If `NOZERO` is set, this zeroing is not performed and `UINTARR` executes faster.

## Examples

To create `L`, a 100-element, unsigned integer vector with each element set to 0, enter:

```
L = UINTARR(100)
```

# UL64INDGEN

The UL64INDGEN function returns an unsigned 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

$$\text{Result} = \text{UL64INDGEN}(D_1 [, \dots, D_8])$$

## Return Value

Returns the specified unsigned integer array.

## Arguments

$D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

# ULONG

The ULONG function returns a result equal to *Expression* converted to the unsigned longword integer type.

## Syntax

$$\text{Result} = \text{ULONG}(\text{Expression}[, \text{Offset} [, D_1 [, \dots, D_8]]])$$

## Return Value

Returns the specified dimensions of the given expression as an unsigned longword integer type.

## Arguments

### Expression

The expression to be converted to unsigned longword integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned longword integer data. See the description in [Chapter 13, “Working with Data in IDL”](#) in the *Building IDL Applications* manual for details.

### $D_i$

When extracting fields of data, the  $D_i$  arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The  $D_i$  arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. # UNIQ

The UNIQ function returns the subscripts of the unique elements in an array. Note that repeated elements must be adjacent in order to be found. This routine is intended to be used with the SORT function: see the examples below. This function was inspired by the UNIX `uniq(1)` command.

This routine is written in the IDL language. Its source code can be found in the file `uniq.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = UNIQ( *Array* [, *Index*] )

## Return Value

UNIQ returns an array of indices into the original array. Note that the index of the last element in each set of non-unique elements is returned. If the optional *Index* argument is supplied, then the last index in the order provided by the *Index* array is returned.

The following expression returns a copy of the sorted array with duplicate adjacent elements removed:

```
Array[UNIQ(Array)]
```

UNIQ returns 0 (zero) if the argument supplied is a scalar rather than an array.

## Arguments

### Array

The array to be scanned. For UNIQ to work properly, the array must be sorted into monotonic order unless the optional parameter *Index* is supplied.

### Index

This optional parameter is an array of indices into *Array* that order the elements into monotonic order. That is, the expression:

```
Array[Index]
```

yields an array in which the elements of *Array* are rearranged into monotonic order.

The *Index* array can be generated from *Array* using the SORT function:

```
Index = SORT(Array)
```

If *Array* is not already in monotonic order, use the command:

```
UNIQ(Array, SORT(Array))
```

## Examples

Find the unique elements of an unsorted array:

```
; Create an array:
array = [1, 2, 1, 2, 3, 4, 5, 6, 6, 5]

; Variable B holds an array containing the sorted, unique values in
; array:
b = array[UNIQ(array, SORT(array))]
PRINT, b
```

IDL prints

```
1  2  3  4  5  6
```

## Version History

# UNSHARP\_MASK

The UNSHARP\_MASK function performs an unsharp-mask sharpening filter on a two-dimensional array or a TrueColor image. For TrueColor images the unsharp mask is applied to each channel.

The unsharp mask algorithm works by enhancing the contrast between neighboring pixels in an image, and is widely used for astronomical images and for digital photographs.

The algorithm involves the following steps:

1. Smooth the original image with a Gaussian filter, with the width controlled by the RADIUS keyword.
2. Subtract the smoothed image from the original to create a high-pass filtered image.
3. Apply any clipping needed on the high-pass image, as controlled by the THRESHOLD keyword.
4. Add a certain percentage of the high-pass filtered image to the original image, with the percentage controlled by the AMOUNT keyword.

In pseudocode this algorithm can be written as:

```
HighPass = Image - Convolve ( Image, Gaussian )
Result = Image + A * HighPass * ( |HighPass| ≥ T )
```

where A is the amount, T is the threshold, and  $\geq$  indicates a Boolean operation, 1 if true, or 0 otherwise.

---

## Note

To avoid overflow for byte or integer data, the computations are performed using a larger integer type, the result is clipped to the minimum and maximum values for the original type, and the result is then converted back to the original type.

---

This routine is written in the IDL language. Its source code can be found in the file `unsharp_mask.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = UNSHARP_MASK(Image [, AMOUNT=value] [, RADIUS=value]
  [, THRESHOLD=value] [, TRUE={1|2|3}])
```

## Return Value

The *Result* is an array with the same dimensions and type as *Image* that contains the filtered image.

## Arguments

### Image

The two-dimensional array or multichannel image to be filtered. If *Image* is a multichannel image, then the TRUE keyword may be used to indicate which dimension represents the channels.

## Keywords

### AMOUNT

Set this keyword to a floating-point value giving the amount (or strength) of filtering to be applied. The default is AMOUNT=1.0, which implies that 100% of the filter difference will be applied to the *Image*. AMOUNT may be negative, which will have the effect of blurring the image instead of sharpening.

### RADIUS

Set this keyword to a floating-point value giving the radius in pixels of the Gaussian smoothing filter. The default is RADIUS=3. The Gaussian filter is designed to fall to  $1/e$  ( $\sim 0.367$ ) at a distance of RADIUS/sqrt(2). The total width of the Gaussian filter is given by  $\text{ceil}(2 * \text{RADIUS})/2 * 2 + 1$  (if RADIUS is an integer then this is just  $2 * \text{RADIUS} + 1$ ).

#### Note

---

The value of RADIUS must be smaller than one-half of the largest array dimension.

---

#### Tip

---

Use small RADIUS values (such as 3) for small images or images with fine details.  
Use larger RADIUS values for large images with larger details.

---

### THRESHOLD

Set this keyword to a non-negative integer (or a floating-point if *Image* is floating point) giving the clipping threshold. For each element, if the absolute value of the difference between the original image and the low-pass filtered array is greater than

or equal to THRESHOLD then the filter is applied to that point. The default is THRESHOLD=0, which implies that every point will be filtered.

**Tip**

---

Lower values of THRESHOLD will provide greater sharpening but may cause more speckling, while higher values of THRESHOLD will exclude regions of low contrast and cause less speckling.

---

**TRUE**

If *Image* is a three-dimensional array (a multichannel image), set this keyword to 1, 2, or 3 to indicate which dimension represents the channels. The default is 1, for pixel interleaving,  $(3, m, n)$ . A value of 2 indicates line interleaving  $(m, 3, n)$ , and 3 indicates band interleaving,  $(m, n, 3)$ .

**Example**

```
file = FILEPATH('marsglobe.jpg', SUBDIR=['examples','data'])
READ_JPEG, file, image
; Display the original image.
iImage, image, VIEW_GRID=[2,1], DIMENSIONS = [800, 500]
; Display the unsharp-mask-filtered image.
result = UNSHARP_MASK(image, RADIUS=4)
iImage, result, /VIEW_NEXT
```

# USERSYM

The USERSYM procedure is used to define the plotting symbol that marks points when the PSYM keyword symbol is set to plus or minus 8. Symbols can be drawn with vectors or can be filled. Symbols can be of any size and can have up to 49 vertices.

The symbol you define can be drawn using lines or it can be filled using the polygon filling operator. USERSYM accepts two vector parameters: a vector of  $x$  values and a vector of  $y$  values. The coordinate system you use to define the symbol's shape is centered on each data point, and each unit is approximately the size of a character. The color and line thickness used to draw the symbols are also optional keyword parameters of USERSYM.

## Syntax

```
USERSYM, X [, Y] [, COLOR=value] [, /FILL] [, THICK=value]
```

## Arguments

### X, Y

The  $X$  and/or  $Y$  parameters define the vertices of the symbol as offsets from the data point in units of approximately the size of a character. In the case of a vector drawn symbol, the symbol is formed by connecting the vertices in order. If only one argument is specified, it must be a  $(2, N)$  array of vertices, with element  $[0, i]$  containing the  $X$  coordinate of the vertex, and element  $[1, i]$  containing the  $Y$ . If both arguments are provided,  $X$  contains only the  $X$  coordinates.

## Keywords

### COLOR

The color used to draw the symbols, or used to fill the polygon. The default color is the same as the line color.

### FILL

Set this keyword to fill the polygon defined by the vertices. If FILL is not set, lines are drawn connecting the vertices.

## THICK

The thickness of the lines used in drawing the symbol. The default thickness is 1.0.

## Examples

To define the simplest symbol, use a one character-wide dash centered over the data point:

```
USERSYM, [-.5, .5], [0, 0]
```

Make a large, diamond-shaped plotting symbol. Define the vectors of X values by entering:

```
X = [-6, 0, 6, 0, -6]
```

Define the vectors of Y values by entering:

```
Y = [0, 6, 0, -6, 0]
```

Now call `USERSYM` to create the new plotting symbol 8. Enter:

```
USERSYM, X, Y
```

Generate a simple plot to test the plotting symbol by entering:

```
PLOT, FINDGEN(20), PSYM = 8
```

## Creating a Filled Circle Symbol

The following code illustrates the use of `USERSYM` to define a new symbol—a filled circle:

```
; Make a vector of 16 points, A[i] = 2pi/16:
A = FINDGEN(17) * (!PI*2/16.)
; Define the symbol to be a unit circle with 16 points,
; and set the filled flag:
USERSYM, COS(A), SIN(A), /FILL
```

Using the variables defined in a batch file, we then create the plot, specifying 8 (user-defined) for the `PSYM` keyword to `PLOT`:

```
; Define variables.
@plot01
; Use the LINFIT function to fit the data to a line:
coeff = LINFIT(YEAR, SOCKEYE)
; YFIT is the fitted line:
YFIT = coeff[0] + coeff[1]*YEAR

PLOT, YEAR, SOCKEYE, /YNOZERO, PSYM = 8, $
TITLE = 'Quadratic Fit', XTITLE = 'Year', $
```

```

        YTITLE = 'Sockeye Population'
        ; Overplot the smooth curve using a plain line:
        OPLOT, YEAR, YFIT

```

The following figure shows the result of this code:

Figure 3-139: Plotting with User-defined Plotting Symbols

### Note

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the `examples/doc` subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See [!PATH](#) for information on modifying IDL's path.

# VALUE\_LOCATE

The VALUE\_LOCATE function finds the intervals within a given monotonic vector that brackets a given set of one or more search values. This function is useful for interpolation and table-lookup, and is an adaptation of the locate() routine in Numerical Recipes. VALUE\_LOCATE uses the bisection method to locate the interval.

## Syntax

$Result = \text{VALUE\_LOCATE} ( \text{Vector}, \text{Value} [, /L64 ] )$

## Return Value

Each return value,  $Result [i]$ , is an index,  $j$ , into  $Vector$ , corresponding to the interval into which the given  $Value [i]$  falls. The returned values are in the range  $-1 \leq j \leq N-1$ , where  $N$  is the number of elements in the input vector.

If  $Vector$  is monotonically increasing, the result  $j$  is:

if  $j = -1$        $Value [i] < Vector [0]$   
 if  $0 \leq j < N-1$        $Vector [j] \leq Value [i] < Vector [j+1]$   
 if  $j = N-1$        $Vector [N-1] \leq Value [i]$

If  $Vector$  is monotonically decreasing

if  $j = -1$        $Vector [0] \leq Value [i]$   
 if  $0 \leq j < N-1$        $Vector [j+1] \leq Value [i] < Vector [j]$   
 if  $j = N-1$        $Value [i] < Vector [N-1]$

## Arguments

### Vector

A vector of monotonically increasing or decreasing values.  $Vector$  may be of type string, or any numeric type except complex, and may not contain the value NaN (not-a-number).

## Value

The value for which the location of the intervals is to be computed. *Value* may be either a scalar or an array. The return value will contain the same number of elements as this parameter.

## Keywords

### L64

By default, the result of `VALUE_LOCATE` is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set `L64` to force 64-bit integers to be returned in all cases.

### Note

---

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of `!VERSION.MEMORY_BITS` to see if your IDL is 64-bit or not.

---

## Examples

```
; Define a vector of values.
vec = [2,5,8,10]

; Compute location of other values within that vector.
loc = VALUE_LOCATE(vec, [0,3,5,6,12])
PRINT, loc
```

IDL prints:

```
-1  0  1  1  3
```

# VARIANCE

The VARIANCE function computes the statistical variance of an  $n$ -element vector.

## Syntax

```
Result = VARIANCE( X [, /DOUBLE] [, /NAN] )
```

## Return Value

Returns the floating-point or double-precision statistical variance of the input vector.

## Arguments

### X

An  $n$ -element, floating-point or double-precision vector.

## Keywords

### DOUBLE

If this keyword is set, VARIANCE performs its computations in double precision arithmetic and returns a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results).

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 8 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:  
x = [1, 1, 1, 2, 5]  
; Compute the variance:  
result = VARIANCE(x)  
PRINT, result
```

IDL prints:

3.00000

# VECTOR\_FIELD

The VECTOR\_FIELD procedure is used to place colored, oriented vectors of specified length at each vertex in an input vertex array. The output can be sent directly to an IDLgrPolyline object. The generated display is generally referred to as a hedgehog display and is used to convey various aspects of a vector field.

## Syntax

```
VECTOR_FIELD, Field, Outverts, Outconn [, ANISOTROPY=array]  
[, SCALE=value] [, VERTICES=array]
```

## Arguments

### Field

Input vector field array. This can be a [3, *x*, *y*, *z*] array or a [2, *x*, *y*] array. The leading dimension is the vector quantity to be displayed.

### Outverts

Output vertex array ([3, *N*] or [2, *N*] array of floats). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

### Outconn

Output polyline connectivity array to be applied to the output vertices.

## Keywords

### ANISOTROPY

Set this keyword to a two- or three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0] for three-dimensional data and [1.0, 1.0] for two-dimensional data.

### SCALE

Set this keyword to a scalar scaling factor. All vector lengths are multiplied by this value. The default is 1.0.

## VERTICES

Set this keyword to a  $[3, n]$  or  $[2, n]$  array of points. If this keyword is set, the vector field is interpolated at these points. The resulting interpolated vectors are displayed as line segments at these locations. If the keyword is not set, each spatial sample point in the input Field grid is used as the base point for a line segment.

# VEL

The VEL procedure draws a velocity (flow) field with arrows following the field proportional in length to the field strength. Arrows are composed of a number of small segments that follow the streamlines.

This routine is written in the IDL language. Its source code can be found in the file `vel.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
VEL, U, V [, NVECS=value] [, XMAX= value{ysize/ysize}]  
    [, LENGTH=value{longest/steps}] [, NSTEPS=value] [, TITLE=string]
```

## Arguments

### U

The X component at each point of the vector field. *U* must be a 2-D array.

### V

The Y component at each point of the vector field. *V* must have the same dimensions as *U*.

## Keywords

### LENGTH

The length of each arrow line segment expressed as a fraction of the longest vector divided by the number of steps. The default is 0.1.

### NSTEPS

The number of shoots or line segments for each arrow. The default is 10.

### NVECS

The number of vectors (arrows) to draw. If this keyword is omitted, 200 vectors are drawn.

## TITLE

A string containing the title for the plot.

## XMAX

X axis size as a fraction of Y axis size. The default is 1.0. This argument is ignored when !P.MULTI is set.

## Examples

```
; Create a vector of X values:  
X = DIST(20)  
  
; Create a vector of Y values:  
Y = SIN(X)*100  
  
; Plot the vector field:  
VEL, X, Y
```

[FLOW3](#), [PLOT\\_FIELD](#), [VELOVECT](#)

# VELOVECT

The VELOVECT procedure produces a two-dimensional velocity field plot. A directed arrow is drawn at each point showing the direction and magnitude of the field.

This routine is written in the IDL language. Its source code can be found in the file `velovect.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
VELOVECT, U, V [, X, Y] [, COLOR=index] [, MISSING=value] [, /DOTS]]  
      [, LENGTH=value] [, /OVERPLOT] [Also accepts all PLOT keywords]
```

## Arguments

### U

The X component of the two-dimensional field. *U* must be a two-dimensional array.

### V

The Y component of the two dimensional field. *V* must have the same dimensions as *U*.

### X

Optional abscissae values. *X* must be a vector with a length equal to the first dimension of *U* and *V*.

### Y

Optional ordinate values. *Y* must be a vector with a length equal to the second dimension of *U* and *V*.

## Keywords

### Note

---

Keywords not described here are passed directly to the PLOT procedure and may be used to set options such as TITLE, POSITION, NOERASE, etc.

---

## COLOR

Set this keyword equal to the color index used for the plot.

## DOTS

Set this keyword to 1 to place a dot at each missing point. Set this keyword to 0 or omit it to draw nothing for missing points. Has effect only if MISSING is specified.

## LENGTH

Set this keyword equal to the length factor. The default of 1.0 makes the longest ( $U, V$ ) vector the length of a cell.

## MISSING

Set this keyword equal to the missing data value. Vectors with a length greater than MISSING are ignored.

## OVERPLOT

Set this keyword to make VELOVECT “overplot”. That is, the current graphics screen is not erased, no axes are drawn, and the previously established scaling remains in effect.

## PLOT Keywords Accepted

See [PLOT](#) for the description of the following plotting keywords:

[ISOTROPIC](#), [MAX\\_VALUE](#), [MIN\\_VALUE](#), [NSUM](#), [POLAR](#), [THICK](#), [XLOG](#), [YLOG](#), [YNOZERO](#)

## Examples

```
; Create some random data:
U = RANDOMN(S, 20, 20)
V = RANDOMN(S, 20, 20)

; Plot the vector field:
VELOVECT, U, V

; Plot the field, using dots to represent vectors with values
; greater than 18:
VELOVECT, U, V, MISSING=18, /DOTS
```

```
    ; Plot with a title. Note that the XTITLE keyword is passed  
    ; directly to the PLOT procedure:  
    VELOVECT, U, V, MISSING=18, /DOTS, XTITLE='Random Vectors'
```

# VERT\_T3D

The VERT\_T3D function transforms a 3-D array by a 4x4 transformation matrix. The 3-D points are typically an array of polygon vertices that were generated by SHADE\_VOLUME or MESH\_OBJ.

This routine is written in the IDL language. Its source code can be found in the file `vert_t3d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = VERT_T3D( Vertex_List [, DOUBLE=value] [, MATRIX=4x4_array]  
[, /NO_COPY] [, /NO_DIVIDE [, SAVE_DIVIDE=variable]] )
```

## Return Value

Returns the single- or double-precision coordinates of the transformed array.

## Arguments

### Vertex\_List

A 3 x *n* array of 3-D coordinates to transform.

## Keywords

### DOUBLE

Set this keyword to a nonzero value to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the DOUBLE keyword is implied to be non-zero).

### MATRIX

The 4x4 transformation matrix to use. The default is to use the system viewing matrix (!P.T).

## NO\_COPY

Normally, a copy of *Vertex\_list* is transformed and the original *Vertex\_list* is preserved. If NO\_COPY is set, however, then the original *Vertex\_List* will be undefined after the call to VERT\_T3D. Using the NO\_COPY requires less memory.

## NO\_DIVIDE

Normally, when a  $[x, y, z, 1]$  vector is transformed by a 4x4 matrix, the final homogeneous coordinates are obtained by dividing the  $x$ ,  $y$ , and  $z$  components of the result vector by the fourth element in the result vector. Setting the NO\_DIVIDE keyword will prevent VERT\_T3D from performing this division. In some cases (usually when a perspective transformation is involved) the fourth element in the result vector can be very close to (or equal to) zero.

## SAVE\_DIVIDE

Set this keyword to a named variable that will hold receive the fourth element of the transformed vector(s). If *Vertex\_list* is a vector then SAVE\_DIVIDE is a scalar. If *Vertex\_list* is an array then SAVE\_DIVIDE is an array of  $n$  elements. This keyword only has effect when the NO\_DIVIDE keyword is set.

## Examples

Transform four points representing a square in the x-y plane by first translating +2.0 in the positive X direction, and then rotating 60.0 degrees about the Y axis.

```
points = [[0.0, 0.0, 0.0], [1.0, 0.0, 0.0], $
          [1.0, 1.0, 0.0], [0.0, 1.0, 0.0]]
T3D, /RESET
T3D, TRANSLATE=[2.0, 0.0, 0.0]
T3D, ROTATE=[0.0, 60.0, 0.0]
points = VERT_T3D(points)
```

## Version History

[T3D](#)

# VOIGT

The VOIGT function returns the value of the classical Voigt function,  $H(a, u)$ , defined in terms of the Voigt damping parameter  $a$  and the frequency offset  $u$ :

$$H(a, u) = \frac{a}{\pi} \int_{-\infty}^{\infty} \frac{e^{-y^2} dy}{a^2 + (u - y)^2}$$

The dimensionless frequency offset  $u$  and the damping parameter  $a$  are determined by:

$$u = \frac{v - v_0}{\Delta v_D}$$

$$a = \frac{\Gamma}{4\pi\Delta v_D}$$

where  $v_0$  is the line center frequency and the Doppler width  $\Delta v_D$  (assuming no turbulence), is defined as:

$$\Delta v_D = \frac{v_0}{c} b = \frac{v_0}{c} \sqrt{2kT/m}$$

and,  $\Gamma$  is the transition rate:

$$\Gamma = \gamma + 2v_{col}$$

where  $\gamma$  is the spontaneous decay rate, and  $v_{col}$  is the atomic collision rate. (See *Radiative Processes in Astrophysics* by G. B. Rybicki and A. P. Lightman (1979) p. 291 for more information.)

The Voigt function can be used to compute the intensity of an atomic absorption line profile (also known as a VOIGT profile). The line profile  $\phi(a, u)$  is defined as:

$$\phi(a, u) \equiv \frac{H(a, u)}{\Delta v_D \sqrt{\pi}}$$

The algorithm is from Armstrong, *JQSRT* 7, 85. (1967). The definition of the classical Voigt function  $H(a,u)$  can be found in Equation 7.4.13 of Abramowitz, M. and Stegun, I.A., 1964, *Handbook of Mathematical Functions* (Washington:National Bureau of Standards).

## Syntax

*Result* = VOIGT(*A*, *U*)

## Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of *A* and *U*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array. If *A* is double-precision, the result is double-precision, otherwise the result is single-precision.

## Arguments

### A

A scalar or array specifying the values for the Voigt damping parameter.

### U

A scalar or array specifying the values for the dimensionless frequency offset in Doppler widths.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

[LEEFILT](#), [ROBERTS](#), [SOBEL](#)

# VORONOI

The VORONOI procedure computes the Voronoi polygon of a point within an irregular grid of points, given the Delaunay triangulation. The Voronoi polygon of a point contains the region closer to that point than to any other point.

For interior points, the polygon is constructed by connecting the midpoints of the lines connecting the point with its Delaunay neighbors. Polygons are traversed in a counterclockwise direction.

For exterior points, the set is described by the midpoints of the connecting lines, plus the circumcenters of the two triangles that connect the point to the two adjacent exterior points.

This routine is written in the IDL language. Its source code can be found in the file `voronoi.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

VORONOI, X, Y, I0, C, Xp, Yp, Rect

## Arguments

### X

An array containing the X locations of the points.

### Y

An array containing the Y locations of the points.

### I0

An array containing the indices of the points.

### C

A connectivity list from the Delaunay triangulation. This list is produced with the CONNECTIVITY keyword of the TRIANGULATE procedure.

### Xp, Yp

Named variables that will contain the X and Y vertices of Voronoi polygon.

## Rect

The bounding rectangle: [Xmin, Ymin, Xmax, Ymax]. Because the Voronoi polygon (VP) for points on the convex hull extends to infinity, a clipping rectangle must be supplied to close the polygon. This rectangle has no effect on the VP of interior points. If this rectangle does not enclose all the Voronoi vertices, the results will be incorrect. If this parameter, which must be a named variable, is undefined or set to a scalar value, it will be calculated.

## Examples

To draw the Voronoi polygons of each point of an irregular grid:

```

N = 20

; Create a random grid of N points:
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; Triangulate it:
TRIANGULATE, X, Y, tr, CONN=C

FOR I=0, N-1 DO BEGIN & $
  ; Get the ith polygon:
  VORONOI, X, Y, I, C, Xp, Yp & $
  ; Draw it:
  POLYFILL, Xp, Yp, COLOR = (I MOD 10) + 2 & $
ENDFOR

```

[TRIANGULATE](#)

# VOXEL\_PROJ

The VOXEL\_PROJ function generates visualizations of volumetric data by computing 2-D projections of a colored, semi-transparent volume. Parallel rays from any given direction are cast through the volume, onto the viewing plane. User-selected colors and opacities can be assigned to arbitrary data ranges, simulating the appearance of the materials contained within the volume.

The VOXEL\_PROJ function can be combined with the Z-buffer to render volume data over objects. Cutting planes can also be specified to view selected portions of the volume. Other options include: selectable resolution to allow quick “preview” renderings, and average and maximum projections.

VOXEL\_PROJ renders volumes using an algorithm similar to the one described by Drebin, Carpenter, and Hanrahan, in “Volume Rendering”, *Computer Graphics*, Volume 22, Number 4, August 1988, pp. 125-134, but without the surface extraction and enhancement step.

Voxel rendering can be quite time consuming. The time required to render a volume is proportional to the viewing areas size, in pixels, times the thickness of the volume cube in the viewing direction, divided by the product of the user-specified X, Y, and Z steps.

---

## Note

It is necessary to use SCALE3 to initialize a display before calling VOXEL\_PROJ as shown in the following [Examples](#) section.

---

## Syntax

```
Result = VOXEL_PROJ( V [, RGBO] [, BACKGROUND=array]
  [, CUTTING_PLANE=array] [, /INTERPOLATE]
  [, /MAXIMUM_INTENSITY] [, STEP={Sx, Sy, Sz}] [, XSIZE=pixels]
  [, YSIZE=pixels] [, ZBUFFER=int_array] [, ZPIXELS=byte_array] )
```

## Return Value

Returns the specified voxel projection results.

## Arguments

### V

A three-dimensional array containing the volume to be rendered. This array is converted to byte type if necessary.

### RGBO

This optional parameter is used to specify the look-up tables that indicate the color and opacity of each voxel value. This argument can be one of the following types:

- A (256, 4) byte array for TrueColor rendering. This array represents 256 sets of red, green, blue, and opacity (RGBO) components for each voxel value, scaled into the range of bytes (0 to 255). The R, G, and B components should already be scaled by the opacity. For example, if a voxel value of 100 contains a material that is red, and 35% opaque, the RGBO values should be, respectively: [89, 0, 0, 89] because  $255 * 0.35 = 89$ . If more than one material is present, the RGBO arrays contain the sum of the individual RGBO arrays. The content and shape of the RGBO curves is highly dependent upon the volume data and experimentation is often required to obtain the best display.
- A (256, 2) byte array for volumes with only one material or monochrome rendering. This array represents 256 sets of pixel values and their corresponding opacities for each voxel value.
- If this argument is omitted, the average projection method, or maximum intensity method (if the `MAXIMUM_INTENSITY` keyword is set) is used.

## Keywords

### BACKGROUND

A one- or three-element array containing the background color indices. The default is (0,0,0), yielding a black background with most color tables.

### CUTTING\_PLANE

A floating-point array specifying the coefficients of additional cutting planes. The array has dimensions of (4, N), where N is the number of additional cutting planes from 1 to 6. Cutting planes are constraints in the form of:

$$C[0] * X + C[1] * Y + C[2] * Z + D > 0$$

The X, Y, and Z coordinates are specified in voxel coordinates. For example, to specify a cutting plane that excludes all voxels with an X value greater than 10:

CUTTING\_PLANE = [-1.0, 0, 0, 10.], for the constraint:  $-X + 10 > 0$ .

## INTERPOLATE

Set this keyword to use tri-linear interpolation to determine the data value for each step on a ray. Otherwise, the nearest-neighbor method is used. Setting this keyword improves the quality of images produced, especially when the volume has low resolution in relation to the size of the viewing plane, at the cost of more computing time.

## MAXIMUM\_INTENSITY

Set this keyword to make the value of each pixel in the viewing plane the maximum data value along the corresponding ray. The *RGBO* argument is ignored if present.

## STEP

Set this keyword to a three-element vector, [ $S_x$ ,  $S_y$ ,  $S_z$ ], that controls the resolution of the resulting projection. The first two elements contain the step size in the X and Y view plane, in pixels. The third element is the sampling step size in the Z direction, given in voxels.  $S_x$  and  $S_y$  must be integers equal to or greater than one, while  $S_z$  can contain a fractional part. If  $S_x$  or  $S_y$  are greater than one, the values of intermediate pixels in the output image are linearly interpolated. Higher step sizes require less time because fewer rays are cast, at the expense of lower resolution in the output image.

## XSIZE

The width, in pixels, of the output image. If this keyword is omitted, the output image is as wide as the currently-selected output device.

## YSIZE

The height, in pixels, of the output image. If this keyword is omitted, the output image is as tall as the currently selected output device.

## ZBUFFER

An integer array, with the same width and height as the output image, that contains the depth portion of the Z-buffer. Include this parameter to combine the previously-read contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

## ZPIXELS

A byte array, with the same width and height as the output image, that contains the image portion of the Z-buffer. Include this parameter to combine the contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

## Examples

### Example 1

In the following example, assume that variable `V` contains a volume of data, with dimensions  $V_x$  by  $V_y$  by  $V_z$ . The volume contains two materials, muscle tissue represented by a voxel range of 50 to 70, that we want to render with red color, and an opacity of 20; and bone tissue represented by a voxel range of 220-255, that we want to render with white color, and an opacity of 50:

```
; Create the opacity vector:
rgbo = BYTARR(256,4)

; Red and opacity for muscle:
rgbo[50:70, [0,3]] = 20

; White and opacity for bone:
rgbo[220:255, *] = 50
```

### Example 2

Although it is common to use trapezoidal or Gaussian functions when forming the RGBO arrays, this example uses rectangular functions for simplicity.

```
; Set up the axis scaling and default rotation:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute projected image:
C = VOXEL_PROJ(V, rgbo)

; Convert from 24-bit to 8-bit image and display:
TV, COLOR_QUAN(C, 3, R, G, B)

; Load quantized color tables:
TVLCT, R, G, B
```

This example required approximately 27 seconds on a typical workstation to compute the view in a 640- by 512-pixel viewing window. Adding the keyword `STEP=[2, 2, 1]` in the call to `VOXEL_PROJ` decreased the computing time to about 8 seconds, at the expense of slightly poorer resolution.

When viewing a volume with only one constituent, the RGBO array should contain only an intensity/opacity value pair. To illustrate, if in the above example, only muscle was of interest we create the RGBO argument as follows:

```

; Create an empty 256 x 2 array:
rgbo = BYTARR(256,2)

; Intensity and opacity for muscle:
rgbo[50:70, *] = 20
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute and display the projected image:
TV, VOXEL_PROJ(V, rgbo)

; Create color table array for red:
C = (FINDGEN(256)/255.) # [255., 0., 0]

; Load colors:
TVLCT, C[*], C[*], C[*], C[*], 2]

```

### Example 3

This example demonstrates combining a volume with the contents of the Z-buffer:

```

; Set plotting to Z-buffer:
SET_PLOT, 'Z'

; Turn on Z buffering:
DEVICE, /Z_BUFFER

; Set scaling:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Draw a polygon at z equal to half the depth:
POLYFILL, [0, Vx-1, Vx-1, 0], [0, 0, Vy-1, Vy-1], Vz/2., /T3D

; Read pixel values from the Z-buffer:
zpix = TVRD()

; Read depth values from the Z-buffer:
zbuff = TVRD(/WORDS,/CHAN)

; Back to display window:
SET_PLOT, 'X'

; Compute the voxel projection and use the ZPIXELS and ZBUFFER
; keywords to combine the volume with the previously-read contents
; of the Z-buffer:
C = VOXEL_PROJ(V, rgbo, ZPIX=zpix, ZBUFF=zbuff)

```

```
; Convert from 24-bit to 8-bit image.  
IMAGE = COLOR_QUAN(C, 3, R, G, B)  
  
; Load the quantized color tables:  
TVLCT, R, G, B  
  
; Display  
TV, IMAGE
```

# WAIT

The WAIT procedure suspends execution of an IDL program for a specified period. Note that because of other activity on the system, the duration of program suspension may be longer than requested.

## Syntax

WAIT, *Seconds*

## Arguments

### Seconds

The duration of the wait, specified in seconds. This parameter can be a floating-point value to specify a fractional number of seconds.

## Keywords

None.

## Examples

To make an IDL program suspend execution for about five and one half seconds, use the command:

```
WAIT, 5.5
```

# WARP\_TRI

The WARP\_TRI function returns an image array with a specified geometric correction applied. Images are warped using control (tie) points such that locations  $(X_i, Y_i)$  are shifted to  $(X_o, Y_o)$ .

The irregular grid defined by  $(X_o, Y_o)$  is triangulated using TRIANGULATE. Then the surfaces defined by  $(X_o, Y_o, X_i)$  and  $(X_o, Y_o, Y_i)$  are interpolated using TRIGRID to get the locations in the input image of each pixel in the output image. Finally, INTERPOLATE is called to obtain the result. Linear interpolation is used by default. Smooth quintic interpolation is used if the QUINTIC keyword is set.

This routine is written in the IDL language. Its source code can be found in the file `warp_tri.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = WARP_TRI( Xo, Yo, Xi, Yi, Image [, OUTPUT_SIZE=vector] [, /QUINTIC]  
[, /EXTRAPOLATE] [, /TPS] )
```

## Return Value

Returns the warped image array.

## Arguments

### **Xo, Yo**

Vectors containing the locations of the control (tie) points in the output image.

### **Xi, Yi**

Vectors containing the location of the control (tie) points in the input image. *Xi* and *Yi* must be the same length as *Xo* and *Yo*.

### **Image**

The image to be warped. Can be any type of data.

## Keywords

### OUTPUT\_SIZE

Set this keyword equal to a 2-element vector containing the size of the output image. If omitted, the output image is the same size as *Image*.

### QUINTIC

Set this keyword to use smooth quintic interpolation. Quintic interpolation is slower, but the derivatives are continuous across triangles, giving a more pleasing result than the default linear interpolation.

### EXTRAPOLATE

Set this keyword to extrapolate outside the convex hull of the tie points. Setting this keyword implies the use of QUINTIC interpolation.

### TPS

Set this keyword to use Thin Plate Spline interpolation, which interpolates a set of irregularly sampled data value over a regular two dimensional grid. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

## Examples

This example produces a warped image of the world, where the irregular grid has been created using smooth quintic interpolation. The displayed image is in black and white.

```
filename = FILEPATH(SUBDIRECTORY=['examples','data'], $
    'worldelv.dat')
OPENR, lun, filename, /GET_LUN

# WATERSHED

The WATERSHED function applies the morphological watershed operator to a grayscale image. This operator segments images into watershed regions and their boundaries. Considering the gray scale image as a surface, each local minimum can be thought of as the point to which water falling on the surrounding region drains. The boundaries of the watersheds lie on the tops of the ridges. This operator labels each watershed region with a unique index, and sets the boundaries to zero.

Typically, morphological gradients, or images containing extracted edges are used for input to the watershed operator. Noise and small unimportant fluctuations in the original image can produce spurious minima in the gradients, which leads to oversegmentation. Smoothing, or manually marking the seed points are two approaches to overcoming this problem. For further reading, see Dougherty, “An Introduction to Morphological Image Processing”, SPIE Optical Engineering Press, 1992.

## Syntax

```
Result = WATERSHED ( Image [, CONNECTIVITY={4 | 8} ] [, /LONG]
  [, NREGIONS=variable] )
```

## Return Value

Returns an integer array of the same dimensions as the input image. An element of the *Result* array contains the integer identifier of the watershed region in which the corresponding pixel falls, or a zero if the corresponding pixel falls along the separation between regions.

### Note

---

If the LONG keyword is set, *Result* is an array of long integers; otherwise it is an array of short integers. If the LONG keyword is *not* set, *Result* will be clipped to a maximum of 65530 regions. (Regions above 32767 will have negative values; if you have more than 32767 regions you may want to convert your *Result* to unsigned integers using UINT). Use the NREGIONS keyword to determine the actual number of regions.

---

## Arguments

### Image

The two-dimensional image to be segmented. *Image* is converted to byte type if necessary.

## Keywords

### CONNECTIVITY

Set this keyword to either 4 (to select 4-neighbor connectivity) or 8 (to select 8-neighbor connectivity). Connectivity indicates which pixels in the neighborhood of a given pixel are sampled during the segmentation process. 4-neighbor connectivity samples only the pixels that are immediately adjacent horizontally and vertically. 8-neighbor connectivity samples the diagonally adjacent neighbors in addition to the immediate horizontal and vertical neighbors. The default is 4-neighbor connectivity.

### LONG

Set this keyword to return an array of long integers, instead of short integers. This keyword is useful if your image contains more than 32766 regions.

### NREGIONS

Set this keyword to a named variable that will contain the total number of regions within *Image*. In most cases, this will be equal to the maximum value of *Result*.

#### Tip

---

If the LONG keyword is *not* set, and NREGIONS is greater than 32766, then the *Result* overflowed the maximum. If this occurs, you may wish to re-run WATERSHED with the LONG keyword set.

---

## Examples

#### Note

---

Also see [“Creating Image Object Boundaries”](#) in Chapter 9 of the *Image Processing in IDL* manual.

---

The following code crudely segments the grains in the data file in the IDL Demo data directory containing a magnified image of grains of pollen. Note that the IDL Demos must be installed in order to read the image used in this example.

It inverts the image, because the watershed operator finds holes, brightening the grains of pollen. Next, the morphological closing operator is applied with a disc of radius 9, contained within a 19 by 19 kernel, to eliminate holes in the image smaller than the disc. The watershed operator is then applied to segment this image. The borders of the watershed images, which have pixel values of zero, are then merged with the original image and displayed as white.

```
;Radius of disc...
r = 9

;Create a disc of radius r
disc = SHIFT(DIST(2*r+1), r, r) LE r

;Read the image
READ_JPEG, FILEPATH('pollens.jpg', $
    SUBDIR=['examples', 'demo', 'demodata']), a

;Invert the image
b = MAX(a) - a

TVSCL, b, 0

;Remove holes of radii less than r
c = MORPH_CLOSE(b, disc, /GRAY)

TVSCL, c, 1

;Create watershed image
d = WATERSHED(c)

;Display it, showing the watershed regions
TVSCL, d, 2

;Merge original image with boundaries of watershed regions
e = a > (MAX(a) * (d EQ 0b))

TVSCL, e, 3
```

# Wavelet Toolkit

For information, see the [Chapter 1, “Introduction to the IDL Wavelet Toolkit”](#) in the *IDL Wavelet Toolkit* manual.

# WDELETE

The WDELETE procedure deletes IDL windows.

## Syntax

```
WDELETE [, Window_Index [, ...]]
```

## Arguments

### Window\_Index

A list of one or more window indices to delete. If this argument is not specified, the current window (as specified by the system variable !D.WINDOW) is deleted. If the window being deleted is not the active window, the value of !D.WINDOW remains unchanged. If the window being deleted is the active window, !D.WINDOW is set to the highest numbered window index or to -1 if no windows remain open.

If this window index is the widget ID of a draw widget, that widget is deleted.

## Keywords

None.

## Examples

Create IDL graphics window number 5 by entering:

```
WINDOW, 5
```

Delete window 5 by entering:

```
WDELETE, 5
```

# WF\_DRAW

The `WF_DRAW` procedure draws weather fronts of various types using parametric spline interpolation to smooth the lines. `WF_DRAW` uses the `POLYFILL` routine to make the annotations on the front lines.

This routine is written in the IDL language. Its source code can be found in the file `wf_draw.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WF_DRAW, X, Y [[, /COLD |, FRONT_TYPE=1] | [, /WARM |, FRONT_TYPE=2]
| [, /OCCLUDED |, FRONT_TYPE=3] | [, /STATIONARY |, FRONT_TYPE=4]
| [, /CONVERGENCE |, FRONT_TYPE=5]] [, COLOR=value] [, /DATA |,
/DEVICE |, /NORMAL] [, INTERVAL=value] [, PSYM=value]
[, SYM_HT=value] [, SYM_LEN=value] [, THICK=value]
```

## Arguments

### X, Y

Vectors of abscissae and ordinates defining the front to be drawn.

## Keywords

### COLD

Set this keyword to draw a cold front. The default is a plain line with no annotations. A cold front can also be specified by setting the keyword `FRONT_TYPE = 1`.

### COLOR

Use this keyword to specify the color to use. The default = `!P.COLOR`.

### CONVERGENCE

Set this keyword to draw a convergence line. A convergence line can also be specified by setting the keyword `FRONT_TYPE = 5`.

### DATA

Set this keyword if `X` and `Y` are specified in data coordinates.

## DEVICE

Set this keyword if X and Y are specified in device coordinates.

## FRONT\_TYPE

Set this keyword equal to the numeric index of type of front to draw. Front type indices are as follows: COLD=1, WARM=2, OCCLUDED=3, STATIONARY=4, CONVERGENCE = 5. Not required if plain line is desired or if an explicit front type keyword is specified.

## INTERVAL

Use this keyword to specify the spline interpolation interval, in normalized units. The default = 0.01. Larger values give coarser approximations to curves, smaller values make more interpolated points.

## NORMAL

Set this keyword if X and Y are specified in normalized coordinates. This is the default.

## OCCLUDED

Set this keyword to draw an occluded front. An occluded front can also be specified by setting the keyword FRONT\_TYPE = 3.

## PSYM

Set this keyword a standard PSYM value to draw a marker on each actual (X, Y) data point. See “PSYM” on page 4784 for a list of the symbol types.

## STATIONARY

Set this keyword to draw a stationary front. A stationary front can also be specified by setting the keyword FRONT\_TYPE = 4.

## SYM\_HT

Use this keyword to specify the height of front symbols, in normalized units. The default = 0.02.

## SYM\_LEN

Use this keyword to specify the length and spacing factor for front symbols, in normalized units. The default = 0.15.

## THICK

Use this keyword to specify the line thickness. The default = 1.0.

## WARM

Set this keyword to draw a warm front. A warm front can also be specified by setting the keyword `FRONT_TYPE = 2`.

## Examples

This example draws various fronts on a map of the United States.

Note that this example code is in `wf_draw.pro` in the `lib` subdirectory of the IDL installation directory, and can be run by entering `test_wf_draw` at the IDL command line.

```

PRO test_wf_draw

# WHERE

The WHERE function returns a vector that contains the one-dimensional subscripts of the nonzero elements of *Array\_Expression*. The length of the resulting vector is equal to the number of nonzero elements in *Array\_Expression*. Frequently the result of WHERE is used as a vector subscript to select elements of an array using given criteria.

## Note: When WHERE Returns -1

If all the elements of *Array\_Expression* are zero, WHERE returns a scalar integer with a value of -1. Attempting to use this result as an index into another array results in a “subscripts out of bounds” error. In situations where this is possible, code similar to the following can be used to avoid errors:

```
; Use Count to get the number of nonzero elements:
index = WHERE(array, count)

; Only subscript the array if it's safe:
IF count NE 0 THEN result = array[index]
```

## Syntax

*Result* = WHERE(*Array\_Expression* [, *Count*] [, COMPLEMENT=*variable*]  
[, /L64] [, NCOMPLEMENT=*variable*])

## Return Value

Returns a longword vector containing the subscripts of non-zero array elements matching the specified conditions.

## Arguments

### Array\_Expression

The array to be searched. Both the real and imaginary parts of a complex number must be zero for the number to be considered zero.

### Count

A named variable that will receive the number of nonzero elements found in *Array\_Expression*. This value is returned as a longword integer.

**Note**

---

The system variable !ERR is set to the number of nonzero elements. This effect is for compatibility with previous versions of IDL and should *not* be used in new code. Use the COUNT argument to return this value instead.

---

## Keywords

### COMPLEMENT

Set this keyword to a named variable that receives the subscripts of the zero elements of *Array\_Expression*. These are the subscripts that are not returned in *Result*. Together, *Result* and COMPLEMENT specify every subscript in *Array\_Expression*. If there are no zero elements in *Array\_Expression*, COMPLEMENT returns a scalar integer with the value -1.

### L64

By default, the result of WHERE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

**Note**

---

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY\_BITS to see if your IDL is 64-bit or not.

---

### NCOMPLEMENT

Set this keyword to a named variable that receives the number of zero elements found in *Array\_Expression*. This value is the number of subscripts that will be returned via the COMPLEMENT keyword if it is specified.

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL\_MAX\_ELTS, TPOOL\_MIN\_ELTS, and TPOOL\_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

## Examples

### Note

Also see “[Locating Pixel Values in an Image](#)” in Chapter 4 of the *Image Processing in IDL* manual.

### Example 1

```
; Create a 10-element integer array where each element is
; set to the value of its subscript:
array = INDGEN(10)
PRINT, 'array = ', array

; Find the subscripts of all the elements in the array that have
; a value greater than 5:
B = WHERE(array GT 5, count, COMPLEMENT=B_C, NCOMPLEMENT=count_c)

; Print how many and which elements met the search criteria:
PRINT, 'Number of elements > 5: ', count
PRINT, 'Subscripts of elements > 5: ', B
PRINT, 'Number of elements <= 5: ', count_c
PRINT, 'Subscripts of elements <= 5: ', B_C
```

### IDL prints:

```
array = 0 1 2 3 4 5 6 7 8 9
Number of elements > 5: 4
Subscripts of elements > 5: 6 7 8 9
Number of elements <= 5: 6
Subscripts of elements <= 5: 0 1 2 3 4 5
```

### Example 2

The WHERE function behaves differently with different kinds of array expressions. For instance, if a relational operator is used to compare an array, A, with a scalar, B, then every element of A is searched for B. However, if a relational operator is used to compare two arrays, C and D, then a comparison is made between each corresponding element (i.e.  $C_i$  &  $D_i$ ,  $C_{i+1}$  &  $D_{i+1}$ , etc) of the two arrays. If the two arrays have different lengths then a comparison is only made up to the number of elements for the shorter array. The following example illustrates this behavior:

```
; Compare array, a, and scalar, b:
a = [1,2,3,4,5,5,4,3,2,1]
b = 5
PRINT, 'a = ', a
PRINT, 'b = ', b
```

```

result=WHERE(a EQ b)
PRINT, 'Subscripts of a that equal b: ', result

; Now compare two arrays of different lengths:
c = [1,2,3,4,5,5,4,3,2,1]
d = [0,2,4]
PRINT, 'c = ', c
PRINT, 'd = ', d

result=WHERE(c EQ d)
PRINT, 'Subscripts of c that equal d: ', result

```

IDL prints:

```

a = 1 2 3 4 5 5 4 3 2 1
b = 5
Subscripts of a that equal b: 4 5

c = 1 2 3 4 5 5 4 3 2 1
d = 0 2 4
Subscripts of c that equal d: 1

```

Note that `WHERE` found only one element in the array `d` that equals an element in array `c`. This is because only the first three elements of `c` were searched, since `d` has only three elements.

[ARRAY\\_INDICES](#), [UNIQ](#), “[Conditionally Altering Array Elements](#)” in Chapter 15 of the *Building IDL Applications* manual

# WHILE...DO

The WHILE...DO statement performs its subject statement(s) as long as the expression evaluates to true. The subject is never executed if the condition is initially false.

**Note**

---

For information on using WHILE...DO and other IDL program control statements, see [Chapter 7, “Program Control”](#) in the *Building IDL Applications* manual.

---

## Syntax

WHILE *expression* DO *statement*

or

WHILE *expression* DO BEGIN

*statements*

ENDWHILE

## Examples

```
i = 0
WHILE (i EQ 1) DO PRINT, i
```

Because the expression (which is false in this case) is evaluated before the subject statement is executed, this code yields no output.

# WIDGET\_ACTIVEX

The WIDGET\_ACTIVEX function is used to incorporate an ActiveX control into an IDL widget hierarchy. It is available on Microsoft Windows installations of IDL. An ActiveX widget instantiates an ActiveX control within an IDL widget hierarchy.

IDL provides the same object method and property manipulation facilities for ActiveX controls as it does for COM objects incorporated using the IDLcomIDispatch object interface, but adds the ability to process events generated by the ActiveX control using IDL's widget event handling mechanisms.

---

## Note

IDL can only incorporate ActiveX controls on Windows 2000/XP (and later) platforms.

---

When you use the WIDGET\_ACTIVEX routine, IDL automatically creates an IDLcomActiveX object that encapsulates the ActiveX control. You can then call the ActiveX control's methods using IDL object syntax, as discussed in [Chapter 5, "Using ActiveX Controls in IDL"](#) in the *External Development Guide* manual. You should be familiar with the material in that chapter before attempting to incorporate ActiveX controls in your IDL programs.

---

## Note

If the COM object you want to use in your IDL application is *not* an ActiveX control, use the [IDLcomIDispatch](#) object class.

---

---

## Warning

When displaying an ActiveX form or dialog box, it is the responsibility of the COM object to pump messages. Modal dialogs pump messages themselves, but modeless dialogs do not. IDL's COM subsystem does not provide the ability to pump messages explicitly, giving IDL no way to pump messages while a modeless dialog is displayed. As a result, calling a modeless dialog from IDL will result in an error.

---

## Syntax

```
Result = WIDGET_ACTIVEX( Parent, COM_ID, [, /ALIGN_BOTTOM | ,
  /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP ]
  [, EVENT_FUNC=string] [, EVENT_PRO=string]
  [, FUNC_GET_VALUE=string] [ID_TYPE=value] [, KILL_NOTIFY=string]
  [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
```

```
[, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value]  
[, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value is the widget ID of the ActiveX widget. Note that the *widget value* of the ActiveX widget is an object reference to the IDLcomActiveX object that encapsulates the specified ActiveX control. The value cannot be set, and cannot be retrieved before the widget is realized.

## Arguments

### Parent

The widget ID of the parent widget of the new ActiveX control.

### COM\_ID

A string value specifying the class or program ID of the COM object to create. Note that if you specify a COM program ID via this argument, you must also set the ID\_TYPE keyword.

### Note

---

The class or program ID must follow the standard Microsoft naming convention. See [Chapter 5, “Using ActiveX Controls in IDL”](#) in the *External Development Guide* manual for more on class and program IDs, and their use with WIDGET\_ACTIVEX.

---

## Keywords

### ALIGN\_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

### ALIGN\_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## **ALIGN\_LEFT**

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## **ALIGN\_RIGHT**

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## **ALIGN\_TOP**

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## **EVENT\_FUNC**

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## **EVENT\_PRO**

A string containing the name of a procedure to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## **FUNC\_GET\_VALUE**

A string containing the name of a function to be called when the GET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## **ID\_TYPE**

The type of COM object ID specified by the *COM\_ID* parameter (class or program). If set to 0 (zero), the value is a class ID (the default). If set to 1 (one), the value is a program ID.

## **KILL\_NOTIFY**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## **NO\_COPY**

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_BASE` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## **NOTIFY\_REALIZE**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## **PRO\_SET\_VALUE**

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the `PRO_SET_VALUE` keyword to `WIDGET_CONTROL` for information on using this keyword.

## **SCR\_XSIZE**

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the FIND\_BY\_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND\_BY\_UNAME keyword returns the ID of the widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by [WIDGET\\_INFO](#).

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET\_UVALUE and SET\_UVALUE keywords to the WIDGET\_CONTROL procedure.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## Keywords to WIDGET\_CONTROL

ActiveX widgets are controlled using the object methods of the underlying ActiveX control rather than via the WIDGET\_CONTROL and WIDGET\_INFO routines. The [GET\\_VALUE](#) keyword to the [WIDGET\\_CONTROL](#) procedure is used to retrieve an object reference to the IDLcomActiveX object that underlies the ActiveX widget. The object reference returned in this manner can be used to call the ActiveX control's native methods.

## ActiveX Widget Events

ActiveX widgets return a basic widget event structure augmented by fields that are specific to the ActiveX control. See [“ActiveX Widget Events”](#) in Chapter 5 of the *External Development Guide* manual for details.

## Examples

For examples using WIDGET\_ACTIVEX, see [Chapter 5, “Using ActiveX Controls in IDL”](#) in the *External Development Guide* manual.

## Version History

5.5	Introduced
-----	------------

# WIDGET\_BASE

The WIDGET\_BASE function is used to create base widgets. Base widgets serve as containers for other widgets, including other base widgets. Base widgets can optionally contain scroll bars that allow the base to be larger than the space on the screen. In this case, only part of the base is visible at any given time, and the scroll bars are used to control which part is visible.

---

**Note**

In most cases, you will want let IDL determine the placement of widgets within the base widget. Do this by specifying either the COLUMN keyword or the ROW keyword. See [“Positioning Child Widgets Within a Base”](#) in the following section for details.

---

## Exclusive And Non-Exclusive Bases

If the EXCLUSIVE or NONEXCLUSIVE keywords are specified, the base only allows button widget children.

## Positioning Child Widgets Within a Base

The standard base widget does not impose any placement constraints on its child widgets. Children of a “bulletin board” base (a base that was created without setting the COLUMN or ROW keywords) have an offset of (0,0) unless an offset is explicitly specified via the XOFFSET or YOFFSET keywords. This means that if you do not specify any of COLUMN, ROW, XOFFSET, or YOFFSET keywords, child widgets will be placed one on top of the other in the upper left corner of the base.

However, laying out widgets using the XSIZE, YSIZE, XOFFSET, and YOFFSET keywords can be both tedious and error-prone. Also, if you want your widget application to display properly on different platforms, you should use the COLUMN and ROW keywords to influence child widget layouts instead of explicitly formatting your interfaces.

When the ROW or COLUMN keywords are specified, the base decides how to lay out its children, and any XOFFSET and YOFFSET keywords specified for such children are ignored.

## Positioning Top-Level Bases

*Top-level bases* are a special class of base widget created without a parent widget ID. Every widget hierarchy has exactly one top-level base. (Multiple widget hierarchies, represented by their top-level bases, can be organized into an application hierarchy by

specifying the `GROUP_LEADER` keyword. (See “Using Multiple Widget Hierarchies” in Chapter 30 of the *Building IDL Applications* manual for additional discussion of widget applications with multiple widget hierarchies.)

When locating a new top level window, some window managers ignore the program’s positioning requests and either choose a position or allow the user to choose. In such cases, the `XOFFSET` and `YOFFSET` keywords to `WIDGET_BASE` will not have an effect. The window manager may provide a way to disable this positioning style. The Motif window manager (`mwm`) can be told to honor positioning requests by placing the following lines in your `.Xdefaults` file:

```
Mwm*clientAutoPlace: False
Mwm*interactivePlacement: False
```

## Iconizing, Layering, and Destroying Groups of Top-Level Bases

Group membership (defined via the `GROUP_LEADER` keyword) controls the way top-level base widgets are iconized, layered, and destroyed.

### Note

A group can contain sub-groups. Group behavior affects all members of a group and its sub-groups. For example, suppose we create three top-level base widgets with the following group hierarchy:

```
base1 = WIDGET_BASE()
base2 = WIDGET_BASE(GROUP_LEADER=base1)
base3 = WIDGET_BASE(GROUP_LEADER=base2)
```

Effectively, two groups are created. One group has `base2` as its leader and `base3` as its member. The other group has `base1` as its leader and both `base2` and `base3` as members. If `base1` is iconized, both `base2` and `base3` are iconized as well. If `base2` is iconized, `base3` is iconized but `base1` is not.

Widgets behave slightly differently when displayed on different platforms, and depending on whether they are floating or modal bases. The following rules apply to groups of widgets within a group leader/member hierarchy. Widgets that do not belong to the same group hierarchy cannot influence each other.

### Iconization and Mapping

Bases and groups of bases can be *iconized* (or *minimized*) by clicking the system minimize control. Bases and groups of bases can also be *mapped* (made visible) and *unmapped* (made invisible).

Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

## Layering

*Layering* is the process by which groups of widgets seem to share the same plane on the display screen. Within a layer on the screen, widgets have a *Z-order*, or front-to-back order, that defines which widgets appear to be on top of other widgets.

**Motif** — All elements on the screen—widgets, the IDLDE, other Motif applications—share a single layer and have an arbitrary Z-order. There is no special layering of IDL widgets.

**Windows** — All non-floating and non-modal widgets within a group hierarchy share the same layer—that is, when one group member has the input focus, all members of the group hierarchy are displayed in a layer that appears in front of all other groups or applications. Within the layer, the widgets can have an arbitrary Z-order.

Widgets that are floating or modal always float above their group leaders.

## Destruction

When a group leader widget is destroyed, either programmatically or by clicking on the system “close” button, all members of the group and all sub-groups are destroyed as well.

If a modal base is on the display, it must be dismissed before any widget can be destroyed.

## Syntax

```
Result = WIDGET_BASE( [Parent] [, /ALIGN_BOTTOM | , /ALIGN_CENTER | ,
    /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP]
    [, /BASE_ALIGN_BOTTOM | , /BASE_ALIGN_CENTER | ,
    /BASE_ALIGN_LEFT | , /BASE_ALIGN_RIGHT | , /BASE_ALIGN_TOP]
    [, COLUMN=ncols | , ROW=nrows] [, /CONTEXT_EVENTS]
    [, /CONTEXT_MENU] [, EVENT_FUNC=string] [, EVENT_PRO=string]
    [, /EXCLUSIVE | , /NONEXCLUSIVE] [, /FLOATING] [, FRAME=width]
    [, FUNC_GET_VALUE=string] [, /GRID_LAYOUT]
    [, GROUP_LEADER=widget_id{must specify for modal dialogs}]
    [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=string]
    [, /MAP{not for modal bases}] [, MBAR=variable | , /MODAL] [, /NO_COPY]
    [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
```

[, `SCR_XSIZE=width`] [, `SCR_YSIZE=height`] [, `/SCROLL`{not for modal bases}] [, `/SENSITIVE`] [, `SPACE=value`{ignored if exclusive or nonexclusive}] [, `TAB_MODE=value`] [, `TITLE=string`] [, `TLB_FRAME_ATTR=value`{top-level bases only}] [, `/TLB_ICONIFY_EVENTS`{top-level bases only}] [, `/TLB_KILL_REQUEST_EVENTS`{top-level bases only}] [, `/TLB_MOVE_EVENTS`{top-level bases only}] [, `/TLB_SIZE_EVENTS`{top-level bases only}] [, `/TOOLBAR`] [, `/TRACKING_EVENTS`] [, `UNAME=string`] [, `UNITS={0 | 1 | 2}`] [, `UVALUE=value`] [, `XOFFSET=value`] [, `XPAD=value`{ignored if exclusive or nonexclusive}] [, `XSIZE=value`] [, `X_SCROLL_SIZE=value`] [, `YOFFSET=value`] [, `YPAD=value`{ignored if exclusive or nonexclusive}] [, `YSIZE=value`] [, `Y_SCROLL_SIZE=value`] )

**X Windows Keywords:** [, `DISPLAY_NAME=string`] [, `RESOURCE_NAME=string`] [, `RNAME_MBAR=string`]

## Return Value

The returned value of this function is the widget ID of the newly-created base.

## Arguments

### Parent

The widget ID of the parent widget. To create a *top-level* base, omit the *Parent* argument.

## Keywords

### ALIGN\_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

### ALIGN\_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## **ALIGN\_LEFT**

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## **ALIGN\_RIGHT**

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## **ALIGN\_TOP**

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the [KBRD\\_FOCUS\\_EVENTS](#) keyword to keep track of which widget has (or last had) the keyboard focus.

## **BASE\_ALIGN\_BOTTOM**

Set this keyword to make all children of the new base align themselves with the bottom of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN\_XXX keyword when the child widget is created.

## **BASE\_ALIGN\_CENTER**

Set this keyword to make all children of the new base align themselves with the center of the base by default. To take effect, you must also set the COLUMN or ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN\_XXX keyword when the child widget is created. In ROW bases, child widgets will be vertically centered. In COLUMN bases, child widgets will be horizontally centered.

## **BASE\_ALIGN\_LEFT**

Set this keyword to make all children of the new base align themselves with the left side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN\_XXX keyword when the child widget is created.

## **BASE\_ALIGN\_RIGHT**

Set this keyword to make all children of the new base align themselves with the right side of the base by default. To take effect, you must also set the `COLUMN` keyword for the new base. The default can be overridden for individual child widgets by setting a different `ALIGN_XXX` keyword when the child widget is created.

## **BASE\_ALIGN\_TOP**

Set this keyword to make all children of the new base align themselves with the top of the base by default. To take effect, you must also set the `ROW` keyword for the new base. The default can be overridden for individual child widgets by setting a different `ALIGN_XXX` keyword when the child widget is created.

## **COLUMN**

If this keyword is included, the base lays out its children in columns. The value of this keyword specifies the number of columns to be used. The number of child widgets in each column is determined by distributing the children as evenly as possible across the columns.

Specifying both the `COLUMN` and `ROW` keywords causes an error.

### **Column Width**

The width of each column is determined by the width of the widest widget in that column. If the `GRID_LAYOUT` keyword is set, all columns are as wide as the widest widget in the base.

### **Horizontal Size of Widgets**

If any of the `BASE_ALIGN_*` keywords to `WIDGET_BASE` is set, each widget has its “natural” width, determined either by the value of the widget or by the `XSIZE` keyword. Similarly, if any of the child widgets specifies one of the `ALIGN_*` keywords, that widget will have its “natural” width. If none of the `BASE_ALIGN_*` or (`ALIGN_*`) keywords are set, all widgets in the base are as wide as their column.

### **Vertical Placement**

Child widgets are placed vertically one below the other, with no extra space. If the `GRID_LAYOUT` keyword is set, each row is as high as its tallest member.

## **CONTEXT\_EVENTS**

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0

(zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET\\_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

## CONTEXT\_MENU

Set this keyword to create a base widget that can be used as the base for a context-sensitive menu (also known as a pop-up or shortcut menu). A context menu base must have as its parent one of the following types of widgets: `WIDGET_BASE`, `WIDGET_DRAW`, `WIDGET_TEXT`, `WIDGET_LIST`, `WIDGET_PROPERTY SHEET`, `WIDGET_TABLE`, `WIDGET_TEXT` or `WIDGET_TREE`.

For more on creating context menus, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

## DISPLAY\_NAME

Set this keyword equal to a string that specifies the name of the X Windows display on which the base should be displayed. This keyword has no effect on Microsoft Windows platforms.

## EVENT\_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

---

### Note

If you are using `XMANAGER` to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the [EVENT\\_HANDLER](#) keyword to `XMANAGER`.

---

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

**Note**

---

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the [EVENT\\_HANDLER](#) keyword to XMANAGER.

---

**EXCLUSIVE**

Set this keyword to specify that the base can have only button-widget children and that only one button can be set at a time. These buttons, unlike normal button widgets, have two states—set and unset.

When one exclusive button is pressed, any other exclusive buttons (in the same base) that are currently set are automatically released. Hence, only one button can ever be set at one time.

This keyword can be used to create exclusive button menus. See the [CW\\_BGROUP](#) and [CW\\_PDMENU](#) functions for high-level menu-creation utilities.

**Note**

---

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for an exclusive base, the base defaults to COLUMN layout.

---

**FLOATING**

Set this keyword—along with the GROUP\_LEADER keyword—to create a “floating” top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

The iconizing, layering, and destruction behavior of floating bases and their group leaders is discussed in “[Iconizing, Layering, and Destroying Groups of Top-Level Bases](#)” on page 2488.

**FRAME**

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the GET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GRID\_LAYOUT

Set this keyword to force the base to have a grid layout, in which all rows have the same height, and all columns have the same width. The row heights and column widths are taken from the largest child widget.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. Widget application hierarchies are defined by group membership relationships between top-level widget bases. When a group leader is killed, for any reason, all widgets in the group are also destroyed. Iconizing and layering behavior is discussed in “[Iconizing, Layering, and Destroying Groups of Top-Level Bases](#)” on page 2488.

---

### Note

If you specify a floating base (created with the [FLOATING](#) keyword) as a group leader, all member bases must also have either the [FLOATING](#) or [MODAL](#) keywords set. If you specify a modal base (created with the [MODAL](#) keyword) as a group leader, all member bases must have the [MODAL](#) keyword set as well.

---

A given widget can be in more than one group. The WIDGET\_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KBRD\_FOCUS\_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See the “[Events Returned by Base Widgets](#)” section below for more information.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

---

**Note**

A procedure specified via the `CLEANUP` keyword to `XMANAGER` will override a procedure specified for your application's top-level base with `WIDGET_BASE`, `KILL_NOTIFY`.

---

## MAP

Once a widget hierarchy has been realized, it can be mapped (visible) or unmapped (invisible). This keyword specifies the initial map state for the given base and its descendants. Specifying a non-zero value indicates that the base should be mapped when realized (the default). A zero value indicates that the base should be unmapped initially.

After the base is realized, its map state can be altered using the `MAP` keyword to the `WIDGET_CONTROL` procedure.

---

**Note**

Modal bases cannot be mapped and unmapped.

---

---

**Warning**

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This "extra" resize event is generated before any manipulation of the base widget by the user.

---

## MBAR

Set this keyword to a named variable to cause a menubar to be placed at the top of the base (the base must be a top-level base). The menubar is itself a special kind of base widget that can only have buttons as children. Upon return, the named variable contains the widget ID of the new menubar base. This widget ID can then be used to fill the menubar with pulldown menus. For example, the following widget creation commands first create a base with a menubar, then populate the menubar with a simple pulldown menu (`CW_PDMENU` could also have been used to construct the pulldown menu):

```
base = WIDGET_BASE(TITLE = 'Example', MBAR=bar)
file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
```

```
file_btn1=WIDGET_BUTTON(file_menu, VALUE='Item 1', $
    UVALUE='FILE1')
file_btn2=WIDGET_BUTTON(file_menu, VALUE='Item 2', $
    UVALUE='FILE2')
```

Note that to set X Window System resources for menubars created with this keyword, you must use the `RNAME_MBAR` keyword rather than the `RESOURCE_NAME` keyword.

If you use `CW_PDMENU` to create a menu for the menubar, be sure to set the `MBAR` keyword to that function as well.

Note also that the size returned by the `GEOMETRY` keyword to `WIDGET_INFO` does not include the size of the menubar.

---

**Warning**

You cannot specify both the `MBAR` and `MODAL` keywords for the same widget. Doing so will cause an error.

---

---

**Warning**

You cannot specify both an `APP_MBAR` and an `MBAR` for the same top-level base widget. Doing so will cause an error.

---

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the `KBRD_FOCUS_EVENTS` keyword to keep track of which widget has (or last had) the keyboard focus.

## MODAL

Set this keyword to create a modal dialog. While a modal dialog is displayed, IDL blocks event processing.

---

**Note**

Modal dialogs must have a group leader. Specify the group leader for a modal top-level base via the `GROUP_LEADER` keyword.

---

Modal dialogs cannot be scrollable, nor can they support menubars. Setting the `SCROLL`, `MBAR`, or `APP_MBAR` keywords in conjunction with the `MODAL` keyword will cause an error. Modal dialogs cannot be mapped or unmapped. Setting the `MAP` keyword on a modal base will cause an error. Modal dialogs cannot be resized, regardless of the setting of the `TLB_SIZE_EVENTS` keyword.

**Note**

---

On Windows platforms, the group leader of a modal base must be realized before the modal base itself can be realized. If the group leader has not been realized, it will be realized automatically.

---

The iconizing, layering, and destruction behavior of modal bases and their group leaders is discussed in “[Iconizing, Layering, and Destroying Groups of Top-Level Bases](#)” on page 2488.

**NO\_COPY**

Usually, when setting or getting widget user values, either at widget creation or using the SET\_UVALUE and GET\_UVALUE keywords to WIDGET\_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO\_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET\_BASE or the SET\_UVALUE keyword to WIDGET\_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET\_UVALUE keyword to WIDGET\_CONTROL), the user value of the widget in question becomes undefined.

**NONEXCLUSIVE**

Set this keyword to specify that the base can only have button widget children. These buttons, unlike normal button widgets, have two states—set and unset. Non-exclusive bases allow any number of the toggle buttons to be set at one time.

**Note**

---

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Non-exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for a non-exclusive base, the base defaults to COLUMN layout.

---

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the SET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. Once defined, this name can be used in the user’s .Xdefaults file to customize widget resources not directly supported via the IDL widget routines. This keyword is accepted by all widget creation routines. This keyword only works with the “X” device and is ignored on Microsoft Windows platforms.

RESOURCE\_NAME allows unrestricted access to the underlying Motif widgets within the following limitations:

- Users must have the appropriate resources defined in their .Xdefaults or application default resource file, or IDL will not see the definitions and they will not take effect.
- Motif resources are documented in the *OSF/Motif Programmer’s Reference Manual*. To use them with RESOURCE\_NAME, the IDL programmer must determine the type of widget being used by IDL, and then look up the resources that apply to them. Hence, RESOURCE\_NAME requires some programmer-level familiarity with Motif.
- Only resources that are not set within IDL can be modified using this mechanism. Although it is not an error to set resources also set by IDL, the IDL settings will silently override user settings. RSI does not document the resources used by IDL since the actual resources used may differ from release to release as the IDL widgets evolve. Therefore, you should set only those resources that are obviously not being set by IDL. Among the resources that are not being set by IDL are those that control colors, menu mnemonics, and accelerator keys.

## Example

The sample code below produces a pulldown menu named “Menu” with 2 entries named “Item 1” and “Item 2”.

Using the RESOURCE\_NAME keyword in conjunction with X resource definitions, we can alter “Item 1” in several ways not possible through the standard IDL widgets interface. We’ll give Item 1 a red background color. We’ll also assign “I” as the keyboard mnemonic. Note that Motif automatically underlines the “I” in the title to indicate this. We’ll also select Meta-F4 as the keyboard accelerator for selecting “Item 1”. If Meta-F4 is pressed while the pointer is anywhere over this application, the effect will be as if the menu was pulled down and “Item 1” was selected with the mouse.

```

; Simple event handler:
PRO test_event, ev
    HELP, /STRUCTURE, ev
END

; Simple widget creation routine:
PRO test

    ; The base gets the resource name "test":
    a = WIDGET_BASE(RESOURCE_NAME = 'test')
    b = WIDGET_BUTTON(a, VALUE='Menu', /MENU)

    ; Assign the Item 1 button the resource name "item1":
    c = WIDGET_BUTTON(b, VALUE='Item 1', $
        RESOURCE_NAME='item1')
    c = WIDGET_BUTTON(b, VALUE='Item 2')
    WIDGET_CONTROL, /REALIZE, a
    XMANAGER, 'test', a
END

```

Note that we gave the overall application the resource name “test”, and the “Item 1” button the resource name “item1”. Now we can use these names in the following .Xdefaults file entries:

```

Idl*test*item1*mnemonic: I
Idl*test*item1*accelerator: Meta<Key>F4
Idl*test*item1*acceleratorText: Meta-F4
Idl*test*item1*background: red

```

## Note on Specifying Color Resources

If you wish to specify unique colors for your widgets, it is generally a good idea to use a color name (“red” or “lightblue”, for example) rather than specifying an exact color match with a color string (such as “#b1b122222020”). If IDL is not able to

allocate an exact color, the entire operation may fail. Specifying a named color implies “closest color match,” an operation that rarely fails.

If you need an exact color match and IDL fails to allocate the color, try modifying the `Idl.colors` resource in the `$IDL_DIR/resource/X11/lib/app-defaults/Idl` file.

## **RNAME\_MBAR**

A string containing an X Window System resource name to be applied to the menubar created by the MBAR keyword. This keyword is identical to the RESOURCE\_NAME keyword except that the resource it specifies applies only to the menubar.

## **ROW**

If this keyword is included, the base lays out its children in rows. The value of this keyword specifies the number of rows to be used. The number of child widgets in each row is determined by distributing the children as evenly as possible across the rows.

Specifying both the COLUMN and ROW keywords causes an error.

### **Row Height**

The height of each row is determined by the height of the tallest widget in that row. If the GRID\_LAYOUT keyword is set, all rows are as tall as the tallest widget in the base.

### **Vertical Size of Widgets**

If any of the BASE\_ALIGN\_\* keywords to WIDGET\_BASE is set, each widget has its “natural” height, determined either by the value of the widget or by the YSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN\_\* keywords, that widget will have its “natural” height. If none of the BASE\_ALIGN\_\* or (ALIGN\_\*) keywords are set, all widgets in the base are as tall as their row.

### **Horizontal Placement**

Child widgets are placed horizontally one next to the other, with no extra space. If the GRID\_LAYOUT keyword is set, each column is as wide as its widest member.

## **SCR\_XSIZE**

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. You must also set [X\\_SCROLL\\_SIZE](#) and [Y\\_SCROLL\\_SIZE](#) to set the viewport size.

---

### Note

Under UNIX, base widgets with scroll bars do not automatically size themselves to fit their contents. Use the [XSIZE](#) and [YSIZE](#) keywords to explicitly specify the size of the base widget.

---

---

### Warning

You cannot specify both the SCROLL and MODAL keywords for the same widget. Doing so will cause an error.

---

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

---

### Warning

Under Microsoft Windows, a top-level base that is insensitive does not allow the user to control the window using the system close or minimize/maximize buttons.

---

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## SPACE

The space, in units specified by the UNITS keyword (pixels are the default), between children of a row or column major base. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET\\_CONTROL](#) procedure’s TAB\_MODE keyword, or query a widget’s support for tabbing using the [WIDGET\\_INFO](#) procedure’s TAB\_MODE keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TITLE

A string containing the title to be used for the widget. Base widgets use the title only if they are top-level widgets or if they are children of a tab widget. For top-level base widgets, the title appears in the “window dressing” at the top of the base widget; the appearance is platform-specific. For base widgets that have a tab widget as their parent widget, the title is used as the text of the tab.

Note that if the widget base is not wide enough to contain the specified title, the title may appear truncated. If you must be able to see the full title, you have several alternatives:

- Rearrange the widgets in the base so that the base becomes naturally wide enough. This is the best solution.
- Don’t worry about this issue. If the user needs to see the entire label, they can resize the window using the mouse.
- Create the base without using the COLUMN or ROW keywords. Instead, use the XSIZE keyword to explicitly set a usable width. This is an undesirable solution that can lead to strange-looking widget layouts.

For bases that are children of tab widgets, the title may be truncated depending on the width of the largest base that is a child of the tab widget. See the description of the MULTILINE keyword to [WIDGET\\_TAB](#) for additional details.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## TLB\_FRAME\_ATTR

Set this keyword to one of the values shown in the table below to suppress certain aspects of a top-level base’s window frame. This keyword applies only to top-level bases. The settings are merely hints to the window system and may be ignored by some window managers. Valid settings are:

1	Base cannot be resized, minimized, or maximized.
---	--

2	Suppress display of system menu.
4	Suppress title bar.
8	Base cannot be closed.
16	Base cannot be moved.

This keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make a base that has no title bar (value 4) and cannot be moved (value 16), set the `TLB_FRAME_ATTR` keyword to 20 (that is, 4+16).

## TLB\_ICONIFY\_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is iconified or restored by the user. See the “[Events Returned by Base Widgets](#)” section below for more information.

## TLB\_KILL\_REQUEST\_EVENTS

Set this keyword, usable only with top-level bases, to send the top-level base a `WIDGET_KILL_REQUEST` event if a user tries to destroy the widget using the window manager (by default, widgets are simply destroyed). See the “[Events Returned by Base Widgets](#)” section below for more information.

Use this keyword to perform complex actions before allowing a widget application to exit. Note that widgets that have this keyword set are responsible for killing themselves after receiving a `WIDGET_KILL_REQUEST` event—they cannot be destroyed using the usual window system controls.

Use a call to `TAG_NAMES` with the `STRUCTURE_NAME` keyword set to differentiate a `WIDGET_KILL_REQUEST` event from other types of widget events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
    'WIDGET_KILL_REQUEST' THEN ...
```

## TLB\_MOVE\_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is moved on the screen by the user. See the “[Events Returned by Base Widgets](#)” section below for more information.

## TLB\_SIZE\_EVENTS

Set this keyword, when creating a top-level base, to make that base return an event when the base is resized by the user. See the “[Events Returned by Base Widgets](#)” section below for more information.

## TOOLBAR

Set this keyword to indicate that the base is used to hold bitmap buttons that make up a toolbar.

---

### Note

Setting this keyword does not cause any changes in behavior; its only affect is to slightly alter the appearance of the bitmap buttons on the base for cosmetic reasons.

---

---

### Note

On Motif platforms, if bitmap buttons are on a toolbar base that is also `EXCLUSIVE` or `NONEXCLUSIVE`, they will not have a separate “toggle” indicator, they will be grouped closely together, and will have a two-pixel shadow border.

---

---

### Note

This keyword has no effect on Windows platforms.

---

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer *enters* or *leaves* the region covered by that widget. Widget tracking events are returned as structures with the following definition:

```
{ WIDGET_TRACKING, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID, TOP, and HANDLER are the standard fields found in every widget event. ENTER is 1 if the tracking event is an entry event, and 0 if it is an exit event.

See “[Tracking Events](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget’s initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the `GET_UVALUE` and `SET_UVALUE` keywords to the `WIDGET_CONTROL` procedure.

## XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XPAD

The horizontal space, in units specified by the `UNITS` keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of `XPAD` is platform dependent. This keyword is ignored if either the `EXCLUSIVE` or `NONEXCLUSIVE` keyword is present.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

## X\_SCROLL\_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X\_SCROLL\_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget. X\_SCROLL\_SIZE must be less than XSIZE for scrollbars to appear.

Use of the X\_SCROLL\_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X\_SCROLL\_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y\_SCROLL\_SIZE when specifying X\_SCROLL\_SIZE.

### Note

---

X\_SCROLL\_SIZE and Y\_SCROLL\_SIZE are ignored if you specify the screen size using the SCR\_XSIZE and SCR\_YSIZE keywords to the widget creation routine.

---

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YPAD

The vertical space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of YPAD is platform-dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

## Y\_SCROLL\_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y\_SCROLL\_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget. Y\_SCROLL\_SIZE must be less than YSIZE for scrollbars to appear.

Use of the Y\_SCROLL\_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y\_SCROLL\_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X\_SCROLL\_SIZE when specifying Y\_SCROLL\_SIZE.

### Note

---

X\_SCROLL\_SIZE and Y\_SCROLL\_SIZE are ignored if you specify the screen size using the SCR\_XSIZE and SCR\_YSIZE keywords to the widget creation routine.

---

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of base widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [CONTEXT\\_EVENTS](#), [KBRD\\_FOCUS\\_EVENTS](#), [TLB\\_ICONIFY\\_EVENTS](#), [TLB\\_MOVE\\_EVENTS](#), [TLB\\_SIZE\\_EVENTS](#).

## Keywords to WIDGET\_INFO

A number of keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to base widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [CONTEXT\\_EVENTS](#), [KBRD\\_FOCUS\\_EVENTS](#), [MODAL](#), [STRING\\_SIZE](#), [TLB\\_ICONIFY\\_EVENTS](#), [TLB\\_KILL\\_REQUEST\\_EVENTS](#), [TLB\\_MOVE\\_EVENTS](#), [TLB\\_SIZE\\_EVENTS](#).

## Events Returned by Base Widgets

Base widgets do not generate any events by default. They can be configured to generate events when the base widget receives the keyboard focus or the user clicks the right-hand mouse button. In addition, top-level bases can be configured to generate events when the base is resized, moved, iconified, or killed.

### Resize Events

Top-level widget bases return the following event structure only when they are resized by the user and the base was created with the `TLB_SIZE_EVENTS` keyword set:

```
{ WIDGET_BASE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The X and Y fields return the new width of the base, not including any frame provided by the window manager.

### Move Events

Top-level widget bases return the following event structure when the base is moved and the base was created with the `TLB_MOVE_EVENTS` keyword set:

```
{ WIDGET_TLB_MOVE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. X and Y are the new location of the top left corner of the base.

---

#### Note

On Windows, move events are generated while dragging. On UNIX, move events are generated only on the mouse-up.

---

---

#### Note

If both `TLB_SIZE_EVENTS` and `TLB_MOVE_EVENTS` are enabled, a user resize operation that causes the top left corner of the base to move will generate both a move event and a resize event.

---

## Iconify Events

Top-level widget bases return the following event structure when the base is iconified or restored and the base was created with the [TLB\\_ICONIFY\\_EVENTS](#) keyword set:

```
{ WIDGET_TLB_ICONIFY, ID:0L, TOP:0L, HANDLER:0L, ICONIFIED:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. ICONIFIED is 1 (one) if the user iconified the base and 0 (zero) if the user restored the base.

## Keyboard Focus Events

Widget bases return the following event structure when the keyboard focus changes and the base was created with the [KBRD\\_FOCUS\\_EVENTS](#) keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the base is gaining the keyboard focus, or 0 (zero) if the base is losing the keyboard focus.

## Kill Request Events

Top-level widget bases return the following event structure only when a user tries to destroy the widget using the window manager and the base was created with the [TLB\\_KILL\\_REQUEST\\_EVENTS](#) keyword set:

```
{ WIDGET_KILL_REQUEST, ID:0L, TOP:0L, HANDLER:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine.

## Context Menu Events

A base widget created with the [CONTEXT\\_EVENTS](#) keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,  
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the

upper left corner of the base widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

## Version History

Pre-4.0	Introduced
5.6	Added TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, and TOOLBAR keywords; added new event structures for iconify and move events
6.1	Added TAB_MODE keyword Added ROW and COL fields to WIDGET_CONTEXT event structure
Pre-6.2	Deprecated APP_MBAR keyword

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## See Also

[Chapter 28, “Creating Widget Applications”](#) in the *Building IDL Applications* manual.

# WIDGET\_BUTTON

The `WIDGET_BUTTON` function creates button widgets. A button widget is a pushbutton that is activated by moving the mouse cursor over the widget button and pressing a mouse button.

Figure 3-140: A Button Widget

## Exclusive And Non-Exclusive Bases

Buttons placed into exclusive or non-exclusive bases (created via the `EXCLUSIVE` or `NONEXCLUSIVE` keywords to `WIDGET_BASE` function) are created as two-state “toggle” buttons, which are controlled by such bases.

For more information on creating buttons, see “Using Button Widgets” in Chapter 30 of the *Building IDL Applications* manual.

## Bitmap Button Labels

Widget buttons can have either a text label (specified as a string value to the `VALUE` keyword) or a graphic symbol in the form of a bitmap. Bitmap labels are specified in one of the following ways:

1. By setting the `VALUE` keyword equal to a string containing the name of an image file in BMP format, and setting the `BITMAP` keyword:

```
button=WIDGET_BUTTON(base, VALUE='mybitmap.bmp', /BITMAP)
```

For 16- and 256-color bitmap files, IDL uses the color of the pixel in the lower left corner as the transparent color. All pixels of this color become transparent, allowing the button color to show through.

---

### Note

Displaying bitmapped buttons on 8-bit color X Windows displays may require using additional X colormap colors to allocate colors used by the bitmaps. If the required colormap colors are not available, the button bitmap may not display properly.

---

To modify the bitmap after creation, use the `/BITMAP` keyword with `WIDGET_CONTROL`:

```
WIDGET_CONTROL, button, SET_VALUE='mybitmap2.bmp', /BITMAP
```

- By setting the `VALUE` keyword equal to an  $n \times m$  bitmap byte array in which each bit represents a pixel with a value of either zero or one. (Arrays of this type can be produced using the `CVTTOBM` function.) This method creates a black-and-white bitmap label:

```
button=WIDGET_BUTTON(base, VALUE=bw_arr)
```

To modify the bitmap after creation, simply set a new value using `WIDGET_CONTROL`:

```
WIDGET_CONTROL, button, SET_VALUE=bw_array2
```

- By setting the `VALUE` keyword equal to an  $n \times m \times 3$  byte array that represents a 24-bit color image, interleaved by plane, with the planes in the order red, green, blue. There is no transparent pixel in 24-bit button labels. This method creates a color bitmap label:

```
button=WIDGET_BUTTON(base, VALUE=color_array)
```

To modify the bitmap after creation, simply set a new value using `WIDGET_CONTROL`:

```
WIDGET_CONTROL, button, SET_VALUE=color_array2
```

See “Using Button Widgets” in Chapter 30 of the *Building IDL Applications* manual for additional details on creating image files and arrays for use as button bitmaps.

## Syntax

```
Result = WIDGET_BUTTON( Parent [, ACCELERATOR=string]
  [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /BITMAP]
  [, /CHECKED_MENU] [, /DYNAMIC_RESIZE] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FONT=string] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id] [, /HELP]
  [, KILL_NOTIFY=string] [, /MENU] [, /NO_COPY] [, /NO_RELEASE]
  [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, /PUSHBUTTON_EVENTS] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SENSITIVE] [, /SEPARATOR] [, TAB_MODE=value] [, TOOLTIP=string]
  [, /TRACKING_EVENTS] [, UNAME=string] [, UNITS={0 | 1 | 2}]
  [, UVALUE=value] [, VALUE=value] [, X_BITMAP_EXTRA=bits]
  [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

**X Windows Keywords:** [, [RESOURCE\\_NAME=string](#)]

## Return Value

The returned value of this function is the widget ID of the newly-created button.

## Arguments

### Parent

The widget ID of the parent for the new button widget. The parent of a button widget must be one of the following:

1. A base widget.
2. A widget created using the [MBAR](#) keyword on a top-level base.
3. A button widget which has the [MENU](#) keyword set.

## Keywords

### ACCELERATOR

Set this keyword to assign a key combination that will activate a menu item or button event using the keyboard instead of the mouse. The value of the keyword is a case-insensitive string that specifies zero or more modifier keys (**Ctrl**, **Shift**, or **Alt**) and one other key. (The developer must take special steps to enable **Alt** key accelerators for Macintosh users). See “[Enabling Alt Key Accelerators on Macintosh](#)” in Chapter 30 of the *Building IDL Applications* manual for details.) If there is more than one item in the string, a “+” must separate them. For example:

```
bRun = WIDGET_BUTTON( base, VALUE = "Run", ACCELERATOR = "F5" )
bPause = WIDGET_BUTTON( base, VALUE = "Pause", $
    ACCELERATOR = "Ctrl+F5" )
bResume = WIDGET_BUTTON( base, VALUE = "Resume", $
    ACCELERATOR = "Ctrl+Shift+F5" )
```

Accelerators can be defined for menu items and various types of `WIDGET_BUTTON` on Windows. However, on UNIX, only menu item accelerators are supported. Context menu items do not support accelerators on any platform.

The valid combinations are:

Accelerator Keys	Description
<b>Ctrl</b> , <b>Shift</b> , or <b>Alt</b> plus an alphanumeric key	A modifier key plus any alphabetic character, A-Z (which is case-insensitive), or a number, 0-9, creates a valid accelerator.
<b>Ctrl</b> , <b>Shift</b> , or <b>Alt</b> plus a number pad key	A modifier key plus any key on the number pad can be used as an accelerator. However, the <b>NumLock</b> key must be activated for any accelerator using number pad keys to function properly.  <b>Note</b> - On Windows only, a keyboard accelerator using the <b>Shift</b> key and a number key on the number pad will not work.
<b>Ctrl</b> , <b>Shift</b> , or <b>Alt</b> plus the <b>Backspace</b> , <b>Tab</b> or <b>Space</b> key	These miscellaneous keys need a modifier key in the accelerator definition.
Navigation keys ( <b>Home</b> , <b>End</b> , <b>PageUp</b> , <b>PageDown</b> , <b>Up</b> , <b>Down</b> , <b>Left</b> , <b>Right</b> )	The navigation keys do not require a modifier in the accelerator definition. <b>Prior</b> and <b>PageUp</b> are equivalent as are <b>Next</b> and <b>PageDown</b> . <b>Up</b> , <b>Down</b> , <b>Left</b> , and <b>Right</b> map to the arrow keys.
Function keys ( <b>F1</b> to <b>F12</b> )	Function keys do not need a modifier key in the accelerator definition. However, not all platforms support the use of all function keys as accelerators. See <a href="#">“Successfully Implementing Keyboard Accelerators”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual for details.
<b>Return</b> , <b>Escape</b> , <b>Insert</b> , <b>Del</b> keys	These miscellaneous keys do not need a modifier key in the accelerator definition. You must specify <b>Return</b> in the accelerator definition to indicate the Enter key on Windows. You must specify <b>Del</b> in the accelerator definition to indicate the Delete key.

Table 3-123: Valid ACCELERATOR Keyword Combinations

When an accelerator is defined for a menu item, the ACCELERATOR keyword string is automatically displayed next to the menu item value. The ACCELERATOR keyword string is not included with a button value. Therefore, the VALUE keyword

of a `WIDGET_BUTTON` that is not a menu item should also indicate the accelerator keyboard shortcut so that the user is aware of the option.

See “[Assigning Accelerators in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

---

**Note**

Ordinarily, accelerators are processed before keyboard events reach widgets that have keyboard focus. Setting `IGNORE_ACCELERATORS` allows draw widgets and widgets with an editable text area (combobox, property sheet, table and text widgets) to receive keyboard events instead of the accelerator key combinations being captured by the accelerator. See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

---

## **ALIGN\_CENTER**

Set this keyword to do both of the following:

- Center the button’s label within the button.
- Center the button horizontally with respect to its parent base (if the base was created with the `COLUMN` keyword set) or vertically with respect to its parent base (if the base was created with the `ROW` keyword set).

## **ALIGN\_LEFT**

Set this keyword to do both of the following:

- Left justify the button’s label within the button.
- Align the button in the leftmost available horizontal position with respect to its parent base (if the base was created with the `COLUMN` keyword set) or in the highest available vertical position with respect to its parent base (if the base was created with the `ROW` keyword set).

## **ALIGN\_RIGHT**

Set this keyword to do both of the following:

- Right justify the button’s label within the button.
- Align the button in the rightmost available horizontal position with respect to its parent base (if the base was created with the `COLUMN` keyword set) or in the lowest available vertical position with respect to its parent base (if the base was created with the `ROW` keyword set).

## BITMAP

Set this keyword to specify that the `VALUE` keyword specifies the name of a `.bmp` file.

The value of a widget button can be a bitmap as described in “[Bitmap Button Labels](#)” on page 2513. If you specify the name of a bitmap file with the `VALUE` keyword, you must also set the `BITMAP` keyword.

## CHECKED\_MENU

Set this keyword on a menu entry button to enable the ability to place a check (Windows) or selection box (Motif) next to the menu entry. The parent widget of the button must be either a button widget created with the `MENU` keyword or a base widget created with the `CONTEXT_MENU` keyword.

### Note

---

Setting this keyword does not initially “select” the menu item; selection marks are displayed and removed via the [SET\\_BUTTON](#) keyword to `WIDGET_CONTROL`.

---

## DYNAMIC\_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the `SCR_XSIZE`, `SCR_YSIZE`, `XSIZE`, or `YSIZE` keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

## EVENT\_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows

systems). See [“About Device Fonts”](#) on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the GET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET\_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## HELP

Set this keyword to tell the widget toolkit that this button is a “help” button for a menubar and should be given that appearance. For example, Motif specifies that the help menubar item is displayed on the far right of the menubar. This keyword is ignored in all other contexts and may be ignored by window managers that have no such special appearance defined.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## MENU

The presence of this keyword indicates that the button will be used to activate a pull-down menu. Such buttons can have button children that are then placed into a pull-down menu.

Under Motif, if the value specified for `MENU` is greater than 1, the button label is enclosed in a box to indicate that this button is a pull-down menu. See the [CW\\_PDMENU](#) function for a high-level pull-down menu creation utility.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_BUTTON` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## NO\_RELEASE

Set this keyword to make exclusive and non-exclusive buttons generate only *select* events. This keyword has no effect on regular buttons.

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the SET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## PUSHBUTTON\_EVENTS

Set this keyword to cause separate button events to be issued for the widget when the left mouse button is pressed and released, or when the spacebar is pressed and released.

### Note

---

This keyword has no effect on exclusive or non-exclusive buttons.

---

When this keyword is *not* set and the button is selected, pressing and releasing either the left mouse button or the spacebar generates a single button event, with the SELECT field set equal to 1. When this keyword is set:

- Pressing the left mouse button generates a button event with the SELECT field set equal to 1.
- Releasing the left mouse button generates a button event with the SELECT field set equal to 0.
- Pressing the spacebar generates a button event with the SELECT field set equal to 1 immediately followed by a second button event with the SELECT field set equal to 0.
- Pressing and holding the spacebar generates a series of button events, with the value of the SELECT field alternating between 1 and 0. The rate at which events are generated is governed by the key-repeat settings of the operating system.

For the structure of button events, see “[Events Returned by Button Widgets](#)” on page 2528.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## SEPARATOR

Set this keyword to tell the widget toolkit that this button is part of a pulldown menu pane and that a separator line should be added directly above this entry. This keyword is ignored in all other contexts.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the

widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

---

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

---

**Note**

For radio buttons, the TAB\_MODE value is automatically inherited from the parent base and cannot be individually specified. Attempting to set TAB\_MODE on a menu item or menu base will generate an error.

---

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

---

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

Once a `WIDGET_BUTTON` widget receives focus through tabbing, additional navigation capabilities depend upon the platform as follows:

Widget	Description
<code>WIDGET_BUTTON</code> (Grouped, exclusive button widgets)	<ul style="list-style-type: none"> <li>• On Windows – radio buttons can receive and lose focus through tabbing as long as there is a selected button within the group. Use the arrow keys to change the selection within the group.</li> <li>• On UNIX — the Motif library controls tabbing functionality.</li> </ul>
<code>WIDGET_BUTTON</code> (Grouped, non-exclusive button widgets)	<ul style="list-style-type: none"> <li>• On Windows – toggle buttons (or check boxes) can individually receive and lose focus through tabbing. Use the <b>Space</b> key to select or deselect a check box.</li> <li>• On UNIX —the Motif library controls tabbing functionality.</li> </ul>

*Table 3-124: Tabbing Behavior in Windows and UNIX Widget Applications*

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

### Note

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

### Note

If your application uses hardware rendering and a `RETAIN` setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“TRACKING\\_EVENTS”](#) on page 2506 in the documentation for WIDGET\_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the [FIND\\_BY\\_UNAME](#) keyword. The UNAME should be unique to the widget hierarchy because the [FIND\\_BY\\_UNAME](#) keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by [WIDGET\\_INFO](#).

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a widget button is the label for that button. You can set VALUE to any of the following:

- a string value, which displays as text;
- an  $n \times m$  byte array, which displays as a black-and-white bitmap image;
- an  $n \times m \times 3$  byte array, which displays as a 24-bit color bitmap image;
- if the BITMAP keyword is also specified, the name of a bitmap image file that displays as a color bitmap image of the same depth as the image in the file.

See “[Bitmap Button Labels](#)” on page 2513 for additional details on using bitmap images as button labels. Also see “[Using Button Widgets](#)” in Chapter 30 of the *Building IDL Applications* manual for additional details on using bitmap values for button widgets.

---

### Note

Under Microsoft Windows, including the ampersand character (&) in the value of a button widget causes the window manager to place an underline under the character following the ampersand. (This is a feature of Microsoft Windows, and is generally used to indicate which character is used as a keyboard accelerator for the button.) If you are designing an application that will run on different platforms, you should avoid the use of the ampersand in button value strings.

---

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## X\_BITMAP\_EXTRA

When creating a bitmap button that is not of a “byte-aligned” size (i.e., a dimension is not a multiple of 8), this keyword specifies how many bits of the supplied bitmap must be ignored (within the end byte). For example, to create a 10 by 8 bitmap, you need to supply a 2 by 8 array of bytes and ignore the bottom 6 bits. Therefore, you would specify `X_BITMAP_EXTRA = 6`.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## **XSIZE**

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

## **YOFFSET**

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## **YSIZE**

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

## **Keywords to WIDGET\_CONTROL**

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of button widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DYNAMIC\\_RESIZE](#), [DYNAMIC\\_RESIZE](#), [GET\\_VALUE](#), [INPUT\\_FOCUS](#), [PUSHBUTTON\\_EVENTS](#), [SET\\_BUTTON](#), [SET\\_VALUE](#), [TOOLTIP](#), [X\\_BITMAP\\_EXTRA](#).

## **Keywords to WIDGET\_INFO**

Some keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to button widgets. In addition to those keywords that apply to all widgets,

the following are particularly useful: [BUTTON\\_SET](#), [DYNAMIC\\_RESIZE](#), [PUSHBUTTON\\_EVENTS](#), [STRING\\_SIZE](#), [TOOLTIP](#).

## Events Returned by Button Widgets

Pressing the mouse button while the mouse cursor is over a button widget causes the widget to generate an event. The event structure returned by the `WIDGET_EVENT` function is defined by the following statement:

```
{WIDGET_BUTTON, ID:0L, TOP:0L, HANDLER:0L, SELECT:0}
```

`ID` is the widget id of the button generating the event. `TOP` is the widget ID of the top level widget containing `ID`. `HANDLER` contains the widget ID of the widget associated with the handler routine. `SELECT` is set to 1 if the button was set, and 0 if released. Unless the [PUSHBUTTON\\_EVENTS](#) keyword is set, normal buttons do not generate events when released, so `SELECT` will always be 1. Toggle buttons (children of either an exclusive or non-exclusive base) always return separate events for the set and release actions.

## Version History

Pre-4.0	Introduced
5.6	Added <code>CHECKED_MENU</code> and <code>TOOLTIP</code> keywords
6.0	Added <code>PUSHBUTTON_EVENTS</code> keyword
6.1	Added <code>ACCELERATOR</code> and <code>TAB_MODE</code> keywords

## See Also

[CW\\_BGROUP](#), [CW\\_PDMENU](#), “[Using Button Widgets](#)” in Chapter 30 of the *Building IDL Applications* manual

# WIDGET\_COMBOBOX

The WIDGET\_COMBOBOX function creates combobox widgets, which are similar to droplist widgets. The combobox displays a single entry from a list of options. The main difference between the combobox widget and the droplist widget is that the combobox widget can be created in such a way that the text field is editable, allowing the user to enter a value that is not on the list.

A combobox widget displays a text field and an arrow button. If the combobox is not editable, selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently selected option. This action generates an event containing the index of the selected item, which ranges from zero to the number of elements in the list minus one.

Figure 3-141: A ComboBox Widget

If the combobox is editable, text can be entered in the text box without causing the list to drop down. This action causes an event in which the index field is set to -1, allowing you to distinguish this event from list selections.

The text of the current selection is returned in the STR field of the WIDGET\_COMBOBOX event structure. See [“Widget Events Returned by Combobox Widgets”](#) on page 2538 for details.

---

**Note**

WIDGET\_COMBOBOX is not currently available on Compaq True64 UNIX platforms due to that platform’s lack of support for the necessary Motif libraries.

---

## Syntax

```
Result = WIDGET_COMBOBOX( Parent [, /DYNAMIC_RESIZE] [, /EDITABLE]
    [, EVENT_FUNC=string] [, EVENT_PRO=string] [, FONT=string]
    [, FRAME=value] [, FUNC_GET_VALUE=string]
    [, GROUP_LEADER=widget_id] [, IGNORE_ACCELERATORS=value]
    [, KILL_NOTIFY=string] [, /NO_COPY] [, NOTIFY_REALIZE=string]
    [, PRO_SET_VALUE=string] [, RESOURCE_NAME=string]
    [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
    [, TAB_MODE=value] [, /TRACKING_EVENTS] [, UNAME=string]
    [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, XOFFSET=value]
    [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly created combobox widget.

## Arguments

### Parent

The widget ID of the parent widget for the new combobox widget.

## Keywords

### DYNAMIC\_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed.

#### Note

---

This keyword does not take effect when used with the SCR\_XSIZE, SCR\_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

---

### EDITABLE

Set this keyword to create an editable combobox. If the combobox is editable, users can enter or modify items in the text field. Changes in the combobox text field will

cause combobox events with the INDEX field of the event structure set to -1. The current text will be ' in the STR field of the event structure.

## EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 in the *IDL Reference Guide* for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

---

**Note**

This keyword is only a hint to the toolkit, and may be ignored in some instances.

---

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the GET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

## IGNORE\_ACCELERATORS

Set this keyword to specify what accelerators are to be ignored when this combobox widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for `WIDGET_BUTTON`'s `ACCELERATOR` keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “Ctrl+V” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a combobox, attempting to use **Ctrl+V** to paste text into the combobox would fail as this event would be stolen by the accelerator. Setting `IGNORE_ACCELERATORS` to “Ctrl+V” allows a combobox widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the combobox loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the `UVALUE` keyword to `WIDGET_COMBOBOX` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. Upon a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`' '`). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the `PRO_SET_VALUE` keyword to `WIDGET_CONTROL` for information on using this keyword.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See “`RESOURCE_NAME`” on page 2499 in the *IDL Reference Guide* for a complete discussion of this keyword.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

### Note

---

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

---

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#).

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

### Note

---

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

Once the `WIDGET_COMBOBOX` has focus, use the up and down arrow keys to navigate among the individual items.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET\\_CONTROL](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [WIDGET\\_INFO](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“TRACKING\\_EVENTS”](#) on page 2506 in the documentation for `WIDGET_BASE`.

## UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

## UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a combobox widget is a scalar string or array of strings that contains the text of the list items (one list item per array element). Combobox widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

The combobox widget will display up to 20 list items at a time. If the VALUE array contains more than 20 elements, scroll bars are added to the list display.

---

**Note**

Null strings are not allowed in the combobox widget item list.

---

**Note**

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

**XOFFSET**

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

**XSIZE**

The desired width of the combobox widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

**YOFFSET**

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

**YSIZE**

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) affect the behavior of combobox widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [COMBOBOX\\_ADDITEM](#), [COMBOBOX\\_DELETEITEM](#), [COMBOBOX\\_INDEX](#), [DYNAMIC\\_RESIZE](#), [GET\\_VALUE](#), [IGNORE\\_ACCELERATORS](#), [SET\\_COMBOBOX\\_SELECT](#), [SET\\_VALUE](#).

## Keywords to WIDGET\_INFO

A number of keywords to the [WIDGET\\_INFO](#) return information that applies specifically to combobox widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [COMBOBOX\\_GETTEXT](#), [COMBOBOX\\_NUMBER](#), [DYNAMIC\\_RESIZE](#), [STRING\\_SIZE](#).

## Widget Events Returned by Combobox Widgets

Pressing the mouse button while the mouse pointer is over an element of a combobox widget causes the widget to change the text field on the combobox and to generate an event. The event structure returned by the [WIDGET\\_EVENT](#) function is defined by the following statement:

```
{WIDGET_COMBOBOX, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, STR:""}
```

The first three fields are the standard fields found in every widget event. [INDEX](#) returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value. If the event was caused by text changes in an editable combobox, the [INDEX](#) field will be set to -1. If you are using an editable combobox, it is important to check for the value of -1 prior to using the value of the [INDEX](#) field as an index into the array of items. The text of the current selection is returned in the [STR](#) field, which may eliminate the need to use the index field in many cases.

---

### Note

Platform-specific UI toolkits behave differently if a combobox widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

---

## Version History

5.6	Introduced
6.1	Added IGNORE_ACCELERATORS and TAB_MODE keywords

## See Also

# WIDGET\_CONTROL

The WIDGET\_CONTROL procedure is used to realize, manage, and destroy widget hierarchies. It is often used to change the default behavior or appearance of previously-realized widgets.

## Syntax

WIDGET\_CONTROL [, *Widget\_ID*]

**Keywords that apply to all widgets:** [, [BAD\\_ID=variable](#)] [, [/CLEAR\\_EVENTS](#)] [, [DEFAULT\\_FONT=string](#) {do not specify *Widget\_ID*}] [, [/DELAY\\_DESTROY](#) {do not specify *Widget\_ID*}] [, [/DESTROY](#)] [, [EVENT\\_FUNC=string](#)] [, [EVENT\\_PRO=string](#)] [, [FUNC\\_GET\\_VALUE=string](#)] [, [GET\\_UVALUE=variable](#)] [, [GROUP\\_LEADER=widget\\_id](#)] [, [/HOURLASS](#) {do not specify *Widget\_ID*}] [, [KILL\\_NOTIFY=string](#)] [, [/MAP](#)] [, [/NO\\_COPY](#)] [, [NOTIFY\\_REALIZE=string](#)] [, [PRO\\_SET\\_VALUE=string](#)] [, [/REALIZE](#)] [, [/RESET](#) {do not specify *Widget\_ID*}] [, [SCR\\_XSIZE=width](#)] [, [SCR\\_YSIZE=height](#)] [, [SEND\\_EVENT=structure](#)] [, [/SENSITIVE](#)] [, [SET\\_UNAME=string](#)] [, [SET\\_UVALUE=value](#)] [, [/SHOW](#)] [, [TIMER=value](#)] [, [TLB\\_GET\\_OFFSET=variable](#)] [, [TLB\\_GET\\_SIZE=variable](#)] [, [/TLB\\_KILL\\_REQUEST\\_EVENTS](#)] [, [TLB\\_SET\\_TITLE=string](#)] [, [TLB\\_SET\\_XOFFSET=value](#)] [, [TLB\\_SET\\_YOFFSET=value](#)] [, [/TRACKING\\_EVENTS](#)] [, [UNITS={0 | 1 | 2}](#)] [, [/UPDATE](#)] [, [XOFFSET=value](#)] [, [XSIZE=value](#)] [, [YOFFSET=value](#)] [, [YSIZE=value](#)]

 [, SET\_TREE\_SELECT={0 | 1 | widget ID | array of widget IDs}]  
 [, /SET\_TREE\_VISIBLE] [, TAB\_MODE=value]

## Arguments

### Widget\_ID

The widget ID of the widget to be manipulated. This argument is required by all operations, unless the description of the specific keyword states otherwise. Note that

if *Widget\_ID* is not provided for a keyword that needs it, that keyword is quietly ignored.

## Keywords

Not all keywords to `WIDGET_CONTROL` apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

### ALIGNMENT

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to a scalar, 2-D array, or 1-D array specifying the alignment of the contents of each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell.

If the `USE_TABLE_SELECT` keyword is not set:

- If `ALIGNMENT` is set equal to a scalar, all table cells are aligned as specified. If `ALIGNMENT` is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

If the `USE_TABLE_SELECT` keyword is set:

- In standard selection mode, if `ALIGNMENT` is set equal to a scalar, all cells in the selection are aligned as specified. If `ALIGNMENT` is set equal to a 2-D array, the alignment of each selected cell is governed by the corresponding element of the array.
- In disjoint selection mode, if `ALIGNMENT` is set equal to a scalar, all cells in the selection are aligned as specified. If `ALIGNMENT` is set equal to a 1-D array, the alignment of each selected cell is governed by the corresponding element of the array.

### ALL\_TABLE\_EVENTS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to cause the table widget to generate events whenever the user changes the contents of a table cell.

**Note**

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the table widget, even if the ALL\_TABLE\_EVENTS keyword is not set. End-of-line events such as these could be used by the programmer as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between ALL\_TABLE\_EVENTS and EDITABLE.

Keywords		Effects	
ALL_TABLE_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

*Table 3-125: Effects of Using the ALL\_TABLE\_EVENTS and EDITABLE keywords*

**ALL\_TEXT\_EVENTS**

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

Set this keyword to cause the text widget to generate events whenever the user changes the contents of the text area.

**Note**

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL\_EVENTS keyword is not set. See the table below for details on the interaction between ALL\_TEXT\_EVENTS and EDITABLE.

Keywords		Effects	
ALL_TEXT_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

*Table 3-126: Effects of Using the ALL\_TEXT\_EVENTS and EDITABLE keywords*

## AM\_PM

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the `FORMAT` keyword.

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

## APPEND

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

When using the `SET_VALUE` keyword to set the contents of a text widget (as created with the `WIDGET_TEXT` procedure), setting this keyword indicates that the supplied text should be appended to the existing contents of the text widget rather than replace it.

## BACKGROUND\_COLOR

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to one or more RGB triplets to specify cell background colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

---

**Note**

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

---

When you use this keyword in conjunction with [USE\\_TABLE\\_SELECT](#), you can specify the set of affected cells. Otherwise, IDL operates on all of the table's cells. If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

For more information, see [“Cell Attributes”](#) in Chapter 30 of the *Building IDL Applications* manual.

## BAD\_ID

This keyword applies to all widgets.

If *Widget\_ID* is not a valid widget identifier, this `WIDGET_CONTROL` normally issues an error and causes program execution to stop. However, if `BAD_ID` is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

## BASE\_SET\_TITLE

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to a scalar string to change the title of the specified base widget. If the parent of the base widget is a tab widget, the title of the corresponding tab in the tab widget is changed to the provided string. If the parent is not a tab control, this keyword behaves like the keyword `TLB_SET_TITLE`.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## BITMAP

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#) function.

Set this keyword to specify that the `SET_VALUE` keyword specifies the name of a .bmp file.

The value of a widget button can be a bitmap as described in “[Bitmap Button Labels](#)” on page 2513. If you specify the name of a bitmap file with the `VALUE` keyword, you must also set the `BITMAP` keyword.

## CLEAR\_EVENTS

This keyword applies to all widgets.

If set, any events generated by the widget hierarchy rooted at `Widget_ID` which have arrived but have not been processed (via the `WIDGET_EVENT` procedure) are discarded.

## COLUMN\_LABELS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to an array of strings to be used as labels for the columns of the table. If no label is specified for a column, it receives the default label “*n*” where *n* is the column number. If this keyword is set to the empty string (“”), all column labels are set to be empty.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## COLUMN\_WIDTHS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to a one-dimensional array of widths for the columns of the table widget. The widths are given in the units specified with the `UNITS` keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If `COLUMN_WIDTHS` is set to a scalar value, all of the column widths are set to that value.

---

### Note

Column widths are limited to 0.

---

If the `USE_TABLE_SELECT` keyword is set (in either standard or disjoint selection mode), the indices of the elements of an array specified as the value of the `COLUMN_WIDTHS` keyword are interpreted as indices into the list of selected

columns. For example, if the table is in disjoint selection mode, the current selection includes cells from columns 0, 1, 2, 5, 6, and 7, `USE_TABLE_SELECT` is set equal to one, and the `COLUMN_WIDTHS` keyword is set equal to a four-element array `[20, 35, 30, 35]`, the widths of columns 0, 1, 2, and 5 would be modified. Similarly, if the table is in standard selection mode and the `USE_TABLE_SELECT` keyword is set equal to the array `[0, 1, 0, 0]`, and the `COLUMN_WIDTHS` keyword is set equal to a four-element array `[20, 35, 30, 35]`, only the width of the first column would be altered.

## COMBOBOX\_ADDITEM

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to a non-null string that specifies a new item to add to the list of the combobox. By default, the item will be added to the end of the list. The item can be added to a specified position in the list by setting the `COMBOBOX_INDEX` keyword in the same call to `WIDGET_CONTROL`.

## COMBOBOX\_DELETEITEM

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to an integer that specifies the zero-based index of the combobox element to be deleted from the list. If the specified element is outside the range of existing elements, no element is deleted.

## COMBOBOX\_INDEX

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to an integer that specifies the zero-based index of the position at which a new item will be added to the list when using the `COMBOBOX_ADDITEM` keyword. The value -1 is a special case that indicates the item should be added to the end of the list. Note that this special case is provided for convenience, and that an item can also be added to the end of the list by omitting the `COMBOBOX_INDEX` keyword entirely. If the supplied index is not -1, and is outside the range of zero to the length of the existing list, the item is not added to the list.

### Note

---

You can retrieve the length of the existing list using the `COMBOBOX_NUMBER` keyword to `WIDGET_INFO` function.

---

## CONTEXT\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#), [WIDGET\\_LIST](#), [WIDGET\\_PROPERTY SHEET](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) functions.

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET\\_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

---

### Note

You can also capture right mouse button events generated within draw widgets. See the [BUTTON\\_EVENTS](#) keyword to [WIDGET\\_DRAW](#) function for details.

---

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

## DAYS\_OF\_WEEK

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the [FORMAT](#) keyword.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## DEFAULT\_FONT

This keyword applies to all widgets that support fonts. Attempting to set a font on a widget that does not support fonts is not an error, but the attempt is ignored.

---

### Note

The [WIDGET\\_BASE](#), [WIDGET\\_DRAW](#), [WIDGET\\_TAB](#), and [WIDGET\\_TREE](#) widgets do *not* support fonts.

---

Do not specify a *Widget ID* when using this keyword.

A string containing the name of the default font to be used.

If the font to be used for a given widget is not explicitly specified (via the `FONT` keyword to the widget creation function), a default supplied by the window system or server is used. Use this keyword to change the default. See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

## DELAY\_DESTROY

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Normally, when the user destroys a widget hierarchy using the window manager, it is immediately removed. This can cause problems for applications that use the background task facility provided by the `XMANAGER` procedure if the hierarchy is destroyed while a background task is using it.

If `DELAY_DESTROY` is set, attempts to destroy the hierarchy are delayed until the next attempt to obtain an event for it. Setting `DELAY_DESTROY` to zero restores the default behavior.

`XMANAGER` uses this keyword automatically when managing background tasks. It is not expected that applications will need to use it directly.

## DELETE\_COLUMNS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to delete columns that contain selected cells. If a selection is specified via the `USE_TABLE_SELECT` keyword (in either standard or disjoint mode), the columns that contain cells specified in the selection array are deleted. If the `USE_TABLE_SELECT` keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

---

**Warning**

You cannot delete columns from a table which displays structure data in `/ROW_MAJOR` mode (the default).

---

## DELETE\_ROWS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to delete rows that contain selected cells. If a selection is specified via the [USE\\_TABLE\\_SELECT](#) keyword (in either standard or disjoint mode), the rows that contain cells specified in the selection array are deleted. If the [USE\\_TABLE\\_SELECT](#) keyword is *either* absent or set equal to 1, the rows that contain selected cells are deleted.

---

### Warning

You cannot delete rows from a table which displays structure data in /COLUMN\_MAJOR mode.

---

## DESTROY

This keyword applies to all widgets.

Set this keyword to destroy the widget and any child widgets in its hierarchy. Any further attempts to use the IDs for these widgets will cause an error.

## DRAW\_BUTTON\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to enable button press events for draw widgets. Setting a zero value disables such events.

---

### Note

You can use button events generated by draw widgets to simulate the functionality of the [CONTEXT\\_EVENTS](#) keyword to [WIDGET\\_BASE](#), [WIDGET\\_LIST](#), and [WIDGET\\_TEXT](#). See the [BUTTON\\_EVENTS](#) keyword to [WIDGET\\_DRAW](#) for details.

---

## DRAW\_EXPOSE\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to enable viewport expose events for draw widgets. Setting a zero value disables such events.

---

### Note

You must explicitly disable backing store (by setting the [RETAIN](#) keyword to [WIDGET\\_DRAW](#) equal to zero) in order to generate expose events.

---

## DRAW\_KEYBOARD\_EVENTS

This keyword applies to widgets created with [WIDGET\\_DRAW](#).

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See “[Widget Events Returned by Draw Widgets](#)” on page 2605 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: `SHIFT`, `CONTROL`, `CAPS LOCK`, and `ALT`. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

---

### Note

Keyboard events are never generated for function keys.

---

## DRAW\_MOTION\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to enable motion events for draw widgets. Setting a zero value disables such events.

## DRAW\_VIEWPORT\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to enable viewport motion events for draw widgets. Setting a zero value disables such events.

## DRAW\_WHEEL\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to enable wheel events for draw widgets. Setting a zero value disables such events.

**Note**

This keyword is operational only under Microsoft Windows and is quietly ignored under Motif.

**DRAW\_XSIZE**

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to an integer that specifies the new horizontal size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR\_XSIZE or XSIZE. However, for scrolling draw widgets DRAW\_XSIZE is the only way to change the width of the drawable area (XSIZE sets the viewport size).

**DRAW\_YSIZE**

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to an integer that specifies the new vertical size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR\_YSIZE or YSIZE. However, for scrolling draw widgets DRAW\_YSIZE is the only way to change the height of the drawable area (YSIZE sets the viewport size).

**DYNAMIC\_RESIZE**

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#), [WIDGET\\_COMBOBOX](#), [WIDGET\\_DROPLIST](#), and [WIDGET\\_LABEL](#) functions.

Set this keyword to activate (if set to 1) or deactivate (if set to 0) dynamic resizing of the specified WIDGET\_BUTTON, WIDGET\_LABEL, or WIDGET\_DROPLIST widget (see the documentation for the DYNAMIC\_RESIZE keyword to those procedures for more information about dynamic widget resizing).

**EDITABLE**

This keyword applies to widgets created with the [WIDGET\\_PROPERTY SHEET](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) functions.

Set this keyword to directly edit the contents of a property sheet, text, or table widget. For table widgets, you can control individual cell editability by restricting the targeted cells with [USE\\_TABLE\\_SELECT](#). Additionally, when you supply an array

of editability values, the values are distributed across the set of target cells. A scalar value is applied to all targeted cells.

For more information, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

The default value depends on the type of widget as follows:

- Text and table widgets are read-only by default (the default value is 0). The text cannot be modified. See the descriptions of the [ALL\\_TABLE\\_EVENTS](#) and [ALL\\_TEXT\\_EVENTS](#) keywords for additional details.
- Property sheet widgets are editable by default (EDITABLE=1). In this default mode, property values can be modified. When a property sheet is marked as read-only (EDITABLE=0), you can select properties and use any scrollbars, but cannot change any values. Setting this keyword to 0 is roughly equivalent to desensitizing all properties by setting the SENSITIVE attribute of *every* property on the property sheet equal to 0.

### Note

---

To set the SENSITIVE attribute of individual properties within a property sheet, use [IDLitComponent::RegisterProperty](#) or [IDLitComponent::SetPropertyAttribute](#).

---

## EDIT\_CELL

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword equal to a two-element integer array containing the y (row) and x (column) coordinates of a table cell to put that cell into edit mode. For example, to put the top cell in the third column (x index=2) into edit mode, use the following commands:

```
row=0
col=2
WIDGET_CONTROL, table, EDIT_CELL=[row, col]
```

where *table* is the Widget ID of the table widget.

## EVENT\_FUNC

This keyword applies to all widget primitives (non-compound widgets).

A string containing the name of a function to be called by the [WIDGET\\_EVENT](#) function when an event arrives from a widget in the widget hierarchy given by *Widget\_ID*.

This keyword overwrites any event routine supplied by previous uses of the `EVENT_FUNC` or `EVENT_PRO` keywords. To specify no event routine, set this keyword to a null string ( ' ' ).

## EVENT\_PRO

This keyword applies to all widget primitives (non-compound widgets).

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy given by *Widget\_ID*.

This keyword overwrites any event routine supplied by previous uses of the `EVENT_FUNC` or `EVENT_PRO` keywords. To specify no event routine, set this keyword to a null string ( ' ' ).

## FONT

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to the names of the fonts used by the widget. Specified fonts are “device fonts” (an X Windows font on Motif systems, a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

You can restrict the set of targeted cells with `USE_TABLE_SELECT`. Another way to control individual cell fonts is to specify an array of font names. IDL distributes the supplied font names over the set of targeted cells, repeatedly if necessary (if there are fewer fonts than cells). If you provide a scalar string, IDL changes all targeted cells to the same font.

For more information, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

## FOREGROUND\_COLOR

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to one or more RGB triplets to specify cell text colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

### Note

---

A computer’s graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

---

When you use this keyword in conjunction with [USE\\_TABLE\\_SELECT](#), you can specify the set of affected cells. Otherwise, IDL operates on all of the table's cells. If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

For more information, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

## FORMAT

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword equal to a single string or a one- or two-dimensional array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the `FORMAT` keyword to the `PRINT` procedure, and the default format is the same as that used by the [PRINT/PRINTF](#) procedures.

If the [USE\\_TABLE\\_SELECT](#) keyword is set equal to one, the format is changed only for the currently selected cells. If `USE_TABLE_SELECT` is set equal to an array, the format is changed for the specified cells.

- In standard selection mode, `FORMAT` can be set either to a single string or to a two-dimensional array of strings of the same size as the selected area.
- In disjoint selection mode, `FORMAT` can be set either to a single string or to a one-dimensional array of strings with the same number of elements as the selected area.

## FUNC\_GET\_VALUE

This keyword applies to all widgets.

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. The function specified by `FUNC_GET_VALUE` is called with the widget ID as an argument. The function specified by `FUNC_GET_VALUE` should return a value for a widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GET\_DRAW\_VIEW

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Specifies a named variable which will be assigned the current position of a draw widget viewport. The position is returned as a 2-element integer array giving the X and Y position relative to the lower left corner of the graphics area.

## GET\_UVALUE

This keyword applies to all widgets.

Set this keyword to a named variable to contain the current user value of the widget.

Each widget can contain a user set value of any data type and organization. This value is not used by the widget in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to obtain the current user value.

The user value of a widget can be set with the SET\_UVALUE keyword to this routine, or with the UVALUE keyword to the routine that created it.

To improve the efficiency of the data transfer, consider using the NO\_COPY keyword (described below) with GET\_UVALUE.

## GET\_VALUE

This keyword applies to widgets created with the [WIDGET\\_ACTIVEX](#), [WIDGET\\_BUTTON](#), [WIDGET\\_COMBOBOX](#), [WIDGET\\_DRAW](#), [WIDGET\\_DROPLIST](#), [WIDGET\\_LABEL](#), [WIDGET\\_SLIDER](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) functions.

---

### Note

If you would like information about the values returned for a specific compound widget—beginning with the prefix “CW\_”—please refer to the description of the compound widget, which may also include a section titled, “Keywords to WIDGET\_CONTROL and WIDGET\_INFO”. Compound widgets are described in the *Reference Guide*.

---

Set this keyword to a named variable to contain the current value of the widget. The type of value returned depends on the widget type:

- **ActiveX:** An object reference to the IDLcomActiveX object that underlies the ActiveX widget. See [Chapter 5, “Using ActiveX Controls in IDL”](#) in the *External Development Guide* manual for details.
- **Button:** If the button label is text, it is returned as a string. Attempts to obtain the value of a button with a bitmap label is an error.
- **Combobox:** The contents of the list of the combobox widget are returned as a string or string array.

- Draw: The value of a draw widget depends on whether the draw widget uses IDL Direct Graphics or IDL Object Graphics. (The type of graphics used is specified by the `GRAPHICS_LEVEL` keyword to `WIDGET_DRAW`.) The two possibilities are:
  - A. By default, draw widgets use IDL Direct Graphics. In this case, the value of a draw widget is the IDL window ID for the drawing area. This ID is used with procedures such as `WSET`, `WSHOW`, etc., to direct graphics to the widget. The window ID is assigned to drawing area widgets at the time they are realized. If the widget has not yet been realized, a value of -1 is returned.
  - B. If the draw widget uses IDL Object Graphics (that is, if the `GRAPHICS_LEVEL` keyword to `WIDGET_DRAW` is set equal to 2), the value of the draw widget is the object reference of the window object used in the draw widget.

To obtain the window number for a newly created draw widget, use `GET_VALUE` *after* the draw widget has been realized. Draw widgets do not have a window number assigned to them until they are realized. For example, to return the window number of a draw widget in the variable `win_num`, use the command:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE=win_num
```

where `my_drawwidget` is the widget ID of the desired draw widget.

When using Object Graphics for the widget draw, the following command returns an object reference to the draw window:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE=oWindow
```

where `oWindow` is a window object.

- Droplist: The contents of the droplist widget's list are returned as a string or string array.
- Label: The label text is returned as a string.
- Property Sheet: Retrieves the component object(s) that the property sheet is associated with. Use the `GET_VALUE` keyword to `WIDGET_CONTROL`.
- Slider: The current value of the slider is returned as an integer.
- Table: Normally, the data for the whole table are returned as a two dimensional array or a vector of structures.

If the `USE_TABLE_SELECT` keyword is set, the value returned is a subset of the whole data.

- If the table is in standard selection mode and the table data is of a single type, the value returned is a two dimensional array. If the table contains structure data, the value returned is a vector of (possibly anonymous) structures.
- If the table is in disjoint selection mode and the table data is a single type, the value returned is a one-dimensional array of values. If the table contains structure data, the value returned is a single structure in which each field corresponds to a selected cell. In either case, use the `TABLE_SELECT` keyword to `WIDGET_INFO` to get the row and column indices of the disjoint values.

If the `USE_TEXT_SELECT` keyword is set, the value returned is a string corresponding to the currently-selected text in the currently-selected cell.

- Text: The current contents of the text widget are returned as a string array. If the `USE_TEXT_SELECT` keyword is also specified, only the contents of the current selection are returned.
- Widget types not listed above do not return a value. Attempting to retrieve the value of such a widget causes an error.

The value of a widget can be set with the `SET_VALUE` keyword to this routine, or with the `VALUE` keyword to the routine that created it.

## GROUP\_LEADER

This keyword applies to all widgets.

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## HOURGLASS

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Set this keyword to turn on an “hourglass-shaped” cursor for all IDL widgets and graphics windows. The hourglass remains in place until the `WIDGET_EVENT`

function attempts to process the next event. Then the previous cursor is reinstated. If an application starts a time-intensive calculation inside an event-handling routine, the hourglass cursor should be used to indicate that the system is not currently responding to events.

## ICONIFY

This keyword applies to all widgets.

Set this keyword to a non-zero value to cause the specified widget to become iconified. Set this keyword to zero to open an iconified widget.

## IGNORE\_ACCELERATORS

This keyword applies to widgets created with the [WIDGET\\_COMBOBOX](#), [WIDGET\\_DRAW](#), [WIDGET\\_PROPERTY SHEET](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) functions.

Set this keyword to a list of accelerators that should be ignored while the target widget has the keyboard focus. Using this mechanism, keystrokes that IDL would otherwise deliver only to an accelerated button are allowed to fall through to the target widget. If the keyword is set while the widget already has the focus, the effects are immediate. Acceleration is restored when the target widget loses the focus.

### Note

See [WIDGET\\_BUTTON](#)'s description of the [ACCELERATOR](#) keyword for the syntax used to specify accelerators.

If you do not set this keyword to a list, you can set it to one of the following values:

1	All existing accelerators are ignored
0	No accelerators are ignored

## INPUT\_FOCUS

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#), [WIDGET\\_DRAW](#), and [WIDGET\\_TEXT](#) functions.

If *Widget\_ID* is a text widget or a draw widget, set this keyword to cause the widget to receive the keyboard focus. If *Widget\_ID* is a button widget, set this keyword to position the mouse pointer over the button (on Motif), or set the focus to the button so

that it can be “pushed” with the spacebar (on Windows). This keyword has no effect for other widget types.

**Note**

---

You cannot assign the input focus to an unrealized widget.

---

## INSERT\_COLUMNS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to the number of columns to be added to the right of the rightmost column of the table. If the [USE\\_TABLE\\_SELECT](#) keyword is set equal to one, the columns are inserted to the left of the current selection. If [USE\\_TABLE\\_SELECT](#) is set equal to an array, the columns are inserted to the left of the specified selection.

**Warning**

---

You cannot insert columns into a table which displays structure data in `/ROW_MAJOR` (default) mode because it would change the structure.

---

## INSERT\_ROWS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to the number of rows to be added below the bottommost row of the table. If the [USE\\_TABLE\\_SELECT](#) keyword is set equal to one, the rows are inserted above the current selection. If [USE\\_TABLE\\_SELECT](#) is set equal to an array, the rows are inserted above the specified selection.

**Warning**

---

You cannot insert rows into a table which displays structure data in `/COLUMN_MAJOR` mode because it would change the structure.

---

## KBRD\_FOCUS\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) functions.

Set this keyword to cause widget keyboard focus events to be issued for the widget whenever the keyboard focus of that widget changes. See the `KBRD_FOCUS_EVENTS` keywords to [WIDGET\\_BASE](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) for details.

See “[Keyboard Focus Events](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## KILL\_NOTIFY

This keyword applies to all widgets.

Use this keyword to change or remove a previously-specified callback procedure for *Widget\_ID*. A previously-defined callback can be removed by setting this keyword to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET\_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET\_EVENT function is called.

For a top-level base widget in a widget application, the CLEANUP keyword to XMANAGER can also be used to specify a procedure that will be called when the base widget dies. Note that the *last* call to any of:

- WIDGET\_BASE, KILL\_NOTIFY
- XMANAGER, CLEANUP
- WIDGET\_CONTROL, KILL\_NOTIFY

determines the procedure that is executed when the specified top-level base widget dies.

## MANAGED

This keyword applies to all widgets.

This keyword is used by the XMANAGER procedure to mark those widgets that it is currently managing. User applications should not use this keyword directly.

## MAP

This keyword applies to all widgets.

Set this keyword to zero to unmap the widget hierarchy rooted at the widget specified by *Widget\_ID*. The hierarchy disappears from the screen, but still exists.

The mapping operation applies only to base widgets. If the specified widget is not a base, IDL searches upward in the widget hierarchy until it finds the closest base widget. The map operation is applied to that base.

Set MAP to a nonzero value to re-map the widget hierarchy and make it visible. Normally, the widget is automatically mapped when it is realized, so use of the MAP keyword is not required.

## MONTHS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the `FORMAT` keyword.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## MULTIPLE\_PROPERTIES

This keyword applies to widgets created with the [WIDGET\\_PROPERTY SHEET](#) function.

Set this property to 1 to allow multiple properties to be selected at the same time. When this keyword is set, you can hold down the **Ctrl** key while left-clicking with the mouse to make nonadjacent selections, or hold down the **Shift** key to select an adjacent range of properties.

When changing the selection support of a property sheet from multiple selection to single selection (`MULTIPLE_PROPERTIES` equals 0), the current set of selected properties is cleared unless there is only a single selection.

## NO\_COPY

This keyword applies to all widgets.

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

**Note**

The `NO_COPY` keyword increases efficiency when sending event structures using the `SEND_EVENT` keyword to `WIDGET_CONTROL`.

**NO\_NEWLINE**

This keyword applies to widgets created with the `WIDGET_TEXT` function.

When setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. The `NO_NEWLINE` keyword suppresses this action.

**NOTIFY\_REALIZE**

This keyword applies to all widgets.

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. A previously-set callback routine can be removed by setting this keyword to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

**PRO\_SET\_VALUE**

This keyword applies to all widgets.

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget.

The procedure specified by `PRO_SET_VALUE` is called with two arguments: a *Widget ID* and a *Value*. Using this technique allows you to designate a routine that sets the value for the widget specified by *Widget ID*.

This keyword is intended for use in compound widgets, which use it to define the compound widget’s value transparently to the user.

Using this keyword with widget primitives is somewhat problematic, because calling `WIDGET_CONTROL`, `SET_VALUE` *within* the procedure will also call the procedure specified by `PRO_SET_VALUE`. In order to use `PRO_SET_VALUE` with a widget primitive, the specified procedure must do the following:

1. Process the *Value* supplied to the procedure in the necessary way
2. Unset the `PRO_SET_VALUE` keyword for the affected widget by setting its value to a null string

3. Set the affected widget's value using the `SET_VALUE` keyword to `WIDGET_CONTROL`
4. Reset the `PRO_SET_VALUE` keyword to the original procedure

## PROPERTY SHEET\_SET\_SELECTED

This keyword applies to widgets created with the `WIDGET_PROPERTY SHEET` function.

This keyword allows programmatic property selection. Set it to a string or an array of strings to identify the properties to appear selected. The strings should match valid property identifiers. When this keyword is set to an empty string, or an array that contains only empty strings, it clears all property selections.

## PUSHBUTTON\_EVENTS

This keyword applies to widgets created with the `WIDGET_BUTTON` function.

Set this keyword to a non-zero value to enable pushbutton events for the widget specified by *Widget\_ID*. Set the keyword to 0 to disable pushbutton events for the specified widget. For a description of pushbutton events, see “`PUSHBUTTON_EVENTS`” on page 2521 in the documentation for `WIDGET_BUTTON`.

## REALIZE

This keyword applies to all widgets.

If set, the widget hierarchy is realized. Until the realization step, the widget hierarchy exists only within IDL. Realization is the step of actually creating the widgets on the screen (and mapping them if necessary).

When a previously realized widget gets a new child widget, the new child is automatically realized.

---

### Tip

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This “extra” resize event is generated before any manipulation of the base widget by the user.

---

## REFRESH\_PROPERTY

This keyword applies to widgets created with the [WIDGET\\_PROPERTY SHEET](#) function. Set this keyword to:

- A non-zero numeric value to refresh all properties. Refreshing all properties in this manner is more efficient to use `/REFRESH_PROPERTY` than `WIDGET_CONTROL`'s `SET_VALUE` keyword to reload the property sheet.
- A string or string array containing one or more *property identifiers* identifying individual properties to be refreshed. See “[Property Identifiers](#)” in Chapter 4 of the *iTool Developer's Guide* manual for information on property identifiers.

The `REFRESH_PROPERTY` keyword also updates a property's sensitivity and visibility according to the value of the property held by the related component. Although the property sheet knows about its component, the property sheet and underlying component have a clear boundary and can only affect each other through IDL statements. The following example illustrates this. The first selected property in the property sheet is hidden after a 4 second wait as long as the `REFRESH_PROPERTY` keyword is used. When commented out, there is no notification that the first selected property should be hidden.

```
PRO ExPropSheetRefresh

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')
; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
    TITLE = 'Single Property Sheet Example')
wPropAxis = WIDGET_PROPERTY SHEET(base, VALUE = oComp, $
    UNAME = 'PropSheet', xsize = 45)
; Pre-select the color and transparency properties of
; axis component.
WIDGET_CONTROL, wPropAxis, $
    PROPERTY SHEET_SETSELECTED=['Color', 'Transparency']

; Activate the widgets.
WIDGET_CONTROL, base, SET_UVALUE = oComp, /REALIZE
XMANAGER, 'ExSinglePropSheet', base, /NO_BLOCK

; Wait 4 seconds and then hide the first selected property
; and refresh the property sheet.
WAIT, 4
a = WIDGET_INFO(wPropAxis, /property sheet_selected)
oComp->SetPropertyAttribute, a[0], /HIDE
WIDGET_CONTROL, wPropAxis, /REFRESH_PROPERTY

END
```

## RESET

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword. Set the RESET keyword to destroy every currently active widget. This keyword should be used with caution.

## ROW\_LABELS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label “*n*” where *n* is the row number. If this keyword is set to the empty string (“”), all row labels are set to be empty.

## ROW\_HEIGHTS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword equal to a one-dimensional array of heights for the rows of the table widget. The heights are given in the units specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW\_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

---

### Note

On Microsoft Windows platforms, rows cannot have different heights. You should supply a scalar value, but if you supply an array of values, IDL applies the last value to all rows.

---

---

### Note

Row heights are limited to 0 on Motif and 1 on Windows.

---

If the [USE\\_TABLE\\_SELECT](#) keyword is set (in either standard or disjoint selection mode), the indices of the elements of the specified array are interpreted as indices into the list of selected rows. For example, if the table is in disjoint selection mode, the current selection includes cells from rows 0, 1, 2, 5, 6, and 7, [USE\\_TABLE\\_SELECT](#) is set equal to one, and the [ROW\\_HEIGHTS](#) keyword is set equal to a four-element array [20, 35, 30, 35], the height of rows 0, 1, 2, and 5 would be modified. Similarly, if the table is in standard selection mode and the [USE\\_TABLE\\_SELECT](#) keyword is set equal to the array [0, 1, 0, 0], and the [ROW\\_HEIGHTS](#) keyword is set equal to a four-element array [20, 35, 30, 35], only the height of the first row would be altered.

**Note**

---

You can make column header cells taller by first selecting them with `USE_TABLE_SELECT` (using -1 for the row values of the selection indexes the header cells of the selection's columns) and then setting their height with `ROW_HEIGHTS`.

---

**SCR\_XSIZE**

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new horizontal size, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that `[XY]SIZE` sets client area and `SCR_[XY]SIZE` sets total area (title bar, borders, menu, client area).

**SCR\_YSIZE**

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new vertical size, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that `[XY]SIZE` sets client area and `SCR_[XY]SIZE` sets total area (title bar, borders, menu, client area).

**SEND\_EVENT**

This keyword applies to all widgets.

Set this keyword to a structure containing a valid widget event to be sent to the specified widget. The value of `SEND_EVENT` *must* be a structure and the first three fields must be `ID`, `TOP`, and `HANDLER` (all of `LONG` type). Additional fields can be of any type.

As a convenience, you can set the values of the `ID`, `TOP`, and `HANDLER` fields to the long integer zero. Setting these fields to zero will result in their being populated with the following values:

ID	the widget ID of the widget specified in the call to <code>WIDGET_CONTROL</code> .
----	--

TOP	the widget ID of the top-level base containing ID.
HANDLER	the widget ID of the widget associated with the event handling routine for ID.

To improve the efficiency of the data transfer, consider using the `NO_COPY` keyword with `SEND_EVENT`.

## SENSITIVE

This keyword applies to all widgets.

Set this keyword to control the sensitivity state of a widget after creation. Use the `SENSITIVE` keyword with the widget creation function to control the initial sensitivity state.

When a widget is sensitive, it has normal appearance and can receive user input. For instance, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, and ignores any input directed at it. If `SENSITIVE` is zero, the widget hierarchy becomes insensitive. If nonzero, it becomes sensitive.

Sensitivity can be used to control when a user is allowed to manipulate a widget. It should be noted that some widgets do not change their appearance when they are made insensitive, and simply cease generating events.

### Note

For tree widgets (created with the `WIDGET_TREE` function), only the sensitivity of the root node, and thus of the entire tree, can be changed.

## SET\_BUTTON

This keyword applies to widgets created with the `WIDGET_BUTTON` function.

This keyword changes the current state of toggle buttons. If set equal to zero, every toggle button in the hierarchy specified by *Widget\_ID* is set to the unselected state. If set to a nonzero value, the action depends on the type of base holding the buttons:

- For a non-exclusive base:
  - If a single button is specified by *Widget\_ID*, that button is set to the selected state, leaving the state of other buttons in the base unchanged.

- If the base itself is specified by *Widget\_ID*, all buttons are set to the selected state.
- For an exclusive base:
  - If a single button is specified by *Widget\_ID*, that button is set to the selected state, and all other buttons in the base are set to the unselected state.
  - If the base itself is specified by *Widget\_ID*, IDL generates an error, since an exclusive base can contain at most one selected button.

If the specified *Widget\_ID* is a button widget that was created using the `CHECKED_MENU` keyword, the checked state of the menu item is modified. If the keyword value is nonzero, the menu button is placed in a checked state. If the keyword value is zero, the button is placed in a un-checked state.

## SET\_COMBOBOX\_SELECT

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to an integer that specifies the zero-based index of the combobox list element to be displayed. If the specified element is outside the range of existing elements, the selection remains unchanged.

## SET\_DRAW\_VIEW

This keyword applies to widgets created with the `WIDGET_DRAW` function.

A scrollable draw widget provides a large graphics area which is viewed through a smaller viewport. This keyword allows changing the current position of the viewport. The desired position is specified as a 2-element integer array giving the X and Y position in units specified by the `UNITS` keyword (pixels are the default) relative to the lower left corner of the graphics area. For example, to position the viewport to the lower left corner of the image:

```
WIDGET_CONTROL, widget, SET_DRAW_VIEW=[0, 0]
```

## SET\_DROPLIST\_SELECT

This keyword applies to widgets created with the `WIDGET_DROPLIST` function.

Set this keyword to an integer that specifies the droplist element to be current (i.e., the element that is displayed on the droplist button). Positions start at zero. If the specified element is outside the possible range, no new selection is set.

## SET\_LIST\_SELECT

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword to an integer scalar or vector that specifies the list element or elements to be highlighted. The previous selection (if there is a selection) is cleared. Positions start at zero. If the specified element is outside the possible range, no new selection is set. Note that the [MULTIPLE](#) keyword to [WIDGET\\_LIST](#) must have been set if more than a single list element is specified.

If the selected position is not currently on the screen, the list widget automatically move the current scrolling viewport to make it visible. The resulting topmost visible element is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the [SET\\_LIST\\_TOP](#) keyword (described below) to explicitly set the viewport.

## SET\_LIST\_TOP

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword to an integer that specifies the element of the list widget to the positioned at the top of the scrolling list. If the specified element is outside the range of list elements, nothing happens.

## SET\_SLIDER\_MAX

This keyword applies to widgets created with the [WIDGET\\_SLIDER](#) function.

Set this keyword to a new maximum value for the specified slider widget.

---

**Note**

This keyword does not apply to floating-point sliders created with the [CW\\_FSLIDER](#) function.

---

## SET\_SLIDER\_MIN

This keyword applies to widgets created with the [WIDGET\\_SLIDER](#) function.

Set this keyword to a new minimum value for the specified slider widget.

---

**Note**

This keyword does not apply to floating-point sliders created with the [CW\\_FSLIDER](#) function.

---

## SET\_TAB\_CURRENT

This keyword applies to widgets created with the [WIDGET\\_TAB](#) function.

Set this keyword equal to the zero-based index of the tab to be set as the current (visible) tab. If the index value is invalid, the value is quietly ignored.

## SET\_TAB\_MULTILINE

This keyword applies to widgets created with the [WIDGET\\_TAB](#) function.

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and UNIX systems.

### Windows

Set this keyword to cause tabs to be organized in a multi-line display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If `MULTILINE=0` and `LOCATION=0` or `1`, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If `LOCATION=1` or `2`, a multiline display is always used if the tabs exceed the height of the largest child base widget.

### Note

---

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the `MULTILINE` keyword is set.

---

### UNIX

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

**Note**

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. (Tab text may be truncated if the text of a single tab exceeds the space available, however.) This means that if `MULTILINE` is set to any value other than one, some tabs may not be displayed.

## SET\_TABLE\_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` function.

- In standard selection mode, specify a four-element array, of the form `[ left, top, right, bottom ]` specifying the cells to act upon.
- In disjoint selection mode, specify a  $2 \times n$  element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). You can use the value -1 to indicate that IDL should select an entire row or column. For example, to select all of Rows 3 and 4, you can specify either `[-1,3,-1,4]` or `[[[-1,3],[-1,4]]`, depending on the table's selection mode (standard or disjoint, respectively). This method differs from explicitly specifying all the cells of the rows in that IDL also selects the header cells, as if you had clicked on them. To deselect all cells, specify either `[-1,-1,-1,-1]` (in standard selection mode) or `[-1,-1]` (in disjoint selection mode).

See “`USE_TABLE_SELECT`” on page 2585 for details on the selection modes.

If the selected position is not currently on the screen, the table widget automatically moves the current scrolling viewport to make a portion of it visible. The resulting top-left visible cell is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the `SET_TABLE_VIEW` keyword to explicitly set the viewport.

## SET\_TABLE\_VIEW

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to a two-element array of zero-based cell indices that specifies the cell of the table widget to be positioned at the top-left of the widget. If the specified cell is outside the range of valid cells, nothing happens.

## SET\_TEXT\_SELECT

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) and [WIDGET\\_TEXT](#) functions.

Use this keyword to clear any current selection in the specified table cell or text widget, and either set a new selection, or simply set the text insertion point. To set a selection, specify a two-element integer array containing the starting position and the length of the selection. For example, to set a selection covering characters 3 through 23:

```
WIDGET_CONTROL, widgetID, SET_TEXT_SELECT=[3, 20]
```

To move the text insertion point without setting a selection, omit the second element, or set it to zero.

## SET\_TEXT\_TOP\_LINE

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

Set this keyword to the zero-based line number of the line to be positioned on the topmost visible line in the text widget's viewport. No horizontal scrolling is performed. Note that this is a line number, not a character offset.

## SET\_TREE\_BITMAP

This keyword applies to widgets created with the [WIDGET\\_TREE](#) function.

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

Set this keyword equal to zero to revert to the appropriate default system bitmap.

## SET\_TREE\_EXPANDED

This keyword applies to widgets created with the [WIDGET\\_TREE](#) function.

Set this keyword equal to a nonzero value to expand the specified tree widget folder. Set this keyword equal to zero to collapse the specified tree widget folder.

## SET\_TREE\_SELECT

This keyword applies to widgets created with the [WIDGET\\_TREE](#) function.

This keyword has two modes of operation, depending on the widget ID passed to [WIDGET\\_CONTROL](#):

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget):

- If the tree widget is in multiple-selection mode and `SET_TREE_SELECT` is set to an array of widget IDs corresponding to tree widgets that are nodes in the tree, those nodes are selected.
- If the tree widget is *not* in multiple-selection mode and `SET_TREE_SELECT` is set to a single widget ID corresponding to a tree widget that is a node in the tree, that node is selected.
- If the keyword is set to zero, all selections in the tree widget are cleared.
- If the specified widget ID is a tree widget that is a node in a tree:
  - If the keyword is set to a nonzero value, the specified node is selected.
  - If the keyword is set to zero, the specified node is deselected.

---

**Note**

If the tree widget is in multiple-selection mode, the selection changes made to the tree widget via this keyword are additive — that is, the current selections are retained and any additional nodes specified by `SET_TREE_SELECT` are also selected.

---

## SET\_TREE\_VISIBLE

This keyword applies to widgets created with the `WIDGET_TREE` function and whose parent widget was also created using the `WIDGET_TREE` function (that is, tree widgets that are nodes of another tree).

Set this keyword to make the specified tree node *visible* to the user. Setting this keyword has two possible effects:

1. If the specified node is inside a collapsed folder, the folder and all folders above it are expanded to reveal the node.
2. If the specified node is in a portion of the tree that is not currently visible because the tree has scrolled within the parent base widget, the tree view scrolls so that the selected node is at the top of the base widget.

---

**Note**

Use of this keyword does not affect the tree widget selection state.

---

## SET\_UNAME

This keyword applies to all widgets.

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID. You can set the name at creation time, using the UNAME keyword with the creation function.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the FIND\_BY\_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND\_BY\_UNAME keyword returns the ID of the first widget with the specified name.

## SET\_UVALUE

This keyword applies to all widgets.

Each widget can contain a user-set value. This value is not used by IDL in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value.

To improve the efficiency of the data transfer, consider using the NO\_COPY keyword with SET\_UVALUE.

## SET\_VALUE

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#), [WIDGET\\_COMBOBOX](#), [WIDGET\\_DROPLIST](#), [WIDGET\\_LABEL](#), [WIDGET\\_LIST](#), [WIDGET\\_PROPERTY SHEET](#), [WIDGET\\_SLIDER](#), [WIDGET\\_TABLE](#), and [WIDGET\\_TEXT](#) functions.

Sets the value of the specified widget. The meaning of the value differs between widget types:

- Button: The label to be used for the button. This value can be either a scalar string, or a 2D byte array containing a bitmap.
- Combobox: The contents of the combobox widget (string or string array).
- Droplist: The contents of the droplist widget (string or string array).
- Label: The text to be displayed by the label widget.
- List: The contents of the list widget (string or string array).
- Property Sheet: Object references to one or more component objects to be displayed in the property sheet. Any existing associations are lost and the property sheet is reloaded with the new list of properties. To completely clear the property sheet, use a null object reference.
- Slider: The current position of the slider (integer).

- **Table:** Normally, the data for the whole table is changed to the specified data, which must be of the form of a two dimensional array or a vector of structures. In this form, the table is resized to fit the given data (unless the `TABLE_XSIZE` or `TABLE_YSIZE` keywords are given).

If the `USE_TABLE_SELECT` keyword is set, the value given is treated as a subset of the whole data, and only the given range of cells are updated. Used in this form, the type of data stored in the table cannot be changed. The data passed in is converted, as appropriate, to the type of the selected cells. If less data is passed in than fits in the current selection, the cells outside the range of data (but inside the selection) are left unchanged. If more data is passed in than fits in the current selection, the extra data is ignored.

- If the table is in standard selection mode, the data should be a two-dimensional array of values for a single-type table, or a vector of structures for a table that contains structure data.
- If the table is in disjoint selection mode, the data should be a one-dimensional array of values for a single-type table, or a single structure with each field corresponding to a cell for a table that contains structure data.

If the `USE_TEXT_SELECT` keyword is present, the value must be a string, which replaces the currently-selected text in the currently-selected cell.

- **Text:** The text to be displayed. If the `APPEND` keyword is also specified, the text is appended to the current contents instead of completely replacing it (string or string array). If the `USE_TEXT_SELECT` keyword is specified, the new string replaces only the currently-selected text in the text widget.
- Widget types not listed above do not allow the setting of a value. Attempting to set the value of such a widget causes an error.

The value of a widget can also be set with the `VALUE` keyword to the routine that created it.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## SHOW

This keyword applies to all widgets.

Controls the visibility of a widget hierarchy. If set to zero, the hierarchy containing *Widget\_ID* is pushed behind any other windows on the screen. If nonzero, the hierarchy is pulled in front.

## TAB\_MODE

This keyword applies to widgets created with the [WIDGET\\_BASE](#), [WIDGET\\_BUTTON](#), [WIDGET\\_COMBOBOX](#), [WIDGET\\_DROPLIST](#), [WIDGET\\_LIST](#), [WIDGET\\_SLIDER](#), [WIDGET\\_TAB](#), [WIDGET\\_TABLE](#), [WIDGET\\_TEXT](#), [WIDGET\\_TREE](#).

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited at creation time by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

When `WIDGET_CONTROL` is used to change the `TAB_MODE` value, the change affects only the widget upon which it is explicitly set. The change is not propagated along the widget hierarchy after it has been created. The `TAB_MODE` keyword also *cannot* be explicitly set for the following widgets:

- Draw widgets
- Label widgets
- Grouped, exclusive button widgets (radio buttons)
- Menu items or menu bases

Attempting to set `TAB_MODE` on these widgets will generate an error.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default value unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
---	---

1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

After creating the widget hierarchy, you can query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

**TABLE\_BLANK**

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to a nonzero value to cause the specified cells to be blank. Set this keyword equal to zero to cause the specified cells to display values as usual.

**Note**

Hiding cell contents using this keyword is a *display-only operation*. The cell contents are not actually removed from the table, they are simply hidden from view. Any operation that evaluates or changes the value of a cell will operate in the same way on a cell whose contents are hidden as it will on a cell whose contents are visible.

If the `USE_TABLE_SELECT` keyword is set equal to one, the currently selected cells are blanked or restored. If `USE_TABLE_SELECT` is set equal to an array, the specified cells are blanked or restored. If `USE_TABLE_SELECT` is not set, the entire table is hidden or displayed.

**TABLE\_DISJOINT\_SELECTION**

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to enable the ability to select multiple rectangular regions of cells.

## TABLE\_XSIZE

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword equal to the number of data columns in the table widget. Note that if the table widget was created with row titles enabled (that is, if the `NO_HEADERS` or `NO_COLUMN_HEADERS` keywords to `WIDGET_TABLE` were *not* set), the table will contain one column more than the number specified by `TABLE_XSIZE`.

If the table is made smaller as a result of the application of the `TABLE_XSIZE` keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new columns is set according to the following rules:

1. If the table was not created with either the `ROW_MAJOR` or `COLUMN_MAJOR` keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.
2. If the `SET_VALUE` keyword is given, the types of all columns are set according to the new structure.
3. If the table was created with the `ROW_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, the cells in the new columns inherit their type from the cells to their left.
4. <sup>2</sup>If the table was created with the `COLUMN_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, any new columns default to type `INT`.

## TABLE\_YSIZE

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword equal to the number of data rows in the table widget. Note that if the table widget was created with column titles enabled (that is, if the `NO_HEADERS` or `NO_ROW_HEADERS` keywords to `WIDGET_TABLE` were *not* set), the table will contain one row more than the number specified by `TABLE_YSIZE`.

If the table is made smaller as a result of the application of the `TABLE_YSIZE` keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new rows is set according to the following rules:

1. If the table was not created with either the `ROW_MAJOR` or `COLUMN_MAJOR` keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.

2. If the `SET_VALUE` keyword is given, the types of all rows are set according to the new structure.
3. If the table was created with the `COLUMN_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, the cells in the new rows inherit their type from the cells above.
4. If the table was created with the `ROW_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, any new rows default to type `INT`.

## TIMER

This keyword applies to all widgets.

If this keyword is present, a `WIDGET_TIMER` event is generated. Set this keyword to a floating-point value that represents the number of seconds before the timer event arrives. Note that this event is identical to any other widget event except that it contains only the 3 standard event tags. These event structures are defined as:

```
{ WIDGET_TIMER, ID:0L, TOP:0L, HANDLER:0L }
```

It is left to the caller to tell the difference between standard widget events and timer events. The standard way to do this is to use a widget that doesn't normally generate events (e.g., a base or label). Alternately, the `TAG_NAMES` function can be called with the `STRUCTURE_NAME` keyword to differentiate a `WIDGET_TIMER` event from other types of events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
  'WIDGET_TIMER' THEN ...
```

Using the `TIMER` keyword is more efficient than the background task functionality found in the `XMANAGER` procedure because it doesn't "poll" like the original background task code. RSI will eventually eliminate the background task functionality from `XMANAGER`. We encourage all users to modify their code to use the `TIMER` keyword instead.

See "[Timer Events](#)" in Chapter 30 of the *Building IDL Applications* manual for additional details.

## TLB\_GET\_OFFSET

This keyword applies to all widgets.

Set this keyword to a named variable in which the offset of the upper left corner of the top-level base of the specified widget is returned, in units specified by the `UNITS` keyword (pixels are the default). The offset is measured in device coordinates relative to the upper-left corner of the screen.

**Note**

On Windows and Macintosh platforms, the returned position is the upper-left corner of the window *including* border and title bar. On non-Macintosh Motif platforms, the returned position represents the upper-left corner of the window's client area (not including border and titlebar).

**TLB\_GET\_SIZE**

This keyword applies to all widgets.

Set this keyword to a named variable in which the size of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The size is returned as a two-element vector that contains the horizontal and vertical size of the base in device coordinates.

**TLB\_ICONIFY\_EVENTS**

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to make the top-level base return an event when the base is iconified or restored by the user.

**TLB\_KILL\_REQUEST\_EVENTS**

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Use this keyword to set or clear kill request events for the specified top-level base. For more information on these events see "[TLB\\_KILL\\_REQUEST\\_EVENTS](#)" on page 2505.

**TLB\_MOVE\_EVENTS**

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to make the top-level base return an event when the base is moved by the user. Note that if [TLB\\_SIZE\\_EVENTS](#) are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

**TLB\_SET\_TITLE**

This keyword applies to all widgets.

Set this keyword to a scalar string to change the title of the specified top-level base after it has been created.

## TLB\_SET\_XOFFSET

This keyword applies to all widgets.

Use this keyword to set the horizontal position of the top level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

## TLB\_SET\_YOFFSET

This keyword applies to all widgets.

Use this keyword to set the vertical position of the top-level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

## TLB\_SIZE\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to make the top-level base return an event when the base is resized by the user. Note that if [TLB\\_MOVE\\_EVENTS](#) are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

## TOOLTIP

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#) and [WIDGET\\_DRAW](#) functions.

Set this keyword to a string that will be displayed when the cursor hovers over the specified widget. For UNIX platforms, this string must be non-zero in length, which means that a tooltip can be modified but not be removed on UNIX versions of IDL.

---

**Note**

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

---

---

**Note**

If your application uses hardware rendering and a [RETAIN](#) setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

---

**Note**

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## TRACKING\_EVENTS

This keyword applies to all widgets.

Set this keyword to a non-zero value to enable tracking events for the widget specified by *Widget\_ID*. Set the keyword to 0 to disable tracking events for the specified widget. For a description of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for WIDGET\_BASE.

## UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET\_INFO.

**Note**

---

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to [WIDGET\\_LIST](#), [WIDGET\\_TABLE](#), or [WIDGET\\_TEXT](#) functions.

---

## UPDATE

This keyword applies to all widgets.

Use this keyword to enable (if set to 1) or disable (if set to 0) screen updates for the widget hierarchy to which the specified widget belongs. This keyword is useful for preventing unwanted intermediate screen updates when changing the values of many widgets at once or when adding several widgets to a previously-realized widget hierarchy. When first realized, widget hierarchies are set to update.

**Note**

---

Although this keyword is legal for any widget, it affects every widget in the hierarchy defined for the specified widget’s top-level base widget. In other words,

setting UPDATE on a particular widget is equivalent to setting UPDATE on the top-level base widget that is at the top of the specified widget's hierarchy.

---

**Warning**

Do not attempt to resize a widget on the Windows platform while UPDATE is turned off. Doing so may prevent IDL from updating the screen properly when UPDATE is turned back on.

---

See “[Preventing Layout Flicker](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## USE\_TABLE\_SELECT

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to modify the behavior of the [ALIGNMENT](#), [BACKGROUND\\_COLOR](#), [COLUMN\\_WIDTHS](#), [DELETE\\_COLUMNS](#), [DELETE\\_ROWS](#), [EDITABLE](#), [FONT](#), [FOREGROUND\\_COLOR](#), [FORMAT](#), [GET\\_VALUE](#), [INSERT\\_COLUMNS](#), [INSERT\\_ROWS](#), [ROW\\_HEIGHTS](#), [SET\\_VALUE](#), and [TABLE\\_BLANK](#) keywords. If USE\_TABLE\_SELECT is set, these other keywords apply only to the currently selected cells. Normally, these keywords apply to the entire contents of a table widget.

---

**Note**

If either the header row or the header column of the table is selected, this keyword modifies the behavior of only the [ROW\\_HEIGHTS](#) or [COLUMN\\_WIDTHS](#) keywords.

---

---

**Note**

The Microsoft Windows platforms support the [ROW\\_HEIGHTS](#) keyword with the limitation that all rows have the same height. If you supply an array of values, IDL uses the last value for all rows.

---

### Selection Modes

The table widget supports two *selection modes*:

- In *standard selection mode*, only a single selection can be created at a given time. Creating a new selection causes the existing selection to disappear.
- In *disjoint selection mode*, multiple selections can be created at one time. Creating a new selection does not cause the existing selection(s) to disappear. A table can be created in disjoint selection mode using either the

`DISJOINT_SELECTION` keyword to `WIDGET_TABLE` or the `TABLE_DISJOINT_SELECTION` keyword to `WIDGET_CONTROL`.

The keywords listed above generate different output or expect different input based on the selection mode. See the description of each keyword for details. For more information on table selection modes, see “[Selection Modes](#)” in Chapter 30 of the *Building IDL Applications* manual

### Specifying Selections Programmatically

In many cases, your code will use a selection created by the user manually, with the mouse. You can also create selections programmatically, by setting `USE_TABLE_SELECT` equal to an array.

- In standard selection mode, specify a four-element array, of the form [ *left*, *top*, *right*, *bottom* ] specifying the rectangle of cells to act upon.
- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). You can specify row and column headers by using -1 in the index. Row header cells are indexed by using -1 for the column; column header cells are indexed by using -1 for the row. Ranges can span header cells and value cells.

#### Note

---

Setting `USE_TABLE_SELECT` equal to an array does *not* change the current table selection. Operations affect the specified cells without changing the current selection. To change the current table selection, use `SET_TABLE_SELECT`.

---

### Example

To change the column widths of the title column and the first five data columns of a table widget named `wTable`, leaving the widths of the other columns unchanged:

```
WIDGET_CONTROL, wTable, USE_TABLE_SELECT=[-1,0,4,0], $
    COLUMN_WIDTHS=50
```

This command is equivalent to first calling `WIDGET_CONTROL` and setting the `SET_TABLE_SELECT` keyword equal to an array, and then calling `WIDGET_CONTROL` with `USE_TABLE_SELECT` set equal to one. Please note that the command might change your selection.

For additional examples, see “[Using Table Widgets](#)” in Chapter 30 of the *Building IDL Applications* manual.

## USE\_TEXT\_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` and `WIDGET_TEXT` functions.

Set this keyword to modify the behavior of the `GET_VALUE` and `SET_VALUE` keywords. If `USE_TEXT_SELECT` is set, `GET_VALUE` and `SET_VALUE` apply only to the current text selection. Normally, these keywords apply to the entire contents of a text widget.

### Warning

---

If the target widget is a table, the selected cell must be in *edit mode* for `WIDGET_CONTROL` to return the selected text. (A table cell can be selected without being in edit mode; see “Using Table Widgets” in Chapter 30 of the *Building IDL Applications* manual for a discussion of the table widget’s edit mode.) In most cases, to retrieve the value of a table cell, use the `USE_TABLE_SELECT` keyword rather than `USE_TEXT_SELECT`.

---

## X\_BITMAP\_EXTRA

This keyword applies to widgets created with the `WIDGET_BUTTON` function.

When the value of a button widget is a bitmap, the usual width is taken to be 8 times the number of columns in the source byte array. This keyword can be used to indicate the number of bits in the last byte of each row that should be ignored. The value can range between 0 and 7.

## XOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget’s new horizontal offset, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a `ROW` or `COLUMN` base or a widget that is part of a menubar or pulldown menu causes an error.

## XSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget’s new horizontal size.

- Text and List widgets: Size is specified in characters. The `UNITS` keyword is ignored.

- Table widgets: Size is specified in columns. The width of the row labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR\_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw widgets), this keyword adjusts the *viewport* size. Use the DRAW\_XSIZE keyword to change the width of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

See “[Widget Sizing](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## YOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget’s new vertical offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

## YSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget’s new vertical size

- Text and List widgets: Size is specified in lines. The UNITS keyword is ignored.
- Table widgets: Size is specified in rows. The height of the column labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR\_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw and table widgets), this keyword adjusts the *viewport* size. Use the DRAW\_YSIZE keyword to change the height of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

See “[Widget Sizing](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## Version History

Pre-4.0	Introduced
5.6	Added COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DRAW_KEYBOARD_EVENTS, SET_BUTTON, SET_COMBOBOX_SELECT, SET_TAB_CURRENT, SET_TAB_MULTILINE, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP keywords
6.0	Added PUSHBUTTON_EVENTS and REFRESH PROPERTY keywords
6.1	Added EDITABLE, MULTIPLE_PROPERTIES, PROPERTYSHEET_SETSELECTED, and TAB_MODE keywords
6.2	Added BACKGROUND_COLOR, DRAW_WHEEL_EVENTS, FONT, FOREGROUND_COLOR, and IGNORE_ACCELERATORS keywords  Deprecated CANCEL_BUTTON and DEFAULT_BUTTON keywords

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## See Also

[Chapter 30, “Widget Application Techniques”](#) in the *Building IDL Applications* manual.

# WIDGET\_DISPLAYCONTEXTMENU

The `WIDGET_DISPLAYCONTEXTMENU` procedure displays a *context-sensitive menu* (also known as a *pop-up* or *shortcut* menu). Context-sensitive menus appear when the user clicks the right mouse button over a widget for which a context menu is defined. Because the widget programmer must explicitly detect the right-mouse button click and call `WIDGET_DISPLAYCONTEXTMENU` to display the context menu, a widget can have any number of associated context menus, which can be displayed under different circumstances.

Context menus are created by placing one or more button widgets on a base widget constructed with the `CONTEXT_MENU` keyword set. The context menu's base widget must have as its parent a base, draw, list, property sheet, table, tree or text widget; in the case of all but draw widgets, the parent widget must be configured to generate context menu events via the `CONTEXT_EVENTS` keyword. Draw widgets that support context menus must have the `BUTTON_EVENTS` keyword set.

The widget application's event handler routine must detect the presence of a context menu event (base, list, and text widgets) or the right mouse-button event (draw and property sheet widgets) and call `WIDGET_DISPLAYCONTEXTMENU` to display the context menu. Events generated when the user clicks on the context menu's buttons are handled in the normal way. If the user clicks outside the context menu, it is dismissed and no event is generated.

## Syntax

`WIDGET_DISPLAYCONTEXTMENU, Parent, X, Y, ContextBase_ID`

## Arguments

### Parent

The widget ID of the parent widget of the context menu widget.

### Note

---

The parent widget must be either a base, list, or text widget with the `CONTEXT_EVENTS` keyword set or a draw widget with the `BUTTON_EVENTS` keyword set. In most cases the parent widget can be identified via the `ID` field of the `WIDGET_CONTEXT` or `WIDGET_DRAW` event structure.

---

## X

The x location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the x location of the user's right mouse-button click, as reported in the X field of the WIDGET\_CONTEXT or WIDGET\_DRAW event structure.)

## Y

The y location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the y location of the user's right mouse-button click, as reported in the Y field of the WIDGET\_CONTEXT or WIDGET\_DRAW event structure.)

## ContextBase\_ID

The widget ID of the context menu base widget that contains the context menu to be displayed. Use the CONTEXT\_MENU keyword to WIDGET\_BASE to create a context menu base.

### Note

---

The context menu base must be a child of the widget specified by the *Parent* argument.

---

## Keywords

None

## Examples

For examples using WIDGET\_DISPLAYCONTEXTMENU, see [“Context-Sensitive Menus”](#) in Chapter 30 of the *Building IDL Applications* manual.

# WIDGET\_DRAW

The `WIDGET_DRAW` function is used to create draw widgets. Draw widgets are rectangular areas that IDL treats as standard graphics windows. Draw widgets can use either IDL Direct graphics or IDL Object graphics, depending on the value of the `GRAPHICS_LEVEL` keyword. Any graphical output that can be produced by IDL, either through the `WSET` function or by using the object reference of a draw widget's `IDLgrWindow` object, can be directed to a draw widget. Draw widgets can have optional scroll bars to allow viewing a larger graphics area than could otherwise be displayed in the widget's visible area.

Figure 3-142: A Draw Widget

## Note

On some systems, when backing store is provided by the window system (`RETAIN=1`), reading data from a window using `TVRD()` may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (`RETAIN=2`) ensures that the window contents will be read properly.

For a more detailed discussion of the draw widget, along with examples, see “[Using Draw Widgets](#)” in Chapter 30 of the *Building IDL Applications* manual.

## Syntax

```
Result = WIDGET_DRAW(Parent [, /APP_SCROLL] [, /BUTTON_EVENTS]
  [, CLASSNAME=string] [, /COLOR_MODEL] [, COLORS=integer]
  [, EVENT_FUNC=string] [, EVENT_PRO=string] [, /EXPOSE_EVENTS]
  [, FRAME=width] [, FUNC_GET_VALUE=string] [, GRAPHICS_LEVEL=2]
  [, GROUP_LEADER=widget_id]
  [, IGNORE_ACCELERATORS=value][, KEYBOARD_EVENTS={1 | 2}]
```

```
[, KILL_NOTIFY=string] [, /MOTION_EVENTS] [, /NO_COPY]
[, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
[, RENDERER={0 | 1}] [, RESOURCE_NAME=string] [, RETAIN={0 | 1 | 2}]
[, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SCROLL] [, /SENSITIVE]
[, TOOLTIP=string] [, /TRACKING_EVENTS] [, UNAME=string]
[, UNITS={0 | 1 | 2}] [, UVALUE=value] [, /VIEWPORT_EVENTS]
[, /WHEEL_EVENTS] [, XOFFSET=value] [, XSIZE=value]
[, X_SCROLL_SIZE=width] [, YOFFSET=value] [, YSIZE=value]
[, Y_SCROLL_SIZE=height] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created draw widget.

## Arguments

### Parent

The widget ID of the parent widget of the new draw widget.

## Keywords

### APP\_SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

The drawable area of a draw widget created with the APP\_SCROLL keyword is the same size as the viewable area (the *viewport*). This is useful for displaying very large images, because the memory used by a draw widget is directly related to the size of the drawable area. A draw widget created with the APP\_SCROLL keyword also has the concept of a *virtual drawable area*, which is the size of the entire image. The fact that only a portion of the entire image is held in memory means that you must capture events generated when the user adjusts the scroll bars and display the correct portion of the image in your event-handling code.

**Note**

If the image you are displaying is relatively small or memory is not a concern, consider using the `SCROLL` keyword rather than `APP_SCROLL`. With `SCROLL`, the drawable area is the size of the entire image; this allows IDL to display the appropriate portions of the image automatically when the user adjusts the scroll bars. See [“SCROLL”](#) on page 2600 and [“Scrolling Draw Widgets”](#) in Chapter 30 of the *Building IDL Applications* manual for details.

Specify the size of the viewport using the `X_SCROLL_SIZE` and `Y_SCROLL_SIZE` keywords, and the size of the virtual drawable area using the `XSIZE` and `YSIZE` keywords. If `APP_SCROLL` is set, the application generates viewport events even if the `VIEWPORT_EVENTS` keyword is not set.

If the drawable area uses Direct Graphics (that is, if `GRAPHICS_LEVEL` is *not* set equal to 2), system backing store is used by default and the viewport is automatically restored after it has been obscured. If you prefer to manually restore the viewport in an event-handling routine, set `RETAIN=0` and `EXPOSE_EVENTS=1`; this allows you to redraw the virtual canvas when your application receives expose events.

If the drawable area uses Object Graphics (that is, if the `GRAPHICS_LEVEL` keyword is set equal to 2), the application will *not* automatically restore the viewport, and will generate expose events as if `RETAIN=0` and `EXPOSE_EVENTS=1` had been set.

**BUTTON\_EVENTS**

Set this keyword to make the draw widget generate events when the mouse buttons are pressed or released (and the mouse pointer is in the draw widget). Normally, draw widgets do not generate events.

You can use the event structure generated when the `BUTTON_EVENTS` keyword is set to emulate the functionality of the `CONTEXT_EVENTS` keyword to `WIDGET_BASE`, `WIDGET_LIST`, and `WIDGET_TEXT`. To determine whether the user clicked the right mouse button, use the test:

```
IF (event.release EQ 4)
```

where `event` holds the widget event structure.

For more on detecting and handling context menu events, see [“Context-Sensitive Menus”](#) in Chapter 30 of the *Building IDL Applications* manual.

## CLASSNAME

### Note

---

This keyword is honored only if the [GRAPHICS\\_LEVEL](#) keyword is set to 2.

---

Set this keyword to a string containing the name of the window object class to be instantiated and associated with this draw widget. Possible values are:

- IDLgrWindow
- IDLitWindow

The default is IDLgrWindow. If the application needs to process IDLitWindow events (timer events for controlling animations, for example), consider using the IDLitWindow class instead. See [Chapter 10, “Animating Objects”](#) in the *Object Programming* manual for additional information.

## COLOR\_MODEL

Set this keyword equal to 1 (one) to cause the draw widget’s associated IDLgrWindow object to use indexed color. If the COLOR\_MODEL keyword is not set, or is set to a value other than one, the draw widget will use RGB color.

This keyword is only valid when the draw widget uses IDL Object Graphics. (The graphics type used by a draw widget is determined by setting the [GRAPHICS\\_LEVEL](#) keyword to WIDGET\_DRAW.)

## COLORS

The maximum number of color table indices to be used. This parameter has effect *only* if it is supplied when the *first* IDL graphics window is created.

If COLORS is not specified when the first window is created, all or most of the available color indices are allocated, depending upon the window system in use.

To use monochrome windows on a color display, set COLORS equal to 2 when creating the first window. One color table is maintained for all IDL windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be used.

## EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EXPOSE\_EVENTS

Set this keyword to make the draw widget generate event when the visibility of the draw widget changes. This may occur when the widget is hidden behind something else on the screen, brought to the foreground, or when the scroll bars are moved. Normally, draw widgets do not generate events.

If this keyword is set, expose events will be generated only when IDL is unable to restore the contents of the window itself. After the initial draw, expose events are not issued when `GRAPHICS_LEVEL=2` and the software renderer is being used (`RENDERER=1`). In such cases, expose events are not issued because IDL can internally refresh the window itself. On platforms for which OpenGL support is not offered, the software renderer is always being used, and therefore, expose events are not issued after the initial draw.

### Note

---

When using hardware rendering, you must explicitly disable backing store (by setting `RETAIN=0`) in order to generate expose events. Additional expose events may be generated if both `EXPOSE_EVENTS` and `RETAIN=1` are turned on.

---

### Warning

---

Large numbers of events may be generated when `EXPOSE_EVENTS` is specified. You may wish to compress the events (perhaps using a timer) and only act on a subset.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GRAPHICS\_LEVEL

Set this keyword equal to 2 (two) to use IDL Object Graphics in the draw widget. If the GRAPHICS\_LEVEL keyword is not set, or is set to a value other than two, the draw widget will use IDL Direct Graphics.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET\_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## IGNORE\_ACCELERATORS

Set this keyword to specify what WIDGET\_BUTTON accelerators are to be ignored when this draw widget has keyboard focus. Setting IGNORE\_ACCELERATORS allows a defined list of accelerators to be processed by the draw widget instead of by the conflicting accelerated button. Valid values are:

- A string or string array containing any value that is legal for WIDGET\_BUTTON’s [ACCELERATOR](#) keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Setting IGNORE\_ACCELERATORS allows a defined list of accelerators to be processed by the draw widget instead of by associated buttons or menu items. Once the draw widget loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## KEYBOARD\_EVENTS

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the CH or the KEY field of the

event structure, depending on the type of key pressed. See [“Widget Events Returned by Draw Widgets”](#) on page 2605 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the MODIFIERS field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the KEY field of the event structure, and the MODIFIERS field contains zero.

---

**Note**

Keyboard events are never generated for function keys.

---

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET\_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET\_EVENT function is called.

## MOTION\_EVENTS

Set this keyword to make the draw widget generate events when the mouse cursor moves across the widget. Normally, draw widgets do not generate events.

Draw widgets that return motion events can generate a large number of events that can result in poor performance on slower machines.

Note that it is possible to generate motion events with coordinates outside the draw widget. If you position the mouse cursor inside the draw widget, press the mouse button, and drag the cursor out of the draw widget, the X and Y fields of the widget event will specify coordinates outside the draw widget.

See [“Button, Motion, Wheel, and Keyboard Events”](#) in Chapter 30 of the *Building IDL Applications* manual for more information.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_DRAW` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL’s software implementation

By default, your platform’s native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL’s software implementation is used regardless of the value of this property. See [“Hardware vs. Software Rendering”](#)

in Chapter 12 of the *Object Programming* manual for details. Your choice of renderer may also affect the maximum size of a draw widget. See “[IDLgrWindow](#)” on page 4564 for details.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the draw widget. RETAIN=0 specifies no backing store. RETAIN=1 requests that the server or window system provide backing store. RETAIN=2 specifies that IDL provide backing store directly. See “[Backing Store](#)” on page 2610 for details on the use of RETAIN with Direct Graphics. For more information on the use of RETAIN with Object Graphics, see “[IDLgrWindow::Init](#)” on page 4596.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

Specify the dimensions of the viewport using the X\_SCROLL\_SIZE and Y\_SCROLL\_SIZE keywords, and the dimensions of the entire drawable area using the XSIZE and YSIZE keywords. A scrollbar will be added if the viewport dimension is smaller than the corresponding dimension of the drawable area.

**Note**

---

While the viewport of a draw widget created with the `SCROLL` keyword may be smaller than the entire image, the drawable area itself is the same size as the image, and uses memory commensurately. If you want to display a portion of a very large image, consider using the `APP_SCROLL` keyword rather than `SCROLL`. The drawable area of a draw widget created with `APP_SCROLL` is the same size as the viewport. This saves memory when the displayed image is large, but requires extra work on the programmer's part to handle viewport events and display the appropriate portion of the image. See "[APP\\_SCROLL](#)" on page 2593 and "[Scrolling Draw Widgets](#)" in Chapter 30 of the *Building IDL Applications* manual for details.

---

**SENSITIVE**

Set this keyword to control the initial sensitivity state of the widget.

If `SENSITIVE` is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the `SENSITIVE` keyword with the [WIDGET\\_CONTROL](#) procedure.

**TOOLTIP**

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

**Note**

---

If your application uses hardware rendering and a `RETAIN` setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for WIDGET\_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the [FIND\\_BY\\_UNAME](#) keyword. The UNAME should be unique to the widget hierarchy because the [FIND\\_BY\\_UNAME](#) keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by [WIDGET\\_INFO](#).

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VIEWPORT\_EVENTS

Set this keyword to enable viewport motion events for draw widgets.

## WHEEL\_EVENTS

Set this keyword to enable mouse scroll wheel events, which are disabled by default. An event is generated when scroll wheel events are enabled, the widget has the focus, and the user rolls the scroll wheel. This event reports the scroll direction and distance, current mouse coordinates, and modifier keys. See “[Widget Events Returned by Draw Widgets](#)” on page 2605 for more information.

When wheel events are not enabled, rolling the scroll wheel affects the vertical scroll bar, if present.

### Note

---

This keyword is operational only under Microsoft Windows and is quietly ignored under Motif.

---

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

## X\_SCROLL\_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X\_SCROLL\_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the X\_SCROLL\_SIZE keyword implies SCROLL.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

## Y\_SCROLL\_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y\_SCROLL\_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the Y\_SCROLL\_SIZE keyword implies SCROLL.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of draw widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DRAW\\_BUTTON\\_EVENTS](#), [DRAW\\_EXPOSE\\_EVENTS](#), [DRAW\\_KEYBOARD\\_EVENTS](#), [DRAW\\_MOTION\\_EVENTS](#), [DRAW\\_VIEWPORT\\_EVENTS](#), [DRAW\\_WHEEL\\_EVENTS](#), [DRAW\\_XSIZE](#), [DRAW\\_YSIZE](#), [GET\\_DRAW\\_VIEW](#), [GET\\_VALUE](#), [IGNORE\\_ACCELERATORS](#), [INPUT\\_FOCUS](#), [SET\\_DRAW\\_VIEW](#), [TOOLTIP](#).

## Keywords to WIDGET\_INFO

A number of keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to draw widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [DRAW\\_BUTTON\\_EVENTS](#), [DRAW\\_EXPOSE\\_EVENTS](#), [DRAW\\_KEYBOARD\\_EVENTS](#),

[DRAW\\_MOTION\\_EVENTS](#), [DRAW\\_VIEWPORT\\_EVENTS](#),  
[DRAW\\_WHEEL\\_EVENTS](#), [STRING\\_SIZE](#), [TOOLTIP](#).

## Widget Events Returned by Draw Widgets

By default, draw widgets do not generate events. If the [BUTTON\\_EVENTS](#) keyword is set when the widget is created, pressing or releasing any mouse button while the mouse cursor is over the draw widget causes events to be generated. Specifying the [MOTION\\_EVENTS](#) keyword causes events to be generated *continuously* as the mouse cursor moves across the draw widget. Specifying the [EXPOSE\\_EVENTS](#) keyword causes events to be generated whenever the visibility of any portion of the draw window (or viewport) changes. Specifying the [KEYBOARD\\_EVENTS](#) keyword causes events to be generated when the draw widget has keyboard focus and a keyboard key is pressed. Specifying the [WHEEL\\_EVENTS](#) keyword causes events to be generated when the draw widget has focus and the scroll wheel is rolled.

---

### Note

For an example using motion events with `WIDGET_DRAW`, see “[Button, Motion, Wheel, and Keyboard Events](#)” in Chapter 30 of the *Building IDL Applications* manual.

---

The event structure returned by the `WIDGET_EVENT` function is defined by the following statement:

```
{WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
    PRESS:0B, RELEASE:0B, CLICKS:0L, MODIFIERS:0L, CH:0B, KEY:0L }
```

---

### Note

If you defined your own `{WIDGET_DRAW}` structures prior to the IDL 5.3 release before the structure was defined by an internal call, the `MODIFIERS` field will break the existing user code.

---

---

### Note

If you defined your own `{WIDGET_DRAW}` structures prior to the IDL 5.6 release before the structure was defined by an internal call, the `CH` and `KEY` fields will break the existing user code.

---

ID, TOP, and HANDLER are the three standard fields found in every widget event. TYPE returns a value that describes the type of draw widget interaction that generated an event. The values for TYPE are shown in the table below.

0	Button press
1	Button release
2	Motion
3	Viewport moved (scrollbars)
4	Visibility changed (exposed)
5	Key press (ASCII character value reported in CH field)
6	Key press (non-ASCII key value reported in KEY field)
7	Wheel scroll

The X and Y fields give the device coordinates at which the event occurred, measured from the lower left corner of the drawing area.

For button and “viewport moved” events (that is, when the TYPE field contains 0, 1, or 3), the PRESS and RELEASE fields report which of the left, center, or right mouse button was pressed:

Value	Mouse Button
1	Left
2	Middle
4	Right

*Table 3-127: Possible values of the PRESS and RELEASE Fields During Button Events*

**Note**

See “[Note on Middle Mouse Button Emulation](#)” on page 2609 for important information on middle mouse button events.

For motion and wheel events, both PRESS and RELEASE are zero. For keyboard events, PRESS contains 1 (one) if the key is down and 0 (zero) if it is up; RELEASE contains 0 (zero) if the key is down and 1 (one) if it is up.

**Note**

IDL obtains information about which mouse button was pressed from the operating system, not from the mouse hardware itself. This means that if the operating system or some extension thereof remaps the mouse buttons, IDL may receive information that one button was pressed even if a different physical button was pressed. For example, if a user remaps the mouse buttons to reverse left and right, and then presses the right physical mouse button, the widget event structure will reflect a left mouse button press.

The CLICKS field has one of three possible sets of values:

- If the event is a button press, the field is set to either 1 or 2. If the time interval between two button-press events is less than the time interval for a double-click event for the platform, the CLICKS field returns 2. If the time interval between button-press events is greater than the time interval for a double-click event for the platform, the CLICKS field returns 1. This means that if you are writing a widget application that requires the user to double-click on a draw widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.
- If the event is a wheel scroll, the field indicates the direction and distance that the wheel was rolled. Forward movement gives a positive value; backward movement gives a negative value. Normally the value is 1 or -1, but other values are possible if the user scrolls quickly.
- If the event is not a button-press or wheel event, the CLICKS field contains a 0.

The MODIFIERS field is valid for button press, button release, motion, wheel, and “normal” keyboard events. It is a bitmask which returns the current state of several keyboard modifier keys at the time the event was generated. If a bit is zero, the key is up. If the bit is set, the key is depressed.

**Note**

“Normal” keyboard events are generated when the `KEYBOARD_EVENTS` keyword is set equal to one. If `KEYBOARD_EVENTS` is set equal to two, the key-press event for a modifier key contains zero in the `MODIFIERS` field and the key value is reported in the `KEY` field; see below.

The value in the `MODIFIERS` field is generated by OR-ing the following values together if a key is depressed.

Bitmask	Modifier Key
1	Shift
2	Control (see “ <a href="#">Note on Middle Mouse Button Emulation</a> ” on page 2609)
4	Caps Lock
8	Alt (see the note following this table)

*Table 3-128: Bitmask for the MODIFIERS Field*

**Note**

Under UNIX, the **Alt** key is the currently mapped `MOD1` key.

Keyboard events are generated with the value of the `TYPE` field equal to 5 or 6. If the event was generated by an ASCII keyboard character, the `TYPE` field will be set to 5 and the ASCII value of the key will be returned in the `CH` field. (Note that ASCII values can be converted to the string representing the character using the `IDL STRING` routine.) If the event was generated due to a non-ASCII keyboard character, the type of the event will be set to 6 and a numeric value representing the key will be returned in the `KEY` field. The following table lists the possible values of the `KEY` field.

Note that for the key values reported in the **KEY** field for the **Shift**, **Control**, **Caps Lock**, and **Alt** keys are not the same as those reported in the **MODIFIER** field bit mask, since the **KEY** field is not a bitmask.

Key Field Value	Keyboard Key
1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

*Table 3-129: Modifier Key Values Reported in the KEY field*

### Note on Middle Mouse Button Emulation

When a user holds down the **Control** key and presses the left mouse button within a draw widget, IDL emulates a middle mouse button press. This means that the event structure generated will have the **PRESS** field set to 2 (middle button) and the **MODIFIERS** field set to 0 (no modifier). IDL will never generate an event with **PRESS** set to 1 (left button) and **MODIFIERS** set to 2 (control).

### Note on using CURSOR

Note that the **CURSOR** procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, examine the **X**, **Y**, **PRESS**, and **RELEASE** fields in the structures returned by the draw widget in response to cursor events.

## Backing Store

Draw widgets with scroll bars rely on backing store to repaint the visible area of the window as it is moved. Their performance is best on systems that provide backing store. However, if your system does not automatically provide backing store, you can make IDL supply it with the statement:

```
DEVICE, RETAIN=2
```

or by using the RETAIN keyword to WIDGET\_DRAW.

### Note

If you are using graphics acceleration, you may wish to turn off backing store entirely and enable expose events (via the EXPOSE\_EVENTS keyword) and redraw the draw widget's contents manually. However, because the number of events generated may be quite high, you might want to enable a timer as well and only redraw the draw widget periodically.

## Version History

Pre-4.0	Introduced
5.6	Added KEYBOARD_EVENTS and TOOLTIP keywords
6.1	Added IGNORE_ACCELERATORS keyword
6.2	Added CLASSNAME and WHEEL_EVENTS keywords

# WIDGET\_DROPLIST

The `WIDGET_DROPLIST` function creates “droplist” widgets, which display a single entry from a list of options. A droplist widget displays a text field and an arrow button. Selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently selected option. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

Figure 3-143: A Droplist Widget

---

## Note

The `WIDGET_COMBOBOX` function creates a similar widget that optionally allows users to edit the text displayed by the droplist. The combobox widget is intended to replace the droplist widget; RSI recommends that new code use `WIDGET_COMBOBOX` rather than `WIDGET_DROPLIST`.

---

## Note

The appearance of the droplist widget differs on Motif and Windows platforms. Under Windows, the droplist widget looks the same as the `ComboBox` widget; under Motif, it appears as shown in the figure above.

---

## Syntax

```
Result = WIDGET_DROPLIST( Parent [, /DYNAMIC_RESIZE]
    [, EVENT_FUNC=string] [, EVENT_PRO=string] [, FONT=string]
    [, FRAME=value] [, FUNC_GET_VALUE=string]
    [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string] [, /NO_COPY]
```

```
[, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
[, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
[, /SENSITIVE] [, TAB_MODE=value] [, TITLE=string]
[, /TRACKING_EVENTS] [, UNAME=string] [, UNITS={0 | 1 | 2}]
[, UVALUE=value] [, VALUE=value] [, XOFFSET=value] [, XSIZE=value]
[, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created droplist widget.

## Arguments

### Parent

The widget ID of the parent widget for the new droplist widget.

## Keywords

### DYNAMIC\_RESIZE

#### Note

---

This keyword is quietly ignored under UNIX. On UNIX systems, droplists do not change their size after being realized.

---

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR\_XSIZE, SCR\_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

### EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

### Note

---

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_DROPLIST` or the `SET_UVALUE` keyword to [WIDGET\\_CONTROL](#)), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to [WIDGET\\_CONTROL](#)), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the [WIDGET\\_CONTROL](#) procedure is called for this widget. See the description of the `PRO_SET_VALUE` keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

Once a WIDGET\_DROPLIST widget receives focus through tabbing, additional navigation capabilities depend upon the platform as follows:

- On Windows – droplist widgets can receive and lose focus through tabbing.
- On UNIX — the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET\\_CONTROL](#) procedure’s TAB\_MODE keyword, or query a widget’s support for tabbing using the [WIDGET\\_INFO](#) procedure’s TAB\_MODE keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

**TITLE**

Set this keyword to a string to be used as the title for the droplist widget.

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“TRACKING\\_EVENTS”](#) on page 2506 in the documentation for WIDGET\_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the [FIND\\_BY\\_UNAME](#) keyword. The UNAME should be unique to the widget hierarchy because the [FIND\\_BY\\_UNAME](#) keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by [WIDGET\\_INFO](#).

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a droplist widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The desired width of the droplist widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of droplist widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DYNAMIC\\_RESIZE](#), [GET\\_VALUE](#), [SET\\_DROPLIST\\_SELECT](#), [SET\\_VALUE](#).

## Keywords to WIDGET\_INFO

A number of keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to droplist widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [DROPLIST\\_NUMBER](#), [DROPLIST\\_SELECT](#), [DYNAMIC\\_RESIZE](#), [STRING\\_SIZE](#).

## Widget Events Returned by Droplist Widgets

Pressing the mouse button while the mouse cursor is over an element of a droplist widget causes the widget to change the label on the droplist button and to generate an event. The event structure returned by the [WIDGET\\_EVENT](#) function is defined by the following statement:

```
{ WIDGET_DROPLIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L }
```

The first three fields are the standard fields found in every widget event. [INDEX](#) returns the index of the selected item. This can be used to index the array of names originally used to set the widget’s value.

---

### Note

Platform-specific UI toolkits behave differently if a droplist widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

---

## Version History

4.0	Introduced
6.1	Added TAB_MODE keyword

# WIDGET\_EVENT

The `WIDGET_EVENT` function returns events for the widget hierarchy rooted at `Widget_ID`. Widgets communicate information by generating events. Events are generated when a button is pressed, a slider position is changed, and so forth.

---

**Note**

Widget applications should use the `XMANAGER` procedure in preference to calling `WIDGET_EVENT` directly. See “[Widget Event Processing](#)” in Chapter 28 of the *Building IDL Applications* manual.

---

## Event Processing

Events for a given widget are processed in the order that they are generated. The event processing performed by `WIDGET_EVENT` consists of the following steps, applied iteratively:

1. Wait for an event from one of the specified widgets to arrive.
2. Starting with the widget that generated the event, move up the widget hierarchy looking for a widget that has an associated event-handling procedure or function. Event-handling routines are associated with a widget via the `EVENT_PRO` and `EVENT_FUNC` keywords to the widget creation functions or the `WIDGET_CONTROL` procedure.
3. If an event-handling *procedure* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling procedure. When the procedure returns, `WIDGET_EVENT` returns to the first step above and starts searching for events. Hence, event-handling procedures are said to “swallow” events.
4. If an event-handling *function* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling function.

When the function returns, its value is examined. If the value is not a structure, it is discarded and `WIDGET_EVENT` returns to the first step. This behavior allows event-handling functions to selectively act like event-handling procedures and “swallow” events.

If the returned value is a structure, it is checked to ensure that it has the standard first three fields: `ID`, `TOP`, and `HANDLER`. If any of these fields is missing, IDL issues an error. Otherwise, the returned value replaces the event found in the first step and `WIDGET_EVENT` continues moving up the widget

hierarchy looking for another event handler routine, as described in step 2, above.

In situations where an event structure is returned, event functions are said to “rewrite” events. This ability to rewrite events is the basis of *compound widgets*, which combine several widgets to give the appearance of a single, more complicated widget. Compound widgets are an important widget programming concept. For more information, see “[Creating a Compound Widget](#)” in Chapter 28 of the *Building IDL Applications* manual.

5. If an event reaches the top of a widget hierarchy without being swallowed by an event handler, it is returned as the value of `WIDGET_EVENT`.
6. If `WIDGET_EVENT` was called without an argument, and there are no widgets left on the screen that are being managed (as specified via the `MANAGED` keyword to the `WIDGET_CONTROL` procedure) and could generate events, `WIDGET_EVENT` ends the search and returns an *empty event* (a standard widget event structure with the top three fields set to zero).

---

#### Note

Do not interrupt the event loop by placing a `STOP` or `EXIT` command in the event-handler or other callback routine. The presence of either command will cause the widget routine to exit with an error.

---

## Syntax

```
Result = WIDGET_EVENT([Widget_ID]) [, BAD_ID=variable] [, /NOWAIT]
      [, /SAVE_HOURLASS]
```

**UNIX Keywords:** [, /YIELD\_TO\_TTY]

## Return Value

A widget event is returned in a structure. The exact contents of this structure vary depending upon the type of widget involved. The first three elements of this structure, however, are always the same.

```
{ WIDGET, ID:0L, TOP:0L, HANDLER:0L, ... }
```

Any other elements vary from widget type to type. The three fixed elements are:

Value	Meaning
ID	The widget ID of the widget that generated the event.
TOP	The widget ID of the top level base for the widget hierarchy containing ID.
HANDLER	When an event is passed as the argument to an event handling procedure or function, as discussed in the previous section, this field contains the identifier of the widget associated with the handler routine. When an event is returned from WIDGET_EVENT, this value is always zero to indicate that no handler routine was found.

Table 3-130: Common Event Structure Fields

## Arguments

### Widget\_ID

*Widget\_ID* specifies the widget hierarchy for which events are desired. The first available event for the specified widget or any of its children is returned. If this argument is not specified, WIDGET\_EVENT processes events for all existing widgets.

*Widget\_ID* can also be an array of widget identifiers, in which case all of the specified widget hierarchies are searched.

#### Note

Attempting to obtain events for a widget hierarchy which is not producing events will hang IDL, unless the NOWAIT keyword is used.

## Keywords

### BAD\_ID

If one of the values supplied via *Widget\_ID* is not a valid widget identifier, this function normally issues an error and causes program execution to stop. However, if BAD\_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

This keyword can be used to handle the situation in which IDL is waiting within `WIDGET_EVENT` when the user kills the widget hierarchy.

This keyword has meaning only if *Widget\_ID* is explicitly specified.

## NOWAIT

When no events are currently available for the specified widget hierarchy, `WIDGET_EVENT` normally waits until one is available and then returns it. However, if `NOWAIT` is set and no events are present, it immediately returns. In this case, the ID field of the returned structure will be zero.

## SAVE\_HOURLASS

Set this keyword to prevent the hourglass cursor from being cleared by `WIDGET_EVENT`. This keyword can be of use if a program has to poll a widget periodically during a long computation.

## YIELD\_TO\_TTY

*This keyword is only available on UNIX platforms.*

Unless the `NOWAIT` keyword is specified, `WIDGET_EVENT` does not return until the asked for event is available. If the user should enter a line of input from the keyboard, it cannot be processed until `WIDGET_EVENT` returns. If the `YIELD_TO_TTY` keyword is specified and the user enters a line of input, `WIDGET_EVENT` returns immediately. In this case, the ID field of the returned structure will be zero.

### Note

---

This keyword is supported under UNIX only, and there are no plans to extend it to other operating systems. Do not use it if you intend to use non-UNIX systems.

# WIDGET\_INFO

The WIDGET\_INFO function is used to obtain information about the widget subsystem and individual widgets. The specific area for which information is desired is selected by setting the appropriate keyword.

## Syntax

*Result* = WIDGET\_INFO( [*Widget\_ID*] )

**Keywords that apply to all widgets:** [, /ACTIVE] [, /CHILD] [, /EVENT\_FUNC] [, /EVENT\_PRO] [, FIND\_BY\_UNAME=*string*] [, /FONTNAME] [, /GEOMETRY] [, /KBRD\_FOCUS\_EVENTS] [, /MANAGED] [, /MAP] [, /NAME] [, /PARENT] [, /REALIZED] [, /SENSITIVE] [, /SIBLING] [, STRING\_SIZE={*string* | [*string*, *font*]}] [, /SYSTEM\_COLORS] [, /TAB\_MODE] [, /TRACKING\_EVENTS] [, /TYPE] [, UNITS={0 | 1 | 2}] [, /UNAME] [, /UPDATE] [, /VALID\_ID] [, /VERSION] [, /VISIBLE]

**Keywords that apply to widgets created with WIDGET\_BASE:**

[, /CONTEXT\_EVENTS] [, /MODAL] [, /TLB\_ICONIFY\_EVENTS] [, /TLB\_KILL\_REQUEST\_EVENTS] [, /TLB\_MOVE\_EVENTS] [, /TLB\_SIZE\_EVENTS]

**Keywords that apply to widgets created with WIDGET\_BUTTON:**

[, /BUTTON\_SET] [, /DYNAMIC\_RESIZE] [, /PUSHBUTTON\_EVENTS] [, /TOOLTIP]

**Keywords that apply to widgets created with WIDGET\_COMBOBOX:**

[, /COMBOBOX\_GETTEXT] [, /COMBOBOX\_NUMBER] [, /DYNAMIC\_RESIZE]

**Keywords that apply to widgets created with WIDGET\_DRAW:**

[, /DRAW\_BUTTON\_EVENTS] [, /DRAW\_EXPOSE\_EVENTS] [, DRAW\_KEYBOARD\_EVENTS={0 | 1 | 2}] [, /DRAW\_MOTION\_EVENTS] [, /DRAW\_VIEWPORT\_EVENTS] [, /DRAW\_WHEEL\_EVENTS] [, /TOOLTIP]

**Keywords that apply to widgets created with WIDGET\_DROPLIST:**

[, /DROPLIST\_NUMBER] [, /DROPLIST\_SELECT] [, /DYNAMIC\_RESIZE]

**Keywords that apply to widgets created with WIDGET\_LABEL:**

[, /DYNAMIC\_RESIZE]

**Keywords that apply to widgets created with WIDGET\_LIST:**

[, /CONTEXT\_EVENTS] [, /LIST\_MULTIPLE] [, /LIST\_NUMBER]  
 [, /LIST\_NUM\_VISIBLE] [, /LIST\_SELECT] [, /LIST\_TOP]

**Keywords that apply to widgets created with WIDGET\_PROPERTY SHEET:**

[, /CONTEXT\_EVENTS] [, COMPONENT=*objref*]  
 [, /MULTIPLE\_PROPERTIES] [, PROPERTY\_VALID=*string*]  
 [, PROPERTY\_VALUE=*string*] [, /PROPERTY SHEET\_NSELECTED]  
 [, /PROPERTY SHEET\_SELECTED]

**Keywords that apply to widgets created with WIDGET\_SLIDER:**

[, /SLIDER\_MIN\_MAX]

**Keywords that apply to widgets created with WIDGET\_TAB:**

[, /TAB\_CURRENT] [, /TAB\_MULTILINE] [, /TAB\_NUMBER]

**Keywords that apply to widgets created with WIDGET\_TABLE:**

[, /COLUMN\_WIDTHS] [, /CONTEXT\_EVENTS] [, /ROW\_HEIGHTS]  
 [, /TABLE\_ALL\_EVENTS] [, /TABLE\_BACKGROUND\_COLOR]  
 [, /TABLE\_DISJOINT\_SELECTION] [, /TABLE\_EDITABLE]  
 [, /TABLE\_EDIT\_CELL] [, /TABLE\_FONT]  
 [, /TABLE\_FOREGROUND\_COLOR] [, /TABLE\_SELECT] [, /TABLE\_VIEW]  
 [, /TEXT\_SELECT] [, /USE\_TABLE\_SELECT]

**Keywords that apply to widgets created with WIDGET\_TEXT:**

[, /CONTEXT\_EVENTS] [, /TEXT\_ALL\_EVENTS] [, /TEXT\_EDITABLE]  
 [, /TEXT\_NUMBER] [, TEXT\_OFFSET\_TO\_XY=*integer*] [, /TEXT\_SELECT]  
 [, /TEXT\_TOP\_LINE] [, TEXT\_XY\_TO\_OFFSET=*[column, line]*]

**Keywords that apply to widgets created with WIDGET\_TREE:**

[, /CONTEXT\_EVENTS] [, /TREE\_EXPANDED] [, /TREE\_ROOT]  
 [, /TREE\_SELECT]

## Return Value

Returns the specified information for the given widget ID. If the SYSTEM\_COLORS keyword is specified, a structure is returned. See “[The WIDGET\\_SYSTEM\\_COLORS Structure](#)” on page 2648 for details.

## Arguments

### Widget\_ID

Usually this argument should be the widget ID of the widget for which information is desired. If the `ACTIVE` or `VERSION` keywords are specified, this argument is not required.

*Widget\_ID* can also be an array of widget identifiers, in which case the result is an array with the same structure in which information on all the specified widgets is returned.

## Keywords

Not all keywords to `WIDGET_INFO` apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

### ACTIVE

This keyword applies to all widgets.

Set this keyword to return 1 if there is at least one realized, managed, top-level widget on the screen. Otherwise, 0 is returned.

### BUTTON\_SET

This keyword applies to widgets created with the `WIDGET_BUTTON` function.

Set this keyword to return the “set” state of a widget button. If the button is currently set, 1 (one) is returned. If the button is currently not set, 0 (zero) is returned. This keyword is intended for use with exclusive, non-exclusive and checked menu buttons.

### CHILD

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first child of the widget specified by *Widget\_ID*. If the widget has no children, 0 is returned.

### COLUMN\_WIDTHS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to return an array of long integers giving the width of each column in the table. If `USE_TABLE_SELECT` is set equal to one, only the column widths for

columns that contain currently-selected cells are returned. If `USE_TABLE_SELECT` is set equal to an array, only the column widths for columns that contain specified cells are returned.

## COMBOBOX\_GETTEXT

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to return the current text from the text box of the specified combobox widget. Note that when using an editable combobox, the text displayed in the text box may not be an item from the list of values in the combobox list. To obtain the index of the selected item, inspect the `INDEX` field of the event structure returned by the combobox widget.

## COMBOBOX\_NUMBER

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to return the number of elements currently contained in the list of the specified combobox widget.

## COMPONENT

This keyword applies to widgets created with the `WIDGET_PROPERTY SHEET` function.

Set this keyword to an object reference to indicate which object to query. This is most useful when the property sheet references multiple objects. If this keyword is not specified, the first (possibly only) object is queried.

## CONTEXT\_EVENTS

This keyword applies to widgets created with the `WIDGET_BASE`, `WIDGET_LIST`, `WIDGET_PROPERTY SHEET`, `WIDGET_TABLE`, `WIDGET_TEXT` or `WIDGET_TREE` functions.

Set this keyword to return 1 (one) if the widget specified by *Widget\_ID* is configured to generate context events (that is, the widget was created with the `CONTEXT_EVENTS` keyword). Otherwise, 0 (zero) is returned.

## DRAW\_BUTTON\_EVENTS

This keyword applies to widgets created with the `WIDGET_DRAW` function.

Set this keyword to return 1 if *Widget\_ID* is a draw widget with the `BUTTON_EVENTS` attribute set. Otherwise, 0 is returned.

## DRAW\_EXPOSE\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to return 1 if *Widget\_ID* is a draw widget with the EXPOSE\_EVENTS attribute set. Otherwise, 0 is returned.

## DRAW\_KEYBOARD\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to return an integer specifying the type of keyboard events currently generated by the draw widget specified by *Widget\_ID*. Possible values are:

- 0: No keyboard events are generated
- 1: Keyboard events are generated for “normal” keys (all keys except function keys and modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT).
- 2: Keyboard events are generated for “normal” keys and modifier keys.

---

### Note

Keyboard events are never generated for function keys.

---

## DRAW\_MOTION\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to return 1 if *Widget\_ID* is a draw widget with the MOTION\_EVENTS attribute set. Otherwise, 0 is returned.

## DRAW\_VIEWPORT\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

Set this keyword to return 1 if *Widget\_ID* is a draw widget with the VIEWPORT\_EVENTS attribute set. Otherwise, 0 is returned.

## DRAW\_WHEEL\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_DRAW](#) function.

If this keyword is set and the provided widget ID is for a draw widget, WIDGET\_INFO returns True (1) if mouse wheel events are enabled for the given draw widget and False (0) if wheel events are disabled. WIDGET\_INFO also returns False if this keyword is used on non-draw widgets.

**Note**

This keyword is operational only under Microsoft Windows. Under Motif, it always returns a value of False (0).

**DROPLIST\_NUMBER**

This keyword applies to widgets created with the [WIDGET\\_DROPLIST](#) function.

Set this keyword to return the number of elements currently contained in the specified droplist widget.

**DROPLIST\_SELECT**

This keyword applies to widgets created with the [WIDGET\\_DROPLIST](#) function.

Set this keyword to return the zero-based number of the currently-selected element (i.e., the currently-displayed element) in the specified droplist widget.

**DYNAMIC\_RESIZE**

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#), [WIDGET\\_COMBOBOX](#), [WIDGET\\_DROPLIST](#), and [WIDGET\\_LABEL](#) functions.

Set this keyword to return a True value (1) if the widget specified by *Widget\_ID* is a button, droplist, or label widget that has had its `DYNAMIC_RESIZE` attribute set. Otherwise, False (0) is returned.

**EVENT\_FUNC**

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler function associated with *Widget\_ID*. A null string is returned if no event handler function exists.

**EVENT\_PRO**

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler procedure associated with *Widget\_ID*. A null string is returned if no event handler procedure exists.

**FIND\_BY\_UNAME**

This keyword applies to all widgets.

Set this keyword to a UNAME value that will be searched for in the widget hierarchy, and if a widget with the given UNAME is in the hierarchy, its ID is returned. The search starts in the hierarchy with the given widget ID and travels down, and this keyword returns the widget ID of the first widget that has the specified UNAME value.

If a widget is not found, 0 is returned.

## FONTNAME

This keyword applies to all widgets that support fonts. If the specified widget does not support fonts, WIDGET\_INFO returns an empty string.

### Note

The WIDGET\_BASE, WIDGET\_DRAW, WIDGET\_TAB, and WIDGET\_TREE widgets do *not* support fonts.

Set this keyword to return a string containing the name of the font being used by the specified widget. The returned name can then be used when creating other widgets or with the SET\_FONT keyword to the [DEVICE](#) procedure.

### Note

If the widget being queried has not yet been realized, this keyword will return the default font even if another font has been specified. To ensure that you are retrieving the correct font, query for the font name *after* realizing the widget.

You can use this keyword to retrieve the name of the *default* font used by one type of widget and use the same font in other contexts. For example, the following code retrieves the default font used for buttons and writes into the drawable area of a draw widget using the same font:

```
wBase = WIDGET_BASE(/ROW)
wButton = WIDGET_BUTTON(wBase, VALUE="Button")
wDraw = WIDGET_DRAW(wBase, XSIZE=200, YSIZE=100)
WIDGET_CONTROL, wBase, /REALIZE
strFont = WIDGET_INFO(wButton, /FONTNAME)
DEVICE, SET_FONT=strFont
WIDGET_CONTROL, wDraw, GET_VALUE=iWindow
WSET, iWindow
XYOUTS, 100, 50, 'Same Font as Button', FONT=0, /DEVICE, $
ALIGNMENT=.5
```

This method allows you to synchronize the fonts in several widgets without knowing in advance which font is in use.

The format of the returned font name is platform dependent. See “[About Device Fonts](#)” on page 4910 for additional details.

## GEOMETRY

This keyword applies to all widgets.

---

### Note

Some widgets have no geometry values of their own. For example, only the root node of a tree widget hierarchy has associated geometry values. Similarly, buttons created on a pop-up menu have no geometry. Widgets with no intrinsic geometry values will return a `WIDGET_GEOMETRY` structure containing all zeroes.

---

Set this keyword to return a `WIDGET_GEOMETRY` structure that describes the offset and size information for the widget specified by *Widget\_ID*. This structure has the following definition:

```
{ WIDGET_GEOMETRY,
  XOFFSET:0.0,
  YOFFSET:0.0,
  XSIZE:0.0,
  YSIZE:0.0,
  SCR_XSIZE:0.0,
  SCR_YSIZE:0.0,
  DRAW_XSIZE:0.0,
  DRAW_YSIZE:0.0,
  MARGIN:0.0,
  XPAD:0.0,
  YPAD:0.0,
  SPACE:0.0 }
```

With the exception of `MARGIN`, all of the structure’s fields correspond to the keywords of the same name to the various widget routines. `MARGIN` is the width of any frame added to the widget, in units specified by the `UNITS` keyword (pixels are the default). Therefore, the actual width of any widget is:

$$\text{SCR\_XSIZE} + (2 * \text{MARGIN})$$

The actual height of any widget is:

$$\text{SCR\_YSIZE} + (2 * \text{MARGIN})$$

---

### Note

Different window managers may use different *window dressing* (borders, margins, scrollbars, etc.). As a result, running a given segment of widget code on different platforms may yield different geometry.

---

---

**Note**

In most cases, setting `SCR_XSIZE` (or `SCR_YSIZE`) for a base widget should override the value set via the `XSIZE` (or `YSIZE`) keyword. For *unrealized* base widgets on Microsoft Windows platforms, however, the returned `WIDGET_GEOMETRY` structure will report the specified value of `XSIZE` (or `YSIZE`) rather than the value supplied via the `SCR_XSIZE` (or `SCR_YSIZE`) keyword.

---

**Note**

For table widgets, the `YSIZE` and `XSIZE` values return the total number of rows and columns, which may differ from the visible number of rows and columns.

---

## **KBRD\_FOCUS\_EVENTS**

This keyword applies to all widgets.

Set this keyword to return the keyboard focus events status of the widget specified by *Widget ID*. `WIDGET_INFO` returns 1 (one) if keyboard focus events are currently enabled for the widget, or 0 (zero) if they are not. Only base, table, and text widgets can generate keyboard focus events.

## **LIST\_MULTIPLE**

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword equal to a named variable that will contain a non-zero value if the list widget supports multiple item selections. See the `MULTIPLE` keyword to `WIDGET_LIST` for more on multiple item selections.

## **LIST\_NUMBER**

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword to return the number of elements currently contained in the specified list widget.

## **LIST\_NUM\_VISIBLE**

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword to return the number of elements that can be visible in the scrolling viewport of the specified list widget. Note that this value can be larger than the total number of elements actually in the list.

## LIST\_SELECT

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword to return the index or indices of the currently selected (highlighted) element or elements in the specified list widget. Note that this offset is zero-based. If no element is currently selected, -1 is returned.

## LIST\_TOP

This keyword applies to widgets created with the [WIDGET\\_LIST](#) function.

Set this keyword to return the zero-based offset of the topmost element currently visible in the specified list widget.

## MANAGED

This keyword applies to all widgets.

Set this keyword to return 1 if the specified widget is managed, or 0 otherwise. If no widget ID is specified in the call to [WIDGET\\_INFO](#), the return value will be an array containing the widget IDs of all currently-managed widgets.

## MAP

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget\_ID* is mapped (visible), or False (0) otherwise. Note that when a base widget is unmapped, all of its children are unmapped. If [WIDGET\\_INFO](#) reports that a particular widget is unmapped, it may be because a parent in the widget hierarchy has been unmapped.

## MODAL

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function and the [MODAL](#) keyword.

If this keyword is set, [WIDGET\\_INFO](#) will return True (1) if the base widget specified by *Widget\_ID* is a modal base widget, or False (0) otherwise.

## MULTIPLE\_PROPERTIES

This keyword applies to widgets created with the [WIDGET\\_PROPERTY SHEET](#) function.

Set this keyword to return the property sheet's current selection mode. A value of 1 indicates support for multiple property selection. A value of 0 indicates that only single property selection is permitted.

## NAME

This keyword applies to all widgets.

Set this keyword to return the widget type name of the widget specified by *Widget\_ID*. The returned value will be one of the following strings: "BASE", "BUTTON", "COMBOBOX", "DRAW", "DROPLIST", "LABEL", "LIST", "PROPERTY SHEET", "SLIDER", "TAB", "TABLE", "TEXT", or "TREE". Set the TYPE keyword to return the widget's type code.

## PARENT

This keyword applies to all widgets.

Set this keyword to return the widget ID of the parent of the widget specified by *Widget\_ID*. If the widget is a top-level base (i.e., it has no parent), 0 is returned.

## PROPERTY\_VALID

This keyword applies to widgets created with the [WIDGET\\_PROPERTY SHEET](#) function.

Set this keyword to a scalar string or one-element string array that contains a property identifier. If the specified property is included in the property sheet, WIDGET\_INFO will return 1; if the property is not included in the property sheet, WIDGET\_INFO will return 0. Comparisons are case-insensitive.

### Note

---

Property identifiers returned in the IDENTIFIER field of an event structure generated by a property sheet widget can be assumed to be valid.

---

## PROPERTY\_VALUE

This keyword applies to widgets created with the [WIDGET\\_PROPERTY SHEET](#) function.

Set this keyword to a string that contains a property identifier. If the specified property is included in the property sheet, WIDGET\_INFO will return the value of the property. If the specified property is not included in the property sheet, WIDGET\_INFO will generate an error; use the [PROPERTY\\_VALID](#) keyword to

WIDGET\_INFO to check for validity before retrieving the property value. Comparisons are case-insensitive.

If the property sheet contains multiple components, use the **COMPONENT** keyword to indicate which component the property value should be retrieved from.

### Note on use of this keyword

When a user changes a value in the property sheet widget, the actual value of the underlying property does not change automatically. Use this keyword to retrieve the value specified by the user, then apply the new value to the underlying component. The following code snippet illustrates this process:

```
PRO prop_event, e

; Get the value of the changed property, using the component and
; property identifier information contained in the widget event.
value = WIDGET_INFO( e.id, COMPONENT = e.component, $
    PROPERTY_VALUE = e.identifier )

; Set the component's property's value
e.component->SetPropertyByIdentifier, e.identifier, value

END
```

## PROPERTY SHEET\_NSELECTED

This keyword applies to widgets created with the **WIDGET\_PROPERTY SHEET** function.

Set this keyword to return the number of currently selected properties. The **COMPONENT** keyword is not required.

## PROPERTY SHEET\_SELECTED

This keyword applies to widgets created with the **WIDGET\_PROPERTY SHEET** function.

Set this keyword to return the identifiers of the currently selected properties. The return value depends on the number of rows selected as follows:

Selection	Return Value
No Properties Selected	Returns an empty string ( ' ' ).

Table 3-131: Possible Return Values

Selection	Return Value
Single Property Selected	Returns a string containing the property identifier.
Multiple Properties Selected	Returns an array of strings containing each selected property's identifier.

*Table 3-131: Possible Return Values*

The **COMPONENT** keyword is not required.

## **PUSHBUTTON\_EVENTS**

This keyword applies to widgets created with the **WIDGET\_BUTTON** function.

Set this keyword to return the pushbutton events status for the widget specified by *Widget\_ID*. **WIDGET\_INFO** returns 1 if pushbutton events are currently enabled for the widget, or 0 otherwise.

## **REALIZED**

This keyword applies to all widgets.

Set this keyword to return 1 if the widget specified by *Widget\_ID* has been realized. If the widget has not been realized, 0 is returned.

## **ROW\_HEIGHTS**

This keyword applies to widgets created with the **WIDGET\_TABLE** function.

Set this keyword to return an array of floating-point values giving the height of each row in the table. If **USE\_TABLE\_SELECT** is set equal to one, only the row heights for rows that contain currently selected cells are returned. If **USE\_TABLE\_SELECT** is set equal to an array, only the row heights for rows that contain specified cells are returned.

### **Note**

On Microsoft Windows platforms, all value rows have the same height, but the column header can have a distinct height. The column header is indexed by a value of -1 for the row.

## **SENSITIVE**

This keyword applies to all widgets.

Set this keyword to return true (1) if the widget specified by *Widget\_ID* is sensitive (enabled), or false (0) otherwise. Note that when a base is made insensitive, all its children are made insensitive. If `WIDGET_INFO` reports that a particular widget is insensitive, it may be because a parent in the widget hierarchy has been made insensitive.

## SIBLING

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first sibling of the widget specified by *Widget\_ID*. If the widget is the last sibling in the chain, 0 is returned.

## SLIDER\_MIN\_MAX

This keyword applies to widgets created with the `WIDGET_SLIDER` function.

Set this keyword to return the current minimum and maximum values of the specified slider as a two-element integer array. Element 0 is the minimum value and element 1 is the maximum value.

## STRING\_SIZE

This keyword applies to all widget types.

Set this keyword to retrieve the dimensions of a string. The return value is a two-element vector containing the string's width and height in pixels. A widget identifier must always be specified in the call. The keyword's value can be either the measured string or a two-element vector containing first the string and then a font. If a font is specified, that font is used in the calculations. Otherwise, the widget's font is used. In the case of a table widget with multiple fonts, the default font is used. See "[About Device Fonts](#)" on page 4910 for details on specifying names for device fonts.

### Note

---

When you are using the dimensions returned by this keyword, take into account the padding that a widget uses around a string. `STRING_SIZE` returns the exact dimensions, which if used can cut off the string's edges.

---

## SYSTEM\_COLORS

This keyword applies to all widgets.

Set this keyword and supply the widget ID of any widget to cause `WIDGET_INFO` to return an IDL structure that contains RGB values used for 25 IDL display elements.

For more detailed information on the `WIDGET_SYSTEM_COLORS` structure fields and their meaning see the “[The WIDGET\\_SYSTEM\\_COLORS Structure](#)” on page 2648.

## TAB\_CURRENT

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword to return the zero-based index of the current tab in the tab widget.

## TAB\_MODE

This keyword applies to all widgets.

Set this keyword to return what support the specified widget has for navigating among widgets using the **Tab** key. Possible return values are:

0	Navigation is not supported onto or off of the widget
1	Navigation is supported onto and off of the widget
2	Navigation is supported only onto the widget
3	Navigation is supported only off of the widget

---

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

---

## TAB\_MULTILINE

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword to return the current setting of the multi-line mode for the tab widget.

## TAB\_NUMBER

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword to return the number of tabs contained in the tab widget.

## TABLE\_ALL\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return 1 (one) if *Widget\_ID* is a table widget with the ALL\_EVENTS attribute set. Otherwise, 0 (zero) is returned.

## TABLE\_BACKGROUND\_COLOR

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return the background colors of table cells. Colors are returned as RGB triplets, where each byte for red, green, and blue is in the range [0,255].

Normally all of the table's cells are queried, but you can indicate a subset with the [USE\\_TABLE\\_SELECT](#) keyword. If all of the colors are identical, the return value is a three-element vector of bytes (an RGB triplet). If any one color is different, the return value has all of the colors in an array whose dimensions mirror the query set specification.

### Note

---

On systems that do not support a large number of colors, the color value returned by WIDGET\_INFO may not match the value specified via WIDGET\_TABLE or WIDGET\_CONTROL exactly. The value returned by WIDGET\_INFO is the color that was actually applied.

---

For more information on the return value, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

## TABLE\_DISJOINT\_SELECTION

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return 1 (one) if the widget specified by *Widget\_ID* has disjoint selection enabled. Otherwise, 0 (zero) is returned.

## TABLE\_EDITABLE

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return the editability of table cells. Values are returned as single bytes containing 0 (not editable) or 1 (editable). Normally all of the table's cells are queried, but you can indicate a subset with the [USE\\_TABLE\\_SELECT](#) keyword. If all of the values are identical, the return value is a scalar byte. If any one value is

different, the return value has all of the values in an array whose dimensions mirror the query set specification.

For more information on the return value, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

---

**Note**

When using a table with mixed editability, it is important that you take care when using the return value from `TABLE_EDITABLE` in a conditional because the value might not be scalar.

---

## **TABLE\_EDIT\_CELL**

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return a two-element integer array containing the row and column coordinates of the currently editable cell. If none of the cells in the table widget is currently editable, the array [-1, -1] is returned.

## **TABLE\_FONT**

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return the font names of table cells. Values are returned as strings. Normally all of the table's cells are queried, but you can indicate a subset with the [USE\\_TABLE\\_SELECT](#) keyword. If all of the font names are identical, the return value is a scalar string. If any one font is different, the return value has all of the values in an array whose dimensions mirror the query set specification.

For more information on the return value, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

---

**Note**

On Microsoft Windows platforms, the returned font description is functionally equivalent to the originally specified font, but might have modifiers in a different order.

---

## **TABLE\_FOREGROUND\_COLOR**

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) function.

Set this keyword to return the text colors of table cells. Colors are returned as RGB triplets, where each byte for red, green, and blue is in the range [0,255]. Normally all of the table's cells are queried, but you can indicate a subset with the [USE\\_TABLE\\_SELECT](#) keyword. If all of the colors are identical, the return value is

a three-element vector of bytes (an RGB triplet). If any one color is different, the return value has all of the colors in an array whose dimensions mirror the query set specification.

---

### Note

On systems that do not support a large number of colors, the color value returned by `WIDGET_INFO` may not match the value specified via `WIDGET_TABLE` or `WIDGET_CONTROL` exactly. The value returned by `WIDGET_INFO` is the color that was actually applied.

---

For more information on the return value, see “[Cell Attributes](#)” in Chapter 30 of the *Building IDL Applications* manual.

## TABLE\_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to return the currently-selected (highlighted) cells in the specified table widget.

- In standard selection mode, this keyword returns an array of the form [ *left*, *top*, *right*, *bottom* ] containing the zero-based indices of the columns and rows that define the selection.
- In disjoint selection mode (enabled by setting the `DISJOINT_SELECTION` keyword to `WIDGET_TABLE`), this keyword returns a  $2 \times n$  array of column/row pairs containing the zero-based indices the selected cells.

## TABLE\_VIEW

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to return a two-element array of the form [ *left*, *top* ] containing the zero-based offsets of the top-left cell currently visible in the specified table widget.

## TEXT\_ALL\_EVENTS

This keyword applies to widgets created with the `WIDGET_TEXT` function.

Set this keyword to return 1 if *Widget\_ID* is a text widget with the `ALL_EVENTS` attribute set. Otherwise, 0 is returned.

## TEXT\_EDITABLE

This keyword applies to widgets created with the `WIDGET_TEXT` function.

Set this keyword to return 1 if *Widget\_ID* is a text widget that allows user editing of its contents. Otherwise, 0 is returned.

## TEXT\_NUMBER

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

Set this keyword to return the number of characters currently contained in the specified text widget, including end-of-line characters.

### Note

---

On Windows platforms, Carriage Return/Line Feed pairs count as a single character.

---

## TEXT\_OFFSET\_TO\_XY

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

Use this keyword to translate a text widget character offset into column and line form. The value of this keyword should be set to the character offset (an integer) to be translated. [WIDGET\\_INFO](#) returns a two-element integer array giving the column (element 0) and line (element 1) corresponding to the offset. If the offset specified is out of range, the array [-1,-1] is returned.

## TEXT\_SELECT

This keyword applies to widgets created with the [WIDGET\\_TABLE](#) and [WIDGET\\_TEXT](#) functions.

Set this keyword to return the starting character offset and length (in characters) of the selected (highlighted) text in the specified text widget or table cell.

[WIDGET\\_INFO](#) returns a two-element integer array containing the starting position of the highlighted text as an offset from character zero of the text in the text widget or table cell (element 0), and length of the current selection (element 1).

## TEXT\_TOP\_LINE

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

Set this keyword to return the zero-based line number of the line currently at the top of a text widget's display viewport. Note that this value is different from the zero-based character offset of the characters in the line. The character offset can be calculated from the line offset via the [TEXT\\_XY\\_TO\\_OFFSET](#) keyword.

## TEXT\_XY\_TO\_OFFSET

This keyword applies to widgets created with the [WIDGET\\_TEXT](#) function.

Use this keyword to translate a text widget position given in line and column form into a character offset. The value of this keyword should be set to a two-element integer array specifying the column (element 0) and line (element 1) position.

[WIDGET\\_INFO](#) returns the character offset (as a longword integer) corresponding to the position. If the position specified is out of range, -1 is returned.

## TLB\_ICONIFY\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to return 1 if the top-level base widget specified by *Widget\_ID* is set to return iconify events. Otherwise, 0 is returned.

## TLB\_KILL\_REQUEST\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to return 1 if the top-level base widget specified by *Widget\_ID* is set to return kill request events. Otherwise, 0 is returned.

## TLB\_MOVE\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to return 1 if the top-level base widget specified by *Widget\_ID* is set to return move events. Otherwise, 0 is returned.

## TLB\_SIZE\_EVENTS

This keyword applies to widgets created with the [WIDGET\\_BASE](#) function.

Set this keyword to return 1 if the top-level base widget specified by *Widget\_ID* is set to return resize events. Otherwise, 0 is returned.

## TOOLTIP

This keyword applies to widgets created with the [WIDGET\\_BUTTON](#) and [WIDGET\\_DRAW](#) functions.

Set this keyword to have the [WIDGET\\_INFO](#) function return the text of the tooltip of the widget. If the widget does not have a tooltip, a null string will be returned.

## TRACKING\_EVENTS

This keyword applies to all widgets.

Set this keyword to return the tracking events status for the widget specified by *Widget\_ID*. `WIDGET_INFO` returns 1 if tracking events are currently enabled for the widget. Otherwise, 0 is returned.

## TREE\_EXPANDED

This keyword applies to widgets created with the `WIDGET_TREE` function.

Set this keyword to return 1 (one) if the specified tree widget node is a folder that is expanded, or 0 (zero) if the specified node is a folder that is collapsed.

### Note

---

Only tree widget nodes created with the `FOLDER` keyword can be expanded or collapsed. This keyword will always return 0 (zero) if the specified tree widget node is not a folder.

---

## TREE\_ROOT

This keyword applies to widgets created with the `WIDGET_TREE` function.

Set this keyword to return the widget ID of the *root node* of the tree widget hierarchy of which *Widget ID* is a part. The root node is the tree widget whose parent is a base widget.

## TREE\_SELECT

This keyword applies to widgets created with the `WIDGET_TREE` function.

Set this keyword to return information about the nodes selected in the specified tree widget. This keyword has two modes of operation, depending on the widget ID passed to `WIDGET_INFO`:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget), this keyword returns either the widget ID of the selected node or (if multiple nodes are selected) an array of widget IDs of the selected nodes. If no nodes are selected, -1 is returned.
- If the specified widget ID is a tree widget that is a node in a tree, this keyword returns 1 (one) if the node is selected or 0 (zero) if it is not selected.

## TYPE

This keyword applies to all widgets.

Set this keyword to return the type code of the specified *Widget\_ID*. Possible values are given the following table. Note that you can set the NAME keyword to return string names instead.

Value	Type
0	Base
1	Button
2	Slider
3	Text
4	Draw
5	Label
6	List
8	Droplist
9	Table
10	Tab
11	Tree
12	Combobox

Table 3-132: Widget Type Codes

## UNAME

This keyword applies to all widgets.

Set this keyword to have the WIDGET\_INFO function return the user name of the widget.

## UNITS

This keyword applies to all widgets.

Set this keyword to specify the units used when *returning* measurements or position values for most widget types. Set UNITS equal to 0 (zero) to specify that all

measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

---

**Note**

This keyword does not affect all sizing operations. Specifically, the value of `UNITS` is ignored when retrieving the `XSIZE` or `YSIZE` of a `WIDGET_LIST`, `WIDGET_TABLE`, or `WIDGET_TEXT` functions.

---

## UPDATE

This keyword applies to all widgets.

Set this keyword to return 1 if the widget hierarchy that contains *Widget\_ID* is set to display updates. Otherwise, 0 is returned. See “`UPDATE`” on page 2584.

## USE\_TABLE\_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to modify the behavior of the `COLUMN_WIDTHS`, `ROW_HEIGHTS`, `TABLE_BACKGROUND_COLOR`, `TABLE_EDITABLE`, `TABLE_FONT`, and `TABLE_FOREGROUND_COLOR` keywords. If `USE_TABLE_SELECT` is set, these keywords apply only to the currently selected cells. If `USE_TABLE_SELECT` is not set, these keywords apply to the entire contents of a table widget.

The `USE_TABLE_SELECT` keyword can be specified as an array of coordinates (disjoint selection mode) or as a four-element array of the form [*left*, *top*, *right*, *bottom*] (standard selection mode), giving the group of cells to act on. You can specify header cells by using -1 in the appropriate index: row header cells use -1 for the column, and column header cells use -1 for the row. Ranges can span header and value cells.

## VALID\_ID

This keyword applies to all widgets.

Set this keyword to return 1 if *Widget\_ID* represents a currently valid widget. Otherwise, 0 is returned.

## VERSION

This keyword applies to all widgets.

Set this keyword to return a structure that gives information about the widget implementation. This structure has the following definition:

```
{ WIDGET_VERSION, STYLE:'', TOOLKIT:'', RELEASE:'' }
```

STYLE is the style of widget toolkit used. TOOLKIT is the implementation of the toolkit. RELEASE is the version level of the toolkit. This field can be used to distinguish between different releases of a given toolkit, such as Motif 1.0 and Motif 1.1.

## VISIBLE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget\_ID* is visible, or False (0) otherwise. A widget is visible if:

- it has been realized,
- it and all of its ancestors are mapped.

### Note

---

The value returned by WIDGET\_INFO when this keyword is set is not affected if the widget is minimized or obscured by another window. Widgets that are visible in the sense of this keyword may not be immediately apparent to a person viewing a particular display device.

---

## The WIDGET\_SYSTEM\_COLORS Structure

When the SYSTEM\_COLORS keyword is specified in a call to WIDGET\_INFO, IDL returns a WIDGET\_SYSTEM\_COLORS structure. This allows application developers to determine what colors are used in IDL application widgets, so they can design widgets for their application with the same look and feel as the supplied IDL widgets.

The WIDGET\_SYSTEM\_COLORS structure consists of 25 fields, each containing a three-element vector corresponding to the Red, Green, and Blue color values used for various widget elements. The vector elements are integers ranging between 0 and 255 if a color value is available (vector elements contain -1 if the color value is

unavailable). The field names and meaning on the Windows and UNIX operating systems are shown in the following table.

Field Names	Windows Platform	UNIX Platform
DARK_SHADOW_3D	Dark shadow color for 3D display elements.	N/A
FACE_3D	Face color for 3D display elements and dialog boxes.	Base background color for all widgets.
LIGHT_EDGE_3D	Highlight color for 3D edges that face the light source.	Color of top and left edges of 3D widgets.
LIGHT_3D	Light color for 3D display elements.	Color of highlight rectangle around widgets with the keyboard focus.
SHADOW_3D	Color for 3D edges that face away from the light source.	Color of bottom and right edges of 3D widgets.
ACTIVE_BORDER	Active window's border color.	Push button background color when button is armed.
ACTIVE_CAPTION	Active window's caption color.	N/A
APP_WORKSPACE	Background color of MDI applications.	N/A
DESKTOP	Desktop color.	N/A
BUTTON_TEXT	Text color on push buttons.	Widget text color.
CAPTION_TEXT	Color of text in caption, size box, and scroll bar arrow box.	Widget text color.

Table 3-133: WIDGET\_SYSTEM\_COLORS Structure Fields

Field Names	Windows Platform	UNIX Platform
GRAY_TEXT	Color of disabled text.	N/A
HIGHLIGHT	Color of item(s) selected in a widget.	Toggle button fill color.
HIGHLIGHT_TEXT	Color of text of item(s) selected in a widget.	N/A
INACTIVE_BORDER	Inactive window's border color.	N/A
INACTIVE_CAPTION	Inactive window's caption color.	N/A
INACTIVE_CAPTION_TEXT	Inactive window's caption text color.	N/A
TOOLTIP_BK	Background color for tooltip controls.	N/A
TOOLTIP_TEXT	Text color for tooltip controls.	N/A
MENU	Menu background color.	N/A
MENU_TEXT	Menu text color.	N/A
SCROLLBAR	Color of scroll bar "gray" area.	Color of scroll bar "gray" area.
WINDOW_BK	Window background color.	Base background color for all widgets.
WINDOW_FRAME	Window frame color.	Widget border color.
WINDOW_TEXT	Text color in windows.	Widget text color.

*Table 3-133: WIDGET\_SYSTEM\_COLORS Structure Fields (Continued)*

## Version History

Pre-4.0	Introduced
5.6	Added <code>BUTTON_SET</code> , <code>COMBOBOX_GETTEXT</code> , <code>COMBOBOX_NUMBER</code> , <code>FONTNAME</code> , <code>MAP</code> , <code>SENSITIVE</code> , <code>TAB_CURRENT</code> , <code>TAB_MULTILINE</code> , <code>TAB_NUMBER</code> , <code>TABLE_DISJOINT_SELECTION</code> , <code>TLB_ICONIFY_EVENTS</code> , <code>TLB_MOVE_EVENTS</code> , <code>TLB_SIZE_EVENTS</code> , <code>TOOLTIP</code> , <code>TREE_EXPANDED</code> , <code>TREE_ROOT</code> , <code>TREE_SELECT</code> , and <code>VISIBLE</code> keywords
6.0	Added <code>COMPONENT</code> , <code>PROPERTY_VALID</code> , <code>PROPERTY_VALUE</code> , and <code>PUSHBUTTON_EVENTS</code> keywords
6.1	Added <code>MULTIPLE_PROPERTIES</code> , <code>PROPERTY_SHEET_NSELECTED</code> , <code>PROPERTY_SHEET_SELECTED</code> , and <code>TAB_MODE</code> keywords
6.2	Added <code>DRAW_WHEEL_EVENTS</code> , <code>STRING_SIZE</code> , <code>TABLE_BACKGROUND_COLOR</code> , <code>TABLE_FONT</code> , and <code>TABLE_FOREGROUND_COLOR</code> keywords

# WIDGET\_LABEL

The `WIDGET_LABEL` function is used to create label widgets. Label widgets display static text. They are similar to single-line text widgets but are optimized for small labeling purposes. If you need to display more than a single line of text, or if the text must be editable by the user, use a text widget.

Figure 3-144: A Label Widget

## Syntax

```
Result = WIDGET_LABEL( Parent [, /ALIGN_CENTER | , /ALIGN_LEFT | ,
  /ALIGN_RIGHT] [, /DYNAMIC_RESIZE] [, FONT=string] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id]
  [, KILL_NOTIFY=string] [, /NO_COPY] [, NOTIFY_REALIZE=string]
  [, PRO_SET_VALUE=string] [, RESOURCE_NAME=string]
  [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
  [, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=string]
  [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, XOFFSET=value]
  [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created label widget.

## Arguments

### Parent

The widget ID of the parent widget for the new label widget.

## Keywords

### ALIGN\_CENTER

Set this keyword to center justify the label text.

### ALIGN\_LEFT

Set this keyword to left justify the label text.

### ALIGN\_RIGHT

Set this keyword to right justify the label text.

### DYNAMIC\_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword cannot be used with the `SCR_XSIZE`, `SCR_YSIZE`, `XSIZE`, or `YSIZE` keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

### FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

### FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## **FUNC\_GET\_VALUE**

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## **GROUP\_LEADER**

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## **KILL\_NOTIFY**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## **NO\_COPY**

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_LABEL` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE`

keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## **NOTIFY\_REALIZE**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`' '`). The callback routine is called with the widget ID as its only argument.

## **PRO\_SET\_VALUE**

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## **RESOURCE\_NAME**

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## **SCR\_XSIZE**

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

## **SCR\_YSIZE**

Set this keyword to the desired “screen” height of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `YSIZE` keyword.

## **SENSITIVE**

Set this keyword to control the initial sensitivity state of the widget.

If `SENSITIVE` is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## SUNKEN\_FRAME

Set this keyword to create a three dimensional, bevelled border around the label widget. The resulting frame gives the label a “sunken” appearance, similar to what is often seen in application status bars.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for WIDGET\_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the FIND\_BY\_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND\_BY\_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET\_INFO.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a widget label is a string containing the text for the label.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of label widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DYNAMIC\\_RESIZE](#), [GET\\_VALUE](#), [SET\\_VALUE](#).

## Keywords to WIDGET\_INFO

Some keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to label widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [DYNAMIC\\_RESIZE](#), [STRING\\_SIZE](#).

## Widget Events Returned by Label Widgets

Label widgets do not return an event structure.

## Version History

Pre-4.0	Introduced
5.6	Added <code>SUNKEN_FRAME</code> keyword

## See Also

# WIDGET\_LIST

The `WIDGET_LIST` function is used to create list widgets. A list widget offers the user a list of text elements from which to choose. List widgets have a vertical scrollbar when there are more list items than are specified by the `HEIGHT` keyword. The user can select an item by pointing at it with the mouse cursor and pressing a button. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

Figure 3-145: A List Widget

## Syntax

```
Result = WIDGET_LIST( Parent [, /CONTEXT_EVENTS]
    [, EVENT_FUNC=string] [, EVENT_PRO=string] [, FONT=string]
    [, FRAME=width] [, FUNC_GET_VALUE=string]
    [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string] [, /MULTIPLE]
    [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
    [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
    [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
    [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
    [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created list widget.

## Arguments

### Parent

The widget ID of the parent widget for the new list widget.

## Keywords

### CONTEXT\_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET\\_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

### EVENT\_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

### EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

### FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

### FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget.

Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## **FUNC\_GET\_VALUE**

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## **GROUP\_LEADER**

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## **KILL\_NOTIFY**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## **MULTIPLE**

Set this keyword to allow the user to select more than one item from the list in a single operation. Multiple selections are handled using the platform’s native mechanism:

### **Motif**

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the mouse button when selecting items also selects a range. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

## Windows

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET\_UVALUE and GET\_UVALUE keywords to WIDGET\_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO\_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET\_LIST or the SET\_UVALUE keyword to WIDGET\_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET\_UVALUE keyword to WIDGET\_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (''). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the SET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

---

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the <code>TAB_MODE</code> Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

Once the `WIDGET_LIST` has focus, use the up and down arrow keys to navigate among the individual items.

After creating the widget hierarchy, you can change tabbing support using the [`WIDGET\_CONTROL`](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [`WIDGET\_INFO`](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“`TRACKING\_EVENTS`”](#) on page 2506 in the documentation for `WIDGET_BASE`.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

### Note

---

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the `XSIZE` or `YSIZE` keywords to `WIDGET_LIST`.

---

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a list widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the `VALUE` keyword.

**Note**

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

Note that the value of a list widget can only be set. It cannot be retrieved using `WIDGET_CONTROL`.

**XOFFSET**

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

**XSIZE**

The desired width of the widget, in characters. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

**YOFFSET**

The vertical offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

**YSIZE**

The desired height of the widget, in number of list items visible. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of list widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [CONTEXT\\_EVENTS](#), [SET\\_LIST\\_SELECT](#), [SET\\_LIST\\_TOP](#), [SET\\_VALUE](#).

## Keywords to WIDGET\_INFO

A number of keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to list widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [CONTEXT\\_EVENTS](#), [LIST\\_MULTIPLE](#), [LIST\\_NUMBER](#), [LIST\\_NUM\\_VISIBLE](#), [LIST\\_SELECT](#), [LIST\\_TOP](#), [STRING\\_SIZE](#).

## Widget Events Returned by List Widgets

List widgets generate an event when the user selects a value or values from the list. They can also be configured to generate events when the user clicks the right-hand mouse button over the widget.

Pressing the mouse button while the mouse cursor is over an element of a list widget causes the widget to highlight the appearance of that element and to generate an event. The appearance of any previously selected element is restored to normal at the same time. The event structure returned by the [WIDGET\\_EVENT](#) function is defined by the following statement:

```
{WIDGET_LIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, CLICKS:0L}
```

The first three fields are the standard fields found in every widget event. [INDEX](#) returns the index of the selected item. This index can be used to subscript the array of names originally used to set the widget's value. The [CLICKS](#) field returns either 1 or 2, depending upon how the list item was selected. If the list item is double-clicked, [CLICKS](#) is set to 2.

---

### Note

If you are writing a widget application that requires the user to double-click on a list widget, you will need to handle two events. The [CLICKS](#) field will return a 1 on the first click and a 2 on the second click.

---

## Context Menu Events

A list widget created with the `CONTEXT_EVENTS` keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the list widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

## Version History

Pre-4.0	Introduced
6.1	Added <code>TAB_MODE</code> keyword
6.1	Added ROW and COL fields to <code>WIDGET_CONTEXT</code> event structure

# WIDGET\_PROPERTY SHEET

The `WIDGET_PROPERTY SHEET` function creates a property sheet widget, which exposes the *properties* of an IDL object subclassed from the `IDLitComponent` class in a graphical interface. The property sheet widget must be a child of a base or tab widget, and it cannot be the parent of any other widget.

The `IDLitComponent` class was designed for use by the IDL *iTools* system. As a result, all `IDLit*` objects subclass from `IDLitComponent`, so properties of object classes written for the IDL *iTools* system can be displayed in a property sheet. In addition, all `IDLgr*` objects subclass from `IDLitComponent`, which means that properties of standard IDL graphics objects can be displayed in a property sheet even if the rest of the *iTools* framework is not in use.

In order to be shown in a property sheet, object properties must be *registered* and *visible*. In addition, in order for property values shown in a property sheet to be editable by the user, the property must be *sensitive*. For information on registering properties, see “[Registering Properties](#)” in Chapter 4 of the *iTool Developer’s Guide* manual. For information on making properties visible and sensitive, see “[Property Attributes](#)” in Chapter 4 of the *iTool Developer’s Guide* manual.

The name of the changed property is placed into an IDL event, and the object is updated when this event is processed. An existing property sheet can also be assigned a new component, causing it to reload with the new list of properties and their values.

Figure 3-146: A Property Sheet Widget

## Property Sheet Widget Data Types and Controls

The following controls are available for the corresponding data types in property sheet widgets:

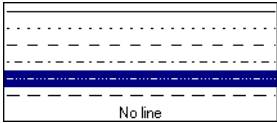

Data Type	Control
Boolean	Droplist with two choices: True or False
Number	One of the following: <ul style="list-style-type: none"> <li>Edit control that accepts +, -, 0123456789, plus decimal points, e, E, d and D for floating point numbers.</li> <li>Slider</li> <li>Spinner</li> </ul>
String	Text box, expandable when string length exceeds visible area.
Color	Color picker.
Line Style	Droplist displaying seven line style choices: <div style="border: 1px solid black; padding: 5px; margin: 10px 0;">  </div>
Line Thickness	Droplist displaying ten line thickness choices: <div style="margin: 10px 0;">  </div>
Symbol	Droplist displaying eight symbol choices: <ul style="list-style-type: none"> <li>No symbol</li> <li>+ Plus sign</li> <li>* Asterisk</li> <li>· Period</li> <li>◊ Diamond</li> <li>△ Triangle</li> <li>□ Square</li> <li>× X</li> <li>&gt; Right arrowhead</li> <li>&lt; Left arrowhead</li> </ul>

Table 3-134: WIDGET\_PROPERTY SHEET Controls for Data Types

Data Type	Control
String list	Droplist displaying a list of strings.
User-Defined	<b>Edit</b> button linked to user-defined control (see “ <a href="#">User-defined Properties</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual).

Table 3-134: WIDGET\_PROPERTY SHEET Controls for Data Types

## Syntax

```
Result = WIDGET_PROPERTY SHEET(Parent [, /ALIGN_BOTTOM
|, /ALIGN_CENTER |, /ALIGN_LEFT |, /ALIGN_RIGHT |, /ALIGN_TOP]
[, /CONTEXT_EVENTS] [, /EDITABLE] [, EVENT_FUNC=string]
[, EVENT_PRO=string] [, FONT=string] [, FRAME=width]
[, FUNC_GET_VALUE=string] [, IGNORE_ACCELERATORS=value]
[, KILL_NOTIFY=string] [, MULTIPLE_PROPERTIES] [, /NO_COPY]
[, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
[, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
[, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=string]
[, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, XOFFSET=value]
[, XSIZE=value] [, YOFFSET=value] [, YSIZE=value])
```

## Return Value

The returned value of this function is the widget ID of the newly-created property sheet widget.

## Arguments

### Parent

The widget ID of the parent for the new property sheet widget. *Parent* must be a base or tab widget.

## Keywords

### ALIGN\_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## ALIGN\_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## ALIGN\_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN\_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN\_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## CONTEXT\_EVENTS

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET\_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see [“Context-Sensitive Menus”](#) in Chapter 30 of the *Building IDL Applications* manual.

---

### Note

With regard to /CONTEXT\_EVENTS, the Motif and Windows version of the property sheet differ very slightly. In the Motif version, individually desensitized cells cannot generate context events, though their row label can.

---

## EDITABLE

Set this keyword to 0 (zero) to mark a property sheet as read-only. Property sheet widgets are editable by default (EDITABLE=1). In this default mode, property values can be modified. When a property sheet is marked as read-only (EDITABLE=0), you

can select properties and use any scrollbars, but cannot change any values. Setting this keyword to 0 is roughly equivalent to desensitizing all properties by setting the SENSITIVE attribute of *every* property on the property sheet equal to 0.

Three things that determine the appearance of a property sheet data cells are, in order of greatest to least precedence:

1. Sensitivity of the entire widget — If SENSITIVE=0 for WIDGET\_PROPERTY SHEET then no selection or scrolling is possible.
2. Editability of the entire widget — If EDITABLE=0 for the property sheet (meaning it is marked as read-only), cells can be selected but cannot be changed. If EDITABLE=1 (the default value meaning properties can be selected and modified), then the editability of individual properties is controlled by their individual sensitivity values.
3. Sensitivity of an individual property — If SENSITIVE=0 for an individual property (set using the RegisterProperty or SetPropertyAttribute methods of IDLitComponent), then the individual property cannot be selected or changed.

---

**Note**

To set the SENSITIVE attribute of individual properties within a property sheet, use [IDLitComponent::RegisterProperty](#) or [IDLitComponent::SetPropertyAttribute](#).

---

## EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” in Appendix I of the *IDL Reference Guide* manual for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

**FRAME**

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances. If `SUNKEN_FRAME` is also set, `FRAME` is ignored.

**FUNC\_GET\_VALUE**

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

**IGNORE\_ACCELERATORS**

Set this keyword to specify what `WIDGET_BUTTON` accelerators are to be ignored when this property sheet widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for `WIDGET_BUTTON`'s `ACCELERATOR` keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator "Ctrl+V" has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a property sheet, attempting to use **Ctrl+V** to paste text into the property sheet would fail as this event would be stolen by the accelerator. Setting `IGNORE_ACCELERATORS` to "Ctrl+V" allows a property sheet widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the property sheet text field loses focus, all specified accelerators are automatically re-enabled.

See "Disabling Button Widget Accelerators" in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## MULTIPLE\_PROPERTIES

Set this property to 1 to allow multiple properties to be selected at the same time. When this keyword is set, you can hold down the **Ctrl** key while left-clicking with the mouse to make nonadjacent selections, or hold down the **Shift** key to select an adjacent range of properties in a property sheet. Set this property to 0 (zero) to disallow multiple property selection. This is the default. See “[Selecting Properties](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. During a set operation (using the `UVALUE` keyword to `WIDGET_BASE` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. During a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such

callback procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the SET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. See the description of the PRO\_SET\_VALUE keyword to WIDGET\_CONTROL for information on using this keyword.

## SCR\_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). If neither XSIZE nor SCR\_XSIZE is specified, then the property sheet widget will be naturally sized based on the width of cell contents. See “Property Sheet Sizing” in Chapter 30 of the *Building IDL Applications* manual for details.

## SCR\_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). If neither YSIZE nor SCR\_YSIZE is specified, the property sheet will use a default height. This default is based on the number of rows: 10, or the number of visible properties, whichever is less.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

---

### Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

---

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET\_CONTROL procedure.

## SUNKEN\_FRAME

Set this keyword to create the appearance of a three-dimensional, beveled border around the property sheet widget. This makes the widget appear slightly inset. If the `FRAME` keyword is also set, `SUNKEN_FRAME` overrides the setting, and the frame's width will be the minimum necessary to give the appearance of indentation.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “`TRACKING_EVENTS`” in the *IDL Reference Guide* manual in the documentation for `WIDGET_BASE`.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

## UVALUE

The user value to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the `GET_UVALUE` and `SET_UVALUE` keywords to the `WIDGET_CONTROL` procedure.

## VALUE

Set this keyword to the object reference or array of object references to objects that subclass from the `IDLitComponent` class. Registered properties of the specified objects will be displayed in the property sheet.

If a single object reference is supplied, the property sheet will have a single column containing the object's properties. If an array of object references is supplied, the property sheet will have multiple columns.

---

### Note

Due to limitations of the user interface controls that underlie the property sheet widget, a property sheet can display properties for at most 100 component objects.

---

---

### Note

All object references must be to objects of the same type.

---

If no object references are supplied, the property sheet will initially be empty. Object references can be loaded into an existing property sheet using the `SET_VALUE` keyword to `WIDGET_CONTROL`. Whenever the value is set, via `SET_VALUE`, the property sheet widget is loaded with the registered, visible properties of the new component. Setting the value to a null object will clear the property sheet widget. A null object can be created by calling the `OBJ_NEW` function without any arguments:

```
nullObject = OBJ_NEW()
```

## XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

The desired width, measured in average character widths of the widget's font, not including a possible vertical scrollbar and any frame thickness. If neither `XSIZE` nor `SCR_XSIZE` is specified, then the property sheet widget will be naturally sized based

on the width of cell contents. See “[Property Sheet Sizing](#)” in Chapter 30 of the *Building IDL Applications* manual for details.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

The desired height of the widget, in number of visible properties. The ultimate height of the property sheet in pixels will include the heights of the column header, the possible horizontal scrollbar, and any frame. If neither YSIZE nor SCR\_YSIZE is specified, the property sheet will use a default height. This default is based on the number of rows: 10, or the number of visible properties, whichever is less.

## Keywords to WIDGET\_CONTROL

A number of keywords to the WIDGET\_CONTROL affect the behavior of property sheet widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [CONTEXT\\_EVENTS](#), [EDITABLE](#), [IGNORE\\_ACCELERATORS](#), [MULTIPLE\\_PROPERTIES](#), [PROPERTY SHEET\\_SELECTED](#), [REFRESH\\_PROPERTY](#).

## Keywords to WIDGET\_INFO

Some keywords to WIDGET\_INFO return information that applies specifically to property sheet widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [COMPONENT](#), [CONTEXT\\_EVENTS](#), [MULTIPLE\\_PROPERTIES](#), [PROPERTY\\_VALID](#), [PROPERTY\\_VALUE](#), [PROPERTY SHEET\\_NSELECTED](#), [PROPERTY SHEET\\_SELECTED](#), [STRING\\_SIZE](#).

## Widget Events Returned by Property Sheet Widgets

Several variations of the property sheet widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields

(ID, TOP, and HANDLER). The select and change events also include an integer TYPE field that indicates which type of structure has been returned or which type of event was generated. Programs should always check the TYPE field before referencing fields that are not present in all property sheet event structures, unless the CONTEXT\_EVENTS keyword is set. When handling context menu events, the event structure name must be used instead of the TYPE field. The different property sheet widget event structures are described below.

## Change Event (TYPE=0)

This event is generated whenever the user enters a new value for a property. It is also used to signal that a user-defined property needs to be changed. The following statement defines the event structure returned by the WIDGET\_EVENT function:

```
{WIDGET_PROPSHEET_CHANGE, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
  COMPONENT:OBJREF, IDENTIFIER:"", PROPTYPE:0L, SET_DEFINED: 0L}
```

The COMPONENT field contains an object reference to the object associated with the property sheet. When multiple objects are associated with the property sheet, this field indicates which object is to change.

The IDENTIFIER field specifies the value of the property's identifier attribute. This identifier is unique among all of the component's properties.

The PROPTYPE field indicates the type of the property (integer, string, etc.). The integer values for these types are:

0	USERDEF
1	BOOLEAN
2	INTEGER
3	FLOAT
4	STRING
5	COLOR
6	LINestyle
7	SYMBOL

8	THICKNESS
9	ENUMLIST

The SET\_DEFINED field indicates whether or not an undefined property is having its value set. In most circumstances, along with its new value, the property should have its UNDEFINED attribute set to zero. If a property is never marked as undefined, this field can be ignored. See [“Changing Properties”](#) in Chapter 30 of the *Building IDL Applications* manual for more information.

## Select Event (TYPE=1)

The select event is generated whenever the current row or column in the property sheet changes. Navigation between cells is performed by clicking on a cell. When the property sheet is realized, no properties are selected by default. However a single property or multiple properties can be selected programmatically using the PROPERTY SHEET\_SETSELECTED keyword to the WIDGET\_CONTROL procedure.

The following statement defines the event structure returned by the WIDGET\_EVENT function:

```
{WIDGET_PROPSHEET_SELECT, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
  COMPONENT:OBJREF, IDENTIFIER:"", NSELECTED:0L }
```

The COMPONENT tag is a reference to the object associated with the selected property value. When multiple objects (also known as components) are associated with the property sheet, this member indicates which one object had one of its property values selected. If a property (instead of a property value) is selected, the COMPONENT tag always contains an object reference to the first object, even if there are multiple objects in the property sheet.

The IDENTIFIER field specifies the value of the property’s identifier attribute. This identifier is unique among all properties of the component. When multiple selections are made, this field holds the identifier of the first item selected. This is not the first item selected with the mouse, but the first item encountered in the property sheet definition among those which are selected. To return the identifiers of all the selected properties, use WIDGET\_INFO with the /PROPERTY SHEET\_SELECTED keyword.

The NSELECTED field specifies the total number of currently selected properties. This is equivalent to calling WIDGET\_INFO with /PROPERTY SHEET\_NSELECTED. See [“Accessing Property Sheet Selection](#)

[Events](#)” in Chapter 30 of the *Building IDL Applications* manual for more information.

## Context Menu Events

A property sheet widget created with the `CONTEXT_EVENTS` keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The `X` and `Y` fields give the device coordinates at which the event occurred, measured from the upper left corner of the property sheet widget. The `ROW` and `COL` fields return meaningful information for table widgets and values of zero (0) for other widgets.

### Note

---

When working with property sheet context menu events, it is important to notice that the event structure does not have a `TYPE` field, so special code is needed for the property sheet event handler. Instead of keying off the `TYPE` field, use the structure's name. See [“Property Sheet Context Menu Example”](#) on page 2685 for sample code.

---

## Example

### Single Property Sheet Example

Enter the following program in the IDL Editor:

```
; ExSinglePropSheet
;
; Creates a base with a property sheet. Only the
; default properties are visible. The property sheet's
; event handler sets values and reveals selection
; changes.

; Handler for selection or value modification events.
PRO PropertyEvent, event

IF (event.type EQ 0) THEN BEGIN ; Value changed.

    ; Get the value of the property identified by
    ; event.identifier.
    value = WIDGET_INFO(event.ID, COMPONENT = event.component, $
        PROPERTY_VALUE = event.identifier)
```

```

; Set the component's property value.
event.component->SetPropertyByIdentifier, event.identifier, $
    value

PRINT, 'Changed: ', event.identifier, ': ', value

ENDIF ELSE BEGIN ; Selection changed.

; Return information about single or multiple property
; selections.
vNumSelected = WIDGET_INFO(event.ID, /PROPERTYSHEET_NSELECTED)
vSelected = WIDGET_INFO(event.ID, /PROPERTYSHEET_SELECTED)
PRINT, 'Number properties selected: ' + STRING(vNumSelected)
PRINT, 'Selected properties: '
PRINT, vSelected

ENDELSE

END

; Handler for property sheet resize event.
PRO ExSinglePropSheet_event, event

prop = WIDGET_INFO(event.top, $
    FIND_BY_UNAME = 'PropSheet')
WIDGET_CONTROL, prop, SCR_XSIZE = event.x, $
    SCR_YSIZE = event.y

END

; Handler for top-level base kill event.
PRO CleanupEvent, baseID

WIDGET_CONTROL, baseID, GET_UVALUE = oComp
OBJ_DESTROY, oComp

END

PRO ExSinglePropSheet

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')

; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
    TITLE = 'Single Property Sheet Example', $
    KILL_NOTIFY = 'CleanupEvent')
prop = WIDGET_PROPERTYSHEET(base, VALUE = oComp, $
    EVENT_PRO = 'PropertyEvent', UNAME = 'PropSheet', $

```

```

        YSIZE=20, /MULTIPLE_PROPERTIES)

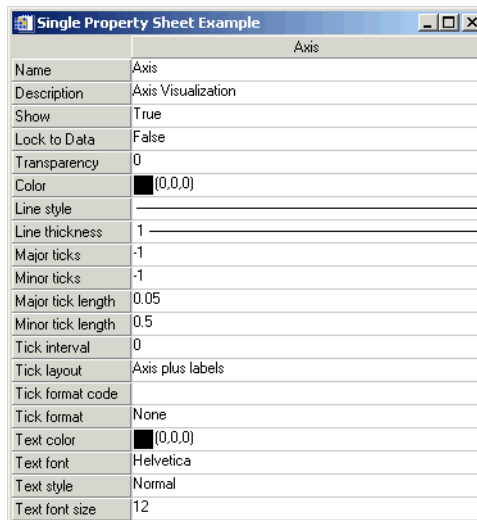

; Activate the widgets.
WIDGET_CONTROL, base, SET_UVALUE = oComp, /REALIZE

XMANAGER, 'ExSinglePropSheet', base, /NO_BLOCK

END

```

Save this program as `exsinglepropsheet.pro`, then compile and run the program. A property sheet entitled `Single Property Sheet Example` is displayed:

*Figure 3-147: Single Property Sheet Example*

For examples of the types of settings possible from the property sheet:

- Click the **Show** setting box, click the drop-down button, and select `False` from the list.
- Click the **Major tick length** setting box, click its drop-down button, and move the slider to select a new value.
- Click the **Text color** setting box, click the drop-down button, and select a new color from the color selector.

## Property Sheet Context Menu Example

The following simple example shows how to key event handling off of the event structure name instead of the event type. Attempting to use the CONTEXT\_EVENTS keyword without this type of code will cause an error, because, unlike the WIDGET\_PROPSHEET\_CHANGE and WIDGET\_PROPSHEET\_SELECT event structures, the WIDGET\_CONTEXT structure does not have a TYPE field.

```

; propsheet_context.pro
; For accessing property sheet widget context menus.

PRO prop_event, event

    ; Initiate event based on event structure name, not
    ; event type.
    SWITCH TAG_NAMES( EVENT, /STRUCTURE_NAME ) OF

        'WIDGET_PROPSHEET_CHANGE': $
            ; Placeholder for desired code.
            BEGIN
            BREAK
            END

        'WIDGET_PROPSHEET_SELECT': $
            ; Placeholder for desired code.
            BEGIN
            BREAK
            END

        'WIDGET_CONTEXT': $
            BEGIN
                contextBase = WIDGET_INFO( event.id, $
                    FIND_BY_UNAME = 'contextMenu' )

                ; Display the context menu at the x, y location
                ; of the right mouse click.
                WIDGET_DISPLAYCONTEXTMENU, $
                    event.id, event.x, event.y, contextBase
            BREAK
            END
    ENDSWITCH

END

PRO prop_cleanup, propSheet

    ; Clean up object references.
    WIDGET_CONTROL, propSheet, GET_UVALUE = oAxis
    OBJ_DESTROY, oAxis

```

```

END

PRO yes_event, event

    print, 'Yes'

END

PRO no_event, event

    print, 'No'

END

PRO propsheet_context

    tlb = WIDGET_BASE( /ROW, XOFFSET = 100, YOFFSET = 100 )

    ; Create a property sheet with axis properties.
    oAxis = OBJ_NEW( 'IDLitVisAxis' )

    propSheet = WIDGET_PROPERTY SHEET( tlb, $
        VALUE=oAxis, UVALUE=oAxis, KILL_NOTIFY='prop_cleanup', $
        /CONTEXT_EVENTS, EVENT_PRO = 'prop_event' )

    ; Create a base for the context menu.
    contextBase = WIDGET_BASE( propSheet, /CONTEXT_MENU, $
        UNAME = 'contextMenu' )

    ; Add two buttons to the context menu's base.
    cb1 = WIDGET_BUTTON( contextBase, VALUE = 'Yes', $
        EVENT_PRO = 'yes_event' )
    cb2 = WIDGET_BUTTON( contextBase, VALUE = 'No', $
        EVENT_PRO = 'no_event' )

    ; Activate the widgets.
    WIDGET_CONTROL, tlb, /REALIZE
    XMANAGER, 'propsheet_context', tlb, /NO_BLOCK

END

```

Save and run the example. Left-clicking selects a property. Right-clicking brings up the context menu. Selecting one of the context menu items prints a related string to the Output Log window.

## Version History

6.0	Introduced
6.1	Added EDITABLE, FRAME, IGNORE_ACCELERATORS, MULTIPLE_PROPERTIES, and SUNKEN_FRAME keywords Added NSELECTED field to WIDGET_PROPSHEET_SELECT event structure Added ROW and COL fields to WIDGET_CONTEXT event structure

[“Using Property Sheet Widgets”](#) in Chapter 30 of the *Building IDL Applications* manual

# WIDGET\_SLIDER

The `WIDGET_SLIDER` function is used to create slider widgets. Slider widgets are used to indicate an integer value from a range of possible values. They consist of a rectangular region which represents the possible range of values. Inside this region is a sliding pointer that displays the current value. This pointer can be manipulated by the user via the mouse, or from within IDL via the `WIDGET_CONTROL` procedure.

Figure 3-148: A Slider Widget

To indicate floating-point values, see [CW\\_FSLIDER](#).

## Syntax

```
Result = WIDGET_SLIDER( Parent [, /DRAG] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FONT=string] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id]
  [, KILL_NOTIFY=string] [, MAXIMUM=value] [, MINIMUM=value]
  [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, SCROLL=units] [, /SENSITIVE] [, /SUPPRESS_VALUE]
  [, TAB_MODE=value] [, TITLE=string] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
  [, /VERTICAL] [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value]
  [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created slider widget.

# Arguments

## Parent

The widget ID of the parent for the new slider widget.

# Keywords

## DRAG

Set this keyword to cause events to be generated continuously while the slider is being dragged by the user. Normally, slider widgets generate position events only when the slider comes to rest at its final position and the mouse button is released.

When a slider widget is set to return drag events, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

## EVENT\_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the GET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET\_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET\_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET\_EVENT function is called.

## MAXIMUM

The maximum value of the range encompassed by the slider. If this keyword is not supplied, a default of 100 is used.

## MINIMUM

The minimum value of the range encompassed by the slider. If this keyword is not supplied, a default of 0 is used.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_SLIDER` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See [“RESOURCE\\_NAME”](#) on page 2499 for a complete discussion of this keyword.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set the SCROLL keyword to an integer value specifying the number of integer units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The default on both platforms is  $0.1 \times (\text{MAXIMUM} - \text{MINIMUM})$ , which is 10% of the slider range.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## SUPPRESS\_VALUE

Set this keyword to inhibit the display of the current slider value.

Sliders work only with integer units. This keyword can be used to suppress the actual value of a slider so that a program can present the user with a slider that seems to work in other units (such as floating-point) or with a non-linear scale.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for WIDGET\_BASE.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets from the parent `WIDGET_BASE` unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

Once the `WIDGET_SLIDER` has focus, use the **Home** and **End** keys, and right and left arrow keys to change the marker value on Windows. The **Page Up** and **Page Down** keys can also be used on Windows to increase or decrease the slider maker

value by multiple units at a time. On UNIX, the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TITLE

A string containing the title to be used for the slider widget.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a widget slider is the integer value of the current slider position.

## VERTICAL

Set this keyword to create a vertical slider. If this keyword is omitted, the slider is horizontal.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

### Note

---

Setting XSIZE for a vertical slider (created with the VERTICAL keyword) does not change the visible width of the slider itself, but does change the amount of horizontal space occupied by the widget within its parent base.

---

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

### Note

---

Setting YSIZE for a horizontal slider does not change the visible height of the slider itself, but does change the amount of vertical space occupied by the widget within its parent base.

---

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of slider widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [GET\\_VALUE](#), [SET\\_SLIDER\\_MAX](#), [SET\\_SLIDER\\_MIN](#), [SET\\_VALUE](#).

## Keywords to WIDGET\_INFO

Some keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to slider widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [SLIDER\\_MIN\\_MAX](#), [STRING\\_SIZE](#).

## Widget Events Returned by Slider Widgets

Slider widgets generate events when the mouse is used to change their value. The event structure returned by the [WIDGET\\_EVENT](#) function is defined by the following statement:

```
{WIDGET_SLIDER, ID:0L, TOP:0L, HANDLER:0L, VALUE:0L, DRAG:0}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. VALUE returns the new value of the slider.

DRAG returns integer 1 if the slider event was generated as part of a drag operation, or zero if the event was generated when the user had finished positioning the slider.

Note that the slider widget only generates events during the drag operation if the DRAG keyword is set. When the DRAG keyword is set, the DRAG field can be used to avoid computationally expensive operations until the user releases the slider.

## Known Implementation Problems

Under Motif 1.0, vertical sliders with a title organized in row bases get horizontally truncated and the slider doesn't show (the title does). Use the XSIZE keyword to work around this.

## Version History

Pre-4.0	Introduced
6.1	Added TAB_MODE keyword

# WIDGET\_TAB

The `WIDGET_TAB` function is used to create a tab widget. Tab widgets present a display area on which different pages (base widgets and their children) can be displayed by selecting the appropriate tab — that is, selecting a tab displays the contents of a specified base widget within the tab widget. The titles of the tabs are supplied as the values of the `TITLE` keyword for each of the tab widget’s child base widgets.

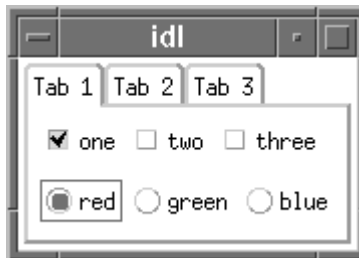

Figure 3-149: A Tab Widget

For a more detailed discussion of the tab widget, along with examples, see “Using Tab Widgets” in Chapter 30 of the *Building IDL Applications* manual.

## Syntax

```
Result = WIDGET_TAB( Parent [, /ALIGN_BOTTOM | , /ALIGN_CENTER | ,
  /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FUNC_GET_VALUE=string]
  [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string]
  [, LOCATION={0 | 1 | 2 | 3}] [, MULTILINE=0 | 1 (Windows) or num tabs per
  row (Motif)] [, /NO_COPY] [, NOTIFY_REALIZE=string]
  [, PRO_SET_VALUE=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value]
  [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created tab widget.

# Arguments

## Parent

The widget ID of the parent for the new tab widget.

### Note

---

Only base widgets can be the parent of a tab widget.

---

# Keywords

## **ALIGN\_BOTTOM**

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## **ALIGN\_CENTER**

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## **ALIGN\_LEFT**

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## **ALIGN\_RIGHT**

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## **ALIGN\_TOP**

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## **EVENT\_FUNC**

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## LOCATION

Set this keyword equal to an integer that specifies which edge of the tab widget will contain the tabs. The possible values are:

0	The tabs are placed along the top of the widget, which is the default behavior.
---	---

1	The tabs are placed along the bottom of the widget.
2	The tabs are placed along the left edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.
3	The tabs are placed along the right edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.

## MULTILINE

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and Motif systems.

### Windows

Set this keyword to cause tabs to be organized in a multiline display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE = 0 and LOCATION = 0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION = 1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

### Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

### Motif

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

**Note**

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. However, tab text may be truncated if the text of a single tab exceeds the space available. If `MULTILINE` is set to any value other than one, some tabs may not be displayed.

**NO\_COPY**

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the `UVALUE` keyword to `WIDGET_TAB` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. Upon a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

**NOTIFY\_REALIZE**

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

**PRO\_SET\_VALUE**

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the `PRO_SET_VALUE` keyword to `WIDGET_CONTROL` for information on using this keyword.

## SCR\_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

---

### Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

---

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#).

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

---

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the <code>TAB_MODE</code> Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

When a `WIDGET_TAB` widget receives focus through tabbing, the tab title is outlined. Navigate to other tabs using the **End** key, **Home** key, or the right and left arrow keys to switch focus between the tabs. Pressing the **Tab** key brings into focus the first child widget on the tab capable of receiving focus. On UNIX, the Motif library controls tabbing functionality

After creating the widget hierarchy, you can change tabbing support using the [`WIDGET\_CONTROL`](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [`WIDGET\_INFO`](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“`TRACKING\_EVENTS`”](#) on page 2506 in the documentation for `WIDGET_BASE`.

## UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

## UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) affect the behavior of tab widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [BASE\\_SET\\_TITLE](#), [SET\\_TAB\\_CURRENT](#), [SET\\_TAB\\_MULTILINE](#).

## Keywords to WIDGET\_INFO

Some keywords to the [WIDGET\\_INFO](#) return information that applies specifically to tab widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [STRING\\_SIZE](#), [TAB\\_CURRENT](#), [TAB\\_MULTILINE](#), [TAB\\_NUMBER](#).

## Widget Events Returned by Tab Widgets

Tab widgets generate events when a new tab is selected. The event structure returned by the [WIDGET\\_EVENT](#) function is defined by the following statement:

```
{WIDGET_TAB, ID:0L, TOP:0L, HANDLER:0L, TAB:0L}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget

associated with the handler routine. TAB returns the zero-based index of the tab selected.

## Version History

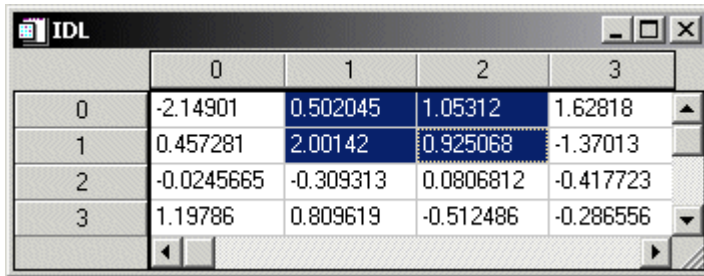

5.6	Introduced
6.1	Added TAB_MODE keyword

## See Also

[“Using Tab Widgets”](#) in Chapter 30 of the *Building IDL Applications* manual

# WIDGET\_TABLE

The WIDGET\_TABLE function creates table widgets. Table widgets are used to display two-dimensional data in tabular format. Individual table cells (or ranges of cells) can be selected for editing by the user. They can have one or more rows and columns, and automatically create scroll bars when viewing more data than can otherwise be displayed on the screen.

	0	1	2	3
0	-2.14901	0.502045	1.05312	1.62818
1	0.457281	2.00142	0.925068	-1.37013
2	-0.0245665	-0.309313	0.0806812	-0.417723
3	1.19786	0.809619	-0.512486	-0.286556

Figure 3-150: A Table Widget

For a more detailed discussion of the table widget, along with examples, see “Using Table Widgets” in Chapter 30 of the *Building IDL Applications* manual.

## Note on Table Sizing

Table widgets are sized according to the value of the following pairs of keywords to WIDGET\_TABLE, in order of precedence: `SCR_XSIZE/SCR_YSIZE`, `XSIZE/YSIZE`, `X_SCROLL_SIZE/Y_SCROLL_SIZE`, `VALUE`. If either dimension remains unspecified by one of the above keywords, the default value of six (columns or rows) is used when the table is created. If the width or height specified is less than the size of the table, scroll bars are added automatically.

## Syntax

```
Result = WIDGET_TABLE( Parent [, ALIGNMENT={0 | 1 | 2}] [, /ALL_EVENTS]
  [, AM_PM=[string, string]] [, BACKGROUND_COLOR=array]
  [, COLUMN_LABELS=string_array]
  [, /COLUMN_MAJOR | , /ROW_MAJOR] [, COLUMN_WIDTHS=array]
  [, /CONTEXT_EVENTS] [, DAYS_OF_WEEK=string_array{7 names}]
  [, /DISJOINT_SELECTION] [, /EDITABLE] [, EVENT_FUNC=string]
```

```
[, EVENT_PRO=string] [, FONT=string] [, FOREGROUND_COLOR=array]
[, FORMAT=value] [, FRAME=width] [, FUNC_GET_VALUE=string]
[, GROUP_LEADER=widget_id] [, IGNORE_ACCELERATORS=value]
[, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=string]
[, MONTHS=string_array{12 names}] [, /NO_COLUMN_HEADERS]
[, /NO_COPY] [, /NO_HEADERS] [, /NO_ROW_HEADERS]
[, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
[, /RESIZEABLE_COLUMNS] [, /RESIZEABLE_ROWS]{not supported in
Windows}] [, RESOURCE_NAME=string] [, ROW_HEIGHTS=array]
[, ROW_LABELS=string_array] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
[, /SCROLL] [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
[, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
[, XOFFSET=value] [, XSIZE=value] [, X_SCROLL_SIZE=width]
[, YOFFSET=value] [, YSIZE=value] [, Y_SCROLL_SIZE=height] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created table widget.

## Arguments

### Parent

The widget ID of the parent widget for the new table widget.

## Keywords

### ALIGNMENT

Set this keyword equal to a scalar or 2-D array specifying the alignment of the text within each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell. If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

### ALL\_EVENTS

Set this keyword to cause the table widget to generate events whenever the user changes the contents of a table cell.

**Note**

If the **EDITABLE** keyword is set, an insert character event (TYPE=0) is generated when you press the **Return** or **Enter** key in the table widget, even if the **ALL\_EVENTS** keyword is not set. You could use such end-of-line events as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between **ALL\_EVENTS** and **EDITABLE**.

Keywords		Effects	
ALL_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated.
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 3-135: Effects of Using the **ALL\_EVENTS** and **EDITABLE** Keywords

**AM\_PM**

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the **FORMAT** keyword.

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

**BACKGROUND\_COLOR**

Set this keyword to one or more RGB triplets to specify cell background colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the

colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

---

**Note**

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

---

For more information, see [“Cell Attributes”](#) in Chapter 30 of the *Building IDL Applications* manual.

## COLUMN\_LABELS

Set this keyword equal to an array of strings used as labels for the columns of the table widget. The default labels are of the form “*n*”, where *n* is the column number. If this keyword is set to the empty string ( ' ' ), all column labels are set to be empty.

---

**Note**

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## COLUMN\_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the [VALUE](#) keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one column's data. Note that the structures must all be of the same type, and must have one field for each row in the table. If this keyword is not set, the table widget behaves as if the `ROW_MAJOR` keyword were set.

## COLUMN\_WIDTHS

Set this keyword equal to an array of widths for the columns of the table widget. The widths are given in any of the units as specified with the `UNITS` keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If `COLUMN_WIDTHS` is set to a scalar value, all columns are set to that width.

---

**Note**

Column widths are limited to 0.

---

## CONTEXT\_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when you click the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. This is the default. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus). Pass the context event ID to the [WIDGET\\_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see [“Context-Sensitive Menus”](#) in Chapter 30 of the *Building IDL Applications* manual.

## DAYS\_OF\_WEEK

Supplies a string array of seven names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the `FORMAT` keyword.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## DISJOINT\_SELECTION

Set this keyword to enable the ability to select multiple rectangular regions of cells. The regions can be overlapping, touching, or entirely distinct.

Setting this keyword changes the data structures returned by the [TABLE\\_SELECT](#) keyword to `WIDGET_INFO` and the [GET\\_VALUE](#) keyword to `WIDGET_CONTROL`. Similarly, the data structures you supply via the [SET\\_TABLE\\_SELECT](#) and [SET\\_VALUE](#) keywords to `WIDGET_CONTROL` are different in disjoint mode.

See [“Selection Modes”](#) in Chapter 30 of the *Building IDL Applications* manual for additional details.

## EDITABLE

Set this keyword to allow or deny direct user editing of table cells. The default value is zero, which prevents user editing. Non-zero values permit user editing. Scalar values are applied to all cells and used as the default for new cells. When you supply an array, the values are applied row by row, left to right, working from the top row to the bottom row. When there are fewer values than cells, IDL cycles through the values repeatedly. Each value should be a single byte.

See “[ALL\\_EVENTS](#)” on page 2709 for a description of how EDITABLE interacts with the ALL\_EVENTS keyword.

---

**Note**

The method by which table widgets are placed into edit mode is dependent upon the windowing system. See “[Edit Mode](#)” in the *Building IDL Applications* manual.

---

## EVENT\_FUNC

Set this keyword to a string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

Set this keyword to a string containing the name of a procedure to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

Set this keyword to the names of the fonts used by the widget. Specified fonts are “device fonts” (an X Windows font on Motif systems, a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

When you supply a scalar value, IDL uses the font for all cells and as the default table font. It uses the default font in headers and new cells. If you supply more than one font, IDL applies these fonts row by row, left to right, working from the top row to the bottom row, repeatedly if necessary (if there are fewer fonts than cells).

---

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

---

## BACKGROUND\_COLOR

Set this keyword to one or more RGB triplets to specify cell text colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the

colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

---

**Note**

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

---

For more information, see [“Cell Attributes”](#) in Chapter 30 of the *Building IDL Applications* manual.

## FORMAT

Set this keyword equal to a single string or array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the `FORMAT` keyword to the `PRINT` procedure, and the default format is the same as that used by the `PRINT` procedure.

---

**Warning**

If the format specified is incompatible with the data displayed in a table cell, an error message is generated. Since the error is generated *for each cell displayed*, the number of messages printed is potentially large, and can slow execution significantly. Note also that each time a new cell is displayed (when scroll bars are repositioned, for example), a new error is generated *for each cell displayed*.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## IGNORE\_ACCELERATORS

Set this keyword to specify what `WIDGET_BUTTON` accelerators are to be ignored when this table widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for `WIDGET_BUTTON`'s [ACCELERATOR](#) keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “Ctrl+V” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a table, attempting to use **Ctrl+V** to paste text into the table cell would fail as this event would be stolen by the accelerator. Setting `IGNORE_ACCELERATORS` to “Ctrl+V” allows a table widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once a table loses focus, all specified accelerators are automatically re-enabled.

### Note

---

Accelerators are suspended only when a table cell is in edit mode.

---

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## KBRD\_FOCUS\_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “[Widget Events Returned by Table Widgets](#)” on page 2724 for more information.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET\_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET\_EVENT function is called.

## MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

### Note

---

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## NO\_COLUMN\_HEADERS

Set this keyword to disable the display of the table widget’s column header area. The setting for the NO\_HEADERS keyword supersedes any setting for this keyword.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET\_UVALUE and GET\_UVALUE keywords to WIDGET\_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO\_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET\_TABLE or the SET\_UVALUE keyword to WIDGET\_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET\_UVALUE

keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## **NO\_HEADERS**

Set this keyword to disable the display of the table widget's header area (where row and column labels are normally displayed).

## **NO\_ROW\_HEADERS**

Set this keyword to disable the display of the table widget's row header area. The setting for the `NO_HEADERS` keyword supersedes any setting for this keyword.

## **NOTIFY\_REALIZE**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## **PRO\_SET\_VALUE**

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the `PRO_SET_VALUE` keyword to `WIDGET_CONTROL` for information on using this keyword.

## **RESIZEABLE\_COLUMNS**

Set this keyword to allow the user to change the size of columns using the mouse. Note that if the `NO_HEADERS` keyword was set, the columns cannot be resized interactively.

## **RESIZEABLE\_ROWS**

Set this keyword to allow the user to change the size of rows using the mouse. Note that if the `NO_HEADERS` keyword was set, the rows cannot be resized interactively.

Under Microsoft Windows, the row size cannot be changed.

## **RESOURCE\_NAME**

A string containing an X Window System resource name to be applied to the widget. See "`RESOURCE_NAME`" on page 2499 for a complete discussion of this keyword.

## ROW\_HEIGHTS

Set this keyword equal to an array of heights for the rows of the table widget. The heights are given in any of the units as specified with the [UNITS](#) keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If `ROW_HEIGHTS` is set to a scalar value, all of the row heights are set to that value.

---

**Note**

On Microsoft Windows platforms, rows cannot have different heights. If you supply an array of values, IDL applies the last value to all rows.

---

---

**Note**

Row heights are limited to 0 on Motif and 1 on Windows.

---

## ROW\_LABELS

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label “*n*”, where *n* is the row number. If this keyword is set to the empty string ( ' ' ), all row labels are set to be empty.

## ROW\_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the [VALUE](#) keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one row’s data. Note that the structures must all be of the same type, and must have one field for each column in the table. This is the default behavior if neither the `COLUMN_MAJOR` or `ROW_MAJOR` keyword is set.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). Note that the screen width of the widget *includes* the width of scroll bars, if any are present. Setting `SCR_XSIZE` overrides values set for the `XSIZE` or `X_SCROLL_SIZE` keywords. See “[Note on Table Sizing](#)” on page 2708.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen height of the widget *includes* the height of scroll bars, if any are present. Setting SCR\_YSIZE overrides values set for the YSIZE or Y\_SCROLL\_SIZE keywords. See “[Note on Table Sizing](#)” on page 2708.

## SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. See “[Note on Table Sizing](#)” on page 2708

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

---

### Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

---

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the <code>TAB_MODE</code> Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

When a `WIDGET_TABLE` widget receives focus through tabbing, the result is platform dependent:

- On Windows – table widgets can receive and lose focus through tabbing, but the focus is not clearly depicted.
- On UNIX – the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the [`WIDGET\_CONTROL`](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [`WIDGET\_INFO`](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure

of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for `WIDGET_BASE`.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

### Note

---

This keyword does not affect all sizing operations. Specifically, the value of `UNITS` is ignored when setting the `XSIZE` or `YSIZE` keywords.

---

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a table widget is either a two-dimensional array of any data type or a vector of structures, representing the contents of the table.

If the value is specified as a two-dimensional array, all data must be of the same data type.

If the value is specified as a vector of structures, it can be displayed either in column-major or row-major format by setting either the `COLUMN_MAJOR` keyword or the `ROW_MAJOR` keyword. All of the structures must be of the same type, and must contain one field for each row (if `COLUMN_MAJOR` is set) or column (if `ROW_MAJOR` is set) in the table. (Setting `ROW_MAJOR` means that each structure is given its own row, and hence the number of columns should match the number of fields.) If neither keyword is set, the data is displayed in row major format. The individual structure fields can be of any data type.

---

**Note**

If the `VALUE` keyword is not specified, the data in the created table will be of type `STRING`.

---

If none of `[XY]SIZE`, `SCR_[XY]SIZE`, or `[XY]_SCROLL_SIZE` is present, the size of the table is determined by the size of the array or vector of structures specified by `VALUE`. See “[Note on Table Sizing](#)” on page 2708.

## XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in columns. If row labels are present, one column is automatically added to this value. See “[Note on Table Sizing](#)” on page 2708.

## X\_SCROLL\_SIZE

The `XSIZE` keyword always specifies the width of a widget, in columns. When the `SCROLL` keyword is specified, this size is not necessarily the same as the width of the visible area. The `X_SCROLL_SIZE` keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget. See “[Note on Table Sizing](#)” on page 2708.

Use of the `X_SCROLL_SIZE` keyword implies `SCROLL`. This means that scroll bars will be added in both the horizontal and vertical directions when `X_SCROLL_SIZE` is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify `Y_SCROLL_SIZE` when specifying `X_SCROLL_SIZE`.

## YOFFSET

The vertical offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## YSIZE

The height of the widget in rows. If column labels are present, one row is automatically added to this value. See [“Note on Table Sizing”](#) on page 2708.

## Y\_SCROLL\_SIZE

The `YSIZE` keyword always specifies the height of a widget, in rows. When the `SCROLL` keyword is specified, this size is not necessarily the same as the height of the visible area. The `Y_SCROLL_SIZE` keyword allows you to set the height of the scrolling viewport independently of the actual width of the widget. See [“Note on Table Sizing”](#) on page 2708.

Use of the `Y_SCROLL_SIZE` keyword implies `SCROLL`. This means that scroll bars will be added in both the horizontal and vertical directions when `Y_SCROLL_SIZE` is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify `X_SCROLL_SIZE` when specifying `Y_SCROLL_SIZE`.

## Keywords to WIDGET\_CONTROL

A number of keywords to the `WIDGET_CONTROL` procedure affect the behavior of table widgets. In addition to those keywords that affect all widgets, the following are particularly useful: `ALIGNMENT`, `ALL_TABLE_EVENTS`, `BACKGROUND_COLOR`, `COLUMN_LABELS`, `COLUMN_WIDTHS`, `CONTEXT_EVENTS`, `DELETE_COLUMNS`, `DELETE_ROWS`, `EDITABLE`, `FOREGROUND_COLOR`, `EDIT_CELL`, `FONT`, `FORMAT`, `GET_VALUE`,

IGNORE\_ACCELERATORS, INSERT\_COLUMNS, INSERT\_ROWS, KBRD\_FOCUS\_EVENTS, ROW\_LABELS, ROW\_HEIGHTS, SET\_TABLE\_SELECT, SET\_TABLE\_VIEW, SET\_TEXT\_SELECT, SET\_VALUE, TABLE\_BLANK, TABLE\_DISJOINT\_SELECTION, TABLE\_XSIZE, TABLE\_YSIZE, USE\_TABLE\_SELECT, USE\_TEXT\_SELECT.

## Keywords to WIDGET\_INFO

A number of keywords to the `WIDGET_INFO` function return information that applies specifically to table widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: `COLUMN_WIDTHS`, `CONTEXT_EVENTS`, `KBRD_FOCUS_EVENTS`, `ROW_HEIGHTS`, `STRING_SIZE`, `TABLE_ALL_EVENTS`, `TABLE_BACKGROUND_COLOR`, `TABLE_DISJOINT_SELECTION`, `TABLE_EDITABLE`, `TABLE_EDIT_CELL`, `TABLE_FONT`, `TABLE_FOREGROUND_COLOR`, `TABLE_SELECT`, `TABLE_VIEW`, `TEXT_SELECT`, `USE_TABLE_SELECT`.

## Widget Events Returned by Table Widgets

There are several variations of the table widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (`ID`, `TOP`, and `HANDLER`). Several contain an integer `TYPE` field that indicates which type of structure has been returned. Others, such as keyboard focus and context menu event structures, do not. If an event structure is known to have a `TYPE` field, check this first before branching to further event handling code. If it is possible that the event structure is a keyboard focus or context menu type, check the `STRUCTURE_NAME` of the event structure first. The different table widget event structures are described below.

### Insert Single Character (`TYPE = 0`)

This is the type of structure returned when a single character is typed into a cell of a table widget by a user.

```
{WIDGET_TABLE_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
  CH:0B, X:0L, Y:0L }
```

`OFFSET` is the (zero-based) insertion position that will result after the character is inserted. `CH` is the ASCII value of the character. `X` and `Y` give the zero-based address of the cell within the table.

## Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a cell by the window system.

```
{WIDGET_TABLE_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:'', X:0L, Y:0L}
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted. X and Y give the zero-based address of the cell within the table.

## Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a cell of a table widget.

```
{WIDGET_TABLE_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L, X:0L, Y:0L}
```

OFFSET is the (zero-based) character position of the first character deleted. It is also the insertion position that will result when the next character is inserted. LENGTH gives the number of characters involved. X and Y give the zero-based address of the cell within the table.

## Text Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{WIDGET_TABLE_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3,
  OFFSET:0L, LENGTH:0L, X:0L, Y:0L}
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that the widget has no selection, and that the insertion position is given by OFFSET. X and Y give the zero-based address of the cell within the table.

### Note

---

Text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is not sent.

---

## Cell Selection (TYPE = 4)

This is the type of structure returned when range of cells is selected (highlighted) or deselected by the user.

```
{WIDGET_TABLE_CELL_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:4,
  SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The event announces a change in the currently selected cells. The range of cells selected is given by the zero-based indices into the table specified by the SEL\_LEFT, SEL\_TOP, SEL\_RIGHT, and SEL\_BOTTOM fields.

---

### Note

If the table is in disjoint selection mode, selecting an additional region will result in a new WIDGET\_TABLE\_CELL\_SEL event that reflects only the newly-selected cells. Use WIDGET\_INFO, /TABLE\_SELECT to obtain the entire selected region in disjoint selection mode.

---

When cells are deselected (either by changing the selection or by clicking in the upper left corner of the table) an event is generated in which the SEL\_LEFT, SEL\_TOP, SEL\_RIGHT, and SEL\_BOTTOM fields contain the value -1. This means that two WIDGET\_TABLE\_CELL\_SEL events are generated when an existing selection is changed to a new selection. If your code pays attention to WIDGET\_TABLE\_CELL\_SEL events, be sure to differentiate between select and deselect events.

---

### Note

If the table is in disjoint selection mode and a new cell range is selected *starting on a previously-selected cell*, the previously selected cells are deselected but a WIDGET\_TABLE\_CELL\_DESEL event is generated for the deselection rather than a WIDGET\_TABLE\_CELL\_SEL event. See [“Cell Deselection \(Disjoint Mode\) \(TYPE = 9\)”](#) on page 2727 for details.

---

## Row Height Changed (TYPE = 6)

This is the type of structure returned when a row height is changed by the user.

```
{WIDGET_TABLE_ROW_HEIGHT, ID:0L, TOP:0L, HANDLER:0L, TYPE:6,
  ROW:0L, HEIGHT:0L}
```

The event announces that the height of the given row has been changed by the user. The ROW field contains the zero-based row number, and the HEIGHT field contains the new height.

## Column Width Changed (TYPE = 7)

This is the type of structure returned when a column width is changed by the user.

```
{WIDGET_TABLE_COL_WIDTH, ID:0L, TOP:0L, HANDLER:0L, TYPE:7,
  COL:0L, WIDTH:0L}
```

The event announces that the width of the given column has been changed by the user. The COL field contains the zero-based column number, and the WIDTH field contains the new width.

## Invalid Data (TYPE = 8)

This is the type of structure returned when the text entered by the user does not pass validation, and the user has finished editing the field (by hitting TAB or ENTER).

```
{WIDGET_TABLE_INVALID_ENTRY, ID:0L, TOP:0L, HANDLER:0L, TYPE:8,
  STR:'', X:0L, Y:0L}
```

When this event is generated, the cell's data is left unchanged. The invalid contents entered by the user is given as a text string in the STR field. The cell location is given by the X and Y fields.

## Cell Deselection (Disjoint Mode) (TYPE = 9)

This is the type of structure returned when selected cells are de-selected by the user *and the table is in disjoint selection mode*. It is identical to the (TYPE = 4) WIDGET\_TABLE\_CELL\_SEL event structure except for the name and type value.

This event occurs when the user holds down the control key when starting a selection and the cell used to start the selection was already selected. In contrast, if the user starts a selection with the control key down but starts on a cell that was not selected, the normal WIDGET\_TABLE\_CELL\_SEL is generated.

```
{WIDGET_TABLE_CELL_DESEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:9,
  SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The range of cells selected is given by the zero-based indices into the table specified by the SEL\_LEFT, SEL\_TOP, SEL\_RIGHT, and SEL\_BOTTOM fields.

## Keyboard Focus Events

Table widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD\_FOCUS\_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the table widget generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget

associated with the handler routine. The ENTER field returns 1 (one) if the table widget is gaining the keyboard focus, or 0 (zero) if the table widget is losing the keyboard focus.

## Context Menu Events

A table widget created with the CONTEXT\_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the table widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

For table widgets, ROW and COL indicate the zero-based index of the cell that was clicked on when the context menu was initiated. The upper-left data cell has a row and column index of 0,0. Row and column headers have indices of -1. If the context-menu event takes place outside of all table cells and headers, then both ROW and COL will have values of -1.

### Note

When working with table widget context menu events or keyboard focus events, it is important to notice that the event structures do not have a TYPE field, so special code is needed for the table event handler. Instead of keying off the TYPE field, use the event structure's name. See [“Property Sheet Context Menu Example”](#) on page 2685 for sample code dealing with the same issue.

## Version History

5.0	Introduced
5.6	Added DISJOINT_SELECTION keyword and cell deselection (TYPE = 9) event
6.1	Added ROW and COL fields to WIDGET_CONTEXT event structure Added CONTEXT_EVENTS, IGNORE_ACCELERATORS, NO_COLUMN_HEADERS, NO_ROW_HEADERS, and TAB_MODE keywords

---

6.2	Added BACKGROUND_COLOR, EDITABLE, FONT, and FOREGROUND_COLOR keywords
-----	---

---

[WIDGET\\_CONTROL](#)

# WIDGET\_TEXT

The WIDGET\_TEXT function creates text widgets. Text widgets display text and optionally get textual input from the user. They can have one or more lines, and can optionally contain scroll bars to allow viewing more text than can otherwise be displayed on the screen.

Figure 3-151: A Text Widget

## Syntax

```
Result = WIDGET_TEXT( Parent [, /ALL_EVENTS] [, /CONTEXT_EVENTS]
  [, /EDITABLE] [, EVENT_FUNC=string] [, EVENT_PRO=string]
  [, FONT=string] [, FRAME=width] [, FUNC_GET_VALUE=string]
  [, GROUP_LEADER=widget_id] [, IGNORE_ACCELERATORS=value]
  [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=string] [, /NO_COPY]
  [, /NO_NEWLINE] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SCROLL] [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
  [, /WRAP] [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value]
  [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created text widget.

## Arguments

### Parent

The widget ID of the parent widget for the new text widget.

## Keywords

### ALL\_EVENTS

Set this keyword to cause the text widget to generate events whenever the user changes the contents of the text area.

#### Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL\_EVENTS keyword is not set. See the table below for details on the interaction between ALL\_EVENTS and EDITABLE.

Keywords		Effects	
ALL_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated.
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 3-136: Effects of using the ALL\_EVENTS and EDITABLE keywords

### CONTEXT\_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET\\_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

## EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See [ALL\\_EVENTS](#) for a description of how EDITABLE interacts with the ALL\_EVENTS keyword.

See “[ALL\\_TEXT\\_EVENTS](#)” on page 2544 for a description of how EDITABLE interacts with the ALL\_TEXT\_EVENTS keyword.

## EVENT\_FUNC

A string containing the name of a function to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the WIDGET\_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

---

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

---

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

---

**Note**

This keyword is only a “hint” to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets *always* have frames.

---

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## IGNORE\_ACCELERATORS

Set this keyword to specify what `WIDGET_BUTTON` accelerators are to be ignored when this text widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for `WIDGET_BUTTON`'s [ACCELERATOR](#) keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “`Ctrl+V`” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a text widget, attempting to use `Ctrl+V` to paste text into the text widget would fail as this event would be stolen by the accelerator. Setting `IGNORE_ACCELERATORS` to “`Ctrl+V`” allows a text widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the text widget loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## KBRD\_FOCUS\_EVENTS

Set this keyword to make the text widget return keyboard focus events whenever the keyboard focus of the widget changes. See “[Widget Events Returned by Text Widgets](#)” on page 2740 for more information.

## **KILL\_NOTIFY**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

## **NO\_COPY**

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_TEXT` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## **NO\_NEWLINE**

Normally, when setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. Set this keyword to suppress this action.

## **NOTIFY\_REALIZE**

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the SET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## RESOURCE\_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE\\_NAME](#)” on page 2499 for a complete discussion of this keyword.

## SCR\_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#) procedure.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets from the parent `WIDGET_BASE` unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

### Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ <a href="#">Inheriting the TAB_MODE Value</a> ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

### Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the `WIDGET_INFO` procedure’s `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for WIDGET\_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) function with the [FIND\\_BY\\_UNAME](#) keyword. The UNAME should be unique to the widget hierarchy because the [FIND\\_BY\\_UNAME](#) keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by [WIDGET\\_INFO](#).

### Note

---

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the [XSIZE](#) or [YSIZE](#) keywords to [WIDGET\\_TEXT](#).

---

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a text widget is the current text displayed by the widget.

VALUE can be either a string or an array of strings. Note that variables returned by the GET\_VALUE keyword to WIDGET\_CONTROL are always string arrays, even if a scalar string is specified in the call to WIDGET\_TEXT. When setting this value using WIDGET\_CONTROL, by default the old text is replaced by the new text. Specifying the APPEND keyword to WIDGET\_CONTROL causes the new text to be appended to the old text.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## WRAP

Set this keyword to indicate that scrolling or multi-line text widgets should automatically break lines between words to keep the text from extending past the right edge of the text display area. Note that carriage returns are *not* automatically entered when lines wrap; the value of the text widget will remain a single-element array unless you explicitly enter a carriage return.

---

### Note

On Windows, the maximum line length for a multi-line text widget is 1024 characters, regardless of this keyword value.

---

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in characters. Note that the physical width of the text widget depends on both the value of XSIZE and on the size of the font used. The default value of XSIZE varies according to your windowing system. On Windows, the default size is roughly 20 characters. On Motif, the default size depends on the width of the text widget.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## YSIZE

The height of the widget in text lines. Note that the physical height of the text widget depends on both the value of YSIZE and on the size of the font used. The default value of YSIZE is one line.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) procedure affect the behavior of text widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [ALL\\_TEXT\\_EVENTS](#), [APPEND](#), [CONTEXT\\_EVENTS](#), [EDITABLE](#), [GET\\_VALUE](#), [KBRD\\_FOCUS\\_EVENTS](#), [IGNORE\\_ACCELERATORS](#), [INPUT\\_FOCUS](#), [NO\\_NEWLINE](#), [SET\\_TEXT\\_SELECT](#), [SET\\_TEXT\\_TOP\\_LINE](#), [SET\\_VALUE](#), [USE\\_TEXT\\_SELECT](#).

## Keywords to WIDGET\_INFO

A number of keywords to the [WIDGET\\_INFO](#) function return information that applies specifically to text widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [CONTEXT\\_EVENTS](#), [KBRD\\_FOCUS\\_EVENTS](#), [STRING\\_SIZE](#), [TEXT\\_ALL\\_EVENTS](#), [TEXT\\_EDITABLE](#), [TEXT\\_NUMBER](#), [TEXT\\_OFFSET\\_TO\\_XY](#), [TEXT\\_SELECT](#), [TEXT\\_TOP\\_LINE](#), [TEXT\\_XY\\_TO\\_OFFSET](#).

## Widget Events Returned by Text Widgets

There are several variations of the text widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all text event structures. The different text widget event structures are described below.

### Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed or pasted into a text widget by a user.

```
{ WIDGET_TEXT_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
  CH:0B }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character.

### Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a text widget by the window system.

```
{ WIDGET_TEXT_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:'' }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted.

### Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a text widget.

```
{ WIDGET_TEXT_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L }
```

OFFSET is the (zero-based) character position of the first character to be deleted. It is also the insertion position that will result when the characters have been deleted. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters were deleted.

## Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{ WIDGET_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3, OFFSET:0L,
  LENGTH:0L }
```

The event announces a change in the insertion point. `OFFSET` is the (zero-based) character position of the first character to be selected. `LENGTH` gives the number of characters involved. A `LENGTH` of zero indicates that no characters are selected, and the new insertion position is given by `OFFSET`.

Note that text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is *not* sent.

## Keyboard Focus Events

Text widgets return the following event structure when the keyboard focus changes and the widget was created with the `KBRD_FOCUS_EVENTS` keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

The first three fields are the standard fields found in every widget event. The `ENTER` field returns 1 (one) if the text widget is gaining the keyboard focus, or 0 (zero) if the text widget is losing the keyboard focus.

## Context Menu Events

A text widget created with the `CONTEXT_EVENTS` keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The `X` and `Y` fields give the device coordinates at which the event occurred, measured from the upper left corner of the text widget. The `ROW` and `COL` fields return meaningful information for table widgets and values of zero (0) for other widgets.

## Version History

Pre-4.0	Introduced
6.1	Added IGNORE_ACCELERATORS and TAB_MODE keywords Added ROW and COL fields to WIDGET_CONTEXT event structure

# WIDGET\_TREE

The `WIDGET_TREE` function is used to create and populate a tree widget. The tree widget presents a hierarchical view that can be used to organize a wide variety of data structures and information. The `WIDGET_TREE` function performs two separate tasks: creating the tree widget and populating the tree widget with *nodes* (branches and leaves). Branches on the tree can be expanded or collapsed by the user, displaying different portions of the structure.

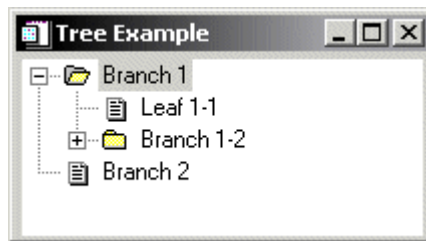

Figure 3-152: A Tree Widget

For a more detailed discussion of the tree widget, along with examples, see “[Using Tree Widgets](#)” in Chapter 30 of the *Building IDL Applications* manual.

## Syntax

```
Result = WIDGET_TREE( Parent [, /ALIGN_BOTTOM | , /ALIGN_CENTER | ,
    /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, BITMAP=array]
    [, /CONTEXT_EVENTS] [, EVENT_FUNC=string] [, EVENT_PRO=string]
    [, /EXPANDED] [, /FOLDER] [, FUNC_GET_VALUE=string]
    [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string] [, /MULTIPLE]
    [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
    [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
    [, TAB_MODE=value] [, /TRACKING_EVENTS] [, /TOP] [, UNAME=string]
    [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=string] [, XOFFSET=value]
    [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

## Return Value

The returned value of this function is the widget ID of the newly-created tree widget.

# Arguments

## Parent

The widget ID of the parent for the new tree widget. *Parent* can be either a base widget or a tree widget.

- If *Parent* is a base widget, `WIDGET_TREE` will create a tree widget that contains no other tree widgets. This type of tree widget is referred to as a *root node*.
- If *Parent* is a tree widget, `WIDGET_TREE` will create a new tree widget (called a *node*) in the specified tree widget.

---

**Note**

With the exception of the first tree widget created (the *root node*, whose *Parent* is a base widget), a tree widget (or *node*) must be created with the `FOLDER` keyword in order to serve as the *Parent* for other tree widgets.

---

# Keywords

## **ALIGN\_BOTTOM**

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a `ROW` base.

## **ALIGN\_CENTER**

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a `ROW` or `COLUMN` base. In `ROW` bases, the new widget will be vertically centered. In `COLUMN` bases, the new widget will be horizontally centered.

## **ALIGN\_LEFT**

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a `COLUMN` base.

## **ALIGN\_RIGHT**

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a `COLUMN` base.

## ALIGN\_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## BITMAP

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

## CONTEXT\_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET\\_DISPLAYCONTEXTMENU](#) within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

## EVENT\_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT\_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EXPANDED

If the tree node being created is a *folder* (specified by the `FOLDER` keyword), set this keyword to cause the folder to be initially displayed expanded, showing all of its immediate child entries. By default, folders are initially displayed collapsed.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## FOLDER

Set this keyword to cause the tree node being created to act as a *folder* (that is, as a branch of the tree rather than a leaf).

### Note

---

With the exception of the root node (the tree widget whose *Parent* widget is a base widget), only tree nodes that have the FOLDER keyword set can act as the parent for other tree widgets.

---

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## FUNC\_GET\_VALUE

A string containing the name of a function to be called when the GET\_VALUE keyword to the WIDGET\_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP\_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET\_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

## KILL\_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET\_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET\_EVENT function is called.

## MULTIPLE

Set this keyword to enable multiple selection operations in the tree widget. If enabled, multiple elements in the tree widget can be selected at one time by holding down the **Control** or **Shift** key while clicking the left mouse button.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

## NO\_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the `UVALUE` keyword to `WIDGET_TAB` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. Upon a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

## NOTIFY\_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (' '). The callback routine is called with the widget ID as its only argument.

## PRO\_SET\_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. See the description of the [PRO\\_SET\\_VALUE](#) keyword to [WIDGET\\_CONTROL](#) for information on using this keyword.

## SCR\_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR\_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

### Note

---

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

---

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET\\_CONTROL](#).

This keyword is only valid if the *Parent* of the tree widget is a base widget.

## TAB\_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB\_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET\\_BASE](#) unless it is explicitly set on an individual widget. If the TAB\_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

**Note**

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in <a href="#">“Inheriting the TAB_MODE Value”</a> in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

**Note**

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB\_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

Once a WIDGET\_TREE widget receives focus through tabbing, additional navigation capabilities are platform dependent:

- On Windows – tree widgets can receive and lose focus through tabbing.
- On UNIX - the Motif library controls tabbing functionality.

Use the arrow keys to select higher or lower level nodes once a tree widget has focus. The TAB\_MODE specified for the root tree widget defines the tabbing support for all of its nodes.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET\\_CONTROL](#) procedure’s TAB\_MODE keyword, or query a widget’s support for tabbing using the [WIDGET\\_INFO](#) procedure’s TAB\_MODE keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

## TRACKING\_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING\\_EVENTS](#)” on page 2506 in the documentation for `WIDGET_BASE`.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

## TOP

Set this keyword to cause the tree node being created to be inserted as the parent node’s top entry. By default, new nodes are inserted as the parent node’s bottom entry.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET\\_INFO](#) with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

## UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by `WIDGET_INFO`.

## UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget’s initial user value is undefined.

## VALUE

Set this keyword equal to a string containing the text that will be displayed next to the branch or leaf of the tree. If the widget value is not explicitly set, either in the call to `WIDGET_TREE` or using the `SET_VALUE` keyword to `WIDGET_CONTROL`, the default value of “Tree” is provided.

---

### Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 19, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the `UNITS` keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## Keywords to WIDGET\_CONTROL

A number of keywords to the [WIDGET\\_CONTROL](#) affect the behavior of tree widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [SET\\_TREE\\_BITMAP](#), [SET\\_TREE\\_EXPANDED](#), [SET\\_TREE\\_SELECT](#), [SET\\_TREE\\_VISIBLE](#).

## Keywords to WIDGET\_INFO

Some keywords to the [WIDGET\\_INFO](#) return information that applies specifically to tree widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [STRING\\_SIZE](#), [TREE\\_EXPANDED](#), [TREE\\_SELECT](#), [TREE\\_ROOT](#).

## Widget Events Returned by Tree Widgets

Tree widgets generate events when tree elements are selected or deselected, expanded or collapsed. They can also be configured to generate events when the user clicks the right-hand mouse button over the widget. Several variations of the tree widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all tree event structures. The different tree widget event structures are described below.

### Select (TYPE = 0)

This structure is returned when the currently selected node in the tree widget changes:

```
{WIDGET_TREE_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, CLICKS:0L}
```

The CLICKS field indicates the number of mouse-button clicks that occurred when the event took place. This field contains 1 (one) when the item is selected, or 2 when the user double-clicks on the item.

## Expand (TYPE = 1)

This structure is returned when a folder in the tree widget expands or collapses:

```
{WIDGET_TREE_EXPAND, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, EXPAND:0L}
```

The EXPAND field contains 1 (one) if the folder expanded or 0 (zero) if the folder collapsed.

## Context Menu Events

A tree widget created with the CONTEXT\_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,  
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the tree widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

## Version History

5.6	Introduced
6.1	Added TAB_MODE keyword Added ROW and COL fields to WIDGET_CONTEXT event structure

## See Also

“Using Tree Widgets” in Chapter 30 of the *Building IDL Applications* manual

# WINDOW

The WINDOW procedure creates a window for the display of graphics or text. It is only necessary to use WINDOW if more than one simultaneous window or a special size window is desired because a window is created automatically the first time any display procedure attempts to access the window system. The newly-created window becomes the current window, and the system variable !D.WINDOW is set to that window's window index. (See the description of the WSET procedure for a discussion of the current IDL window.)

The behavior of WINDOW varies slightly depending on the window system in effect. See the discussion of IDL graphics devices in [Appendix A, "IDL Direct Graphics Devices"](#) for additional details.

## Syntax

```
WINDOW [, Window_Index] [, COLORS=value] [, /FREE] [, /PIXMAP]
      [, RETAIN={0 | 1 | 2}] [, TITLE=string] [, XPOS=value] [, YPOS=value]
      [, XSIZE=pixels] [, YSIZE=pixels]
```

## Arguments

### Window\_Index

The window index for the newly-created window. A window index is an integer value between 0 and 31 that is used to refer to the window. If this parameter is omitted, window index 0 is used. If the value of *Window\_Index* specifies an existing window, the existing window is deleted and a new one is created. If you need to create more than 32 windows, use the FREE keyword described below.

## Keywords

### COLORS

#### Note

---

This keyword is ignored under Microsoft Windows.

---

The maximum number of color table indices to be used when drawing. This keyword has an effect only if supplied when the first window is created. If COLORS is not present when the first window is created, all or most of the available color indices are allocated depending upon the window system in use.

To use monochrome windows on a color display in X Windows, use `COLORS = 2` when creating the first window. One color table is maintained for all windows. A negative value for `COLORS` specifies that all but the given number of colors from the shared color table should be allocated.

Although this keyword is ignored under Microsoft Windows, we could use the following code to use a monochrome window on all platforms:

```
WINDOW, COLORS=2 ; ignored on Windows
white=!D.N_COLORS-1
PLOT, FINDGEN(20), COLOR=white
```

## FREE

Set this keyword to create a window using the smallest unused window index above 32. If this keyword is present, the *Window\_Index* argument can be omitted. The default position of the new window is opposite that of the current window. Using the `FREE` keyword allows the creation of a large number of windows. The system variable `!D.WINDOW` is set to the index of the newly-created window.

## PIXMAP

Set the `PIXMAP` keyword to specify that the window being created is actually an invisible portion of the display memory called a pixmap.

## RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the window:

- 0 = no backing store
- 1 = requests that the server or window system provide backing store
- 2 = specifies that IDL provide backing store directly

See “[Backing Store](#)” on page 4728 for details.

## TITLE

A scalar string that contains the window’s label. If not specified, the window is given a label of the form “IDL *n*”, where *n* is the index number of the window. For example, to create a window with the label “IDL Graphics”, enter:

```
WINDOW, TITLE='IDL Graphics'
```

## XPOS

The X position of the window, specified in device coordinates. On Motif platforms, XPOS specifies the X position of the *lower* left corner and is measured from the lower left corner of the screen. On Windows platforms, XPOS specifies the X position of the *upper* left corner and is measured from the upper left corner of the screen. That is, specifying

```
WINDOW, XPOS = 0, YPOS = 0
```

will create a window in the lower left corner on Motif machines and in the upper left corner on Windows machines.

If no position is specified, the position of the window is determined from the value of Window Index using the following rules:

- Window 0 is placed in the upper right hand corner.
- Even numbered windows are placed on the top half of the screen and odd numbered windows are placed on the bottom half.
- Windows 0,1,4,5,8, and 9 are placed on the right side of the screen and windows 2,3,6, and 7 are placed on the left.

---

### Note

The order of precedence (highest to lowest) for positioning windows is: XPOS/YPOS keywords to WINDOW, the value of the [IDL\\_GR\\_WIN\\_LAYOUT](#) preference (Microsoft Windows only), and the optional index argument to WINDOW. Also realize that setting LOCATION is only a request to the Window manager and may not always be honored due to system peculiarities.

---

## YPOS

The Y position of the window, specified in device coordinates. See the description of XPOS for details.

## XSIZE

The width of the window in pixels.

## YSIZE

The height of the window in pixels.

## Examples

Create graphics window number 0 with a size of 400 by 400 pixels and a title that reads “Square Window” by entering:

```
WINDOW, 0, XSIZE=400, YSIZE=400, TITLE='Square Window'
```

# WRITE\_BMP

The `WRITE_BMP` procedure writes an image and its color table vectors to a Microsoft Windows Version 3 device independent bitmap file (.BMP).

`WRITE_BMP` does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file `write_bmp.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WRITE_BMP, Filename, Image [, R, G, B] [, /FOUR_BIT] [, IHDR=structure]  
          [, HEADER_DEFINE=h{define h before call}] [, /RGB]
```

## Arguments

### Filename

A scalar string containing the full pathname of the bitmap file to write.

### Image

The array to write into the new bitmap file. The array should be scaled into a range of bytes for 8- and 24-bit deep images. Scale to 0-15 for 4-bit deep images. If the image has 3 dimensions and the first dimension is 3, a 24-bit deep bitmap file is created.

### Note

---

For 24-bit images, color interleaving is blue, green, red:  $Image[0, i, j]$  = blue,  $Image[1, i, j]$  = green,  $Image[2, i, j]$  = red.

---

### R, G, B

Color tables. If omitted, the colors loaded in the `COLORS` common block are used.

## Keywords

### FOUR\_BIT

Set this keyword to write as a 4-bit device independent bitmap. If omitted or zero, an 8-bit deep bitmap is written.

### IHDR

Set this keyword to a BITMAPINFOHEADER structure containing the file header fields that are not obtained from the image itself. The fields in this structure that can be set are: `bi{XY}PelsPerMeter`, `biClrUsed`, and `biClrImportant`.

### HEADER\_DEFINE

If this keyword is set, `WRITE_BMP` returns an empty BITMAPINFOHEADER structure, containing zeros. No other actions are performed. This structure may be then modified with the pertinent fields and passed in via the `IHDR` keyword parameter. See the Microsoft Windows Programmers Reference Guide for a description of each field in the structure.

Note: this parameter must be defined *before* the call. For example:

```
H = 0
WRITE_BMP, HEADER_DEFINE = H
```

### RGB

Set this keyword to reverse the color interleaving for 24-bit images to red, green, blue:  $Image[0, i, j] = \text{red}$ ,  $Image[1, i, j] = \text{green}$ ,  $Image[2, i, j] = \text{blue}$ . By default, 24-bit images are written with color interleaving of blue, green, red.

## Examples

The following command captures the contents of the current IDL graphics window and saves it to a Microsoft Windows Bitmap file with the name `test.bmp`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_BMP, 'test.bmp', TVRD()
```

The following commands scale an image to 0-15, and then write a 4-bit BMP file, using a grayscale color table:

```
; Create a ramp from 0 to 255:
r = BYTSCL(INDGEN(16))

WRITE_BMP, 'test.bmp', BYTSCL(Image, MAX=15), r, r, r, /FOUR
```

## Version History

Pre-4.0	Introduced

## See Also

[READ\\_BMP, QUERY\\_\\* Routines](#)

# WRITE\_GIF

The WRITE\_GIF procedure writes an image and its color table vectors to a Graphics Interchange Format (GIF) file.

WRITE\_GIF produces 8-bit GIF files of the standard type: non-interlaced, global colormap.

---

**Note**

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact RSI for information about licensing options.

---

This routine is written in the IDL language. Its source code can be found in the file `write_gif.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WRITE_GIF, Filename, Image [, R, G, B] [, /MULTIPLE [, /CLOSE]]
```

## Arguments

### Filename

A scalar string containing the full pathname of the GIF file to write.

### Image

The array to write into the new GIF file.

### R, G, B

The Red, Green, and Blue color vectors to be written with to the GIF file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is saved, and the table is padded to 256 entries. If no color table has been established, WRITE\_GIF calls LOADCT to load the grayscale entry (table 0).

## Keywords

### CLOSE

Set this keyword to close any open files. The CLOSE keyword is only useful if a file containing multiple images (as specified by the MULTIPLE keyword) is being written. If the CLOSE keyword is specified, nothing is written to the file, and all other parameters are ignored.

### MULTIPLE

Set this keyword to write multiple images to a file. Each call to WRITE\_GIF writes the next image, with the file remaining open between calls. The *Filename* argument is ignored after the first call, *but must be supplied*. After the first image has been written, any R, G, and B color vectors supplied are ignored. All images written to a GIF file must be the same size.

## Example

The following command captures the contents of the current IDL graphics window and saves it to a GIF file named `test.gif`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_GIF, 'test.gif', TVRD()
```

# WRITE\_IMAGE

The `WRITE_IMAGE` procedure writes an image and its color table vectors, if any, to a file of a specified type. `WRITE_IMAGE` can write most types of image files supported by IDL.

## Syntax

```
WRITE_IMAGE, Filename, Format, Data [, Red, Green, Blue] [, /APPEND]
```

## Arguments

### Filename

A scalar string containing the name of the file to write.

### Format

A scalar string containing the name of the file format to write. The following are the supported formats:

- BMP
- GIF
- JPEG
- PNG
- PPM
- SRF
- TIFF

### Data

An IDL variable containing the image data to write to the file.

### Red

An optional vector containing the red channel of the color table if a colortable exists.

### Green

An optional vector containing the green channel of the color table if a colortable exists.

## Blue

An optional vector containing the blue channel of the color table if a colortable exists.

## Keywords

### APPEND

Set this keyword to force the image to be appended to the file instead of overwriting the file. APPEND may be used with image formats that supports multiple images per file and is ignored for formats that support only a single image per file.

## Version History

5.3	Introduced

# WRITE\_JPEG

The WRITE\_JPEG procedure writes compressed images to files. JPEG (Joint Photographic Experts Group) is a standardized compression method for full-color and gray-scale images. This procedure is based in part on the work of the Independent JPEG Group.

As the Independent JPEG Group states, JPEG is intended for real-world scenes (such as digitized photographs). Line art, such as drawings or IDL plots, and other unrealistic images are not its strong suit. Note also that JPEG is a lossy compression scheme. That is, the output image is *not* identical to the input image. Hence you cannot use JPEG if you must have identical output bits. On typical images of real-world scenes, however, very good compression levels can be obtained with no visible change, and amazingly high compression levels are possible if you can tolerate a low-quality image. You can trade off output image quality against compressed file size by adjusting a compression parameter. Files are encoded in JFIF, the JPEG File Interchange Format; however, such files are usually simply called JPEG files.

If you need to store images in a format that uses lossless compression, consider using the WRITE\_PNG procedure. This procedure writes a Portable Network Graphics (PNG) file using lossless compression with either 8 or 16 data bits per channel. To store 8-bit or 24-bit images without compression, consider using WRITE\_BMP (for Microsoft Bitmap format files) or WRITE\_TIFF (to write Tagged Image Format Files).

For a short technical introduction to the JPEG compression algorithm, see: Wallace, Gregory K. “The JPEG Still Picture Compression Standard”, *Communications of the ACM*, April 1991 (vol. 34, no. 4), pp. 30-44.

---

**Note**

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

---

## Syntax

```
WRITE_JPEG [, Filename], Image [, /ORDER] [, /PROGRESSIVE]  
          [, QUALITY=value{0 to 100}] [, TRUE={1 | 2 | 3}] [, UNIT=lun]
```

## Arguments

### Filename

A string containing the name of file to be written in JFIF (JPEG) format. If this parameter is not present, the UNIT keyword must be specified.

### Image

A byte array of either two or three dimensions, containing the image to be written. Grayscale images must have two dimensions. TrueColor images must have three dimensions with the index of the dimension that contains the color specified with the TRUE keyword.

## Keywords

### ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image array is in the standard IDL order (i.e., from bottom-to-top) set ORDER to 0, its default value. If the image array is in top-to-bottom order, ORDER must be set to 1.

### PROGRESSIVE

Set this keyword to write the image as a series of scans of increasing quality. When used with a slow communications link, a decoder can generate a low-quality image very quickly, and then improve its quality as more scans are received.

#### Warning

---

Not all JPEG applications can handle progressive JPEG files, and it is up to the JPEG reader to progressively display the JPEG image. For example, IDL's READ\_JPEG routine ignores the progressive readout request and reads the entire image in at the first reading.

---

### QUALITY

This keyword specifies the quality index, in the range of 0 (terrible) to 100 (excellent) for the JPEG file. The default value is 75, which corresponds to very good quality. Lower values of QUALITY produce higher compression ratios and smaller files.

## TRUE

This keyword specifies the index, starting at 1, of the dimension over which the color is interleaved. For example, for an image that is pixel interleaved and has dimensions of  $(3, m, n)$ , set TRUE to 1. Specify 2 for row-interleaved images  $(m, 3, n)$ ; and 3 for band-interleaved images  $(m, n, 3)$ . If TRUE is not set, the image is assumed to have no interleaving (it is not a TrueColor image).

## UNIT

This keyword designates the logical unit number of an already open file to receive the output, allowing multiple JFIF images per file or the embedding of JFIF images in other data files. If this keyword is used, *Filename* should not be specified.

### Note

---

When opening a file intended for use with the UNIT keyword, if the filename does not end in .jpg, or .jpeg, you must specify the STUDIO keyword to OPEN in order for the file to be compatible with WRITE\_JPEG.

---

## Examples

Write the image contained in the array A, using JPEG compression with a quality index of 25. The image is stored in bottom-to-top order:

```
image = DIST(100)
WRITE_JPEG, 'test1.jpg', image, QUALITY=25
```

Write a TrueColor image to a JPEG file. The image is contained in the band-interleaved array A with dimensions  $(m, n, 3)$ . Assume it is stored in top-to-bottom order:

```
WRITE_JPEG, 'test2.jpg', image, TRUE=3, /ORDER
```

Also see the example in [“Converting Indexed Images to RGB Images”](#) on page 2396.

# WRITE\_JPEG2000

The `WRITE_JPEG2000` procedure writes image data into a JPEG2000 file. This procedure is a wrapper around the `IDLffJPEG2000` object interface that presents JPEG2000 image writing in a familiar way to users of the `WRITE_*` image routines. However this procedure is not as efficient as the object interface and the object interface should be used whenever possible. See “[IDLffJPEG2000](#)” in Chapter 6 of the *IDL Reference Guide* manual for information about the object interface.

## Syntax

```
WRITE_JPEG2000, Filename, Image [, Red, Green, Blue] [, N_LAYERS=value]
  [, N_LEVELS=value] [, /ORDER] [, /REVERSIBLE]
```

## Arguments

### Filename

A scalar string containing the full path and filename of the JPEG2000 file to write. If the file suffix is `.jp2` or `.jpx` (case insensitive), the file is written using the JP2 file format. Otherwise the file is written as a raw JPEG2000 code stream.

### Image

A byte or integer array of either two or three dimensions, containing the image to be written. Single channel images must have dimensions of [*Width*, *Height*]. Multi-channel images must have dimensions of [*nComponents*, *Width*, *Height*], where *nComponents* is the number of components present in the image.

### Red, Green, Blue

For single-channel images, *Red*, *Green*, and *Blue* should contain the red, green, and blue color vectors to be stored within the JPEG2000 palette. For multi-channel images, these arguments are ignored.

## Keywords

### N\_LAYERS

Set this keyword to a positive integer specifying the number of quality layers. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A larger number of layers takes

longer to encode and produces a larger file, but provides more flexibility when decoding. The default is 1. If `N_LAYERS` is greater than 1, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of the compressed bits.

## **N\_LEVELS**

Set this keyword to an integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15. A value of zero indicates that no wavelet transform will be used. Higher values will typically give better compression. If this keyword is omitted, then the default value of 5 is used. If the file is in JP2 format, and a *Red, Green, Blue* palette is present, then the default is `N_LEVELS=0`.

## **ORDER**

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `WRITE_JPEG2000` will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting `ORDER` to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

## **REVERSIBLE**

Set this keyword to specify that reversible (lossless) compression should be used. The default is to use irreversible (lossy) compression. If the file is in JP2 format, and a *Red, Green, Blue* palette is present, then the default is `REVERSIBLE=1`.

## **Example**

For an example, see [READ\\_JPEG2000](#).

# WRITE\_NRIF

The WRITE\_NRIF procedure writes an image and its color table vectors to an NCAR Raster Interchange Format (NRIF) rasterfile.

WRITE\_NRIF only writes 8- or 24-bit deep rasterfiles of types “Indexed Color” (8-bit) and “Direct Color integrated” (24-bit). The color map is included only for 8-bit files.

See the document “NCAR Raster Interchange Format and TAGS Raster Reference Manual,” available from the Scientific Computing Division, National Center for Atmospheric Research, Boulder, CO, 80307-3000, for information on the structure of NRIF files.

This routine is written in the IDL language. Its source code can be found in the file `write_nrif.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WRITE_NRIF, File, Image [, R, G, B]
```

## Arguments

### File

A scalar string containing the full path name of the NRIF file to write.

### Image

The byte array to be written to the NRIF file. If *Image* has the dimensions  $(n,m)$ , an 8-bit NRIF file with color tables is created. If *Image* has the dimensions  $(3,n,m)$ , a 24-bit NRIF file is created, where each byte triple represents the red, green, and blue intensities at  $(n,m)$  on a scale from 0 to 255. The NRIF image will be rendered from bottom to top, in accordance with IDL standards.

### R, G, B

The Red, Green, and Blue color vectors to be used as a color table with 8-bit images. If color vectors are supplied, they are included in the output (8-bit images only). If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE\_NRIF calls LOADCT to load the grayscale entry (table 0).

**Note**

WRITE\_NRIF does not recognize color vectors loaded directly using TVLCT, so if a custom color table is desired and it is not convenient to use XPALETTE, include the R, G, and B vectors that were used to create the color table.

## Version History

Pre-4.0	Introduced
---------	------------

# WRITE\_PICT

The `WRITE_PICT` procedure writes an image and its color table vectors to a PICT (version 2) format image file. The PICT format is used by Apple Macintosh computers.

Note: `WRITE_PICT` only works with 8-bit displays

This routine is written in the IDL language. Its source code can be found in the file `write_pict.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WRITE_PICT, Filename [, Image, R, G, B]
```

## Arguments

### Filename

A scalar string containing the full pathname of the PICT file to write.

### Image

The byte array to be written to the PICT file. If *Image* is omitted, the entire current graphics window is read into an array and written to the PICT file.

### R, G, B

The Red, Green, and Blue color vectors to be written to the PICT file. If *R*, *G*, *B* values are not provided, the last color table established using `LOADCT` is included. If no color table has been established, `WRITE_PICT` calls `LOADCT` to load the grayscale entry (table 0).

## Examples

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_PICT, 'test.pict', TVRD()
```

## Version History

Pre-4.0	Introduced

[READ\\_PICT, QUERY\\_\\* Routines](#)

# WRITE\_PNG

The `WRITE_PNG` procedure writes a 2-D or 3-D IDL variable into a Portable Network Graphics (PNG) file. The data in the file is stored using lossless compression with either 8 or 16 data bits per channel, based on the input IDL variable type. 3-D IDL variables must have the number of channels as their leading dimension (pixel interleaved). For `BYTE` format 2-D IDL variables, an optional palette may be stored in the image file along with a list of pixel values which are to be considered transparent by a reading program.

**Note**

---

IDL supports version 1.2.7 of the PNG Library.

---

## Syntax

```
WRITE_PNG, Filename, Image [, R, G, B] [, /ORDER] [, /VERBOSE]  
[, /TRANSPARENT=array]
```

## Arguments

### Filename

A scalar string containing the full pathname of the PNG file to write.

### Image

The array to write into the new PNG file. If *Image* is one of the integer data types, it is converted to type unsigned integer (UINT) and written out at 16 data bits per channel. All other data types are converted to bytes and written out at 8-bits per channel.

**Note**

---

If *Image* is two-dimensional (single-channel) and *R*, *G*, and *B* are provided, all input data types (including integer) are converted to bytes and written out as 8-bit data.

---

### R, G, B

For single-channel images, *R*, *G*, and *B* should contain the red, green, and blue color vectors, respectively. For multi-channel images, these arguments are ignored.

## Keywords

### ORDER

Set this keyword to indicate that the rows of the image should be written from bottom to top. The rows are written from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

### VERBOSE

Produces additional diagnostic output during the write.

### TRANSPARENT

Set this keyword to an array of pixel index values which are to be treated as “transparent” for the purposes of image display. This keyword is valid only if *Image* is a single-channel (color indexed) image and the R, G, B palette is provided.

## Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bits/channel) image with a palette.

```

rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = INDGEN(256)
green = INDGEN(256)
blue = INDGEN(256)
WRITE_PNG, 'rgb_image.png', rgbdata
WRITE_PNG, 'ci_image.png', cidata, red, green, blue

; Query and Read the data:
names = ['rgb_image.png', 'ci_image.png', 'unknown.png']
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
  ok = QUERY_PNG(names[i],s)
  IF (ok) THEN BEGIN
    HELP, s, /STRUCTURE
    IF (s.HAS_PALETTE) THEN BEGIN
      img = READ_PNG(names[i], rpal, gpal, bpal)
      HELP, img, rpal, gpal, bpal
    ENDIF ELSE BEGIN
      img = READ_PNG(names[i])
      HELP, img
    ENDELSE
  ENDIF ELSE BEGIN

```

```
        PRINT,names[i], ' is not a PNG file'  
    ENDELSE  
ENDFOR
```

## Version History

# WRITE\_PPM

The `WRITE_PPM` procedure writes an image to a PPM (TrueColor) or PGM (gray scale) file. This routine is written in the IDL language. Its source code can be found in the file `write_ppm.pro` in the `lib` subdirectory of the IDL distribution.

## Note

---

`WRITE_PPM` only writes 8-bit deep PGM/PPM files of the standard type. Images should be ordered so that the first row is the top row.

PPM/PGM format is supported by the `PBMPLUS` toolkit for converting various image formats to and from portable formats, and by the `Netpbm` package.

---

## Syntax

```
WRITE_PPM, Filename, Image [, /ASCII]
```

## Arguments

### Filename

A scalar string specifying the full pathname of the PPM or PGM file to write.

### Image

The 2D (gray scale) or 3D (TrueColor) array to be written to a file.

## Keywords

### ASCII

Set this keyword to force `WRITE_PPM` to use formatted ASCII input/output to write the image data. The default is to use the far more efficient binary input/output (RAWBITS) format.

## Examples

```
image = DIST(100)
WRITE_PPM, 'file.ppm', image
```

## Version History

4.0	Introduced

# WRITE\_SPR

The WRITE\_SPR procedure writes a row-indexed sparse array structure to a specified file. Row-indexed sparse arrays are created using the SPRSIN function.

## Syntax

WRITE\_SPR, AS, *Filename*

## Arguments

### AS

A row-indexed sparse array created by SPRSIN.

### Filename

The name of the file that will contain AS.

## Keywords

None.

## Examples

```

; Create an array:
A = [[3.,0., 1., 0., 0.],$
      [0.,4., 0., 0., 0.],$
      [0.,7., 5., 9., 0.],$
      [0.,0., 0., 0., 2.],$
      [0.,0., 0., 6., 5.]]

; Convert it to sparse storage format:
A = SPRSIN(A)

; Store it in the file sprs.as:
WRITE_SPR, A, 'sprs.as'

```

# WRITE\_SRF

The `WRITE_SRF` procedure writes an image and its color table vectors to a Sun Raster File (SRF).

`WRITE_SRF` only writes 32-, 24-, and 8-bit-deep rasterfiles of type `RT_STANDARD`. Use the UNIX command `rasfilter8to1` to convert these files to 1-bit deep files. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `write_srf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WRITE_SRF, Filename [, Image, R, G, B] [, /ORDER] [, /WRITE_32]
```

## Arguments

### Filename

A scalar string containing the full pathname of the SRF to write.

### Image

The array to be written to the SRF. If *Image* has dimensions  $(3,n,m)$ , a 24-bit SRF is written. If *Image* is omitted, the entire current graphics window is read into an array and written to the SRF file. *Image* should be of byte type, and in top to bottom scan line order.

### R, G, B

The Red, Green, and Blue color vectors to be written to the file. If *R*, *G*, *B* values are not provided, the last color table established using `LOADCT` is included. If no color table has been established, `WRITE_SRF` calls `LOADCT` to load the grayscale entry (table 0).

## Keywords

### ORDER

Set this keyword to write the image from the top down instead of from the bottom up. This setting is only necessary when writing a file from the current IDL graphics window; it is ignored when writing a file from a data array passed as a parameter.

## WRITE\_32

Set this keyword to write a 32-bit file. If the input image is a TrueColor image, dimensioned  $(3, n, m)$ , it is normally written as a 24-bit raster file.

## Examples

Create a pseudo screen dump from the current window:

```
WRITE_SRF, 'test.srf', TVRD()
```

## Version History

# WRITE\_SYLK

The WRITE\_SYLK function writes the contents of an IDL variable to a SYLK (Symbolic Link) format spreadsheet data file.

---

**Note**

This routine writes only numeric and string SYLK data. It cannot handle spreadsheet and cell formatting information (cell width, text justification, font type, date, time, monetary notations, etc.). A given SYLK data file cannot be appended with data blocks through subsequent calls.

---

This routine is written in the IDL language. Its source code can be found in the file `write_sylk.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = WRITE\_SYLK( *File*, *Data* [, STARTCOL=*column*] [, STARTROW=*row*] )

## Return Value

The function returns TRUE if the write operation was successful.

## Arguments

### File

A scalar string specifying the full path name of the SYLK file to write.

### Data

A scalar, vector, or 2D array to be written to *File*.

## Keywords

### STARTCOL

Set this keyword to the first column of spreadsheet cells to write. If not specified, the write operation begins with the first column found in the file (column 0).

## STARTROW

Set this keyword to the first row of spreadsheet cells to write. If not specified, the write operation begins with the first row of cells found in the file (row 0).

## Examples

Suppose you wish to write the contents of a 2 by 2 floating-point array, `data`, to a SYLK data file called “`bar.slk`” such that the matrix would appear with its upper left data at the cell in the 10th row and the 20th column. Use the following command:

```
status = WRITE_SYLK('bar.slk', data, STARTROW = 9, STARTCOL = 19)
```

The IDL variable `status` will contain the value 1 if the operation was successful.

## Version History

4.0	Introduced

# WRITE\_TIFF

The WRITE\_TIFF procedure can write TIFF files with one or more channels, where each channel can contain 1, 4, 8, 16, or 32-bit integer pixels, or floating-point values.

## Syntax

```
WRITE_TIFF, Filename [, Image] [, /APPEND]
    [, BITS_PER_SAMPLE={1 | 4 | 8}] [, RED, GREEN, BLUE=value] [, /CMYK]
    [, COMPRESSION={0 | 1 | 2 | 3}] [, DESCRIPTION=string]
    [, DOCUMENT_NAME=string] [, DOT_RANGE=intarray]
    [, GEOTIFF=structure] [, /LONG | /SHORT | /FLOAT]
    [, ICC_PROFILE=bytearray] [, ORIENTATION=value] [, PHOTOSHOP=array]
    [, PLANARCONFIG={1 | 2}] [, UNITS={1 | 2 | 3}] [, /VERBOSE]
    [, XPOSITION=units] [, XRESOL=pixels/inch] [, YPOSITION=units]
    [, YRESOL=pixels/inch]
```

## Arguments

### Filename

A scalar string containing the full pathname of the TIFF to write.

### Image

The array to be written to the TIFF. If *Image* has dimensions (k,n,m), a k-channel TIFF is written. *Image* should be in top to bottom scan line order. By default, this array is converted to byte format before being written (see the LONG, SHORT and FLOAT keywords below). Note that many TIFF readers can read only one- or three-channel images.

#### Note

---

The Image argument is ignored if PLANARCONFIG is set to 2 and the RED, GREEN, and BLUE keywords have been set to 2D arrays.

---

#### Note

---

Grayscale TIFF images are written out with the PhotometricInterpretation tag set to BlackIsZero, implying that values of 0 should correspond to black. If you want values of 0 to correspond to white, you should invert your pixel values before calling WRITE\_TIFF.

---

# Keywords

## APPEND

Set this keyword to specify that the image should be added to the existing file, creating a multi-image TIFF file.

## BITS\_PER\_SAMPLE

Set this keyword to either 1, 4, or 8 to create a grayscale image file with the specified number of bits per pixel. For 1-bit (bi-level) images, an output pixel is assigned the value 1 (one) if the corresponding input pixel is nonzero. For 4-bit grayscale images, the input pixel values *must* be in the range 0 through 15, or the image will be garbled. The default is BITS\_PER\_SAMPLE=8. This keyword is ignored if an RGB image or color palette is present, or if one of the FLOAT, LONG, or SHORT keywords is set.

## CMYK

Set this keyword to indicate that *Image* contains a 4-channel image, where the channels represent colors in the CMYK color-separated format. This corresponds to setting PhotometricInterpretation = 5 in the resulting TIFF file, which allows TIFF readers to interpret the image as CMYK. The *Image* argument can either be (4, *Columns*, *Rows*) or (*Columns*, *Rows*, 4) depending upon the PLANARCONFIG keyword.

### Note

---

If *Image* has 4 channels but the CMYK keyword is not set, then the image is written as a standard multi-channel image, with PhotometricInterpretation = 2.

---

## COMPRESSION

Set this keyword to select the type of compression to be used:

0	None (default)
1	LZW
2	PackBits
3	JPEG (ITIFF files)

**Note**

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and the ORIENTATION keyword should not be specified. If your input image is not in top-to-bottom order, you should use REVERSE(*image*, 2) to flip the order before calling WRITE\_TIFF.

**DESCRIPTION**

Set this keyword to a scalar string containing the value of the ImageDescription tag to be stored in the TIFF file. If this keyword is not provided then the ImageDescription tag is set to "IDL TIFF file".

**DOCUMENT\_NAME**

Set this keyword to a scalar string containing the value of the DocumentName tag to be stored in the TIFF file. If this keyword is not provided then the DocumentName tag is set to the filename.

**DOT\_RANGE**

Set this keyword to a two-element integer array containing the TIFF DotRange tag value. If this keyword is not provided then the DotRange tag is not stored. The DotRange tag is typically only present in CMYK TIFF files. DOT\_RANGE[0] gives the image value that corresponds to a 0% dot, while DOT\_RANGE[1] gives the image value that corresponds to a 100% dot.

**FLOAT**

Set this keyword to write the pixel components as floating-point entities (the default is 8-bit).

**GEOTIFF**

Set this keyword to an anonymous structure containing one field for each of the GeoTIFF tags and keys to be written into the file. The GeoTIFF structure is formed using fields named from the following table.

Anonymous Structure Field Name	IDLDatatype
--------------------------------	-------------

**TAGS:**

*Table 3-137: GEOTIFF Structures*

"VERTICALUNITSGEOKEY"	INT

Table 3-137: GEOTIFF Structures (Continued)

---

**Note**

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

---

## ICC\_PROFILE

Set this keyword to a byte array containing the ICC\_PROFILE tag, as returned by the READ\_TIFF routine.

---

**Note**

The ICC\_PROFILE tag is an opaque byte array. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

---

## LONG

Set this keyword to write the pixel components as unsigned 32-bit entities (the default is 8-bit).

## ORIENTATION

Set this keyword to an integer value to specify the orientation of the TIFF image. The default is ORIENTATION=1.

---

**Note**

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and this keyword should not be specified.

---

Possible values are:

0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.

2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

**Warning**

Not all TIFF readers honor the value of the ORIENTATION field. IDL writes the value into the file, but some readers are known to ignore this value. In such cases, we recommend that you convert the image to top-to-bottom order with the REVERSE function and then set ORIENTATION to 1. If your image is a True Color three-channel image, which is pixel- or line-interleaved, then set the REVERSE call's optional 'Subscript\_Index' argument to 3. If your image is band-interleaved or is a one-channel image, set that argument to 2.

**PHOTOSHOP**

Set this keyword to a byte array containing the TIFF PHOTOSHOP tag value, as returned by the READ\_TIFF routine.

**Note**

The PHOTOSHOP tag is an opaque byte array. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

## PLANARCONFIG

This keyword determines the order in which a multi-channel image is stored and written. It has no effect with a single-channel image. Set this keyword to 2 to if the Image parameter is interleaved by “plane”, or band, and its dimensions are (*Columns*, *Rows*, *Channels*). The default value is 1, indicating that multi-channel images are interleaved by color, also called channel, and its dimensions are (*Channels*, *Columns*, *Rows*).

As a special case, this keyword may be set to 2 to write an RGB image that is contained in three separate arrays (color planes), stored in the variables specified by the RED, GREEN, and BLUE keywords. Otherwise, omit this parameter (or set it to 1).

### Note

---

Many TIFF readers can read only one- or three-channel images.

---

## RED

## GREEN

## BLUE

If you are writing a Palette color image, set these keywords equal to the color table vectors, scaled from 0 to 255.

If you are writing an RGB interleaved image (i.e., if the PLANARCONFIG keyword is set to 2), set these keywords to the names of the variables containing the three image components.

## SHORT

Set this keyword to write the pixel components as unsigned 16-bit entities (the default is 8-bit).

## UNITS

Set this keyword to one of the following values to specify the units used for the values specified by the XRESOL and YRESOL keywords:

1	No units
2	Inches (the default)

3	Centimeters
---	-------------

## VERBOSE

Set this keyword to produce additional diagnostic output during the write.

## XPOSITION

Set this keyword to the X offset relative to the left side of the image, in units specified by the UNITS keyword. XPOSITION must be nonnegative. If XPOSITION is not specified then this tag is not written to the file.

### Note

The XPOSITION tag is usually ignored by most TIFF readers.

## XRESOL

Set this keyword to the horizontal resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of XRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

## YPOSITION

Set this keyword to the Y offset relative to the top of the image (with positive Y increasing downwards), in units specified by the UNITS keyword. YPOSITION must be nonnegative. If YPOSITION is not specified then this tag is not written to the file.

### Note

The YPOSITION tag is usually ignored by most TIFF readers.

## YRESOL

Set this keyword to the vertical resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of YRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

## Examples

### Example 1

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_TIFF, 'test.tiff', TVRD()
```

### Example 2

Write a three-channel image from three one-channel (two-dimensional) arrays, contained in the variables Red, Green, and Blue:

```
WRITE_TIFF, 'test.tif', Red, Green, Blue, PLANARCONFIG=2
```

### Example 3

Write and read a multi-image TIFF file. The first image is a 16-bit single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF, 'multi.tif', data, COMPRESSION=1, /SHORT
WRITE_TIFF, 'multi.tif', rgbdata, /LONG, /APPEND
; Read the image data back
ok = QUERY_TIFF('multi.tif', s)
IF (ok) THEN BEGIN
  FOR i=0, s.NUM_IMAGES-1 DO BEGIN
    imp = QUERY_TIFF('multi.tif', t, IMAGE_INDEX=i)
    img = READ_TIFF('multi.tif', IMAGE_INDEX=i)
    HELP, t, /STRUCTURE
    HELP, img
  ENDFOR
ENDIF
```

# WRITE\_WAV

The WRITE\_WAV procedure writes the audio stream to the named .WAV file.

## Syntax

WRITE\_WAV, *Filename*, *Data*, *Rate*

## Arguments

### Filename

A scalar string containing the full pathname of the .WAV file to write.

### Data

The array to write into the new .WAV file. The array can be a one- or two-dimensional array. A two-dimensional array is written as a multi-channel audio stream where the leading dimension of the IDL array is the number of channels. If the input array is in BYTE format, the data is written as 8-bit samples, otherwise, the data is written as signed 16-bit samples.

### Rate

The sampling rate for the data array in samples per second.

## Keywords

None

## Version History

5.3	Introduced
-----	------------

# WRITE\_WAVE

The `WRITE_WAVE` procedure writes a three dimensional IDL array to a `.wave` or `.bwave` file for use with the Wavefront Advanced Data Visualizer. Note that this routine only writes one scalar field for each Wavefront file that it creates.

This routine is written in the IDL language. Its source code can be found in the file `write_wave.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
WRITE_WAVE, File, Array [, /BIN] [, DATANAME=string]  
          [, MESHNAME=string] [, /NOMESHDEF] [, /VECTOR]
```

## Arguments

### File

A scalar string containing the full path name of the Wavefront file to write.

### Array

A 3D array to be written to the file.

## Keywords

### BIN

Set this keyword to create a binary file. By default, text files are created.

### DATANAME

Set this keyword to the name of the data inside of the Wavefront file. If not specified, the name used is “`idldata`”.

### MESHNAME

Set this keyword to the name of the mesh used in the Wavefront file. If not specified, the name used is “`idlmesh`”.

### NOMESHDEF

Set this keyword to *omit* the mesh definition from the Wavefront file.

## VECTOR

Set this keyword to write the variable as a vector. The data is written as an array of 3-space vectors. The array may contain any number of dimensions but must have a leading dimension of 3. If the leading array dimension is not 3, this keyword is ignored.

## Version History

Pre-4.0	Introduced
---------	------------

## See Also

[READ\\_WAVE](#)

# WRITEU

The WRITEU procedure writes unformatted binary data from an expression into a file. This procedure performs a direct transfer with no processing of any kind being done to the data.

## Syntax

```
WRITEU, Unit, Expr1 ..., Exprn [, TRANSFER_COUNT=variable]
```

## Arguments

### Unit

The IDL file unit to which the output is sent.

### Expr<sub>*i*</sub>

The expressions to be output. For non-string variables, the number of bytes implied by the data type is output. When WRITEU is used with a variable of type string, IDL outputs exactly the number of bytes contained in the existing string.

## Keywords

### TRANSFER\_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the output operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, writing more data than an output device will accept causes an error. Files opened with the RAWIO keyword will not generate such an error. Instead, the programmer must keep track of the transfer count to judge the success or failure of a WRITEU operation.

## Examples

```
; Create some data to store in a file:  
D = BYTSLC(DIST(200))
```

```
; Open a new file for writing as IDL file unit number 1:  
OPENW, 1, 'newfile'  
; Write the data in D to the file:  
WRITEU, 1, D  
; Close file unit 1:  
CLOSE, 1
```

## Version History

Original	Introduced
Pre-6.2	Deprecated REWRITE keyword

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

## See Also

# WSET

The WSET procedure selects the current window. Most IDL graphics routines do not explicitly require the IDL window to be specified. Instead, they use the window known as the current window. The window index number of the current window is contained in the read-only system variable !D.WINDOW. WSET only works with devices that have windowing systems.

## Syntax

```
WSET [, Window_Index]
```

## Arguments

### Window\_Index

This argument specifies the window index of the window to be made current. If this argument is not specified, a default of 0 is used.

If you set *Window\_Index* equal to -1, IDL will try to locate an existing window to make current, ignoring any managed draw widgets that may exist. If there is no window to make current, WSET changes the value of the WINDOW field of the !D system variable to -1, indicating that there are no current windows.

If there are no existing IDL windows, and you call WSET without the *Window\_Index* argument or with a *Window\_Index* of 0, a new window with the index 0 is opened. Calling WSET with a *Window\_Index* for a window that does not exist, except for window 0, results in a “Window is closed and unavailable” error message.

## Keywords

None

## Examples

Create IDL windows 1 and 2 by entering:

```
WINDOW, 1 & WINDOW, 2
```

Set the current window to window 1 and display an image by entering:

```
WSET, 1 & TVSCL, DIST(100)
```

Set the current window to window 2 and display an image by entering:

```
WSET, 2 & TVSCL, DIST(100)
```

## Version History

Original	Introduced
----------	------------

## See Also

[WDELETE](#), [WINDOW](#), [WSHOW](#)

# WSHOW

The WSHOW procedure exposes or hides the designated window.

## Syntax

```
WSHOW [, Window_Index [, Show]] [, /ICONIC]
```

## Arguments

### Window\_Index

The window index of the window to be hidden or exposed. If this argument is not specified, the current window is assumed. If this index is the window ID of a draw widget, the widget base associated with that drawable is brought to the front of the screen.

### Show

Set *Show* to 0 to hide the window. Omit this argument or set it to 1 to expose the window.

## Keywords

### ICONIC

Set this keyword to iconify the window. Set **ICONIC** to 0 to de-iconify the window.

Under windowing systems, iconification is the task of the window manager, and client applications such as IDL have no direct control over it. The **ICONIC** keyword serves as a hint to the window manager, which is free to iconify the window or ignore the request as it sees fit.

## Examples

To bring IDL window number 0 to the front, enter:

```
WSHOW, 0
```

# WTN

The WTN function returns a multi-dimensional discrete wavelet transform of the input array *A*. The transform is based on a Daubechies wavelet filter.

WTN is based on the routine `wtn` described in section 13.10 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

```
Result = WTN( A, Coef [, /COLUMN] [, /DOUBLE] [, /INVERSE]
             [, /OVERWRITE] )
```

## Return Value

Returns an output array of the same dimensions as *A*, containing the discrete wavelet transform over each dimension.

## Arguments

### A

The input vector or array. The dimensions of *A* must all be powers of 2.

### Note

---

If WTN is complex then only the real part is used for the computation.

---

### Coef

An integer that specifies the number of wavelet filter coefficients. The allowed values are 4, 12, or 20. When *Coef* is 4, the `daub4()` function (see *Numerical Recipes*, section 13.10) is used. When *Coef* is 12 or 20, `pwt()` is called, preceded by `pwt.set()` (see *Numerical Recipes*, section 13.10).

## Keywords

### COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## INVERSE

If the INVERSE keyword is set, the inverse transform is computed. By default, WTN performs the forward wavelet transform.

## OVERWRITE

Set the OVERWRITE keyword to perform the transform “in place.” The result overwrites the original contents of the array.

## Examples

### Note

---

Also see [“Transforming Between Domains with Wavelets”](#) in Chapter 7 of the *Image Processing in IDL* manual.

---

This example demonstrates the use of IDL’s discrete wavelet transform and sparse array storage format to compress and store an 8-bit gray-scale digital image. First, an image selected from the `people.dat` data file is transformed into its wavelet representation and written to a separate data file using the `WRITEU` procedure.

Next, the transformed image is converted, using the `SPRSIN` function, to row-indexed sparse storage format retaining only elements with an absolute magnitude greater than or equal to a specified threshold. The sparse image is written to a data file using the `WRITE_SPR` procedure.

Finally, the transformed image is reconstructed from the storage file and displayed alongside the original.

```

; Begin by choosing the number of wavelet coefficients to use and a
; threshold value:
coeffs = 12 & thres = 10.0

; Open the people.dat data file, read an image using associated
; variables, and close the file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])
images = assoc(1, bytarr(192, 192))
image_1 = images[0]
close, 1

; Expand the image to the nearest power of two using cubic
; convolution, and transform the image into its wavelet

```

```

; representation using the WTN function:
pwr = 256
image_1 = CONGRID(image_1, pwr, pwr, /CUBIC)
wtn_image = WTN(image_1, coeffs)

; Write the image to a file using the WRITEU procedure and check
; the size of the file (in bytes) using the FSTAT function:
OPENW, 1, 'original.dat'
WRITEU, 1, wtn_image
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the file is ', status.size, ' bytes.'

; Now, we convert the wavelet representation of the image to a
; row-indexed sparse storage format using the SPRSIN function,
; write the data to a file using the WRITE_SPR procedure, and check
; the size of the "compressed" file:
sprs_image = SPRSIN(wtn_image, THRES = thres)
WRITE_SPR, sprs_image, 'sparse.dat'
OPENR, 1, 'sparse.dat'
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the compressed file is ', status.size, ' bytes.'

; Determine the number of elements (as a percentage of total
; elements) whose absolute magnitude is less than the specified
; threshold. These elements are not retained in the row-indexed
; sparse storage format:
PRINT, 'Percentage of elements under threshold: ', $
      100.*N_ELEMENTS(WHERE(ABS(wtn_image) LT thres, $
      count)) / N_ELEMENTS(image_1)

; Next, read the row-indexed sparse data back from the file
; sparse.dat using the READ_SPR function and reconstruct the
; image from the non-zero data using the FULSTR function:
sprs_image = READ_SPR('sparse.dat')
wtn_image = FULSTR(sprs_image)

; Apply the inverse wavelet transform to the image:
image_2 = WTN(wtn_image, COEFFS, /INVERSE)

; Calculate and print the amount of data used in reconstruction of
; the image:
PRINT, 'The image on the right is reconstructed from:', $
      100.0 - (100.* count/N_ELEMENTS(image_1)), $
      '% of original image data.'

; Finally, display the original and reconstructed images side by
; side:

```

```
WINDOW, 1, XSIZE = pwr*2, YSIZE = pwr, $  
    TITLE = 'Wavelet Image Compression and File I/O'  
TV, image_1, 0, 0  
TV, image_2, pwr - 1, 0
```

### IDL Output

```
Size of the file is 262144 bytes.  
Size of the compressed file is 69600 bytes.  
Percentage of elements under threshold: 87.0331  
The image on the right is reconstructed from: 12.9669% of original  
image data.
```

The sparse array contains only 13% of the elements contained in the original array. The following figure is created from this example. The image on the left is the original 256 by 256 image. The image on the right was compressed by the above process and was reconstructed from 13% of the original data. The size of the compressed image's data file is 26.6% of the size of the original image's data file. Note that due to limitations in the printing process, differences between the images may not be as evident as they would be on a high-resolution printer or monitor.

*Figure 3-153: Original image (left) and image reconstructed from 13% of the data (right).*

## WV\_\* Routines

For information, see the [Chapter 1, “Introduction to the IDL Wavelet Toolkit”](#) in the *IDL Wavelet Toolkit* manual.

# XBM\_EDIT

The XBM\_EDIT procedure is a utility for creating and editing icons for use with IDL widgets as bitmap labels for widget buttons.

The icons created with XBM\_EDIT can be saved in two different file formats. IDL “array definition files” are text files that can be inserted into IDL programs. “Bitmap array files” are data files that can be read into IDL programs. Bitmap array files should be used temporarily until the final icon design is determined and then they can be saved as IDL array definitions for inclusion in the final widget code. This routine does not check the file types of the files being read and assumes that they are of the correct size and type for reading. XBM\_EDIT maintains its state in a common block so it is restricted to one working copy at a time.

This routine is written in the IDL language. Its source code can be found in the file `xbm_edit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XBM_EDIT [, /BLOCK] [, FILENAME=string] [, GROUP=widget_id]  
        [, XSIZE=pixels] [, YSIZE=pixels]
```

## Arguments

None

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

---

### Note

Only the outermost call to XMANAGER can block. Therefore, to have XBM\_EDIT block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

## FILENAME

Set this keyword to a scalar string that contains the filename to be used for the new icon. If this argument is not specified, the name “idl.bm” is used. The filename can be changed in XBM\_EDIT by editing the “Filename” field before selecting a file option.

## GROUP

The widget ID of the widget that calls XBM\_EDIT. When this ID is specified, the death of the caller results in the death of XBM\_EDIT.

## XSIZE

The number of pixels across the bitmap is in the horizontal direction. The default value is 16 pixels.

## YSIZE

The number of pixels across the bitmap is in the vertical direction. The default value is 16 pixels.

## Version History

Pre-4.0	Introduced

[WIDGET\\_BUTTON](#)

# XDISPLAYFILE

The XDISPLAYFILE procedure is a utility for displaying ASCII text files using a widget interface. In addition to allowing users to read and optionally edit text files, the utility allows you programmatically interact with the text widget.

This routine is written in the IDL language. Its source code can be found in the file `xdisplayfile.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XDISPLAYFILE, Filename [, /BLOCK] [, DONE_BUTTON=string]  
  [, /EDITABLE] [, FONT=string] [, GROUP=widget_id]  
  [, /GROW_TO_SCREEN] [, HEIGHT=lines] [, /MODAL]  
  [, RETURN_ID=variable] [, TEXT=string or string array] [, TITLE=string]  
  [, WIDTH=characters] [, WTEXT=variable]
```

## Arguments

### Filename

A scalar string that contains the filename of the file to display. *Filename* can include a path to that file.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XDISPLAYFILE block, any earlier calls to XMANAGER must have been called with the [NO\\_BLOCK](#) keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

## DONE\_BUTTON

Set this keyword to a string containing the text to use for the Done button label. If omitted, the text “Done with <filename>” is used.

## EDITABLE

Set this keyword to allow modifications to the text displayed in XDISPLAYFILE. Setting this keyword also adds a “Save” button in addition to the Done button.

## FONT

A string containing the name of the font to use. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4910 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

## GROUP

The widget ID of the widget that calls XDISPLAYFILE. If this keyword is specified, the death of the group leader results in the death of XDISPLAYFILE.

## GROW\_TO\_SCREEN

Set this keyword to cause XDISPLAYFILE to display as many lines of text as possible without making the display too tall to fit on the screen. If this keyword is set, the value specified by the HEIGHT keyword is taken to be the minimum number of lines to display.

## HEIGHT

The number of text lines that the widget should display at one time. If this keyword is not specified, 24 lines is the default.

## MODAL

Set this keyword to create the XDISPLAYFILE dialog as a modal dialog. Setting the MODAL keyword allows you to call XDISPLAYFILE from another modal dialog.

## RETURN\_ID

Set this keyword equal to a named variable that will contain the widget ID of the top level base created by XDISPLAYFILE.

## TEXT

A string or string array to be displayed in the widget instead of the contents of a file. If this keyword is present, the *Filename* input argument is ignored (but is still required). String arrays are displayed one element per line.

## TITLE

A string to use as the widget title rather than the file name or “XDisplayFile”.

## WIDTH

The width of the widget display in characters. If this keyword is not specified, 80 characters is the default.

## WTEXT

Set this keyword to a named variable that will contain the widget ID of the text widget. This allows setting text selections and cursor positions programmatically. For example, the following code opens the XDISPLAYFILE widget and selects the first 10 characters of the file displayed in the text widget:

```
XDISPLAYFILE, 'myfile.txt', /EDITABLE, WTEXT=w
WIDGET_CONTROL, w, SET_TEXT_SELECT=[0, 10]
```

## Version History

# XDXF

The XDXF procedure is a utility for displaying and interactively manipulating DXF objects. It also displays a dialog that contains block and layer information for the DXF file, allowing the user to turn on and off the display of individual layers.

## Using XDXF

XDXF displays a resizable top-level base with a menu and draw widget used to display and manipulate the orientation of a DXF object.

Figure 3-154: The XDXF Utility

XDXF also displays a dialog that contains block and layer information and allows the user to turn on and off the display of individual layers.

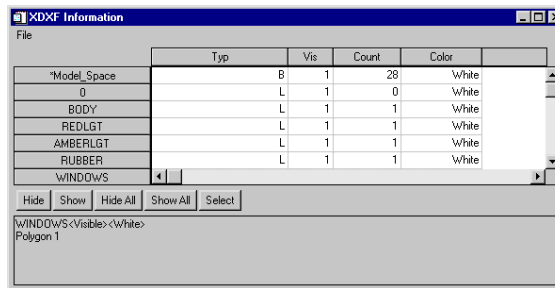

Figure 3-155: The XDXF Information Dialog

## The XDXF Toolbar

The XDXF toolbar contains the following buttons:

Button	Tool Name	Function
	<b>Reset</b>	Resets rotation, scaling, and panning.
	<b>Rotate</b>	Click the left mouse button on the object and drag to rotate.
	<b>Pan</b>	Click the left mouse button on the object and drag to pan.
	<b>Zoom</b>	Click the left mouse button on the object and drag to zoom in or out.
	<b>Select</b>	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 3-138: XDXF Toolbar Buttons

## The XDXF Information Dialog

The XDXF Information dialog displays information about the blocks and layers contained in the currently displayed object, and allows you to turn on and off the display of each layer.

To show or hide layers in the DXF object, select the layer from the list of layers on the left of the dialog, and click the **Show** or **Hide** button. Alternatively, you can click in the “Vis” field for the desired layer. To show or hide all layers, click the **Show All** or **Hide All** buttons.

If the **View Block Outlines** checkbox is selected, a green box will be displayed around the currently selected block, if any.

## Syntax

```
XDXF [, Filename] [, /BLOCK] [, GROUP=widget_id] [, SCALE=value] [, /TEST]
      [keywords to XOBJVIEW]
```

## Arguments

### Filename

A string specifying the name of the DXF file to display. If this argument is not specified, a file selection dialog is opened.

## Keywords

XDXF accepts the keywords to [XOBJVIEW](#). (Note, however, that specifying the XOBJVIEW keyword MODAL is interpreted by XDXF as a call to the BLOCK keyword.) In addition, XDXF supports the following keywords:

### BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XDXF block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

## GROUP

The widget ID of the widget that calls XDXF. When this ID is specified, the death of the caller results in the death of XDXF.

## SCALE

Set this keyword to the zoom factor for the initial view. The default is  $1/\text{SQRT}(3)$ . This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XDXF window, regardless of the object's orientation.

## TEST

If this keyword is set, the file `heart.dxf` in the IDL distribution is automatically opened in XDXF.

## Examples

Display the file `heart.dxf`, contained in the IDL distribution:

```
XDXF, FILEPATH('heart.dxf', $
             SUBDIR=['examples', 'data'])
```

# XFONT

The XFONT function is a utility that creates a modal widget for selecting and viewing an X Windows font.

Calling XFONT resets the current X Windows font.

---

**Note**

This routine is only available on UNIX platforms.

---

This routine is written in the IDL language. Its source code can be found in the file `xfont.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
Result = XFONT( [, GROUP=widget_id] [, /PRESERVE_FONT_INFO] )
```

## Return Value

The function returns a string containing the name of the last selected font. If no font is selected, or the “Cancel” button is clicked, a null string is returned.

## Arguments

None.

## Keywords

### GROUP

The widget ID of the widget that calls XFONT. When this ID is specified, the death of the caller results in the death of XFONT.

### PRESERVE\_FONT\_INFO

Set this keyword to make XFONT save the server font directory in common blocks so that subsequent calls to XFONT start-up much faster. If this keyword is not set, the common block is cleaned.

## Version History

Pre-4.0	Introduced

# XINTERANIMATE

The XINTERANIMATE procedure is a utility for displaying an animated sequence of images using off-screen pixmaps or memory buffers. The speed and direction of the display can be adjusted using the widget interface.

MPEG animation files can be created either programmatically using keywords to open and save a file, or interactively using the widget interface. Note that the MPEG standard does not allow movies with odd numbers of pixels to be created.

---

## Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

---

---

## Note

Only a single copy of XINTERANIMATE can run at a time. If you need to run multiple instances of the animation widget concurrently, use the CW\_ANIMATE compound widget.

---

This routine is written in the IDL language. Its source code can be found in the file `xinteranimate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using XINTERANIMATE

Displaying an animated series of images using XINTERANIMATE requires at least three calls to the routine: one to initialize the animation widget, one to load images, and one to display the images. When initialized using the SET keyword, XINTERANIMATE creates an approximately square pixmap or memory buffer, large enough to contain the requested number of frames of the requested size. Images are loaded using the IMAGE and FRAME keywords. Finally, images are displayed by copying them from the pixmap or memory buffer to the visible draw widget.

See [CW\\_ANIMATE](#) for a description of the widget interface controls used by XINTERANIMATE.

## Syntax

```
XINTERANIMATE [, Rate]
```

**Keywords for initialization:** [, SET=[*sizex*, *sizey*, *nframes*]] [, /BLOCK]  
 [, /CYCLE] [, GROUP=*widget\_id*] [, /MODAL] [, MPEG\_BITRATE=*value*]  
 [, MPEG\_IFRAME\_GAP=*integer value*]  
 [, MPEG\_MOTION\_VEC\_LENGTH={1 | 2 | 3}]

```
[, /MPEG_OPEN, MPEG_FILENAME=string]
[ MPEG_QUALITY=value{0 to 100}] [, /SHOWLOAD] [, /TRACK]
[, TITLE=string]
```

**Keywords for loading images:** [, FRAME=*value*{0 to (*nframes*-1)}  
[, IMAGE=*value*]] [, /ORDER] [, WINDOW=[*window\_num* [, *x0*, *y0*, *sx*, *sy*]]]

**Keywords for running animations:** [, /CLOSE] [, /KEEP\_PIXMAPS]  
[, /MPEG\_CLOSE] [, XOFFSET=*pixels*] [, YOFFSET=*pixels*]

## Arguments

### Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation is with a value of 100 and the slowest is with a value of 0. The default animation rate is 100. The animation must be initialized using the SET keyword before calling XINTERANIMATE with a rate value.

## Keywords: Initialization

The following keywords are used to initialize the animation display. The SET keyword *must* be provided. Other keywords described in this section are optional; note that they work only when SET is specified.

### SET

Set this keyword to a three-element vector [*Sizex*, *Sizey*, *Nframes*] to initialize XINTERANIMATE. *Sizex* and *Sizey* represent the width and height of the images to be displayed, in pixels. *Nframes* is the number of frames in the animation sequence. Note that *Nframes* must be at least 2 frames.

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO\_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XINTERANIMATE block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

**CYCLE**

Normally, frames are displayed going either forward or backwards. If the CYCLE keyword is set, the animation reverses direction after the last frame in either direction is displayed.

**GROUP**

Set this keyword to the widget ID of the widget that calls XINTERANIMATE. When GROUP is specified, the death of the calling widget results in the death of XINTERANIMATE.

**MODAL**

Set this keyword to block processing of events from other widgets until the user quits XINTERANIMATE. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XINTERANIMATE does not block event processing.

**MPEG\_BITRATE**

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

*Table 3-139: BITRATE Value Range*

If you do not set this keyword, IDL computes the MPEG\_BITRATE value based upon the value you have specified for the MPEG\_QUALITY keyword.

**Note**

---

Only use the MPEG\_BITRATE keyword if changing the MPEG\_QUALITY keyword value does not produce the desired results. It is highly recommended to set the MPEG\_BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

---

**MPEG\_FILENAME**

Set this keyword equal to a string specifying the name of the MPEG file. If no file name is specified, the default value (`idl.mpg`) is used.

**MPEG\_IFRAME\_GAP**

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the MPEG\_IFRAME\_GAP value based upon the value you have specified for the MPEG\_QUALITY keyword.

**Note**

---

Only use the MPEG\_IFRAME\_GAP keyword if changing the MPEG\_QUALITY keyword value does not produce the desired results.

---

**MPEG\_MOTION\_VEC\_LENGTH**

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

1	Small motion vectors
2	Medium motion vectors
3	Large motion vectors

If you do not set this keyword, IDL computes the MPEG\_MOTION\_VEC\_LENGTH value based upon the value you have specified for the MPEG\_QUALITY keyword.

**Note**

---

Only use the MPEG\_MOTION\_VEC\_LENGTH keyword if changing the MPEG\_QUALITY value does not produce the desired results.

---

**MPEG\_OPEN**

Set this keyword to open an MPEG file.

**MPEG\_QUALITY**

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

**Note**

---

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting QUALITY to its highest setting.

---

**SHOWLOAD**

Set this keyword to display each frame and update the frame slider as frames are loaded.

**TRACK**

Set this keyword to cause the frame slider to track the current frame when the animation is in progress. The default is not to track.

**TITLE**

Use this keyword to specify a string to be used as the title of the animation widget. If TITLE is not specified, the title is set to "XInterAnimate."

**Keywords: Loading Images**

The following keywords are used to load images into the animation display. They have no effect when initializing or running animations.

## FRAME

Use this keyword to specify the frame number when loading frames. FRAME must be set to a number in the range 0 to  $Nframes-1$ .

## IMAGE

Use this keyword to specify a single image to be loaded at the animation position specified by the FRAME keyword. (FRAME *must* also be specified.)

## ORDER

Set this keyword to display images from the top down instead of the default bottom up.

## WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap or memory buffer. (When using some windowing systems, using this keyword is much faster than reading from the display and then calling XINTERANIMATE with a 2-D array.)

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

## Keywords: Running Animations

The following keywords are used when running the animation. They have no effect when initializing the animation or loading images.

## CLOSE

Set this keyword to delete the offscreen pixmaps or buffers and the animation widget itself. This also takes place automatically when the user presses the “Done With Animation” button or closes the window with the window manager.

## KEEP\_PIXMAPS

If this keyword is set, XINTERANIMATE will not destroy the animation pixmaps or buffers when it is killed. Calling XINTERANIMATE again without going through the SET and LOAD steps will play the same animation without the overhead of creating the pixmaps.

## MPEG\_CLOSE

Set this keyword to close and save the MPEG file. This keyword has no effect if MPEG\_OPEN was not used during initialization.

## XOFFSET

Use this keyword to specify the horizontal offset, in pixels from the left of the frame, of the image in the destination window.

## YOFFSET

Use this keyword to specify the vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

## Examples

Enter the following commands to open the file ABNORM.DAT (a series of images of a human heart) and animate the images it contains using XINTERANIMATE.

```
OPENR, unit, FILEPATH('abnorm.dat', SUBDIR=['examples','data']), $
  /GET_LUN
H = BYTARR(64, 64, 16)
READU, unit, H
CLOSE, unit

; Read the images into variable H:
H = REBIN(H, 128, 128, 16)

; Initialize XINTERANIMATE:
XINTERANIMATE, SET=[128, 128, 16], /SHOWLOAD

; Load the images into XINTERANIMATE:
FOR I=0,15 DO XINTERANIMATE, FRAME = I, IMAGE = H[*,*,I]

; Play the animation:
XINTERANIMATE, /KEEP_PIXMAPS
```

### Note

---

Since the KEEP\_PIXMAPS keyword was supplied, the same animation can be replayed (after the animation widget has been destroyed) with the single command XINTERANIMATE.

---

Also see [T3D](#) for an example that draws and rotates a simple house.

[CW\\_ANIMATE](#)

# XLOADCT

The XLOADCT procedure is a utility that provides a graphical widget interface to the LOADCT procedure. XLOADCT displays the current Direct Graphics color table and shows a list of available predefined color tables. Clicking on the name of a color table causes that color table to become IDL's current color table. IDL maintains a color table on PseudoColor displays or when the DECOMPOSED keyword to the DEVICE command is set to zero (`DEVICE, DECOMPOSED = 0`) on TrueColor displays. Many other options, such as Gamma correction, stretching, and transfer functions can also be applied to the colortable.

This routine is written in the IDL language. Its source code can be found in the file `xloadct.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XLOADCT [, /BLOCK] [, BOTTOM=value] [, FILE=string] [, GROUP=widget_id]
        [, /MODAL] [, NCOLORS=value] [, /SILENT]
        [, UPDATECALLBACK='procedure_name' [, UPDATECBDATA=value]]
        [, /USE_CURRENT]
```

## Arguments

None.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XLOADCT block, any earlier calls to XMANAGER must have been called with the [NO\\_BLOCK](#) keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

## BOTTOM

The first color index to use. XLOADCT will use color indices from BOTTOM to BOTTOM+NCOLORS-1. The default is BOTTOM=0.

## FILE

Set this keyword to a string representing the name of the file to be used instead of the file `colors1.tbl` in the IDL directory.

## GROUP

The widget ID of the widget that calls XLOADCT. When this ID is specified, a death of the caller results in a death of XLOADCT.

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XLOADCT. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XLOADCT does not block event processing.

## NCOLORS

The number of colors to use. Use color indices from 0 to the smaller of !D.TABLE\_SIZE-1 and NCOLORS-1. The default is all available colors (!D.TABLE\_SIZE).

## SILENT

Normally, no informational message is printed when a color map is loaded. If this keyword is set to zero, the message is printed.

## UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

## UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any.

If the `UPDATECBDATA` keyword is not set the value accepted by the `DATA` keyword to the procedure specified by `UPDATECALLBACK` will be undefined.

## USE\_CURRENT

Set this keyword to use the current color tables, regardless of the contents of the `COLORS` common block.

## Examples

The `XLOADCT` utility allows you to load one of IDL's 41 pre-defined color tables and change that color table if necessary.

### Using the XLOADCT Utility

The following example shows how to use `XLOADCT` to load a color table and then change that table to highlight specific features of an image. The indexed image used in this example is a computed tomography (CT) scan of a human thoracic cavity and is contained (without a default color table) within the `ctscan.dat` file in IDL's `examples/data` directory. Complete the following steps for a detailed description of the process.

#### Example Code

---

See `usingxloadct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. The `BLOCK` keyword is set when using `XLOADCT` to force the example routine to wait until the **Done** button is pressed to continue. If the `BLOCK` keyword was not set, the example routine would produce all of the displays at once and then end.

---

1. Determine the path to the `ctscan.dat` binary file:

```
ctscanFile = FILEPATH('ctscan.dat', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
ctscanSize = [256, 256]
```

3. Import the image from the file:

```
ctscanImage = READ_BINARY(ctscanFile, $
    DATA_DIMS = ctscanSize)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword of the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

Since the imported image does not have an associated color table, you need to apply a pre-defined color table to display the image.

5. Initialize the display by applying the B-W LINEAR color table (index number 0):

```
LOADCT, 0  
WINDOW, 0, TITLE = 'ctscan.dat', $  
    XSIZE = ctscanSize[0], YSIZE = ctscanSize[1]
```

6. Display the image using this color table:

```
TV, ctscanImage
```

As the following figure shows, the B-W LINEAR color table does not highlight all of the aspects of this image. The `XLOADCT` utility can be used to change the color table to highlight more features.

*Figure 3-156: CT Scan Image with Grayscale Color Table*

7. Open the XLOADCT utility:

XLOADCT

Select Rainbow + white and click **Done** to apply the color table.

The following figure shows the resulting XLOADCT display.

*Figure 3-157: Selecting Rainbow + white Color Table in XLOADCT Utility*

After applying the new color table, you can now see the spine, liver, and kidney within the image, as shown in the following figure. However, the separations between the skin, the organs, and the cartilage and bone within the spine are hard to distinguish.

8. Now re-display the image to show it on the Rainbow + white color table:

```
TV, ctscanImage
```

---

**Note**

You do not have to perform the previous step on a PseudoColor display. Changes to the current color table automatically show in the current image window within a PseudoColor display.

---

The following figure shows the CT scan image with the Rainbow+white color table.

*Figure 3-158: CT Scan Image with the Rainbow + white Color Table*

9. Redisplay the color table with the XLOADCT utility:

```
XLOADCT
```

Comparing the image to the color table, you can see that most image pixels are not within the black to purple range. Therefore the black to purple pixels in the image can be replaced by black. The black range can be stretched to move the purple range to help highlight more features.

The **Stretch Bottom** slider in the XLOADCT utility increases the range of the lowest color index. For example, if black was the color of the lowest index and you increased the bottom stretch by 50 percent, the lower half of the color table would become all black. The remaining part of the color table will contain a scaled version of all the previous color ranges.

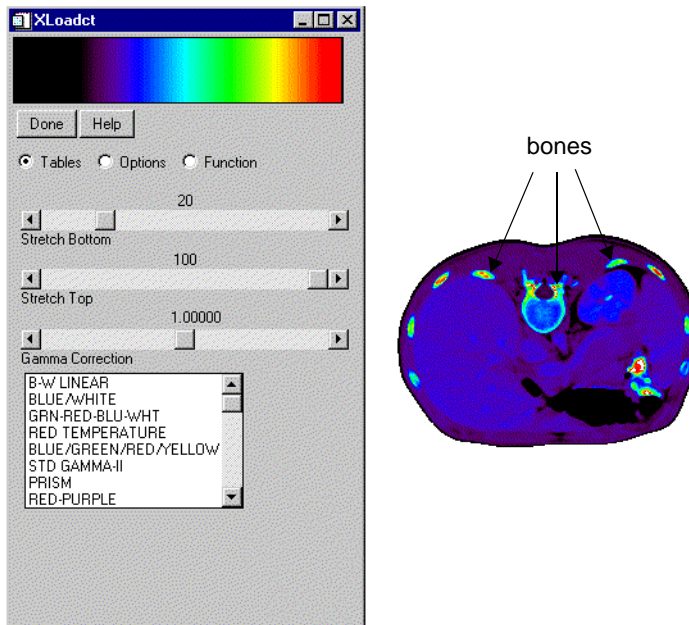

10. Within XLOADCT, stretch the bottom part of the color table by 20 percent by moving the slider as shown in the following figure:

TV, ctscanImage

### Note

Remember to click on the **Done** button after changing the **Stretch Bottom** slider, then use TV to re-display the image to include the last changing made in the XLOADCT utility.

In the following figure, you can now see the difference between skin and organs. You can also see where cartilage and bone is located within the spine, but now organs are hard to see. Most of the values in the top (the yellow to red to white ranges) of the color table show just the bones. You can use less of these ranges to show bones by stretching the top of the color table.

*Figure 3-159: CT Scan Image with Bottom Stretched by 20%*

The **Stretch Top** slider in the XLOADCT utility allows you increase the range of the highest color index. For example, if white was the color of the highest index and you increased the top stretch by 50 percent, the higher half of the

color table would become all white. The remaining part of the color table will contain a scaled version of all the previous color ranges.

#### 11. Open XLOADCT:

```
XLOADCT
```

Stretch the bottom part of the color table by 20 percent and stretch the top part of the color table by 20 percent (changing it from 100 to 80 percent).

Click **Done** and redisplay the image:

```
TV, ctscanImage
```

The following figure shows that the organs are more distinctive, but now the liver and kidneys are not clearly distinguished. These features occur in the blue range. You can shift the green range more toward the values of these organs with a gamma correction.

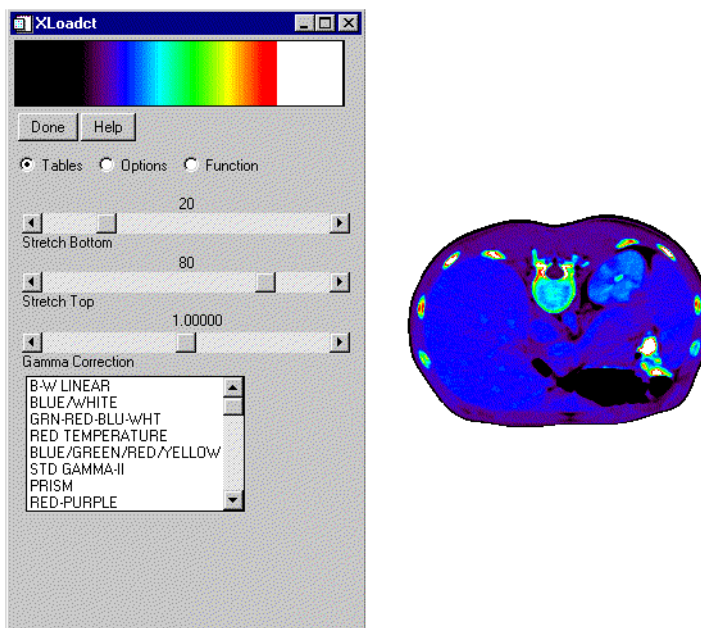

Figure 3-160: CT Scan Image with Bottom and Top Stretched by 20%

With the **Gamma Correction** slider in the XLOADCT utility you can change the contrast within the color table. A value of 1.0 indicates a linear ramp (no

gamma correction). Values other than 1.0 indicate a logarithmic ramp. Higher values of gamma give more contrast. Values less than 1.0 yield lower contrast.

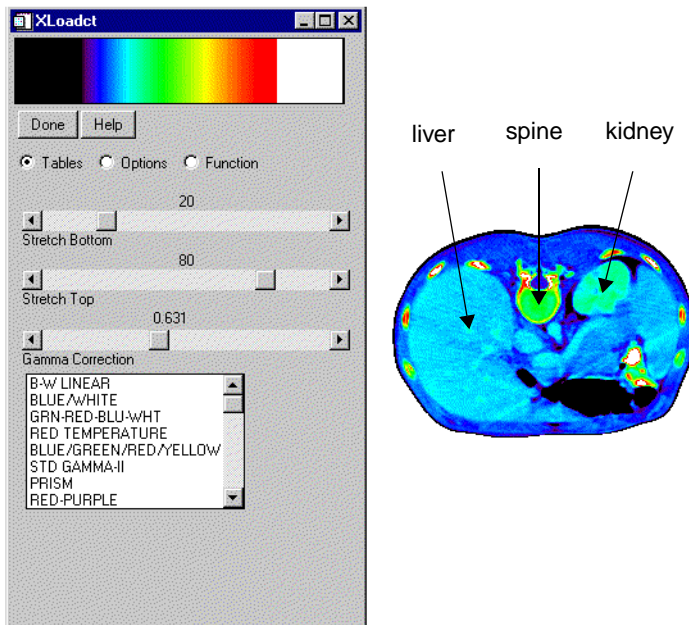

12. Within XLOADCT, stretch the bottom part of the color table by 20 percent, stretch the top part of the color table by 20 percent (change it from 100 percent to 80 percent), and decrease the Gamma Correction factor to 0.631:

```
XLOADCT
```

Redisplay the image:

```
TV, ctscanImage
```

All the features are now highlighted within the image as shown in the following figure:

*Figure 3-161: CT Scan Image with Bottom and Top Stretched by 20% and Gamma Correction at 0.631*

The previous steps showed how to use the **Tables** section of the XLOADCT utility. XLOADCT also contains two other sections: **Options** and **Function**. The **Options** section allows you to change what the sliders represent and how they are used. When the **Gang** option is selected, the sliders become dependent

upon each other. When either the **Stretch Bottom** or **Stretch Top** sliders are moved, the other ones reset to their default values (0 or 100, respectively). With the **Chop** option, you can chop off the top of the color table (the range of the **Stretch Top** is now black instead of the color at the original highest index). With the **Intensity** option, you can change the slider to control the intensity instead of the index location. The **Stretch Bottom** slider will darken the color table and the **Stretch Top** slider will brighten the color table.

The **Function** section allows you to place control points which you can use to change the color table with respect to the other colors in that table. The color table function is shown as a straight line increasing from the lowest index (0) to the highest index (255). The x-axis ranges from 0 to 255 and the y-axis ranges from 0 to 255. Moving a control point in the x-direction has the same effects as the previous sliders. Moving a control point in the y-direction changes the color of that index to another color within the color table. For example, if a control point is red at an index of 128 and the color table is green at an index of 92, when the control point is moved in the y-direction to an index of 92, the color at that x-location will become green. To understand how the **Function** section work, you can use it to highlight just the bones with the CT scan image.

13. Open XLOADCT:

```
XLOADCT
```

Select the Rainbow + white color table.

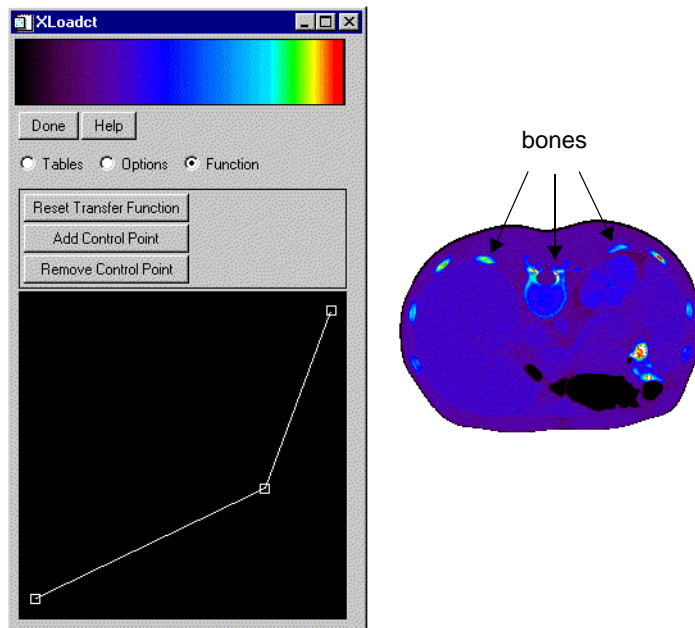

Switch to the **Function** section by selecting that option.

Select the **Add Control Point** button, and drag this new center control point one half of the way to the right and one quarter of the way down as shown in the following figure.

Click **Done** and redisplay the image:

```
TV, ctscanImage
```

The bones in the image are now highlighted.

*Figure 3-162: CT Scan Image with Central Control Point Moved One Half to the Right and One Quarter Down*

# XMANAGER

The XMANAGER procedure provides the main event loop and management for widgets created using IDL. Calling XMANAGER “registers” a widget program with the XMANAGER event handler. XMANAGER takes control of event processing until all widgets have been destroyed.

Beginning with IDL version 5.0, IDL supports an *active command line* that allows the IDL command line to continue accepting input while properly configured widget applications are running. See “[A Note About Blocking in XMANAGER](#)” on page 2845 for a more detailed explanation of the active command line.

This routine is written in the IDL language. Its source code can be found in the file `xmanager.pro` in the `lib` subdirectory of the IDL distribution.

## Warning

---

Although this routine is written in the IDL language, it may change in the future in its internal implementation. For future upgradability, it is best not to modify or even worry about what this routine does internally.

---

## Syntax

```
XMANAGER [, Name, ID] [, /CATCH] [, CLEANUP=string]
           [, EVENT_HANDLER='procedure_name'] [, GROUP_LEADER=widget_id]
           [, /JUST_REG] [, /NO_BLOCK]
```

## Arguments

### Name

A string that contains the name of the routine that creates the widget (i.e., the name of the widget creation routine that is calling XMANAGER).

### Note

---

The *Name* argument is stored in a COMMON block for use by the XREGISTERED routine. The stored name is case-sensitive.

---

### ID

The widget ID of the top-level base that is the root of the widget hierarchy being to be managed.

## Keywords

### CATCH

Set this keyword to cause XMANAGER to catch any errors, using the **CATCH** procedure, when dispatching widget events. If the **CATCH** keyword is set equal to zero, execution halts and IDL provides traceback information when an error is detected. This keyword is set by default (errors are caught and processing continues).

Do not specify either the *Name* or *ID* argument to XMANAGER when specifying the **CATCH** keyword (they are ignored). **CATCH** turns error catching on and off for *all* applications managed by XMANAGER. When **CATCH** is specified, XMANAGER changes its error-catching behavior and returns immediately, without taking any other action.

#### Note

---

Beginning with IDL version 5.0, the default behavior of XMANAGER is to catch errors and continue processing events. In versions of IDL prior to version 5.0, XMANAGER halted when an error was detected. This change in default behavior was necessary in order to allow multiple widget applications (all being managed by XMANAGER) to coexist peacefully. When **CATCH** is set equal to zero, (the old behavior), any error halts XMANAGER, and thus halts event processing for all running widget applications.

Note also that **CATCH** is only effective if XMANAGER is blocking to dispatch errors. If event dispatching for an active IDL command line is in use, the **CATCH** keyword has no effect.

The **CATCH=0** setting (errors are not caught and processing halts in XMANAGER when an error is detected) is intended as a debugging aid. Finished programs should not set **CATCH=0**.

---

### CLEANUP

Set this keyword to a string that contains the name of the routine to be called when the widget program dies. If this keyword is not specified, the routine (if any) specified for the program's top-level base by the **KILL\_NOTIFY** keyword to **WIDGET\_BASE** or **WIDGET\_CONTROL** is used.

The routine specified by **CLEANUP** becomes the **KILL\_NOTIFY** routine for the widget application, overriding any cleanup routines that have been set previously via the **KILL\_NOTIFY** keyword to **WIDGET\_BASE** or **WIDGET\_CONTROL**.

**Note**

---

Specifying a routine for the widget application's top-level base via the `KILL_NOTIFY` keyword to `WIDGET_CONTROL` *after* the call to `XMANAGER` will override the value of the `CLEANUP` keyword.

---

The cleanup routine is called with the widget identifier as its only argument.

**EVENT\_HANDLER**

Set this keyword to a string that contains the name of a routine to be called when a widget event occurs in the widget program being registered. If this keyword is not supplied, `XMANAGER` will construct a default name by adding the “\_event” suffix to the *Name* argument. See the example below for a more detailed explanation.

**GROUP\_LEADER**

The widget ID of the group leader for the widget being processed. When the leader dies either by the users actions or some other routine, all widgets that have that leader will also die.

For example, a widget that views a help file for a demo widget would have that demo widget as its leader. When the help widget is registered, it sets the keyword `GROUP_LEADER` to the widget ID of the demo widget. If the demo widget were destroyed, the help widget led by it would be killed by the `XMANAGER`.

**JUST\_REG**

Set this keyword to indicate that `XMANAGER` should just register the widget and return immediately. This keyword is useful if you want to register a group of related top-level widgets before beginning event processing and one or more of the registered widgets requests that `XMANAGER` block event processing. (Note that in this case a later call to `XMANAGER` without the `JUST_REG` keyword is necessary to begin blocking.)

(See “[A Note About Blocking in XMANAGER](#)” on page 2845 for further discussion of the active command line.)

**Warning**

---

`JUST_REG` is not the same as `NO_BLOCK`. See “[JUST\\_REG vs. NO\\_BLOCK](#)” on page 2845 for additional details.

---

## NO\_BLOCK

Set this keyword to tell XMANAGER that the registering client does not require XMANAGER to block if active command line event processing is available. If active command line event processing is available *and* every current XMANAGER client specifies NO\_BLOCK, then XMANAGER will not block and the user will have access to the command line while widget applications are running.

It is important to understand the result of making nested calls to XMANAGER. XMANAGER can only block event processing for one client at a time. In applications involving multiple calls to XMANAGER (either directly or via calls to other routines that call XMANAGER, such as XLOADCT), blocking occurs only for the outermost call to XMANAGER, unless XMANAGER is told not to block in that call. If an application contains two calls to XMANAGER, the second call cannot block unless the first call sets the NO\_BLOCK keyword. If an application contains a call to XMANAGER, followed by a call to XLOADCT, XLOADCT will not block unless the NO\_BLOCK keyword was set in the call to XMANAGER (and the BLOCK keyword to XLOADCT is set). Consider the following example:

```

PRO blocking_example_event, event
    ; The following call blocks only if the NO_BLOCK keyword to
    ; XMANAGER is set:
    XLOADCT, /BLOCK
END

PRO blocking_example
    base=WIDGET_BASE(/COLUMN)
    button1=WIDGET_BUTTON(base,VALUE='Run XLOADCT')
    WIDGET_CONTROL,base, /REALIZE
    XMANAGER,'blocking_example', base, /NO_BLOCK
END

```

If the NO\_BLOCK keyword to XMANAGER was not set in the above example, XLOADCT would not block, even though the BLOCK keyword was set. Setting the NO\_BLOCK keyword to XMANAGER prevents XMANAGER from blocking, thereby allowing the subsequent call to XMANAGER (via XLOADCT) to block.

### Warning

NO\_BLOCK is not the same as JUST\_REG. See [“JUST\\_REG vs. NO\\_BLOCK”](#) on page 2845 for additional details.

## A Note About Blocking in XMANAGER

By default, IDL widget application blocking is *enabled*. Unless you take the appropriate steps, widget applications will block all other processing from occurring in IDL. Keeping the following issues in mind when writing widget applications will give you the best chance to create applications that coexist with other applications and the IDL command line.

### Active Command Line

Beginning with IDL version 5.0, most versions of IDL's command-processing front-end are able to support an *active command line* while running properly constructed widget applications. What this means is that—provided the widget application is properly configured—the IDL command line is available for input while a widget application is running and widget events are being processed.

There are currently 3 separate IDL command-processing front-end implementations:

- Microsoft Windows IDLDE
- Motif IDLDE (UNIX)
- UNIX plain tty

Note that widget applications must be well-behaved with respect to blocking widget event processing. Since in most cases XMANAGER is used to handle widget event processing, this means that in order for the command line to remain active, all widget applications must be run with the NO\_BLOCK keyword to XMANAGER set. (Note that since NO\_BLOCK is *not* the default, it is quite likely that some application will block.) If a single application runs in blocking mode, the command line will be inaccessible until the blocking application exits. When a blocking application exits, the IDL command line will once again become active.

### JUST\_REG vs. NO\_BLOCK

Although their names imply a similar function, the JUST\_REG and NO\_BLOCK keywords perform very different services. It is important to understand what they do and how they differ.

The JUST\_REG keyword tells XMANAGER that it should simply register a client and then return immediately. The result is that the client becomes known to XMANAGER, and that future calls to XMANAGER will take this client into account. Therefore, JUST\_REG only controls how the registering call to XMANAGER should behave. The client can still be registered as requiring

XMANAGER to block by setting `NO_BLOCK=0`. In this case, *future* calls to XMANAGER will block.

The `NO_BLOCK` keyword tells XMANAGER that the registered client does not require XMANAGER to block if the command-processing front-end is able to support active command line event processing. XMANAGER remembers this attribute of the client until the client exits, even after the call to XMANAGER that registered the client returns. `NO_BLOCK` is just a “vote” on how XMANAGER should behave—the final decision is made by XMANAGER by considering the `NO_BLOCK` attributes of *all* of its current clients as well as the ability of the command-processing front-end in use to support the active command line.

## Blocking vs. Non-blocking Applications

The issue of blocking in XMANAGER requires some explanation. IDL widget events are not processed until the `WIDGET_EVENT` function is called to handle them. Otherwise, they are queued by IDL indefinitely. Knowing how and when to call `WIDGET_EVENT` is the primary service provided by XMANAGER.

There are two ways blocking is typically handled:

1. The first call to XMANAGER processes events by calling `WIDGET_EVENT` as necessary until no managed widgets remain on the screen. This is referred to as “blocking” because XMANAGER does not return to the caller until it is done, and the IDL command line is not available.
2. XMANAGER does not block, and instead, the part of IDL that reads command input also watches for widget events and calls `WIDGET_EVENT` as necessary while also reading command input. This is referred to as “non-blocking” or “active command line” mode.

XMANAGER will block unless the following conditions are met:

- All registered widget applications have the `NO_BLOCK` keyword to XMANAGER set.
- No modal dialogs are displayed. (Modal dialogs always block until dismissed.)

In general, we suggest that new widget applications be written with XMANAGER blocking disabled (that is, with the `NO_BLOCK` keyword set).

Since a widget application that does block event processing for itself will block event processing for all other widget applications (and the IDL command line) as well, we suggest that older widget applications be upgraded to take advantage of the new, non-blocking behavior by adding the `NO_BLOCK` keyword to most calls to XMANAGER.

## Examples

The following code creates a widget named EXAMPLE that is just a base widget with a “Done” button and registers it with the XMANAGER. Widgets being registered with the XMANAGER must provide at least two routines. The first routine creates the widget and registers it with the manager and the second routine processes the events that occur within that widget. An example widget is supplied below that uses only two routines. A number of other “Simple Widget Examples”, can be viewed by entering WEXMASTER at the IDL prompt. These simple programs demonstrate many aspects of widget programming.

The following lines of code would be saved in a single file, named `example.pro`:

```

; Begin the event handler routine for the EXAMPLE widget:
PRO example_event, ev

; The uservalue is retrieved from a widget when an event occurs:
WIDGET_CONTROL, ev.id, GET_UVALUE = uv

; If the event occurred in the Done button, kill the widget
; example:
if (uv eq 'DONE') THEN WIDGET_CONTROL, ev.top, /DESTROY

; End of the event handler part:
END

; This is the routine that creates the widget and registers it with
; the XMANAGER:
PRO example

; Create the top-level base for the widget:
base = WIDGET_BASE(TITLE='Example')

; Create the Done button and set its uservalue to "DONE":
done = WIDGET_BUTTON(base, VALUE = 'Done', UVALUE = 'DONE')
; Realize the widget (i.e., display it on screen):
WIDGET_CONTROL, base, /REALIZE

; Register the widget with the XMANAGER, leaving the IDL command
; line active:
XMANAGER, 'example', base, /NO_BLOCK

; End of the widget creation part:
END

```

First the event handler routine is listed. The handler routine has the same name as the main routine with the characters “\_event” added. If you would like to use another

event handler name, you would need to pass its name to XMANAGER using the `EVENT_HANDLER` keyword.

Notice that the event routine is listed before the main routine. If you include both the event routine and the main routine in a single `.pro` file with the name of the main routine (a common practice), this is necessary to ensure that the event routine is compiled. If the event routine were placed after the main routine in the file, IDL would compile and execute the main routine — and the compiler would exit — before the event routine was compiled. Alternatively, you can save your event routine in its own file with its own name (which in the above example would be `example_event.pro`), and IDL will compile the routine when it is required.

Notice also the `NO_BLOCK` keyword to XMANAGER has been included. This allows IDL to continue processing events and accepting input at the command prompt while the `example` widget application is running.

## Version History

Pre-4.0	Introduced
Pre-6.2	Deprecated BACKGROUND and MODAL

For information on obsolete keywords, see [Appendix J, “Obsolete Features”](#).

# XMNG\_TMPL

The `XMNG_TMPL` procedure is a template for widgets that use the `XMANAGER`. Use this template instead of writing your widget applications from “scratch”. This template can be found in the file `xmng_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

The documentation header should be altered to reflect the actual implementation of the `XMNG_TMPL` widget. Use a global search and replace to replace the word `XMNG_TMPL` with the name of the routine you would like to use. All the comments with a “\*\*\*” in front of them should be read, decided upon and removed from the final copy of your new widget routine.

## Syntax

```
XMNG_TMPL [, /BLOCK] [, GROUP=widget_id]
```

## Arguments

None

## Keywords

### BLOCK

Set this keyword to have `XMANAGER` *block* when this application is registered. By default, `BLOCK` is set equal to zero, providing access to the command line if active command line processing is available. Note that setting `BLOCK=1` will cause *all* widget applications to block, not just this application. For more information, see the documentation for the `NO_BLOCK` keyword to `XMANAGER`.

### Note

---

Only the outermost call to `XMANAGER` can block. Therefore, to have `XMNG_TMPL` block, any earlier calls to `XMANAGER` must have been called with the `NO_BLOCK` keyword. See the documentation for the `NO_BLOCK` keyword to `XMANAGER` for an example.

---

### GROUP

The widget ID of the widget that calls `XMNG_TMPL`. When this ID is specified, the death of the caller results in the death of `XMNG_TMPL`.

## Version History

Pre-4.0	Introduced

[CW\\_TMPL](#)

# XMTOOL

The XMTOOL procedure displays a tool for viewing widgets currently being managed by the XMANAGER. Only one instance of the XMTOOL can run at one time.

This routine is written in the IDL language. Its source code can be found in the file `xmtool.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XMTOOL [, /BLOCK] [, GROUP=widget_id]
```

## Arguments

None.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XMTOOL block, any earlier calls to XMANAGER must have been called with the [NO\\_BLOCK](#) keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

### GROUP

The widget ID of the widget that calls XMTOOL. If the calling widget is destroyed, the XMTOOL is also destroyed.

[XMANAGER](#)

# XOBJVIEW

The XOBJVIEW procedure is a utility used to quickly and easily view and manipulate IDL Object Graphics on screen. It displays given objects in an IDL widget with toolbar buttons and menus providing functionality for manipulating, printing, and exporting the resulting graphic. The mouse can be used to rotate, scale, or translate the overall model shown in a view, or to select graphic objects in a view.

This routine is written in the IDL language. Its source code can be found in the file `xobjview.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Note

Two routines associated with the XOBJVIEW utility — `XOBJVIEW_ROTATE` and `XOBJVIEW_WRITE_IMAGE` — do not provide a graphical interface themselves, but act on an existing instance of the XOBJVIEW utility.

## Using XOBJVIEW

XOBJVIEW displays a resizable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

Figure 3-163: The XOBJVIEW widget

## The XOBJVIEW Toolbar

The XOBJVIEW toolbar contains the following buttons:

Button	Tool Name	Function
	<b>Reset</b>	Resets rotation, scaling, and panning.
	<b>Rotate</b>	Click the left mouse button on the object and drag to rotate.
	<b>Pan</b>	Click the left mouse button on the object and drag to pan.
	<b>Zoom</b>	Click the left mouse button on the object and drag to zoom in or out.
	<b>Select</b>	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 3-140: XOBJVIEW Toolbar Buttons

## Syntax

```
XOBJVIEW, Obj [, BACKGROUND=[r, g, b]] [, /BLOCK] [, /DOUBLE_VIEW ]
  [, GROUP=widget_id] [, /JUST_REG] [, /MODAL] [, REFRESH=widget_id]
  [, RENDERER={0 | 1}] [, SCALE=value] [, STATIONARY=objref(s)] [, /TEST]
  [, TITLE=string] [, TLB=variable] [, XOFFSET=value] [, XSIZE=pixels]
  [, YOFFSET=value] [, YSIZE=pixels]
```

## Arguments

### Obj

A reference to an atomic graphics object, an IDLgrModel, or an array of such references. If *Obj* is an array, the array can contain a mixture of such references. Also, if *Obj* is an array, all object references in the array must be unique (i.e. no two references in the array can refer to the same object).

*Obj* is not destroyed when XOBJVIEW is quit or killed.

## Keywords

### BACKGROUND

Set this keyword to a three-element [r, g, b] color vector specifying the background color of the XOBJVIEW window.

### BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

---

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XOBJVIEW block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

### DOUBLE\_VIEW

Set this keyword to cause XOBJVIEW to set the DOUBLE property on the IDLgrView that it uses to display graphical data.

### GROUP

The widget ID of the widget that calls XOBJVIEW. When this ID is specified, the death of the caller results in the death of XOBJVIEW.

### JUST\_REG

Set this keyword to indicate that the XOBJVIEW utility should just be registered and return immediately. This is useful if you want to register XOBJVIEW before beginning event processing and one or more widgets requests that XMANAGER block event processing. See “[JUST\\_REG vs. NO\\_BLOCK](#)” on page 2845 for additional details.

### MODAL

Set this keyword to block processing of events from other widgets until the user quits XOBJVIEW. The MODAL keyword does not require a group leader to be specified.

If no group leader is specified, and the MODAL keyword is set, XOBJVIEW fabricates an invisible group leader for you.

---

**Note**

To be modal, XOBJVIEW does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2488 for more information.)

To provide a simple means of invoking XOBJVIEW as a modal widget in applications that contain no other widgets, XOBJVIEW can be invoked as MODAL without specifying a group leader, in which case XOBJVIEW fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XOBJVIEW, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

---

## REFRESH

Set this keyword to the widget ID of the XOBJVIEW instance to be refreshed. To retrieve the widget ID of an instance of XOBJVIEW, first call XOBJVIEW with the TLB keyword. To refresh that instance of XOBJVIEW, call XOBJVIEW again and set REFRESH to the value retrieved by the TLB keyword in the earlier call to XOBJVIEW. For example, in the initial call to XOBJVIEW, use the TLB keyword as follows:

```
XOBJVIEW, myobj, TLB=tlb
```

If the properties of `myobj` are changed in your application or at the IDL command line, refresh the view in XOBJVIEW by calling XOBJVIEW again with the REFRESH keyword:

```
XOBJVIEW, REFRESH=tlb
```

For an example application demonstrating the use of the REFRESH keyword, see [“Example 3”](#) on page 2860.

**Note**

Currently, the REFRESH keyword can only be used to refresh the object itself. All other keywords and arguments to XOBJVIEW are ignored when REFRESH is specified, therefore, properties such as the background color and scale are not affected.

## RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects in the XOBJVIEW draw window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See [“Hardware vs. Software Rendering”](#) in Chapter 12 of the *Object Programming* manual for details. Your choice of renderer may also affect the maximum size of the XOBJVIEW draw window. See [“IDLgrWindow”](#) on page 4564 for details.

## SCALE

Set this keyword to the zoom factor for the initial view. The default is  $1/\text{SQRT}(3)$ . This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XOBJVIEW window, regardless of the object's orientation.

## STATIONARY

Set this keyword to a reference to an atomic graphics object, an IDLgrModel, or an array of such references. If this keyword is an array, the array can contain a mixture of such references. Also, if this keyword is an array, all object references in the array must be unique (i.e., no two references in the array can refer to the same object). Objects passed to XOBJVIEW via this keyword will not scale, rotate, or translate in response to mouse events. Default stationary objects are two lights. These two lights are replaced if one or more lights are supplied via this keyword. Objects specified via this keyword are not destroyed by XOBJVIEW when XOBJVIEW is quit or killed.

For example, to change the default lights used by XOBJVIEW, you could specify your own lights using the STATIONARY keyword as follows:

```
mylight1 = OBJ_NEW('IDLgrLight', TYPE=0, $
  COLOR=[255,0,0]) ; Ambient red
```

```

mylight2 = OBJ_NEW('IDLgrLight', TYPE=2, $
    COLOR=[255,0,0], LOCATION=[2,2,5]) ; Directional red

mymodel = OBJ_NEW('IDLgrModel')
mymodel->Add, mylight1
mymodel->Add, mylight2

XOBJVIEW, /TEST, STATIONARY=mymodel

```

## TEST

If set, the *Obj* argument is not required (and is ignored if provided). A blue sinusoidal surface is displayed. This allows you to test code that uses XOBJVIEW without having to create an object to display.

## TITLE

Set this keyword to the string that appears in the XOBJVIEW title bar.

## TLB

Set this keyword to a named variable that upon return will contain the widget ID of the top level base.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

Set this keyword to the width of the drawable area in pixels. The default is 400.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the upper left corner of the parent widget.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is

primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

Set this keyword to the height of the drawable area in pixels. The default is 400.

## Examples

### Example 1

This example displays a simple IDLgrSurface object using XOBJVIEW:

```
oSurf = OBJ_NEW('IDLgrSURFACE', DIST(20))
XOBJVIEW, oSurf
```

### Example 2

This example displays an IDLgrModel object consisting of two separate objects:

```
; Create contour object:
oCont = OBJ_NEW('IDLgrContour', DIST(20), N_LEVELS=10)

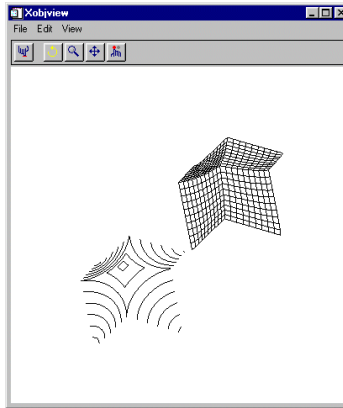

; Create surface object:
oSurf = OBJ_NEW('IDLgrSurface', $
    DIST(20), INDGEN(20)+20, INDGEN(20)+20)

; Create model object:
oModel = OBJ_NEW('IDLgrModel')

; Add contour and surface objects to model:
oModel->Add, oCont
oModel->Add, oSurf

; View model:
XOBJVIEW, oModel
```

This code results in the following view in the XOBJVIEW widget:

*Figure 3-164: Using XOBJVIEW to view a model consisting of two objects*

Note that when you click the Select button, and then click on an object, the class of that object appears next to the Select button. If the selected object has a non-null NAME property associated with it, that string value will be displayed, otherwise the name of the selected object's class will be displayed.

If you want the class of the model to appear when you click over any object in the model, you can set the SELECT\_TARGET property of the model as follows:

```
oModel->SetProperty, /SELECT_TARGET
```

Also note that it is not necessary to create a model to view more than one object using XOBJVIEW. We could view the oCont and oSurf objects created in the above example by placing them in an array as follows:

```
XOBJVIEW, [oCont, oSurf]
```

### Example 3

This example demonstrates how the REFRESH keyword can be used to refresh the object displayed in an instance of XOBJVIEW.

```
PRO xobjview_refresh_event, event
    WIDGET_CONTROL, event.id, GET_UVALUE=uval
    WIDGET_CONTROL, event.top, GET_UVALUE=state
```

```

CASE uval OF
  'red': BEGIN
    WIDGET_CONTROL, event.id, GET_VALUE=val
    state.myobj->GetProperty, COLOR=c
    state.myobj->SetProperty, COLOR=[val,c[1],c[2]]
    XOBJVIEW, REFRESH=state.tlb
  END
  'green': BEGIN
    WIDGET_CONTROL, event.id, GET_VALUE=val
    state.myobj->GetProperty, COLOR=c
    state.myobj->SetProperty, COLOR=[c[0],val,c[2]]
    XOBJVIEW, REFRESH=state.tlb
  END
  'blue': BEGIN
    WIDGET_CONTROL, event.id, GET_VALUE=val
    state.myobj->GetProperty, COLOR=c
    state.myobj->SetProperty, COLOR=[c[0],c[1],val]
    XOBJVIEW, REFRESH=state.tlb
  END
ENDCASE
END

PRO xobjview_refresh_cleanup, wID
  WIDGET_CONTROL, wID, GET_UVALUE=state
  OBJ_DESTROY, state.myobj
END

PRO xobjview_refresh
  base = WIDGET_BASE(/COLUMN, TITLE='Adjust Object Color', $
    XOFFSET=420, XSIZE=200)

  myobj = OBJ_NEW('IDLgrSurface', $
    BESELJ(SHIFT(DIST(40), 20, 20) / 2,0) * 20, $
    COLOR=[255, 60, 60], STYLE=2, SHADING=1)
  XOBJVIEW, myobj, TLB=tlb, GROUP=base, BACKGROUND=[0,0,0]

  red = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, TITLE='Red', $
    UVALUE='red', VALUE=255)
  green = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
    TITLE='Green', UVALUE='green', VALUE=60)
  blue = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
    TITLE='Blue', UVALUE='blue', VALUE=60)

  WIDGET_CONTROL, base, /REALIZE

  state = {myobj:myobj, tlb:tlb}
  WIDGET_CONTROL, base, SET_UVALUE=state

```

```
XMANAGER, 'xobjview_refresh', base, /NO_BLOCK, $
    CLEANUP='xobjview_refresh_cleanup'
END
```

# XOBJVIEW\_ROTATE

The XOBJVIEW\_ROTATE procedure is used to programmatically rotate the object currently displayed in XOBJVIEW. XOBJVIEW must be called prior to calling XOBJVIEW\_ROTATE. This procedure can be used to create animations of object displays.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XOBJVIEW_ROTATE, Axis, Angle [, /PREMULTIPLY]
```

## Arguments

### Axis

A 3-element vector of the form  $[x, y, z]$  describing the axis about which the model is to be rotated.

### Angle

The amount of rotation, measured in degrees.

## Keywords

### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

## Examples

The following example creates an animation of the test object (a surface) currently displayed in XOBJVIEW. It does this by rotating the surface through 360 degrees in increments of 10 degrees using XOBJVIEW\_ROTATE, and writing the display image to a BMP file for each increment using XOBJVIEW\_WRITE\_IMAGE.

```
PRO RotateAndWriteObject

XOBJVIEW, /TEST
FOR i = 0, 359 DO BEGIN
    XOBJVIEW_ROTATE, [0, 1, 0], 1, /PREMULTIPLY;
    XOBJVIEW_WRITE_IMAGE, 'img' + $
    STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
ENDFOR

END
```

## Version History

# XOBJVIEW\_WRITE\_IMAGE

The XOBJVIEW\_WRITE\_IMAGE procedure is used to write the object currently displayed in XOBJVIEW to an image file with the specified name and file format. XOBJVIEW must be called prior to calling XOBJVIEW\_WRITE\_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XOBJVIEW_WRITE_IMAGE, Filename, Format [, DIMENSIONS=[x, y] ]
```

## Arguments

### Filename

A scalar string containing the name of the file to write.

### Format

A scalar string containing the name of the file format to write. See [WRITE\\_IMAGE](#) for a list of supported formats.

## Keywords

### DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XOBJVIEW draw widget.

## Examples

See [XOBJVIEW\\_ROTATE](#).

## Version History

5.5	Introduced

# XPALETTE

The XPALETTE procedure is a utility that displays a widget interface that allows interactive creation and modification of color tables using the RGB, CMY, HSV, or HLS color systems. This procedure can interpolate the space between color indices (to create smooth color transitions) or edit individual colors.

This routine is written in the IDL language. Its source code can be found in the file `xpalette.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using the XPALETTE Interface

Calling XPALETTE causes a graphical interface to appear. The elements of this interface are described below.

### Plots on Left Side of Interface

Three plots show the current red, green, and blue vectors.

### Status Region

The center of the XPALETTE widget is a status region containing:

- The total number of colors.
- The current color index. XPALETTE allows changing one color at a time. This color is known as the “current color” and is indicated in the color spectrum display with a special marker.
- The current mark index. The mark is used to remember a color index. Click the “Set Mark Button” to make the current color index the mark index.
- A sample of the current color. The special marker used in the color spectrum display prevents the user from seeing the color of the current index, but it is visible here.

### Control Panel

A panel of 8 buttons control common XPALETTE functions:

- **Done:** Click this button to exit XPALETTE. The new color tables are saved in the `COLORS` common block and loaded to the display.
- **Predefined:** Click this button to start XLOADCT, allowing selection of one of the predefined color tables. Note that when you change the color map via XLOADCT, XPALETTE is not always able to keep its display accurate. This problem can be overcome by pressing the XPALETTE “Redraw” button after changing the colortable via XLOADCT.

- **Help:** Click this button to display help information.
- **Redraw:** Click this button to redraw the display using the current state of the color map.
- **Set Mark:** Click this button to set the value of the mark index to the current color index.
- **Switch Mark:** Click this button to exchange the mark and the current index.
- **Copy Current:** Click this button to make every color lying between the current index and the mark index (inclusive) the same color as the current color.
- **Interpolate:** Click this button to smoothly interpolate colors between the current index and the mark index.

### Color System Control

This section of the interface allows you to select the color system used to modify individual colors. The “Select Color System” pulldown menu lets you select from four different systems—RGB, CMY, HSV, and HLS. Depending upon the current system, 3 sliders below the pulldown menu allow you to alter the current color.

### Right Side Color Spectrum Display

A display on the right side of the XPALETTE interface shows the current color map as a series of squares. Color index 0 is at the upper left. The color index increases monotonically by rows going left to right and top to bottom. The current color index is indicated by a special marker symbol. There are 4 ways to change the current color:

- Click on any square in the color map display.
- Use the “By Index” slider to move to the desired color index.
- Use the “Row” Slider to move the marker vertically.
- Use the “Column” Slider to move the marker horizontally.

### A Note about the Colors Used in the Interface

XPALETTE uses two colors from the current color table as drawing foreground and background colors. These are used for the RGB plots on the left, and the current index marker on the right. This means that if the user set these two colors to the same value, the XPALETTE display could become unreadable (like writing on black paper with black ink). XPALETTE minimizes this possibility by noting changes to the color map and always using the brightest available color for the foreground color and the darkest for the background. Thus, the only way to make XPALETTE’s display

unreadable is to set the entire color map to a single color, which is highly unlikely. The only side effect of this policy is that you may notice XPALETTE redrawing the entire display after you've modified the current color. This simply means that the change has made XPALETTE pick new drawing colors.

## Syntax

```
XPALETTE [, /BLOCK] [, GROUP=widget_id]  
        [, UPDATECALLBACK='procedure_name' [, UPDATECADATA=value]]
```

## Arguments

None

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

#### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XPALETTE block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

### GROUP

The widget ID of the widget that calls XPALETTE. When this ID is specified, a death of the caller results in a death of XPALETTE.

### UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECADATA keyword.

## UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

## Examples

This example uses a single color (orange) to highlight pixels within the spine of the CT scan image. Then, starting with the entry that was changed to orange, a range of entries is selected and replaced with a ramp from orange to white to highlight the bones within this image. Complete the following steps for a detailed description of the process.

### Example Code

---

See `usingxpalette.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. The BLOCK keyword is set when using XPALETTE to force the example routine to wait until the **Done** button is pressed to continue. If the BLOCK keyword was not set, the example routine would produce all of the displays at once and then end.

---

1. Determine the path to the `ctscan.dat` binary file:

```
ctscanFile = FILEPATH('ctscan.dat', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
ctscanSize = [256, 256]
```

3. Import the image from the file:

```
ctscanImage = READ_BINARY(ctscanFile, $
    DATA_DIMS = ctscanSize)
```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Display the image from the `ctscan.dat` file with the B-W LINEAR color table:

```
LOADCT, 0
WINDOW, 0, TITLE = 'ctscan.dat', $
    XSIZE = ctscanSize[0], YSIZE = ctscanSize[1]
```

TV, ctscanImage

As shown in the following figure, the B-W LINEAR color table does not distinguish all of the aspects of this image. The XPALETTE utility can be used to change the color table.

*Figure 3-165: CT Scan Image with Grayscale Color Table*

6. Open the XPALETTE utility:

XPALETTE

Select the **Predefined** button in the XPALETTE utility to change the color table to Rainbow + white.

Click on the **Done** button after you select the Rainbow + white color table in XLOADCT and then click on the **Done** button in XPALETTE.

The following figure shows the resulting XPALETTE and XLOADCT displays.

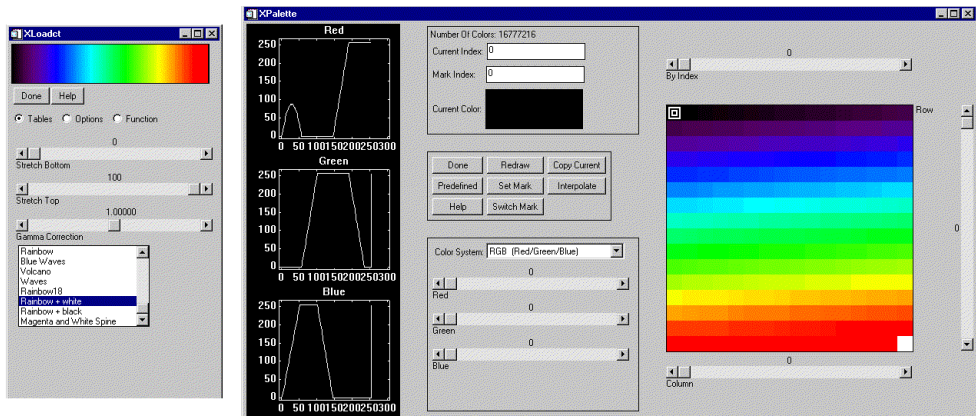

Figure 3-166: Selecting Rainbow + white Color Table in XPALETTE Utility

- Now redisplay the image to show it with the Rainbow + white color table:

```
TV, ctscanImage
```

Your display should be similar to the following figure.

Figure 3-167: CT Scan Image with the Rainbow + white Color Table

You can use XPALETTE to change a single color within the current color table. For example, you can change the color at index number 115 to orange.

- Open XPALETTE and click on the 115th index (in column 3 and row 7):

```
XPALETTE
```

Change its color to orange by moving the RGB (red, green, and blue) sliders (Orange is made up of 255 red, 128 green, and 0 blue)

Click on the **Done** button after changing the **Red**, **Green**, and **Blue** sliders.

Use TV to redisplay the image to include the last changes made in the XPALETTE utility:

```
TV, ctscanImage
```

The orange values now highlight some areas of the spine, kidney, and bones as shown in the following figure.

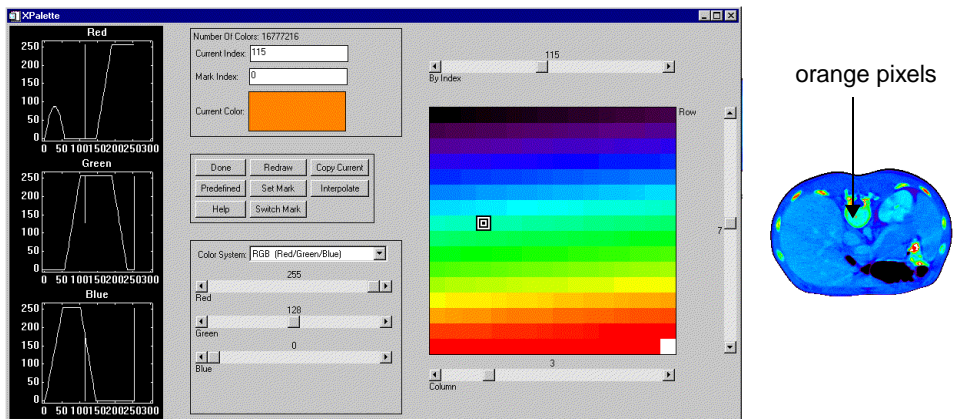

Figure 3-168: CT Scan Image with Orange Added to the Color Table

You can highlight the bones even further by interpolating a new range in between the orange and white indices.

- Open XPALETTE:

Click on the 115th index and select the **Set Mark** button.

Click on the highest index (which is usually 255 but it could be less) and then select the **Interpolate** button.

To see the result of this interpolation within XPALETTE, click on the **Redraw** button.

Click **Done** and redisplay the image:

```
TV, ctscanImage
```

The following figure displays the image using the modified color table.

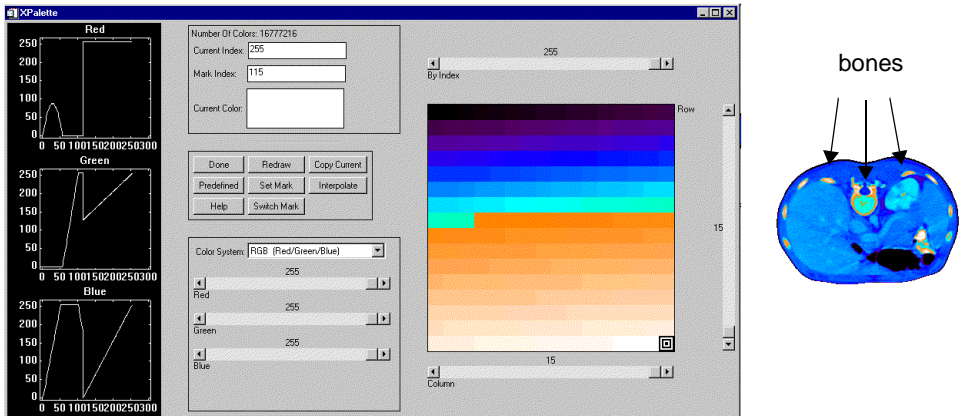

Figure 3-169: CT Scan Image with Orange to White Range Added

### Note

You can add this modified color table to the list of pre-defined color tables using `MODIFYCT`. See the “Examples” section of “`MODIFYCT`” on page 1552.

# XPCOLOR

The XPCOLOR procedure is a utility that allows you to adjust the value of the current Direct Graphics plotting color (foreground) using sliders, and store the desired color in the global system variable, !P.COLOR.

When XPCOLOR is called from the IDL input command line, the **Set Plot Color** dialog box appears. The dialog has two buttons (**Done** and **Help**) a single color swatch window, three sliders, and a pulldown menu with the four color systems: red, green, blue (RGB); cyan, magenta, yellow (CMY); hue, saturation, value (HSV); and hue, lightness, and saturation (HLS).

When you have chosen the color system and adjusted the sliders to your liking, click **Done** to store the color selected in the !P.COLOR system variable. Any plots generated in IDL afterwards use the color selected as the plotting (foreground) color until !P.COLOR is changed again.

## Note

---

For a more flexible color editor, use the XPALETTE User Library routine.

---

This routine is written in the IDL language. Its source code can be found in the file `xpcolor.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XPCOLOR [, GROUP=widget_id ]
```

## Arguments

None

## Keywords

### GROUP

Set this keyword to the group leader widget ID as passed to XMANAGER.

## Version History

4.0	Introduced
-----	------------

# XPLOT3D

The XPLOT3D procedure is a utility for creating and interactively manipulating 3-D plots.

This routine is written in the IDL language. Its source code can be found in the file `xplot3d.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using XPLOT3D

XPLOT3D displays a resizable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

Figure 3-170: The XPLOT3D Utility

## The XPLOT3D Toolbar

The XPLOT3D toolbar contains the following buttons:

Button	Tool Name	Function
	<b>Reset</b>	Resets rotation, scaling, and panning.
	<b>Rotate</b>	Click the left mouse button on the object and drag to rotate.
	<b>Pan</b>	Click the left mouse button on the object and drag to pan.
	<b>Zoom</b>	Click the left mouse button on the object and drag to zoom in or out.
	<b>Select</b>	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 3-141: XPLOT3D Toolbar Buttons

### Projecting Data onto Plot “Walls”

To turn on or off the projection of data onto the walls of the box enclosing the 3-D plot, select **All On**, **All Off**, **XY**, **YZ**, or **XZ** from the **View** → **2D Projection** menu.

### Changing the Axis Type

The **View** → **Axes** menu allows you to select one of the following types of axes:

- Simple Axes — displays the X, Y, and Z axes as lines.
- Box Axes — displays the X, Y, and Z axes as planes.
- No Axes — turns off the display of axes.

## Syntax

```
XPLOT3D, X, Y, Z [, /BLOCK] [, COLOR={r,g,b}] [, /DOUBLE_VIEW]
  [, GROUP=widget_id] [, LIFESTYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}] [, /MODAL]
  [, NAME=string] [, /OVERPLOT] [, SYMBOL=objref(s)] [, /TEST]
  [, THICK=points{1.0 to 10.0}] [, TITLE=string] [, XRANGE=[min, max]]
  [, XTITLE=string] [, YRANGE=[min, max]] [, YTITLE=string]
  [, ZRANGE=[min, max]] [, ZTITLE=string]
```

## Arguments

### X

A vector of X data values.

### Y

A vector of Y data values.

### Z

A vector of Z data values.

## Keywords

### BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

#### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XPLOT3D block, any earlier calls to XMANAGER must have been called with the [NO\\_BLOCK](#) keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

### COLOR

Set this keyword to an  $[r, g, b]$  triplet specifying the color of the curve.

### DOUBLE\_VIEW

Set this keyword to cause XPLOT3D to set the DOUBLE property on the IDLgrView that it uses to display the plot.

### GROUP

Set this keyword to the widget ID of the widget that calls XPLOT3D. When this keyword is specified, the death of the caller results in the death of XPLOT3D.

## LINestyle

Set this keyword to a value indicating the line style that should be used to draw the curve. The value can be either an integer value specifying a pre-defined line style, or a 2-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINestyle keyword to one of the following integer values:

0	Solid line (default)
1	Dotted
2	Dashed
3	Dash-dot
4	Dash-dot-dot-dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1s or 0s in the *bitmask* should be repeated. (That is, if three consecutive 0s appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range  $1 \leq \text{repeat} \leq 255$ .

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. The *bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, LINestyle = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XPLOT3D. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XPLOT3D fabricates an invisible group leader for you.

**Note**

To be modal, XPLOT3D does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2488 for more information.)

To provide a simple means of invoking XPLOT3D as a modal widget in applications that contain no other widgets, XPLOT3D can be invoked as MODAL without specifying a group leader, in which case XPLOT3D fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XPLOT3D, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

**NAME**

Set this keyword to a string specifying the name for the data curve being plotted. The name is displayed on the XPLOT3D toolbar when the curve is selected with the mouse. (To select the curve with the mouse, XPLOT3D must be in select mode. You can put XPLOT3D in select mode by clicking on the rightmost button on the XPLOT3D toolbar.)

**OVERPLOT**

Set this keyword to draw the curve in the most recently created view. The TITLE, [XYZ]TITLE, [XYZ]RANGE, and MODAL keywords are ignored if this keyword is set.

**SYMBOL**

Set this keyword to a vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

## TEST

If set, the *X*, *Y*, and *Z* arguments are not required (and are ignored if provided). A sinusoidal curve is displayed instead. This allows you to test code that uses XPLOT3D without having to specify plot data.

## THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

## TITLE

Set this keyword to a string to appear in the XPLOT3D title bar.

## XRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the X-axis range.

## XTITLE

Set this keyword to a string specifying the title for the X axis of the plot.

## YRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Y-axis range.

## YTITLE

Set this keyword to a string specifying the title for the Y axis of the plot.

## ZRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Z-axis range.

## ZTITLE

Set this keyword to a string specifying the title for the Z axis of the plot.

## Examples

The following example displays two curves in XPLOT3D, using a custom plotting symbol for one of the curves:

```
;Define plot data:
X = INDGEN(20)
Y1 = SIN(X/3.)
Y2 = COS(X/3.)
Z = X

;Display curve 1 in XPLOT3D:
XPLOT3D, X, Y1, Z, NAME='Curve1', THICK=2

;Define custom plotting symbols:
oOrb = OBJ_NEW('orb', COLOR=[0, 0, 255])
oOrb->Scale, .75, .1, .5
oSymbol = OBJ_NEW('IDLgrSymbol', oOrb)

;Overplot curve 2 in XPLOT3D:
XPLOT3D, X, Y2, Z, COLOR=[0,255,0], NAME='Curve2', $
    SYMBOL=oSymbol, THICK=2, /OVERPLOT
```

This code results in the following:

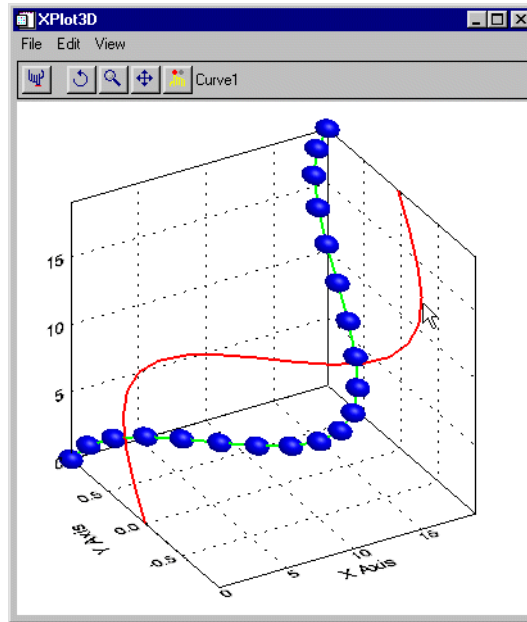

Figure 3-171: Two curves displayed in XPLOT3D

[IPLLOT](#)

# XREGISTERED

The XREGISTERED function returns the number of instances of the widget named as its argument that are currently registered with the XMANAGER. The registered widget is brought to the front of the desktop unless the NOSHOW keyword is set.

If the specified widget is not currently registered with XMANAGER, XREGISTERED returns zero.

This routine is written in the IDL language. Its source code can be found in the file `xregistered.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = XREGISTERED(*Name* [, /NOSHOW] )

## Arguments

### Name

A string containing the name of the widget in question.

### Note

---

XREGISTERED checks for *Name* in a COMMON block created by XMANAGER. The stored name is case-sensitive.

---

## Keywords

### NOSHOW

If the widget in question is registered, it is brought to the front of all the other windows by default. Set this keyword to keep the widget from being brought to the front.

## Examples

Suppose that you have a widget program that registers itself with the XMANAGER with the command:

```
XMANAGER, 'mywidget', base
```

You could limit this widget to one instantiation by adding the following line as the first line (after the procedure definition statement) of the widget creation routine:

```
IF ( XREGISTERED('mywidget') NE 0 ) THEN RETURN
```

## Version History

Pre-4.0	Introduced

[XMANAGER](#)

# XROI

The XROI procedure is a utility for interactively defining regions of interest (ROIs), and obtaining geometry and statistical data about these ROIs.

This routine is written in the IDL language. Its source code can be found in the file `xroi.pro` in the `lib/utilities` subdirectory of the IDL distribution.

---

## Note

See “Using XROI” on page 2892, for detailed information describing importing images, modifying image and ROI colors, retrieving ROI information and growing regions.

---

## Syntax

```
XROI [, ImageData] [, R] [, G] [, B] [, /BLOCK]
      [, /FLOATING] [, GROUP=widget_ID] [, /MODAL] [, REGIONS_IN=value]
      [, REGIONS_OUT=value] [, REJECTED=variable] [, RENDERER={0 | 1}]
      [, ROI_COLOR=[r, g, b] or variable] [, ROI_GEOMETRY=variable]
      [, ROI_SELECT_COLOR=[r, g, b] or variable] [, STATISTICS=variable]
      [, TITLE=string] [, TOOLS=string/string array { valid values are
      'Translate-Scale', 'Rectangle', 'Ellipse', 'Freehand Draw', 'Polygon Draw', and
      'Selection' }] [, X_SCROLL_SIZE=value] [, Y_SCROLL_SIZE=value]
```

## Arguments

### ImageData

*ImageData* is both an input and output argument. It is an array representing an 8-bit or 24-bit image to be displayed. *ImageData* can be any of the following:

- $[m, n]$  — 8-bit image
- $[3, m, n]$  — 24-bit image
- $[m, 3, n]$  — 24-bit image
- $[m, n, 3]$  — 24-bit image

If *ImageData* is not supplied, the user will be prompted for a file via `DIALOG_PICKFILE`. On output, *ImageData* will be set to the current image data. (The current image data can be different than the input image data if the user imported an image via the **File** → **Import Image** menu item.)

## R, G, B

*R*, *G*, and *B* are arrays of bytes representing red, green, or blue color table values, respectively. *R*, *G*, and *B* are both input and output arguments. On input, these values are applied to the image if the image is 8-bit. To get the red, green, or blue color table values for the image on output from XROI, specify a named variable for the appropriate argument. (If the image is 24-bit, this argument will output a 256-element byte array containing the values given at input, or BINDGEN(256) if the argument was undefined on input.)

## Keywords

### BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

---

#### Note

Only the outermost call to XMANAGER can block. Therefore, to have XROI block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the NO\_BLOCK keyword to XMANAGER for an example.

---

### FLOATING

Set this keyword, along with the GROUP keyword, to create a floating top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

---

#### Note

Floating widgets must have a group leader. Setting this keyword without also setting the GROUP keyword causes an error.

---

### GROUP

Set this keyword to the widget ID of the widget that calls XROI. When this keyword is specified, the death of the caller results in the death of XROI.

## MODAL

Set this keyword to block other IDL widgets from receiving events while XROI is active.

## REGIONS\_IN

Set this keyword to an array of IDLgrROI references. This allows you to open XROI with previously defined regions of interest (see [Example: Save ROI Data](#)). This is also useful when using a loop to open multiple images in XROI. By using the same named variable for both the REGIONS\_IN and REGIONS\_OUT keywords, you can reuse the same ROIs in multiple images (see [Example: Preserving ROIs Among Images](#)). This keyword also accepts -1, or OBJ\_NEW() (Null object) to indicate that there are no ROIs to read in. This allows you to assign the result of a previous REGIONS\_OUT to REGIONS\_IN without worrying about the case where the previous REGIONS\_OUT is undefined.

## REGIONS\_OUT

Set this keyword to a named variable that will contain an array of IDLgrROI references. This keyword is assigned the null object reference if there are no ROIs defined. By using the same named variable for both the REGIONS\_IN and REGIONS\_OUT keywords, you can reuse the same ROIs in multiple images (see [Example: Preserving ROIs Among Images](#)).

---

**Note**

This keyword must be used in conjunction with the BLOCK keyword.

---

## REJECTED

Set this keyword to a named variable that will contain those REGIONS\_IN that are not in REGIONS\_OUT. The objects defined in the variable specified for REJECTED can be destroyed with a call to OBJ\_DESTROY, allowing you to perform cleanup on objects that are not required (see [Example: Preserving ROIs Among Images](#)). This keyword is assigned the null object reference if no REGIONS\_IN are rejected by the user.

---

**Note**

This keyword must be used in conjunction with the BLOCK keyword.

---

## RENDERER

Set this keyword to an integer value to indicate which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation (the default)

## ROI\_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array,  $[r, g, b]$ , indicating the color of ROI outlines when they are not selected. This color will be used by XROI unless and until the color is changed by the user via the “Unselected Outline Color” portion of the “ROI Outline Colors” dialog (which is accessed by selecting **Edit** → **ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current  $[r, g, b]$  value at the time that XROI returns.

## ROI\_GEOMETRY

Set this keyword to a named variable that will contain an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
area	The area of the region of interest, in square pixels.
centroid	The coordinates $(x, y, z)$ of the centroid of the region of interest, in pixels.
perimeter	The perimeter of the region of interest, in pixels.

*Table 3-142: Fields of the structure returned by ROI\_GEOMETRY*

If there are no valid regions of interest when this routine returns, ROI\_GEOMETRY will be undefined.

### Note

If there are no REGIONS\_IN, XROI must either be modal or must block control flow in order for ROI\_GEOMETRY to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and ROI\_GEOMETRY will therefore be undefined.

**Note**

---

This keyword must be used in conjunction with the BLOCK keyword.

---

**ROI\_SELECT\_COLOR**

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array,  $[r, g, b]$ , indicating the color of ROI outlines when they are selected. This color will be used by XROI unless and until the color is changed by the user via the “Selected Outline Color” portion of the “ROI Outline Colors” dialog (which is accessed by selecting **Edit** → **ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current  $[r, g, b]$  value at the time that XROI returns.

**STATISTICS**

Set this keyword to a named variable to receive an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
count	Number of pixels in region.
minimum	Minimum pixel value.
maximum	Maximum pixel value.
mean	Mean pixel value.
stddev	Standard deviation of pixel values.

*Table 3-143: Fields of the structure returned by STATISTICS*

If *ImageData* is 24-bit, or if there are no valid regions of interest when the routine exits, STATISTICS will be undefined.

**Note**

---

If there are no REGIONS\_IN, XROI must either be modal or must block control flow in order for STATISTICS to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and STATISTICS will therefore be undefined.

---

## TITLE

Set this keyword to a string to appear in the XROI title bar.

## TOOLS

Set this keyword a string or vector of strings from the following list to indicate which ROI manipulation tools should be supported when XROI is run:

- 'Translate-Scale' — Translation and scaling of ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
- 'Rectangle' — Rectangular ROI drawing. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
- 'Ellipse' — Elliptical ROI drawing. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
- 'Freehand Draw' — Freehand ROI drawing. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
- 'Polygon Draw' — Polygon ROI drawing. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
- 'Selection' — ROI selection. Mouse down/up selects the nearest region. The nearest vertex in that region is identified with a crosshair symbol.

If more than one string is specified, a series of bitmap buttons will appear at the top of the XROI widget in the order specified (to the right of the fixed set of bitmap buttons used for saving regions, displaying region information, copying to clipboard, and flipping the image). If only one string is specified, no additional bitmap buttons will appear, and the manipulation mode is implied by the given string. If this keyword is not specified, bitmap buttons for all three manipulation tools are included on the XROI toolbar.

## X\_SCROLL\_SIZE

Set this keyword to the width of the scroll window. If this keyword is larger than the image width then it will be set to the image width. The default is to use the image width or the screen width, whichever is smaller.

## Y\_SCROLL\_SIZE

Set this keyword to the height of the scroll window. If this keyword is larger than the image height then it will be set to the image height. The default is to use the image height or the screen height, whichever is smaller.

## Using XROI

XROI displays a top-level base with a menu, toolbar and draw widget. After defining an ROI, the **ROI Information** window appears, as shown in the following figure:

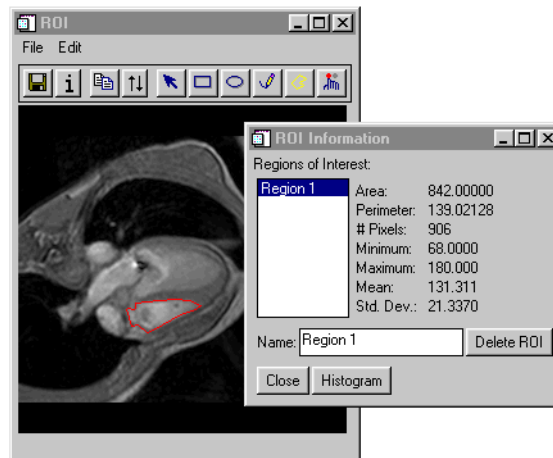

Figure 3-172: The XROI Utility

As you move the mouse over an image, the x and y pixel locations are shown in the status line on the bottom of the XROI window. For 8-bit images, the data value (z) is also shown. If an ROI is defined, the status line also indicates the mouse position relative to the ROI using the text “Inside”, “Outside”, “On Edge,” or “On Vertex.”

## The XROI Toolbar

The XROI toolbar contains the following buttons:

**Save:** Opens a file selection dialog for saving the currently defined ROIs to a save file.

**Info:** Opens the **ROI Information** window.

-  **Copy:** Copies the contents of the display area to the clipboard.
-  **Flip:** Flips image vertically. Note that only the image is flipped; any ROIs that have been defined do not move.

Depending on the value of the TOOLS keyword, the XROI toolbar may also contain the following buttons:

-  **Translate/Scale:** Click this button to translate or scale ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
-  **Draw Rectangle:** Click this button to draw rectangular ROIs. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
-  **Draw Ellipse:** Click this button to draw elliptical ROIs. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
-  **Draw Freehand:** Click this button to draw freehand ROIs. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
-  **Draw Polygon:** Click this button to draw polygon ROIs. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
-  **Select:** Click this button to select an ROI region. Clicking the image causes a cross hairs symbol to be drawn at the nearest vertex of the selected ROI.

## Importing an Image into XROI

To import an image into XROI, select **File** → **Import Image**. This opens a DIALOG\_READ\_IMAGE dialog, which can be used to preview and select an image.

## Changing the Image Color Table

To change the color table properties for the current image, select **Edit** → **Image Color Table**. This opens the `CW_PALETTE_EDITOR` dialog, which is a compound widget used to edit color palettes. See [CW\\_PALETTE\\_EDITOR](#) for more information. This menu item is grayed out if the image does not have a color palette.

## Changing the ROI Outline Colors

To change the outline colors for selected and unselected ROIs, select **Edit** → **ROI Outline Colors**. This opens the **ROI Outline Colors** dialog, which consists of two `CW_RGBSLIDER` widgets for interactively adjusting the ROI outline colors. The left widget is used to define the color for the selected ROI, and the right widget is used to define the color of unselected ROIs. You can select the RGB, CMY, HSV, or HLS color system from the **Color System** drop-down list.

## Viewing ROI Information

To view geometry and statistical data about the currently selected ROI, click the **Info** button or select **Edit** → **ROI Information**. This opens the **ROI Information** dialog, which displays area, perimeter, number of pixels, minimum and maximum pixel values, mean, and standard deviation. Values for statistical information (minimum, maximum, mean, and standard deviation) appear as “N/A” for 24-bit images.

## Viewing a Histogram Plot for an ROI

To view a histogram for an ROI, use either the shortcut menu or the ROI Information dialog.

To view an ROI’s histogram plot using the shortcut menu:

1. Position the cursor on the line defining the boundary of an ROI in the drawing window and click the right mouse button. This selects the region and brings up its shortcut menu.
2. Select the **Plot Histogram** menu option from the shortcut menu.

To view an ROI’s histogram plot using the ROI Information dialog:

1. Open the ROI Information dialog by clicking the **Info** button or selecting **Edit** → **ROI Information**.
2. Select a region from the list and click the **Histogram** button on the ROI Information dialog.

Either of the previous methods opens an iTool showing the ROI’s histogram that can be used to interactively control the plot properties.

**Note**

XROI's histogram plot feature now supports RGB images.

## Growing an ROI

Once a region has been created, it may be used as a source ROI for region growing. Region growing is a process of generating one or more new ROIs based upon the image pixel values that fall within the source ROI and the values of the neighboring pixels. New pixels are added to the new grown region if those image pixel values fall within a specified threshold.

**Note**

This option is an interactive implementation of the `REGION_GROW` function.

To create a new, grown region, do the following:

1. Within the draw area, click the right mouse button on the ROI that is to be grown. This will select the region and bring up its shortcut menu.
2. Select **Grow Region** → **By threshold** or select **Grow Region** → **By std. dev. multiple** from the shortcut menu to control how the region is grown.

The **By threshold** option grows the region to include all neighboring pixels that fall within a specified threshold range. By default, the range is defined by the minimum and maximum pixel values occurring within the original region. To specify a different threshold range, see [Using the Region Grow Properties Dialog](#) in the following section.

The **By std. dev. multiple** option grows a region to include all neighboring pixels that fall within the range of:

$$\text{Mean} \pm \text{StdDevMultiplier} * \text{StdDev}$$

where `Mean` is the mean value of the pixel values within the source ROI, `StdDevMultiplier` is a multiplier that is set using the Region Grow Properties dialog (described below), and `StdDev` is the sample standard deviation of the pixel values within the original region.

## Using the Region Grow Properties Dialog

The Region Grow Properties dialog allows you to view and edit the properties associated with a region growing process. To bring up the Region Grow Properties dialog, do one of the following:

- Click the right mouse button on an ROI in the drawing window and select **Grow Region** → **Properties...** shortcut menu option.
- Select **Edit** → **Region Grow Properties...** from the XROI menu bar.

This brings up the Region Grow Properties dialog, shown in the following figure.

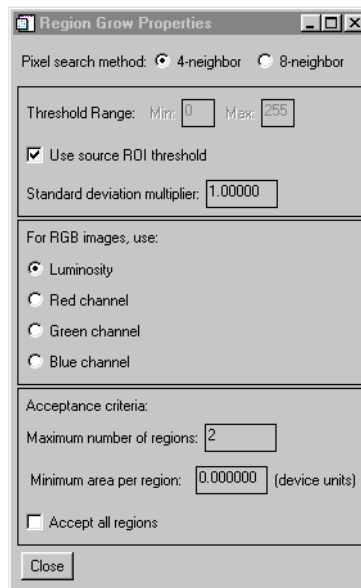

Figure 3-173: XROI's Region Grow Properties Dialog

The Region Grow Properties dialog offers the following options:

Option	Description
Pixel search method:	<p>Describes which pixels are searched when growing the original ROI. The option are:</p> <ul style="list-style-type: none"> <li>• <b>4-neighbor</b> — Searches only the four neighboring pixels that share a common edge with the current pixel. This is the default.</li> <li>• <b>8-neighbor</b> — Searches all eight neighboring pixels, including those that are located diagonally relative to the original pixel and share a common corner.</li> </ul>
Threshold range:	<p>Represents the minimum and maximum image pixel values that are to be included in the grown region when using the <b>Grow Region → By threshold</b> option (described in “<a href="#">Growing an ROI</a>” on page 2895). By default, the range of pixel values used are those occurring in the ROI to be grown.</p> <p>To change the threshold values, uncheck <b>Use source ROI threshold</b> and enter the minimum and maximum threshold values in the <b>Min:</b> and <b>Max:</b> fields provided.</p>
Standard deviation multiplier:	<p>Represents the factor by which the sample standard deviation of the original ROI’s pixel values is multiplied. This factor only applies when the <b>Grow Region → By std. dev. multiple</b> option (described in “<a href="#">Growing an ROI</a>” on page 2895) is used.</p> <p>Change the multiplier value by typing the value into the <b>Standard deviation multiplier</b> field provided.</p>

Table 3-144: Options of the Region Grow Properties Dialog

Option	Description
For RGB image, use:	<p>Determines the basis of region growing for an RGB (rather than indexed) image. The image data values used when growing a RGB region can be one of the following:</p> <ul style="list-style-type: none"> <li>• <b>Luminosity</b> — Uses the luminosity values associated with an RGB image. This is the default method. Luminosity is computed as:  <math display="block">\text{Luminosity} = (0.3 * \text{Red}) + (0.59 * \text{Green}) + (0.11 * \text{Blue})</math> </li> <li>• <b>Red Channel, Green Channel or Blue Channel</b> — Uses the ROI's red, green or blue channel as a basis for region growing. Click the channel's associated button to specify the channel to be used.</li> </ul> <p><b>Note</b> - For indexed images, the image data itself is always used for region growing.</p>
Acceptance criteria:	<p>Determines which contours of the grown region are accepted as new regions, (which will also be displayed in the draw area and in the ROI Information dialog list of regions). The region growing process can result in a large number of contours, some of which may be considered insignificant. By default, no more than two regions (those with the greatest geometrical area) are accepted. Modify the acceptance criteria by altering the following values:</p> <ul style="list-style-type: none"> <li>• <b>Maximum number of regions:</b> — Specifies the upper limit of the number of regions to create when growing an ROI.</li> <li>• <b>Minimum area per region:</b> — Specifies that only contours having a geometric area (computed in device coordinates) of at least the value stated are accepted and displayed.</li> <li>• <b>Accept all regions:</b> — Select this option to accept all generated contours, regardless of count or area.</li> </ul>

Table 3-144: Options of the Region Grow Properties Dialog (Continued)

## Deleting an ROI

An ROI can be deleted using either the shortcut menu or using the ROI Information dialog.

To delete an ROI using the shortcut menu:

1. Click the right mouse button on the line defining the boundary of the ROI in the drawing area that you wish to delete. This selects the region and bring up the shortcut menu.
2. Select the **Delete** menu option from the shortcut menu.

To delete an ROI using the ROI Information dialog:

1. Click the **Info** button or select **Edit** → **ROI Information**. This opens the **ROI Information** dialog.
2. In the **ROI Information** dialog, select the ROI you wish to delete from the list of ROIs. You can also select an ROI by clicking the **Select** button on the XROI toolbar, then clicking on an ROI on the image.
3. Click the **Delete ROI** button.

## Examples

See the following examples:

- [“Example: Open Image File in XROI”](#)
- [“Example: Preserving ROIs Among Images”](#) on page 2900
- [“Example: Save ROI Data”](#) on page 2901
- [“Example: Save the XROI Utility with ROI Data”](#) on page 2901

### Example: Open Image File in XROI

This example opens a single image in XROI:

```
image = READ_PNG(FILEPATH('mineral.png', $
    SUBDIR=['examples', 'data']))
XROI, image
```

## Example: Preserving ROIs Among Images

This example reads 3 images from the file `mr_abdomen.dcm`, and calls XROI for each image. A single list of regions is maintained, saving the user from having to redefine regions on each image:

```

PRO docs_xroi_maintain_rois

; Read 3 images from mr_abdomen.dcm and open each one in XROI:
FOR i=0,2 DO BEGIN
    image = READ_DICOM(FILEPATH('mr_abdomen.dcm', $
        SUBDIR=['examples', 'data']), IMAGE_INDEX=i)
    XROI, image, r, g, b, REGIONS_IN = regions, $
        REGIONS_OUT = regions, $
        ROI_SELECT_COLOR = roi_select_color, $
        ROI_COLOR = roi_color, REJECTED = rejected, /BLOCK
    OBJ_DESTROY, rejected
ENDFOR

OBJ_DESTROY, regions

END

```

Perform the following steps:

1. Run the example code and draw an ROI on the first image, then close that XROI window. Note that the next image contains the ROI defined in the first image. This is accomplished by setting `REGIONS_IN` and `REGIONS_OUT` to the same named variable in the FOR loop of the above code.
2. Draw another ROI on the second image.
3. Click the **Select** button and select the first ROI. Then click the **Info** button to open the **ROI Information** window, and click the **Delete ROI** button.
4. Close the second XROI window. Note that the third image contains the ROI defined in the second image, but not the ROI deleted on the second image. This example sets the `REJECTED` keyword to a named variable, and calls `OBJ_DESTROY` on that variable. Use of the `REJECTED` keyword is not necessary to prevent deleted ROIs from appearing on subsequent images, but allows you perform cleanup on objects that are no longer required.

## Example: Save ROI Data

XROI's **File** → **Save ROIs** option allows you to save selected regions of interest. This example shows how to restore such a save file. Suppose you have a file named `mineralRoi.sav` that contains regions of interest selected in the `mineral.png` image file. You would need to complete the following steps to restore the file:

1. First, restore the file, `mineralRoi.sav`. Provide a value for the **RESTORE** procedure's **RESTORED\_OBJECTS** keyword. Using the scenario stated above, you could enter the following:

```
RESTORE, 'mineralRoi.sav', RESTORED_OBJECTS = myRoi
```

2. Pass the restored object data containing your regions of interest into XROI by specifying `myRoi` as the value for **REGIONS\_IN** as follows:

```
XROI, READ_PNG(FILEPATH('mineral.png', SUBDIRECTORY = $
['examples', 'data'])), REGIONS_IN = myRoi
```

This opens the previously selected regions of interest in the XROI utility.

## Example: Save the XROI Utility with ROI Data

You can easily share your own IDL routines or utilities with other IDL users by using the **SAVE** routine to create a binary file of your compiled code. The following example creates a **SAVE** file of the XROI utility (a `.pro` file) and from within this file, restores a secondary **SAVE** file containing selected regions of interest.

1. Type **XROI** at the command line to open the XROI utility.
2. In the file selection dialog, select `mineral.png` from the `examples/data` subdirectory of the IDL distribution.
3. Select the **Draw Polygon** toolbar button and roughly outline the three large, angular areas of the image.
4. Select **File** → **Save ROIs** and name the file `mineralROI.sav`. This creates a **SAVE** file containing the regions of interest selected within the image.
5. In the IDL Editor or any text editor, enter the following routine:

```
PRO myXRoi

; Restore ROI object data by specifying a value for the
; RESTORED_OBJECTS keyword.
RESTORE, 'mineralROI.sav', RESTORED_OBJECTS = myROI

; Open XROI, specifying the previously defined value for the
; restored object data as the value for "REGIONS_IN".
XROI, READ_PNG(FILEPATH('mineral.png', $
```

```
SUBDIRECTORY = ['examples', 'data']), $
REGIONS_IN = myROI, /BLOCK
```

```
END
```

Save the routine as `myXRoi.pro`

- Exit and restart IDL or enter `.FULL_RESET_SESSION` at the IDL command line before creating a SAVE file to avoid saving unwanted session information.
- Compile the program you just created:

```
.COMPILE myXRoi.pro
```

- Use `RESOLVE_ALL` to iteratively compile any uncompiled user-written or library procedures or functions that are called in any already-compiled procedure or function:

```
RESOLVE_ALL
```

---

### Note

`RESOLVE_ALL` does not resolve procedures or functions that are called via quoted strings such as `CALL_PROCEDURE`, `CALL_FUNCTION`, or `EXECUTE`, or in keywords that can contain procedure names such as `TICKFORMAT` or `EVENT_PRO`. You must manually compile these routines.

---

- Create a SAVE file named `myXRoi.sav`, containing all of the XROI utility routines. When the SAVE procedure is called with the `ROUTINES` keyword and no arguments, it creates a SAVE file containing all currently compiled routines. Because the routines associated with the XROI utility are the only ones that are currently compiled in our IDL session, we can create a SAVE file as follows:

```
SAVE, /ROUTINES, FILENAME='myXRoi.sav'
```

- It is not necessary to use `RESTORE` to open `myXRoi.sav`. If the SAVE file uses the `.sav` extension and has the same base name as the main level routine, and all necessary files (in this case, `mineralROI.sav` and `myXRoi.sav`) are stored in the current working directory, simply type the name of the file, minus the `.sav` extension, at the command line:

```
myXRoi
```

The following figure will appear, showing the selected regions of interest.

Figure 3-174: Example of Restoring the XROI Utility and ROI Image Data

[IIMAGE](#)

# XSQ\_TEST

The XSQ\_TEST function computes the chi-square goodness-of-fit test between observed frequencies and the expected frequencies of a theoretical distribution.

Expected frequencies of magnitude less than 5 are combined with adjacent elements resulting in a reduction of cells used to formulate the chi-squared test statistic. If the observed frequencies differ significantly from the expected frequencies, the chi-square test statistic will be large and the fit is poor. This situation requires the rejection of the hypothesis that the given observed frequencies are an accurate approximation to the expected frequency distribution.

This routine is written in the IDL language. Its source code can be found in the file `xsq_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

```
Result = XSQ_TEST( Obfreq, Exfreq [, EXCELL=variable] [, OBCELL=variable]  
[, RESIDUAL=variable] )
```

## Return Value

The result is a two-element vector containing the Chi-square test statistic X2 and the one-tailed probability of obtaining a value of X2 or greater.

## Arguments

### Obfreq

An  $n$ -element integer, single-, or double-precision floating-point vector containing observed frequencies.

### Exfreq

An  $n$ -element integer, single-, or double-precision floating-point vector containing expected frequencies.

## Keywords

### EXCELL

Set this keyword to a named variable that will contain a vector of expected frequencies used to formulate the chi-square test statistic. If each of the expected frequencies contained in *Exfreq*, has a magnitude of 5 or greater, then this vector is identical to *Exfreq*. If *Exfreq* contains elements of magnitude less than 5, adjacent expected frequencies are combined. The identical combinations are performed on the corresponding elements of *Obfreq*.

### OBCELL

Set this keyword to a named variable that will contain a vector of observed frequencies used to formulate the chi-square test statistic. The elements of this vector are often referred to as the “cells” of the observed frequencies. The length of this vector is determined by the length of EXCELL described below.

### RESIDUAL

Set this keyword to a named variable that will contain a vector of signed differences between corresponding cells of observed frequencies and expected frequencies.

$$\text{RESIDUAL}[i] = \text{OBCELL}[i] - \text{EXCELL}[i].$$

The length of this vector is determined by the length of EXCELL described above.

## Examples

```
; Define the vectors of observed and expected frequencies:
obfreq = [2, 1, 4, 15, 10, 5, 3]
exfreq = [0.5, 2.1, 5.9, 10.3, 10.7, 7.0, 3.5]

; Test the hypothesis that the given observed frequencies are an
; accurate approximation to the expected frequency distribution:
result = XSQ_TEST(obfreq, exfreq)
PRINT, result
```

### IDL Output

```
3.05040      0.383920
```

Since the vector of expected frequencies contains elements of magnitude less than 5, adjacent expected frequencies are combined resulting in fewer cells. The identical combinations are performed on the corresponding elements of observed frequencies.

The computed value of 0.383920 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level.

[CTL\\_TEST](#)

# XSURFACE

The XSURFACE procedure is a utility that provides a graphical interface to the SURFACE and SHADE\_SURF commands. Different controls are provided to change the viewing angle and other plot parameters. The command used to generate the resulting surface plot is shown in a text window. Note that this procedure does not accept SURFACE or SHADE\_SURF keywords. Because XSURFACE relies on IDL direct graphics rather than object graphics, the image manipulation facilities are less sophisticated than those of XOBJVIEW.

This routine is written in the IDL language. Its source code can be found in the file `xsurface.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XSURFACE, Data [, /BLOCK] [, GROUP=widget_id]
```

## Arguments

### Data

The two-dimensional array to display as a wire-mesh or shaded surface.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

### Note

---

Only the outermost call to XMANAGER can block. Therefore, to have XSURFACE block, any earlier calls to XMANAGER must have been called with the [NO\\_BLOCK](#) keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

## GROUP

Set this keyword to the widget ID of the widget that calls XSURFACE. When GROUP is specified, the death of the calling widget results in the death of XSURFACE.

## Examples

```
; Make a 2-D array:  
z = DIST(30)  
  
; Call XSURFACE. The XSURFACE widget appears:  
XSURFACE, z
```

## Version History

Pre-4.0	Introduced

# XVAREEDIT

The XVAREEDIT procedure is a utility that provides a widget-based editor for any IDL variable. Use the input fields to change desired values of the variable or array. Click “Accept” to write the new values into the variable. Click “Cancel” to exit XVAREEDIT without saving changes.

---

**Note**

When XVAREEDIT runs in the IDL Virtual Machine, variable values can be displayed, but not edited.

---

This routine is written in the IDL language. Its source code can be found in the file `xvareedit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XVAREEDIT, Var [, NAME='variable_name' {ignored if variable is a structure}]  
    [, GROUP=widget_id] [, X_SCROLL_SIZE=columns]  
    [, Y_SCROLL_SIZE=rows]
```

## Arguments

### Var

The variable to be edited. On output, this variable contains the edited value if the user selects the “Accept” button, or the original value if the user selects the “Cancel” button.

## Keywords

### NAME

The NAME of the variable. This keyword is overwritten with the structure name if the variable is a structure.

### GROUP

The widget ID of the widget that calls XVAREEDIT. When this ID is specified, a death of the caller results in a death of XVAREEDIT.

## **X\_SCROLL\_SIZE**

Set this keyword to the column width of the scrolling viewport. The default is 4.

## **Y\_SCROLL\_SIZE**

Set this keyword to the row width of the scrolling viewport. The default is 4.

## **Version History**

Pre-4.0	Introduced
---------	------------

# XVOLUME

The XVOLUME procedure is a utility for viewing and interactively manipulating volumes and isosurfaces. The utility provides a graphical interface for manipulating the volume orientation, adjusting the color table and opacity, viewing image planes and contours, and adjusting the color, opacity, and threshold value of an isosurface.

This routine is written in the IDL language. Its source code can be found in the file `xvolume.pro` in the `lib/utilities` subdirectory of the IDL distribution.

---

**Tip**

The `XVOLUME_ROTATE` and `XVOLUME_WRITE_IMAGE` procedures, which can be called only after a call to `XVOLUME`, can be used to easily create animations of volumes and isosurfaces displayed in `XVOLUME`. See [XVOLUME\\_ROTATE](#) for an example.

---

**Note**

IDL converts and stores volume data in a `BYTE` array. Thus, all incoming volume data is converted to `BYTE` type. This could alter the volume data values if the incoming data cannot accurately be stored as `BYTE` data.

---

## Using XVOLUME

XVOLUME displays a resizable top-level base with a toolbar, a menu, a graphical interface for controlling volume and isosurface properties, and a draw widget for displaying and manipulating the volume, as shown in the following figure:

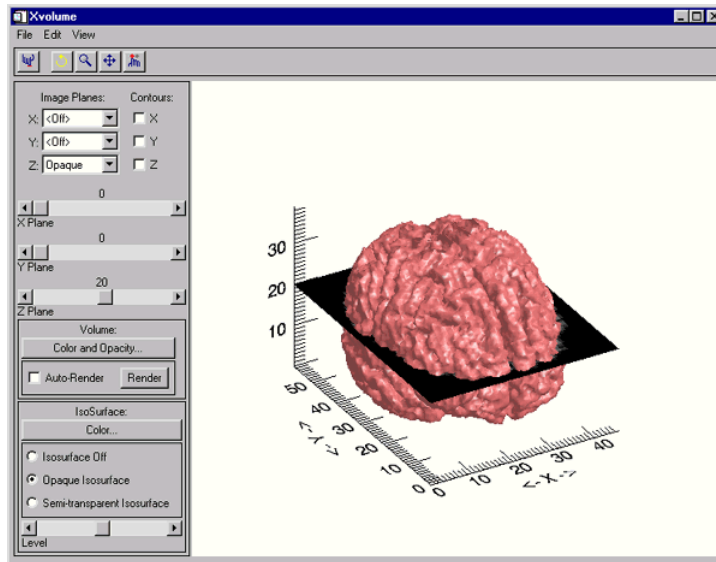

Figure 3-175: The XVOLUME Utility

## The XVOLUME Toolbar

The XVOLUME toolbar contains the following buttons.

### Note

If you have the **Auto-Render** option selected, the Rotate, Zoom, and Pan features may be more difficult to use. For the best performance while manipulating the orientation of a volume using these features, uncheck the **Auto-Render** option.

Button	Tool Name	Function
	<b>Reset</b>	Resets rotation, scaling, and panning.

Table 3-145: XVOLUME Toolbar Buttons

Button	Tool Name	Function
	<b>Rotate</b>	Click the left mouse button on the object and drag to rotate.
	<b>Pan</b>	Click the left mouse button on the object and drag to pan.
	<b>Zoom</b>	Click the left mouse button on the object and drag to zoom in or out.
	<b>Select</b>	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 3-145: XVOLUME Toolbar Buttons (Continued)

## The XVOLUME Interface

The XVOLUME interface provides the following elements for controlling the display of image planes and contours, volumes, and isosurfaces:

### Image Planes and Contours

Image planes and contours allow you to visualize the values associated with the volume or isosurface at a specified X, Y, or Z plane.

- **Image Planes** — Select one of the following options from the drop-down list for each dimension to control the display of image planes:
  - **Off:** Turns off the image plane display.
  - **Opaque:** Displays an opaque image plane at the location specified by the corresponding plane slider.
  - **Transparent:** Displays a transparent image plane at the location specified by the corresponding plane slider. The transparency value of the plane is taken from the volume at the current location of the image plane.
- **Contours** — Check this option to display contours on the specified plane at the location specified by corresponding the plane slider.
- **Plane Sliders** — Move these sliders to change the position of the plane in each dimension.

## Volume

- **Color and Opacity:** Click this button to change the color and/or opacity of the current volume. This opens a `CW_PALETTE_EDITOR` dialog, which is a compound widget used to edit color palettes. See [CW\\_PALETTE\\_EDITOR](#) for more information.
- **Auto-Render:** Select this option to have rendering executed automatically after each change you make to the volume. If **Auto-Render** is unchecked, you must manually click the **Render** button to see changes you have made to the volume. If **Auto-Render** is checked, the **Render** button will be grayed out.
- **Render:** Click on this button to execute rendering computations and display the current volume. If **Auto-Render** is checked, this button will be grayed out.

## Isosurface

An isosurface is a 3-D surface on which the data values are constant along the entire surface. Use the following elements to control the appearance of the isosurface:

- **Color:** Click this button to change the color system and/or values for the current isosurface. This opens a `CW_RGBSLIDER` dialog, which is a compound widget that provides a drop-down list for selecting the RGB, CMY, HSV, or HLS color system, and three sliders for adjusting the values associated with each color system.
- **Isosurface Off:** Select this option to turn off the isosurface display.
- **Opaque Isosurface:** Select this option to display an opaque isosurface.
- **Semi-transparent Isosurface:** Select this option to display a semi-transparent isosurface.
- **Level:** Use this slider to adjust the threshold value of the isosurface.

## Syntax

```
XVOLUME, Vol, [, /BLOCK] [, GROUP=widget_id] [, /INTERPOLATE]
  [, /MODAL] [, RENDERER={0 | 1}] [, /REPLACE] [, SCALE=value] [, /TEST]
  [, XSIZE=pixels] [, YSIZE=pixels]
```

## Arguments

### Vol

A 3-dimensional array of the form  $[x, y, z]$  that specifies a data volume.

## Keywords

### BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER.

---

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XVOLUME block, any earlier calls to XMANAGER must have been called with the NO\_BLOCK keyword. See the documentation for the [NO\\_BLOCK](#) keyword to XMANAGER for an example.

---

### GROUP

Set this keyword to the widget ID of the widget that calls XVOLUME. When this keyword is specified, the death of the caller results in the death of XVOLUME.

### INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used when rendering the volume and the image planes. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

### MODAL

Set this keyword to block processing of events from other widgets until the user quits XVOLUME. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XVOLUME fabricates an invisible group leader for you.

**Note**

To be modal, XVOLUME does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2488 for more information.)

To provide a simple means of invoking XVOLUME as a modal widget in applications that contain no other widgets, XVOLUME can be invoked as MODAL without specifying a group leader, in which case XVOLUME fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XVOLUME, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

**RENDERER**

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL (the default)
- 1 = IDL’s software implementation

**REPLACE**

If this keyword is set, and there is a current instance of XVOLUME running, the volume displayed in XVOLUME is replaced with the volume specified by *Vol*. For example, display volume1 using the command

```
XVOLUME, volume1
```

To replace volume1 with volume2, you would use the command

```
XVOLUME, volume2, /REPLACE
```

**SCALE**

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the volume, while ensuring that no portion of the volume will be clipped by the XVOLUME window, regardless of the volume’s orientation.

When using the `SCALE` keyword for `XVOLUME`, you can scale with a 3-element array of values `[x, y, z]`.

## TEST

If set, the `Vol` argument is not required (and is ignored if provided). A volume of random numbers is displayed instead. This allows you to test code that uses `XVOLUME` without having to specify volume data.

## XSIZE

The width of the drawable area in pixels.

## YSIZE

The height of the drawable area in pixels.

## Examples

Create a volume and display using `XVOLUME`:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

## Displaying Volumes Using `XVOLUME`

Unlike `SLICER3`, the IDL Object Graphics procedure, `XVOLUME`, allows you to interactively manipulate 3D volumes and isosurfaces. While the following example requires more processing time to display the same data (`head.dat`) as that previously displayed with `SLICER3`, remember that the output is not the same. The `XVOLUME` example is rendering an opaque volume of the data set whereas the previous `SLICER3` example simply displayed an isosurface. Although Object Graphics display methods can require more processing time, they also offer significant advantages including greater interactivity, true volume rendering with the ability to specify opacities, and finer control over image and volumetric data.

Complete the following steps to load the `head.dat` volume into the `XVOLUME` application.

### Example Code

See `displayxvolume.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Select the file and read in the data, specifying known data dimensions:

```
file = FILEPATH('head.dat', SUBDIRECTORY = ['examples',
'data'])
volume = READ_BINARY(file, DATA_DIMS = [80, 100, 57])
```

2. Reduce the size of the original array to speed up processing:

```
smallVol = CONGRID(volume, 40, 50, 27)
```

3. Using the INTERPOLATE keyword to smooth the data, display the volume using the XVOLUME procedure:

```
XVOLUME, smallVol, /INTERPOLATE
```

After the data is passed to the XVOLUME application, an image similar to the following figure appears.

*Figure 3-176: Visualizing a Volume with XVOLUME*

## Manipulating Volumetric Data Using XVOLUME

Once data has been loaded into the XVOLUME application, you can create color coded contoured slices of data. Complete the following steps to create x-, y- and z-dimensional contours of the `head.dat` volume.

1. Rotate the image of the head so that the nose is facing toward the right. Click in the display window and, with your mouse button depressed, drag the mouse cursor to reposition the image display.
2. Select the **X**, **Y**, and **Z** “Contours” options, located on the upper-left portion of the XVOLUME interface.

---

**Note**

Turning off the XVOLUME “Auto-Render” feature produces faster responses to processing requests.

---

3. Move the **X Plane** slider to a value of 22. A contour line appears in the display window, running down the center of the image of the head. When you click in the display window, the planar slice is visible.
4. Move the **Y Plane** slider to a value of 27. A contour line appears along the middle of the y-dimension.
5. Move the **Z Plane** slider to a value of 12. Another contour line appears near the middle of the z-dimension.

The XVOLUME interface should appear similar to the following figure.

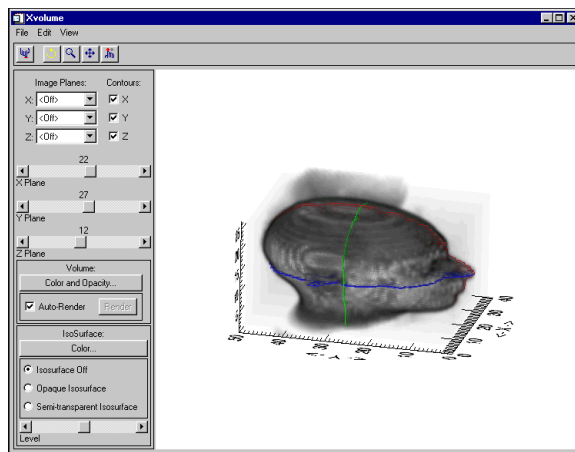

Figure 3-177: Creating Dimensional Contours Using XVOLUME

Click in the image display window to show the contour lines.

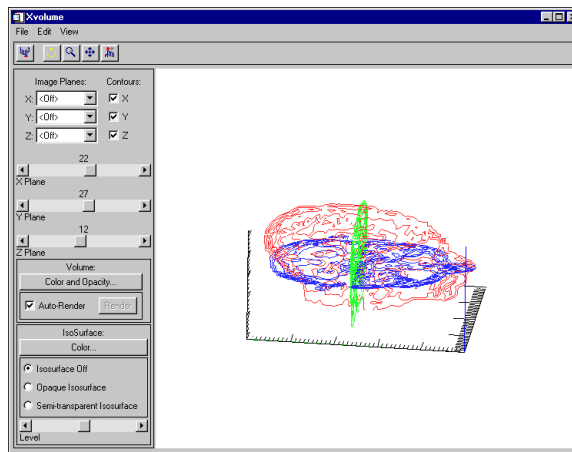

Figure 3-178: Displaying Contours of Planar Slices Using XVOLUME

### Tip

After a volumetric array has been loaded into the XVOLUME application, it can be animated using the `XVOLUME_ROTATE` procedure. To rotate the image above, run the example program for [XVOLUME\\_ROTATE](#).

## Version History

5.4	Introduced
-----	------------

## See Also

[IVOLUME](#), [XVOLUME\\_ROTATE](#), [XVOLUME\\_WRITE\\_IMAGE](#), [IDLgrVolume](#), [INTERPOLATE](#), [ISOSURFACE](#), [SHADE\\_VOLUME](#), [SLICER3](#), “Creating a Volume Object” in Chapter 7 of the *Object Programming* manual.

# XVOLUME\_ROTATE

The `XVOLUME_ROTATE` procedure is used to programmatically rotate the volume currently displayed in `XVOLUME`. `XVOLUME` must be called prior to calling `XVOLUME_ROTATE`. This procedure can be used to create animations of volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XVOLUME_ROTATE, Axis, Angle [, /PREMULTIPLY]
```

## Arguments

### Axis

A 3-element vector of the form  $[x, y, z]$  describing the axis about which the model is to be rotated.

### Angle

The amount of rotation, measured in degrees.

## Keywords

### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

## Examples

The following example creates an animation of the volume currently displayed in `XVOLUME`. It does this by rotating the volume through 360 degrees in increments of 10 degrees using `XVOLUME_ROTATE`, and writing the volume to a BMP file for each increment using `XVOLUME_WRITE_IMAGE`. It then loops through the images and uses `TV` to display each image.

First, display a volume as follows:

```

; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol

```

Now, use the `XVOLUME` interface to modify the orientation and appearance of the volume or isosurface as desired. Once you have the volume or isosurface displayed the way you want it, run the following program:

```

PRO spin_volume

inc = 10. ; degrees.
; Create images
FOR i=0,(360./inc)-2 DO BEGIN
  XVOLUME_WRITE_IMAGE, $
    'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
  XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY
ENDFOR
XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY

; Read images
img = READ_BMP('spin0.bmp')
siz = SIZE(img, /DIM)
arr = BYTARR(3, siz[1], siz[2], 360./inc-1)
FOR i=0,360./inc-2 DO BEGIN
  img = READ_BMP( $
    'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', /RGB)
  arr[0,0,0, i] = img
  PRINT, i
ENDFOR

; Display animation
FOR i=0,2 DO BEGIN ; num rotations
  FOR j=0,(360./inc)-2 DO BEGIN
    TV, arr[*,*,*,j], /TRUE
  ENDFOR
ENDFOR

TV, arr[*,*,*,0], /TRUE

END

```

# XVOLUME\_WRITE\_IMAGE

The `XVOLUME_WRITE_IMAGE` procedure is used to write the volume currently displayed in `XVOLUME` to an image file with the specified name and file format. `XVOLUME` must be called prior to calling `XVOLUME_WRITE_IMAGE`.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

```
XVOLUME_WRITE_IMAGE, Filename, Format [, DIMENSIONS=[x, y] ]
```

## Arguments

### Filename

A scalar string containing the name of the file to write.

### Format

A scalar string containing the name of the file format to write. See [QUERY\\_IMAGE](#) for a list of supported formats.

## Keywords

### DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current `XVOLUME` draw widget.

## Examples

See [XVOLUME\\_ROTATE](#).

# XYOUTS

The XYOUTS procedure draws text on the currently-selected graphics device starting at the designated coordinate.

Arguments *X*, *Y*, and *String* can be any combination of scalars or arrays. If the arguments are arrays, multiple strings are output.

If the optional *X* and *Y* arguments are omitted, the text is positioned at the end of the most recently output text string.

Important keywords that control the appearance and positioning of the text include: ALIGNMENT, the justification of the text; CHARSIZE, the size of the text; FONT, chooses between vector drawn and hardware fonts; COLOR, the color of the text; and ORIENTATION, the angle between the baseline of the text and the horizontal. With hardware fonts, most of the text attributes, (e.g., size and orientation), are predetermined and not changeable.

---

## Note

Specify the Z coordinate with the Z keyword when positioning text in three dimensions.

---

## Syntax

```
XYOUTS, [X, Y] String [, ALIGNMENT=value{0.0 to 1.0}] [, CHARSIZE=value]
  [, CHARTHICK=value] [, TEXT_AXES={0 | 1 | 2 | 3 | 4 | 5}]
  [, WIDTH=variable]
```

```
Graphics Keywords: [, CLIP=[X0, Y0, X1, Y1]] [, COLOR=value][, /DATA | ,
  /DEVICE | , /NORMAL] [, FONT=integer]
  [, ORIENTATION=ccw_degrees_from_horiz] [, /NOCLIP] [, /T3D] [, Z=value]
```

## Arguments

### X, Y

The horizontal and vertical coordinates used to position the string(s). *X* and *Y* are normally interpreted in data coordinates. The DEVICE and NORMAL keywords can be used to specify the coordinate units.

*X* and *Y* can be arrays of positions if *String* is an array.

## String

The string(s) to be output. This argument can be a scalar string or an array of strings. If this argument is not a string, it is converted prior to use using the default formatting rules. If *String* is an array, *X*, *Y*, and the **COLOR** keyword can also be arrays so that each string can have a separate location and color.

## Keywords

### ALIGNMENT

Specifies the alignment of the text baseline. An alignment of 0.0 (the default) aligns the left edge of the text baseline with the given  $(x, y)$  coordinate. An alignment of 1.0 right-justifies the text, while 0.5 results in text centered over the point  $(x, y)$ .

### CHARSIZE

The overall character size for the annotation. A CHARSIZE of 1.0 is normal. Setting CHARSIZE = -1 suppresses output of the text string. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see “[Scaled Hardware Fonts](#)” on page 2930.

### CHARTHICK

The line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see “[Scaled Hardware Fonts](#)” on page 2930. The default value is 1.0.

### TEXT\_AXES

This keyword specifies the plane of vector drawn text when three-dimensional plotting is enabled. By default, text is drawn in the plane of the XY axes. The horizontal text direction is in the X plane, and the vertical text direction is in the Y plane. Values for this keyword can range from 0 to 5, with the following effects: 0 for XY, 1 for XZ, 2 for YZ, 3 for YX, 4 for ZX, and 5 for ZY. The notation ZY means that the horizontal direction of the text lies in the Z plane, and the vertical direction of the text is drawn in the Y plane.

### WIDTH

Set this keyword to a named variable in which to return the width of the text string, in normalized coordinate units.

## Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of the following graphics and plotting keywords:

[CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [NOCLIP](#), [NORMAL](#), [ORIENTATION](#), [T3D](#), [Z](#)

## Examples

Print the string “This is text” at device coordinate position (100,100):

```
XYOUTS, 100, 100, 'This is text', /DEVICE
```

Print an array of strings with each element of the array printed at a different location. Use larger text than in the previous example:

```
XYOUTS, [0, 200, 250], [200, 50, 100], $
['This', 'is', 'text'], CHARSIZE = 3, /DEVICE
```

Determine the text size for a window device before opening an on-screen window:

```
WINDOW, /FREE, /PIXMAP, XSIZE=myWinXSize, YSIZE=myWinYSize
XYOUTS, 'Check this out', WIDTH=w
WDELETE
```

*myWinXSize* and *myWinYSize* are chosen to match your onscreen window. Since we can not know the characteristics of a given device (such as character size) until a window has been opened, the `PIXMAP` keyword to `WINDOW` allows you to compute appropriate dimensions for text with an invisible window before displaying a window on your screen.

## Labeling Lines of Data in a Plot

This example adds to the example shown in [O PLOT](#) by annotating each graph with its name. This plot is exactly the same as the `O PLOT` example except that the *x*-axis range is extended to the year 1990 to allow room for the titles. To accomplish this, the keyword parameter `XRANGE = [1967, 1990]` was added to the call to `PLOT`.

A string vector, `NAMES`, containing the names of each sample population also is defined.

*Figure 3-179: Example of Annotating Each Line*

First, we define an array containing names for each of the lines plotted. (This array is also defined by the `plot01` batch file.)

```
NAMES= ['Coho', 'Sockeye', 'Humpback', 'Chinook']
```

The plot was produced with the following statements:

```
; Define variables:
@plot01
; Index of last point:
N1 = N_ELEMENTS(YEAR) - 1
; Plot first graph. Set the y-axis min and max
; from the min and max of all data sets. Default linestyle is 0.
PLOT, YEAR, COHO, YRANGE = [MIN(ALLPTS), MAX(ALLPTS)], $
    TITLE='Salmon Populations', XTITLE = 'Year', $
    YTITLE = 'Fish (thousands)', XRANGE = [1965, 1990], $
    /XSTYLE
; Loop for the three remaining scores, varying the linestyle:
FOR I = 1, 3 DO OPLOT, YEAR, ALLPTS[*], I], LINE = I
; Append the title of each graph on the right:
FOR I = 0, 3 DO XYOUTS, 1984, ALLPTS[N1, I], NAMES[I]
```

**Note**

---

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the `examples/doc/plot` subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See [!PATH](#) for information on modifying IDL's path.

---

## Font Selection

The previous example illustrates the use of a PostScript font (Times-Roman, in this case) for the titles and annotations. Note that PostScript fonts can only be used when the current graphics devices is set to PostScript.

This font was selected by first setting the default font, controlled by the system variable `!P.FONT`, to the hardware-font index of zero, and then calling the `DEVICE` procedure to set the Times-Roman font.

**Example Code**

---

To recreate the plot using this font on your system enter `@plot02` at the IDL command prompt. You can also inspect the batch file `plot02`, located in the `examples/doc/plot` subdirectory of the IDL distribution. Running this batch files creates a PostScript file named `plot.ps` in your current working directory.

---

**Warning**

---

Because not all devices have selectable hardware fonts, default hardware fonts vary. Use of other PostScript fonts and their bold, italic, oblique, and other variants is described in [Appendix H, "Fonts"](#).

---

## Scaled Hardware Fonts

One example of hardware fonts which can be scaled are PostScript fonts. If you are using PostScript fonts, the keywords `CHARTHICK` and `CHARSIZE` will have an effect on a call to `XYOUTS`. Of the devices we provide that support hardware fonts, only the PostScript device uses scalable PostScript fonts for its "hardware" font system. All other devices use a bitmapped font technology.

Scaling is related to whether or not a device supports Hershey formatting commands when hardware fonts are used. Formatting requires the ability to scale the text on a per-character basis (i.e. for subscripting). To see if a given device supports Hershey formatting when hardware fonts are used, look at bit 12 of `!D.FLAGS`. You can also use this indicator to determine whether or not the hardware fonts will be scaled.

# ZOOM

The ZOOM procedure displays part of an image from the current window enlarged in a new (“zoom”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

## Note

---

ZOOM only works with color systems.

---

This routine is written in the IDL language. Its source code can be found in the file `zoom.pro` in the `lib` subdirectory of the IDL distribution.

## Using ZOOM

After calling ZOOM, place the mouse cursor over an image in an IDL graphics window. Click the left mouse button to display a magnified version of the image in a new window. The zoomed image is centered around the pixel selected in the original window. Click the middle mouse button to display a menu of zoom factors. Click the right mouse button to exit the procedure.

## Using ZOOM with Draw Widgets

Note that the ZOOM procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the `CW_ZOOM` function.

## Syntax

```
ZOOM [, /CONTINUOUS] [, FACT=integer] [, /INTERP] [, /KEEP]
      [, /NEW_WINDOW] [, XSIZE=value] [, YSIZE=value]
      [, ZOOM_WINDOW=variable]
```

## Arguments

None

## Keywords

### CONTINUOUS

Set this keyword to make the zoom window track the mouse without requiring the user to press the left mouse button. This feature only works well on fast computers.

## **FACT**

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

## **INTERP**

Set this keyword to use bilinear interpolation. The default is to use pixel replication.

## **KEEP**

Set this keyword to keep the zoom window after exiting the procedure.

## **NEW\_WINDOW**

Normally, if `ZOOM` is called with `KEEP` and then called again, it will use the same window to display the new zoomed image. Set the `NEW_WINDOW` keyword to force `ZOOM` to create a new window for this purpose.

## **XSIZE**

Use this keyword to specify the X size of the zoom window. The default is 512.

## **YSIZE**

Use this keyword to specify the Y size of the zoom window. The default is 512.

## **ZOOM\_WINDOW**

Set this keyword to a named variable that will contain the index of the zoom window. `KEEP` must also be set. If `KEEP` is not set, `ZOOM_WINDOW` will contain the integer -1.

## **Examples**

### **Zooming in on a Direct Graphics Image Display**

The following example imports a grayscale image from the `convec.dat` binary file. This grayscale image shows the convection of the Earth's mantle. The image contains byte data values and is 248 pixels by 248 pixels. The `ZOOM` procedure, which is a Direct Graphics routine, is used to zoom in on the lower left corner of the image.

**Example Code**

See `zooming_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example.

1. Determine the path to the `convec.dat` file:

```
file = FILEPATH('convec.dat', $  
    SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
imageSize = [248, 248]
```

3. Import the image from the file:

```
image = READ_BINARY(file, DATA_DIMS = imageSize)
```

4. If you are running IDL on a TrueColor display, set the `DECOMPOSED` keyword to the `DEVICE` command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Load a grayscale color table:

```
LOADCT, 0
```

6. Create a window and display the original image with the `TV` procedure:

```
WINDOW, 1, XSIZE = imageSize[0], YSIZE = imageSize[1], $  
    TITLE = 'A Grayscale Image'  
TV, image
```

The following figure shows the resulting grayscale image display.

*Figure 3-180: A Grayscale Image in Direct Graphics*

7. Use the **ZOOM** to enlarge the lower left quarter of the image:

```
ZOOM, /NEW_WINDOW, FACT = 2, $  
      XSIZE = imageSize[0], YSIZE = imageSize[1]
```

Click in the lower left corner of the original image window.

The following figure shows the resulting zoomed image.

*Figure 3-181: Enlarged Image Area in Direct Graphics*

8. Right-click in the original image window to quit out of the **ZOOM** procedure.

# ZOOM\_24

The ZOOM\_24 procedure displays part of a 24-bit color image from the current window expanded in a new (“zoom”) window, and provides information about cursor location and color values in an auxiliary (“data”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

---

**Note**

ZOOM only works on 24-bit color systems.

---

This routine is written in the IDL language. Its source code can be found in the file `zoom_24.pro` in the `lib` subdirectory of the IDL distribution.

## Using ZOOM\_24

After calling ZOOM\_24, windows titled “Zoomed Image” (the zoom window) and “Pixel Values” (the data window) appear on the screen. Place the mouse cursor over a 24-bit color image in an IDL graphics window and click the left mouse button to display a magnified version of the image in the zoom window. The zoomed image is centered around the pixel selected in the original window. Move the mouse cursor in the zoom window to determine the coordinates (in the original image) and color values of individual pixels.

With the cursor located in the zoom window, click the right mouse button to return to selection mode, which allows you to either choose a new zoom center, change the zoom factor, or exit the procedure. Move the cursor to the original image and click the middle mouse button to display a menu of zoom factors, or click the right mouse button to exit the procedure.

## Using ZOOM\_24 with Draw Widgets

Note that the ZOOM\_24 procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the `CW_ZOOM` function.

## Syntax

```
ZOOM_24 [, FACT=integer] [, /RIGHT] [, XSIZE=value] [, YSIZE=value]
```

## Arguments

None.

## Keywords

### FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

### RIGHT

Set this keyword to position the zoom and data windows to the right of the original window.

### XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

### YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

# Using the Class Reference

IDL's object class library is documented in this section. The page or pages describing each class include references to any superclasses of the class, to the properties of the class, and to the methods associated with the class. Class methods are documented alphabetically following the description of the class itself.

A description of each method follows its name. Beneath the general description of the method are a number of sections that describe the Syntax for the method, its arguments (if any), its keywords (if any). These sections are described below.

## Object Method Syntax

In the *IDL Reference Guide*, the Syntax section of each object method shows the proper syntax for calling the method.

### Procedure Methods

IDL procedure methods have the syntax:

*Obj->Procedure\_Name, Argument [, Optional\_Arguments]*

where *Obj* is a valid object reference, *Procedure\_Name* is the name of the procedure method, *Argument* is a required parameter, and *Optional\_Argument* is an optional parameter to the procedure method. The square brackets around optional arguments are not used in the actual call to the procedure, they are simply used to denote the optional nature of the arguments within this document.

### Function Methods

IDL function methods have the syntax:

*Result = Obj->Function\_Name(Argument [, Optional\_Arguments])*

where *Obj* is a valid object reference, *Result* is the returned value of the function method, *Function\_Name* is the name of the function method, *Argument* is a required parameter, and *Optional\_Argument* is an optional parameter. The square brackets around optional arguments are not used in the actual call to the function, they are simply used to denote the optional nature of the arguments within this document.

#### Note

---

All arguments and keywords to functions should be supplied *within* the parentheses that follow the function's name.

---

## Arguments

The *Arguments* section describes each valid argument to the method.

---

**Note**

These arguments are positional parameters that must be supplied in the order indicated by the method's syntax.

---

## Named Variables

Often, arguments that contain values upon return from the function or procedure method (“output arguments”) are described as accepting “named variables.” A named variable is simply a valid IDL variable name. This variable *does not* need to be defined before being used as an output argument. Note, however that when an argument calls for a named variable, only a named variable can be used—sending an expression causes an error.

## Keywords

The *Keywords* section describes each valid keyword argument to the method.

---

**Note**

Keyword arguments are formal parameters that can be supplied in any order.

---

Keyword arguments are supplied to IDL methods by including the keyword name followed by an equal sign (“=”) and the value to which the keyword should be set. Note that keywords can be abbreviated to their shortest unique length. For example, the XSTYLE keyword can be abbreviated to XST.

---

**Note**

In the case of Init, GetProperty and SetProperty methods, keywords often correspond to object *properties*. See [“Object Properties”](#) on page 2945 for additional discussion.

---

## Setting Keywords

When the documentation for a keyword says something similar to, “Set this keyword to enable logarithmic plotting,” the keyword is simply a switch that turns an option on and off. In general, setting such keywords equal to 1 (or using the /KEYWORD syntax) causes the option to be turned on. Explicitly setting the keyword to zero (or not including the keyword) turns the option off.

## Creating Objects from the Class Library

To create an object from the IDL object class library, use the `OBJ_NEW` function. See “[OBJ\\_NEW](#)” on page 1605. The `Init` method for each class describes the arguments and keywords available when you are creating a new object.

For example, to create a new object from the `IDLgrAxis` class, use the following call to `OBJ_NEW` along with the arguments and keywords accepted by the `IDLgrAxis::Init` method:

```
myAxis = OBJ_NEW(IDLgrAxis, DIRECTION = 1, RANGE = [0.0, 40.0])
```

# Object Properties

Some IDL objects have *properties* associated with them — things like color, line style, size, and so on. Properties are set or changed by supplying property-value pairs in a call to the object class' `Init` or `SetProperty` method:

```
Obj->OBJ_NEW('ObjectClass', PROPERTY = value, ... )
```

or

```
Obj->SetProperty, PROPERTY = value, ...
```

where *PROPERTY* is the name of a property and *value* is the associated property value.

Property values are retrieved by supplying property-value pairs in a call to the object class' `GetProperty` method:

```
Obj->GetProperty, PROPERTY = variable, ...
```

where *PROPERTY* is the name of a property and *variable* is the name of an IDL variable that will hold the associated property value.

## Note

---

Property-value pairs behave in exactly the same way as Keyword-value pairs. This means that you can set the value of a boolean property to 1 by preceding the name of the property with a “/” character. The following are equivalent:

```
Obj->SetProperty, PROPERTY = 1
```

```
Obj->SetProperty, /PROPERTY
```

---

If you are familiar with IDL Direct Graphics, you will note that many of the properties of IDL objects correspond to keywords to the Direct Graphics routines. Unlike IDL Direct Graphics, the IDL Object Graphics system allows you to change the value of an object's properties without re-creating the entire object. Objects must be redrawn, however, with a call to the destination object's `Draw` method, for the changes to become visible.

## Properties and the Property Sheet Interface

In addition to being able to set and change object property values programmatically, IDL provides a way for users to change property values via a graphical user interface. The [WIDGET\\_PROPERTY SHEET](#) function creates a user interface that allows users to select and change property values using the mouse and keyboard.

For an object property to be displayed in a property sheet, the property must be registered.

See “[Registered Properties](#)” on page 2949 for additional discussion.

## Setting Properties at Initialization

Often, you will set an object’s properties when creating the object for the first time, which is done by specifying any keywords to the object’s `Init` method directly in the call of `OBJ_NEW` that creates the object. For example, suppose you are creating a plot and wish to use a red line to draw the plot line. You could specify the `COLOR` keyword to the `IDLgrPlot::Init` method directly in the call to `OBJ_NEW`:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, COLOR = [255, 0, 0])
```

In most cases, an object’s `Init` method cannot be called directly. Arguments to `OBJ_NEW` are passed directly to the `Init` method when the object is created.

For some graphics objects, you can specify a keyword that has the same meaning as an argument. In Object Graphics, the value of the keyword overrides the value set by the argument. For example,

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, DATAX = newXData)
```

The `Plot` object uses the data in `newXData` for the plot’s X data.

## Setting Properties of Existing Objects

After you have created an object, you can also set its properties using the object’s `SetProperty` method. For example, the following two statements duplicate the single call to `OBJ_NEW` shown above:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata)
myPlot->SetProperty, COLOR = [255, 0, 0]
```

---

### Note

Not all keywords available when the object is being initialized are necessarily available via the `SetProperty` method. Keywords available when using an object’s `SetProperty` method are noted with the word “Set” in the table included after the text description of the property.

---

## Retrieving Property Settings

You can retrieve the value of a particular property using an object’s `GetProperty` method. The `GetProperty` method accepts a list of keyword-variable pairs and returns

the value of the specified properties in the variables specified. For example, to return the value of the COLOR property of the plot object in our example, use the statement:

```
myPlot->GetProperty, COLOR = plotcolor
```

The value of the COLOR property is returned in the IDL variable `plotcolor`.

You can retrieve the values of all of the properties associated with a graphics object by using the ALL keyword to the object's GetProperty method. The following statement:

```
myPlot->GetProperty, ALL = allprops
```

returns an anonymous structure in the variable `allprops`; the structure contains the values of all of the retrievable properties of the object.

### Note

Not all keywords available when the object is being initialized are necessarily available via the GetProperty method. Keywords available when using an object's GetProperty method are noted with the word "Get" in the table included after the text description of the property.

## About Object Property Descriptions

In the documentation for the IDL object class library, the description of each class is followed by a section describing the properties of the class. Each property description is followed by a table that looks like this:

<b>Property Type</b>	Boolean		
<b>Name String</b>	Hide		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> Yes

where

- **Property Type** describes the property type associated with the property. If the property is *registered*, the property type will be one of a number of registered property data types. If the property is not registered, this field will describe the generic IDL data type of the property value.
- **Name String** is the default value of the Name property attribute. If the property is registered, this is the value that appears in the left-hand column when the property is displayed in a property sheet widget. If the property is not registered, this field will contain the words *not displayed*.

- **Get, Set,** and **Init** describe whether the property can be specified as a keyword to the `GetProperty`, `SetProperty`, and `Init` methods, respectively.
- **Registered** describes whether the property is registered for display in a property sheet widget.

See [“Registered Property Data Types”](#) on page 2950 and [“Registered Properties”](#) on page 2949 for additional information.

# Registered Properties

In order for an object property to be displayed in the WIDGET\_PROPERTY SHEET interface, which makes it possible for a user to interactively change the value of the property using the mouse and keyboard, the following two conditions must be met:

- The property must belong to an object that subclasses from the [IDLitComponent](#) class. IDLitComponent provides the infrastructure necessary to display property sheets.
- The property must be *registered*. Properties that are not registered will never be displayed in a property sheet. (Note that registered properties can also be *hidden*, which prevents them from being displayed in a property sheet.)

---

## Note

This section provides a brief overview of property registration. See [Chapter 4, “Property Management”](#) in the *iTool Developer’s Guide* manual for a more in-depth discussion.

---

## Registering a Property

To register a property, use the RegisterProperty method of the IDLitComponent class:

```
Obj->IDLitComponent::RegisterProperty, PropertyIdentifier, $  
    [, TypeCode] [, ATTRIBUTE = value]
```

where *PropertyIdentifier* is a string that uniquely identifies the property, *TypeCode* is an integer between 0 and 9 specifying the property data type, and *ATTRIBUTE* is a property attribute.

Property identifier strings must obey certain rules; see [“Property Identifiers”](#) in Chapter 4 of the *iTool Developer’s Guide* manual for details. Property type codes are discussed in [“Registered Property Data Types”](#) on page 2950. Property attributes are discussed in [“Property Attributes”](#) in Chapter 4 of the *iTool Developer’s Guide* manual.

## Registering All Available Properties

Some of the classes in the IDL object class library include a mechanism to register all available properties in a single operation. If an object class has a REGISTER\_PROPERTIES property, then setting that property to 1 when creating the object automatically registers all properties that can be registered. If a property

contains a “Yes” in the Registered box of the property description table, it will be registered automatically if the REGISTER\_PROPERTIES property is set when the object is created. (See “[About Object Property Descriptions](#)” on page 2947 for a description of the property description table.)

## Registered Property Data Types

Registered properties must be of one of the data types listed in the following table.

### Note

Properties of objects that are *not* registered (that is, properties that cannot appear in a property sheet) can be of any IDL data type.

Type Code	Type	Description
0	USERDEF	User Defined properties can contain values of any IDL type, but must also include a string value that will be displayed in the property sheet. See the following discussion for additional information.
1	BOOLEAN	Boolean properties contain either the integer 0 or the integer 1.
2	INTEGER	Integer properties contain an integer value. If a property of integer data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually.
3	FLOAT	Float properties contain a double-precision floating-point value. If a property of float data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually.
4	STRING	String properties contain a scalar string value

Table 4-1: iTools Property Data Types

Type Code	Type	Description
5	COLOR	Color properties contain an RGB color triplet
6	LINESTYLE	<p>Linestyle properties contain an integer value between 0 and 6, corresponding to the following IDL line styles:</p> <ul style="list-style-type: none"> <li>• 0 = Solid</li> <li>• 1 = Dotted</li> <li>• 2 = Dashed</li> <li>• 3 = Dash Dot</li> <li>• 4 = Dash Dot Dot</li> <li>• 5 = Long Dashes</li> <li>• 6 = No Line</li> </ul> <p>See <a href="#">Appendix B, “Property Controls”</a> in the <i>iTool User’s Guide</i> manual for a visual example of the available line styles.</p>
7	SYMBOL	<p>Symbol properties contain an integer value between 0 and 8, corresponding to the following IDL symbol types:</p> <ul style="list-style-type: none"> <li>• 0 = No symbol</li> <li>• 1 = Plus sign</li> <li>• 2 = Asterisk</li> <li>• 3 = Period (Dot)</li> <li>• 4 = Diamond</li> <li>• 5 = Triangle</li> <li>• 6 = Square</li> <li>• 7 = X</li> <li>• 8 = “Greater-than” Arrow Head (&gt;)</li> <li>• 9 = “Less-than” Arrow Head (&lt;)</li> </ul> <p>See <a href="#">Appendix B, “Property Controls”</a> in the <i>iTool User’s Guide</i> manual for a visual example of the available symbols.</p>

Table 4-1: *iTools Property Data Types (Continued)*

Type Code	Type	Description
8	THICKNESS	Thickness properties contain an integer value between 1 and 10, corresponding to the thickness (in points) of the line.
9	ENUMLIST	Enumerated List properties contain an array of string values defined when the property is registered. The <code>GetProperty</code> method returns the zero-based index of the selected item.

Table 4-1: *iTools Property Data Types (Continued)*

## User Defined Property Types

The User Defined property type lets you create a custom interface that allow users of your iTool to select data of types other than the predefined iTool property types.

Creating a user defined property type entails the following:

- Creating an `EditUserDefProperty` method for the iTool component (usually a visualization or operation) that uses the user defined property. See [“IDLitComponent::EditUserDefProperty”](#) in the *IDL Reference Guide* manual for details.
- Creating user interface code to allow users to select a value. In the initial release of the iTool system, this means writing an IDL widget interface, but in future releases other users interfaces may be available.
- Creating a *user interface service* to display the interface. See [Chapter 13, “Creating a User Interface Service”](#) in the *iTool Developer’s Guide* manual for details.

# Undocumented Object Classes

Some of IDL's object classes are subclassed from more generic IDL objects. You may see references to the generic IDL objects when using IDL's HELP procedure to get information on an object, or when you use the OBJ\_ISA or OBJ\_CLASS functions. You may also notice that the generic objects are not documented in this section. This is not an oversight.

We have chosen not to document the workings of the more generic objects from which the IDL graphics objects are subclassed because we reserve the right to make changes to their operation. We strongly recommend that you do not use the undocumented object classes directly, or subclass your own object classes from them. Research Systems, Inc. does not guarantee that user-written code that uses undocumented features will continue to function in future releases of IDL.

## Chapter 5

# Analysis Object Classes

This chapter describes IDL's built-in analysis class library.

---

<a href="#">IDLanROI</a> .....	2956	<a href="#">IDLanROIGroup</a> .....	2984
--------------------------------	------	-------------------------------------	------

# IDLanROI

The IDLanROI object class represents a region of interest.

**Note**

---

The IDLan\* naming convention is used for objects in the analysis domain.

---

Regions of interest are described as a set of vertices that may be connected to generate a path or a polygon, or may be treated as separate points. This object may be used as a source for analytical computations on regions. (For additional information about display of ROIs in Object Graphics, refer to the [IDLgrROI](#) object class.)

## Superclasses

None

## Creation

See [IDLanROI::Init](#).

## Properties

Objects of this class have the following properties. See “[IDLanROI Properties](#)” on page 2958 for details on individual properties.

- [ALL](#)
- [BLOCK\\_SIZE](#)
- [DATA](#)
- [DOUBLE](#)
- [INTERIOR](#)
- [N\\_VERTS](#)
- [ROI\\_XRANGE](#)
- [ROI\\_YRANGE](#)
- [ROI\\_ZRANGE](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLanROI class has the following methods.

- [IDLanROI::AppendData](#)
- [IDLanROI::Cleanup](#)
- [IDLanROI::ComputeGeometry](#)
- [IDLanROI::ComputeMask](#)
- [IDLanROI::ContainsPoints](#)
- [IDLanROI::GetProperty](#)
- [IDLanROI::Init](#)
- [IDLanROI::RemoveData](#)
- [IDLanROI::ReplaceData](#)
- [IDLanROI::Rotate](#)
- [IDLanROI::Scale](#)
- [IDLanROI::SetProperty](#)
- [IDLanROI::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See “[Programmatically Defining ROIs](#)” in Chapter 6 of the *Image Processing in IDL* manual.

## Version History

5.3	Introduced
-----	------------

## IDLanROI Properties

IDLanROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLanROI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLanROI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLanROI::SetProperty](#).

---

**Note**

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [BLOCK\\_SIZE](#)
- [DATA](#)
- [DOUBLE](#)
- [INTERIOR](#)
- [N\\_VERTS](#)
- [ROI\\_XRANGE](#)
- [ROI\\_YRANGE](#)
- [ROI\\_ZRANGE](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

### ALL

An anonymous structure containing the values of all of the properties associated with the state of this object. State information about the object includes things like block size, type, etc., but not vertex data.

---

**Note**

The fields in this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## BLOCK\_SIZE

The number of vertices to allocate per block as needed for the region. When additional vertices are required, an additional block is allocated. The default is 100.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DATA

A  $2 \times n$  or a  $3 \times n$  array that defines the 2-D or 3-D vertex data, respectively. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is stored as single precision floating point.

<b>Property Type</b>	Array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DOUBLE

A non-zero value that indicates whether or not data should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default. The DOUBLE property controls the precision used for storing the data in the AppendData, Init, and ReplaceData methods via the X, Y, and Z arguments and in SetProperty method via the DATA keyword. IDL converts any data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point.

This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## INTERIOR

A Boolean variable that marks this region as an interior region (i.e., a region treated as a hole). By default, the region is treated as an exterior region.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_VERTS

An integer that contains the number of vertices currently being used by the region.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ROI\_XRANGE

A two-element double-precision floating-point vector of the form  $[xmin, xmax]$  that specifies the range of X data coordinates covered by the region.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ROI\_YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] specifying the range of Y data coordinates covered by the region.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ROI\_ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of Z data coordinates covered by the region.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## TYPE

An integer that indicates the type of the region. The TYPE keyword determines how computational operations, such as mask generation, are performed. Valid values include:

- 0 = points
- 1 = path
- 2 = closed polygon (the default)

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLanROI::AppendData

The IDLanROI::AppendData procedure method appends vertices to the region.

### Syntax

```
Obj->[IDLanROI::]AppendData, X [, Y] [, Z] [, XRANGE=variable]  
    [, YRANGE=variable] [, ZRANGE=variable]
```

### Arguments

#### X

A vector providing the X components of the vertices to be appended. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2,\*] or [3,\*]), in which case, X[0,\*] represents the X values, X[1,\*] represents the Y values, and X[2,\*] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

#### Y

A vector providing the Y components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

#### Z

A vector providing the Z components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

### Keywords

#### XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [xmin, xmax], representing the X range of the modification to the region. The reported

range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

## YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin*, *ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

## ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin*, *zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

## Version History

5.3	Introduced
-----	------------

## IDLanROI::Cleanup

The IDLanROI::Cleanup procedure method performs all cleanup for a region of interest object.

---

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLanROI::]Cleanup *(In a lifecycle method only.)*

## Arguments

None.

## Keywords

None.

## Version History

---

5.3	Introduced
-----	------------

---

## IDLanROI::ComputeGeometry

The IDLanROI::ComputeGeometry function method computes the geometrical values for area, perimeter, and/or centroid of the region.

### Syntax

```
Result = Obj->[IDLanROI::]ComputeGeometry( [, AREA=variable]
      [, CENTROID=variable] [, PERIMETER=variable]
      [, SPATIAL_OFFSET=vector] [, SPATIAL_SCALE=vector] )
```

### Return Value

#### Result

This function method returns a 1 for success, or a 0 for failure. Each computed value is returned in the *variable* name assigned to each keyword.

### Arguments

None.

### Keywords

#### AREA

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the area of the region. Interior regions (holes) return a negative area.

Note that the computed area represents the geometric area described by the region's vertex data. A pixel-based area can be computed as follows:

1. Compute a mask for the region.

```
mask = oROI->ComputeMask()
```

2. Call IMAGE\_STATISTICS to count number of samples within the mask.

```
IMAGE_STATISTICS, myImage, MASK = mask, COUNT = nSamples
```

3. Compute pixel area.

```
pixelArea = nSamples * pixelXSize * pixelYSize
```

## CENTROID

Set this keyword to a named variable that upon return contains a double-precision floating-point vector  $[x,y,z]$  representing the centroid for the region. If the TYPE of the region is 0 (points), the centroid is computed as the average of each of the vertices in the region. If the TYPE of the region is 1 (path), the centroid is computed as the weighted average of each of the midpoints of the lines in the region. Weights are proportional to the length of the lines. If the TYPE of the region is 2 (polygon), the centroid is computed as a weighted average of the centroids of the polygons making up the ROI (interior centroids use negative weights). Weights are proportional to the polygon area.

## PERIMETER

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the perimeter of the region.

## SPATIAL\_OFFSET

Set this keyword to a two or three-element vector,  $[tx, ty]$  or  $[tx, ty, tz]$ , representing the spatial calibration offset factors to be applied for the geometry calculations. The value of SPATIAL\_SCALE is applied before the spatial offset values are applied. The default is  $[0.0, 0.0, 0.0]$ . IDL converts and maintains this value in double-precision floating-point.

## SPATIAL\_SCALE

Set this keyword to a two or three-element vector,  $[sx, sy]$  or  $[sx, sy, sz]$ , representing the spatial calibration scaling factors to be applied for the geometry calculations. The spatial calibration scale is applied first, then the value of SPATIAL\_OFFSET is applied. The default is  $[1.0, 1.0, 1.0]$ . IDL converts and maintains this value in double-precision floating-point.

## Version History

5.3	Introduced
-----	------------

## IDLanROI::ComputeMask

The IDLanROI::ComputeMask function method prepares a two-dimensional mask for the region.

### Syntax

```
Result = Obj->[IDLanROI::]ComputeMask( [, INITIALIZE={ -1 | 0 | 1 }]  
  [, DIMENSIONS=[xdim, ydim]] | [, MASK_IN=array] [, LOCATION=[x, y  
  [, z]]] [, MASK_RULE={ 0 | 1 | 2 }] [, PIXEL_CENTER=[x, y]  
  [, PLANE_NORMAL=[x, y, z]] [, PLANE_XAXIS=[x,y,z]] [, /RUN_LENGTH]  
  )
```

### Return Value

#### Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(255, (M_{roi} * Ext) + M_{in}), 0)$$

where  $M_{roi}$  is 255 and  $Ext$  is 1 for points within an exterior region and -1 for points within an interior region.

If the TYPE of the region is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the region is 1 (path), one-pixel-wide line segments are set within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a region, and the pixel falls within the region (according to the MASK\_RULE).

### Arguments

None.

## Keywords

### DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If `MASK_IN` is provided, the value of this keyword is ignored and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

### INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- -1 = The mask is not initialized. This option is useful when updating an already existing mask. This is the default if the `MASK_IN` keyword is set.
- 0 = The mask is initialized so that each pixel is set to 0. This is the default if the `MASK_IN` keyword is not set.
- 1 = The mask is initialized so that each pixel is set to 255.

### LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0]. IDL converts and maintains this value in double-precision floating-point.

### MASK\_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type `BYTE` and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the `DIMENSIONS` keyword.

### MASK\_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary only. All pixels falling on a region's boundary are set.
- 1 = Interior only. All pixels falling within the region's boundary, but not on the boundary, are set.

- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set. This is the default.

## PIXEL\_CENTER

Set this keyword to a 2-element vector,  $[x, y]$ , to indicate where the lower-left mask pixel is centered relative to a Cartesian grid. The default value is  $[0.0, 0.0]$ , indicating that the lower-left pixel is centered at  $[0.0, 0.0]$ .

## PLANE\_NORMAL

Set this keyword to a three-element vector,  $[x, y, z]$ , specifying the normal vector for the plane on which the mask is to be computed. The default is  $[0, 0, 1]$ .

## PLANE\_XAXIS

Set this keyword to a three-element vector,  $[x, y, z]$ , specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is  $[1, 0, 0]$ .

## RUN\_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

## Examples

See [“Creating and Displaying an ROI Mask”](#) in Chapter 6 of the *Image Processing in IDL* manual.

## Version History

5.3	Introduced
5.6	Added RUN_LENGTH keyword

## IDLanROI::ContainsPoints

The IDLanROI::ContainsPoints function method determines whether the given data coordinates are contained within the closed polygon region.

### Syntax

*Result* = *Obj*->[IDLanROI::]ContainsPoints( *X* [, *Y* [, *Z*]] )

### Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly out of bounds of the ROI
- 1 = Interior. The point lies strictly inside the bounds of the ROI
- 2 = On edge. The point lies on an edge of the ROI boundary
- 3 = On vertex. The point matches a vertex of the ROI

A point is considered to be exterior if:

- The point falls within the boundary of an interior region (hole)
- The point does not lie in the plane of the region
- The region TYPE property is set to 0 (points) or 1 (path)

### Arguments

#### X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,\*] or [3,\*]), in which case, *X*[0,\*] represents the *X* values, *X*[1,\*] represents the *Y* values, and *X*[2,\*] represents the *Z* values.

#### Y

A vector providing the *Y* components of the points to be tested.

#### Z

A scalar or vector providing the *Z* component(s) of the points to be tested. If not provided, the *Z* components default to 0.0.

## Keywords

None.

## Examples

See [“Testing an ROI for Point Containment”](#) in Chapter 6 of the *Image Processing in IDL* manual.

## Version History

5.3	Introduced
-----	------------

## IDLanROI::GetProperty

The IDLanROI::GetProperty procedure method retrieves the value of a property or group of properties for the region.

### Syntax

*Obj*->[IDLanROI::]GetProperty [, *PROPERTY=variable*]

### Arguments

None.

### Keywords

Any property listed under “[IDLanROI Properties](#)” on page 2958 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.3	Introduced
-----	------------

## IDLanROI::Init

The IDLanROI::Init function method initializes a region of interest object.

---

### Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Obj = OBJ_NEW( 'IDLanROI' [, X [, Y [, Z ]]] [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLanROI::]Init( [X [, Y [, Z ]]] [, PROPERTY=value] ) (In a  
lifecycle method only.)
```

---

### Note

Keywords can be used in either form. They are omitted in the second form for brevity.

---

## Arguments

### X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2,\*] or [3,\*]), in which case, X[0,\*] represents the X values, X[1,\*] represents the Y values, and X[2,\*] represents the Z values. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

### Y

A vector providing the Y components of the vertices. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

## Z

A scalar or vector providing the Z component(s) of the vertices. If not provided, Z values default to 0.0. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

## Keywords

Any property listed under “[IDLanROI Properties](#)” on page 2958 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

5.3	Introduced
-----	------------

## IDLanROI::RemoveData

The IDLanROI::RemoveData procedure method removes vertices from the region.

### Syntax

```
Obj->[IDLanROI:]RemoveData[, COUNT=vertices] [, START=index]  
    [, XRANGE=variable] [, YRANGE=variable] [, ZRANGE=variable]
```

### Arguments

None.

### Keywords

#### COUNT

Set this keyword to the number of vertices to remove. The default is one vertex.

#### START

Set this keyword to an index (into the region's current vertex list) where the removal is to begin. By default, the final vertex is removed.

#### XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin*, *xmax*], that represents the X range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

#### YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin*, *ymax*], that represents the Y range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

## ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin*, *zmax*], that represents the *Z* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

## Version History

5.3	Introduced
-----	------------

## IDLanROI::ReplaceData

The IDLanROI::ReplaceData procedure method replaces vertices in the region with alternate values. The number of replacement values need not match the number of values being replaced.

### Syntax

```
Obj->[IDLanROI::]ReplaceData, X[, Y[, Z]] [, START=index] [, FINISH=index]  
    [, XRANGE=variable] [, YRANGE=variable] [, ZRANGE=variable]
```

### Arguments

#### X

A vector providing the X components of the new replacement vertices. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2, \*] or [3, \*]), in which case, X[0, \*] represents the X values, X[1, \*] represents the Y values, and X[2, \*] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

#### Y

A vector providing the Y components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

#### Z

A vector providing the Z components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

## Keywords

### FINISH

Set this keyword to the index of the region's current subregion vertex list where the replacement ends. If the START keyword value is  $\geq 0$ , the default FINISH is given by

$$\text{FINISH} = ((\text{START} + \text{N\_NEW} - 1) \text{ MOD } \text{N\_OLD})$$

where N\_NEW is the number of replacement vertices provided via the [X, Y, Z] arguments and N\_OLD is the number of vertices (prior to replacement) in the current subregion.

If the START keyword is not set or is negative, the default FINISH is given by

$$\text{FINISH} = \text{N\_OLD} - 1$$

FINISH may be less than START in which case the vertices, including and following START and the vertices preceding and including FINISH, are replaced with the new values.

### START

Set this keyword to an index of the region's current subregion vertex list where the replacement begins. If the FINISH keyword value is  $\geq 0$ , the default START is given by

$$\text{START} = ((\text{FINISH} - \text{N\_NEW} + 1) \text{ MOD } \text{N\_OLD})$$

where N\_NEW is the number of replacement vertices provided via the [X, Y, Z] arguments and N\_OLD is the number of vertices (prior to replacement) in the current subregion.

If the FINISH keyword is not set (or negative), the default START is clamped to 0 and is given by

$$\text{N\_OLD} - \text{N\_NEW}$$

### XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [xmin, xmax], representing the X range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

## YRANGE

Set this keyword to a named variable that upon return contains a two-element vector,  $[ymin, ymax]$ , representing the  $Y$  range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

## ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector,  $[zmin, zmax]$ , representing the  $Z$  range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

## Version History

5.3	Introduced
-----	------------

## IDLanROI::Rotate

The IDLanROI::Rotate procedure method modifies the vertices for the region by applying a rotation.

### Syntax

*Obj*->[IDLanROI::]Rotate, *Axis*, *Angle* [, CENTER=[*x*, *y*, *z*]]

### Arguments

#### Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the region is to be rotated.

#### Angle

The angle, measured in degrees, by which the rotation is to occur.

### Keywords

#### CENTER

Set this keyword to a two or three-element vector of the form [*x*, *y*], or [*x*, *y*, *z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

### Version History

5.3	Introduced
-----	------------

## IDLanROI::Scale

The IDLanROI::Scale procedure method modifies the vertices for the region by applying a scale.

### Syntax

*Obj*->[IDLanROI::]Scale, *Sx*[, *Sy*[, *Sz*]]

### Arguments

#### Sx

The X scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in X, *Sx*[1] represents the scale in Y, *Sx*[2] represents the scale in Z. IDL converts and applies this data in double-precision floating-point.

#### Sy

The Y scale factor. IDL converts and applies this data in double-precision floating-point.

#### Sz

The Z scale factor. IDL converts and applies this data in double-precision floating-point.

### Keywords

None.

### Version History

5.3	Introduced
-----	------------

## IDLanROI:: SetProperty

The IDLanROI::SetProperty procedure method sets the value of a property or group of properties for the region.

### Syntax

*Obj*->[IDLanROI::]SetProperty

### Arguments

None.

### Keywords

Any property listed under “[IDLanROI Properties](#)” on page 2958 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

5.3	Introduced
-----	------------

## IDLanROI::Translate

The IDLanROI::Translate procedure method modifies the vertices for the region by applying a translation.

### Syntax

*Obj*->[IDLanROI::]Translate, *Tx*[, *Ty*[, *Tz*]]

### Arguments

#### **Tx**

The X translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in X, *Tx*[1] represents translation in Y, *Tx*[2] represents translation in Z. IDL converts and applies this data in double-precision floating-point.

#### **Ty**

The Y translation factor. IDL converts and applies this data in double-precision floating-point.

#### **Tz**

The Z translation factor. IDL converts and applies this data in double-precision floating-point.

### Keywords

None.

# IDLanROIGroup

The IDLanROIGroup object class is an analytical representation of a group of regions of interest.

## Superclasses

[IDL\\_Container](#)

## Creation

See [IDLanROIGroup::Init](#).

## Properties

Objects of this class have the following properties. See “[IDLanROIGroup Properties](#)” on page 2986 for details on individual properties.

- [ALL](#)
- [ROIGROUP\\_XRANGE](#)
- [ROIGROUP\\_YRANGE](#)
- [ROIGROUP\\_ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLanROIGroup class has the following methods:

- [IDLanROIGroup::Add](#)
- [IDLanROIGroup::Cleanup](#)
- [IDLanROIGroup::ComputeMask](#)
- [IDLanROIGroup::ComputeMesh](#)
- [IDLanROIGroup::ContainsPoints](#)
- [IDLanROIGroup::GetProperty](#)
- [IDLanROIGroup::Init](#)
- [IDLanROIGroup::Rotate](#)

- [IDLanROIGroup::Scale](#)
- [IDLanROIGroup::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See “[Creating a Surface Mesh of an ROI Group](#)” in Chapter 6 of the *Image Processing in IDL* manual.

## Version History

5.3	Introduced
-----	------------

## IDLanROIGroup Properties

IDLanROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “[IDLanROIGroup::GetProperty](#)” on page 2997. Properties with the word “Yes” in the “Init” column of the property table can be set via “[IDLanROIGroup::Init](#)” on page 2998.

---

### Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 2947.

---

Objects of this class have the following properties.

- [ALL](#)
- [ROIGROUP\\_XRANGE](#)
- [ROIGROUP\\_YRANGE](#)
- [ROIGROUP\\_ZRANGE](#)

In addition, objects of this class inherit:

- [IDL\\_Container](#)

### ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

---

### Note

The fields in this structure may change in subsequent releases of IDL.

---

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ROIGROUP\_XRANGE

A two-element double-precision floating-point vector of the form  $[xmin, xmax]$  specifying the range of X data coordinates covered by the region.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ROIGROUP\_YRANGE

A two-element double-precision floating-point vector of the form  $[ymin, ymax]$  specifying the range of Y data coordinates covered by the region.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ROIGROUP\_ZRANGE

A two-element double-precision floating-point vector of the form  $[zmin, zmax]$  specifying the range of Z data coordinates covered by the region.

<b>Property Type</b>	Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IDLanROIGroup::Add

The IDLanROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLanROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

### Syntax

*Obj*->[\[IDLanROIGroup::\]Add](#), *ROI*

### Arguments

#### ROI

A reference to an instance of the IDLanROI object class representing the region of interest to be added to the group.

### Keywords

Accepts all keywords accepted by the [IDL\\_Container::Add](#) method.

### Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::Cleanup

The IDLanROIGroup::Cleanup procedure method performs all cleanup for a region of interest group object.

### Note

---

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLanROIGroup::]Cleanup (In a lifecycle method only.)

## Arguments

None.

## Keywords

None.

## Version History

---

5.3	Introduced
-----	------------

---

## IDLanROIGroup::ComputeMask

The IDLanROIGroup::ComputeMask function method prepares a two-dimensional mask for this group of regions.

### Syntax

```
Result = Obj->[IDLanROIGroup::]ComputeMask( [, INITIALIZE={ -1 | 0 | 1 } ]
  [, DIMENSIONS=[xdim, ydim] ] | [, MASK_IN=array] [, LOCATION=[x, y
  [, z] ] [, MASK_RULE={ 0 | 1 | 2 } ] [, PLANE_NORMAL=[x, y, z] ]
  [, PLANE_XAXIS=[x, y, z] ] [, RUN_LENGTH ] )
```

### Return Value

#### Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(0, (M_{roi} * Ext) + M_{in}), 255)$$

where  $M_{roi}$  is 255 and  $Ext$  is 1 for points within an exterior region and -1 for points within an interior region.

If the TYPE of the contained regions is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the contained regions is 1 (path), each pixel along the paths of the regions is set if it falls within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a contained region, and the pixel falls within that region (according to the MASK\_RULE).

### Arguments

None.

## Keywords

### DIMENSIONS

Set this keyword to a two-element vector,  $[xdim, ydim]$ , specifying the requested dimensions of the returned mask. If `MASK_IN` is provided, the value of this keyword is ignored, and the dimensions of that mask are used. Otherwise, the default dimensions are  $[100, 100]$ .

### INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- `-1` = The mask is not initialized; the default if the `MASK_IN` keyword is set. This option is useful when updating an already existing mask.
- `0` = The mask is initialized with each pixel set to 0; the default if the `MASK_IN` keyword is not set.
- `1` = The mask is initialized with each pixel set to 255.

### LOCATION

Set this keyword to a vector of the form  $[X, Y, Z]$  specifying the location of the origin of the mask. The default is  $[0, 0, 0]$ .

### MASK\_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type `BYTE` and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the `DIMENSIONS` keyword.

### MASK\_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- `0` = Boundary Only. All pixels falling on a region's boundary are set.
- `1` = Interior Only. All pixels falling within the region's boundary, but not on the boundary, are set.
- `2` = Boundary + Interior. All pixels falling on or within a region's boundary are set. This is the default.

## PLANE\_NORMAL

Set this keyword to a three-element vector,  $[x, y, z]$ , specifying the normal vector for the plane on which the mask is to be computed. The default is  $[0, 0, 1]$ .

## PLANE\_AXIS

Set this keyword to a three-element vector,  $[x, y, z]$ , specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is  $[1, 0, 0]$ .

## RUN\_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

## Version History

5.3	Introduced
5.6	Added RUN_LENGTH keyword

## IDLanROIGroup::ComputeMesh

The IDLanROIGroup::ComputeMesh function method triangulates a surface mesh with optional capping from the stack of regions contained within this group.

### Note

---

The contained regions may be concave. However, this method will fail under the following conditions:

- The region group contains fewer than two regions.
  - The TYPE property of the contained regions is 0 (points) or 1 (path).
  - Any of the contained regions are not simple (i.e., a region is self-intersecting).
  - The region group contains interior regions (holes).
  - More than one region lies on the same plane (i.e., the region group contains branches).
- 

Each region pair is normalized by perimeter and the triangulation is computed by walking the contours in parallel, keeping the normalized progress along each contour in sync. The returned triangulation minimizes the mesh surface area. Each vertex may appear only once in the output, and the resulting polygon mesh is solid with outward facing normals computed via the right-hand rule. If capping is requested, it is computed using the [IDLgrTessellator](#) on the top and bottom regions, and/or the regions on either side of an inter-slice gap.

## Syntax

```
Result = Obj->[IDLanROIGroup::]ComputeMesh( Vertices, Conn  
[, CAPPED={ 0 | 1 | 2}] [, SURFACE_AREA=variable] )
```

## Return Value

### Result

The return value of this function method is the number of triangles generated if the surface mesh triangulation is successful, or zero if unsuccessful.

## Arguments

### Vertices

An output [3, n] array of vertices. If all regions in the group are defined with single precision vertices (DOUBLE property is zero), then IDL returns a single precision floating point array. Otherwise, if any of the regions in the group are defined with double precision vertices (DOUBLE property is non-zero), then IDL returns a double precision floating point array.

### Conn

An output polygon mesh connectivity array.

## Keywords

### CAPPED

Set this keyword to a value to indicate whether flat caps are to be computed at the top-most or bottom-most regions (as selected by a counter-clockwise rule), or at the regions on either side of an inter-slice gap. The value of this keyword is a bit-wise OR of the values shown below. For example, to cap the top-most and bottom-most regions only, set the CAPPED keyword to 3. The default is 0 (no caps).

- 0 = no caps
- 1 = cap the top-most region
- 2 = cap the bottom-most region

### SURFACE\_AREA

Set this keyword to a named variable that upon return contains the overall surface area of the computed triangulation. This value was minimized in the computation of the triangulation. IDL returns this value in a double-precision floating-point variable.

## Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::ContainsPoints

The IDLanROIGroup::ContainsPoints function method determines whether the given points (in data coordinates) are contained within this region group.

The regions within this group must have a TYPE of 2 (closed polygon) and must fall on parallel planes for successful containment testing to occur.

For each point to be tested:

- If the point lies directly on one of the region planes, it is tested for containment within each of the regions that fall on that plane.
- If the point lies between two of the region planes, it is projected onto the nearest region plane, and tested for containment within each of the regions on that plane.
- If the point lies above or below the stack of parallel region planes, the point will be considered to be exterior to the region group.

On a given plane, a point will be considered to be exterior if either of the following conditions are true:

- The point does not fall within any of the regions on that plane.
- The point falls within as many or more holes than non-hole regions on that plane.

## Syntax

*Result* = *Obj*->[IDLanROIGroup::]ContainsPoints( *X*[, *Y*[, *Z*]] )

## Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly outside the bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On Edge. The point lies on an edge of the ROI boundary.
- 3 = On Vertex. The point matches a vertex of the ROI.

## Arguments

### X

A vector providing the  $X$  components of the points to be tested. If the  $Y$  and  $Z$  arguments are not specified,  $X$  must be a two-dimensional array with the leading dimension either 2 or 3 ( $[2,*]$  or  $[3,*]$ ), in which case,  $X[0,*]$  represents the  $X$  values,  $X[1,*]$  represents the  $Y$  values, and  $X[2,*]$  represents the  $Z$  values.

### Y

A vector providing the  $Y$  components of the points to be tested.

### Z

A scalar or vector providing the  $Z$  components of the points to be tested. If not provided, the  $Z$  components default to 0.0.

## Keywords

None.

## Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::GetProperty

The IDLanROIGroup::GetProperty procedure method retrieves the value of a property or group of properties for the region group.

### Syntax

*Obj*->[\[IDLanROIGroup::\]](#)GetProperty [, *PROPERTY=value*]

### Arguments

None.

### Keywords

Any property listed under “[IDLanROIGroup Properties](#)” on page 2986 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::Init

The IDLanROIGroup::Init function method initializes a region of interest group object.

### Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ\_NEW('IDLanROIGroup')

or

*Result* = *Obj*->[IDLanROIGroup::]Init( ) *(In a lifecycle method only.)*

## Arguments

None.

## Keywords

Any property listed under “IDLanROIGroup Properties” on page 2986 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::Rotate

The IDLanROIGroup::Rotate procedure method modifies the vertices for all regions within the group by applying a rotation.

### Syntax

*Obj*->[IDLanROIGroup::]Rotate, *Axis*, *Angle*[, CENTER=[ *x*, *y* [, *z* ] ] ]

### Arguments

#### Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the region group is to be rotated.

#### Angle

The angle, measured in degrees, by which to rotate the ROI group.

### Keywords

#### CENTER

Set this keyword to a two or three-element vector of the form [*x*, *y*], or [*x*, *y*, *z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

### Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::Scale

The IDLanROIGroup::Scale procedure method modifies the vertices for the region by applying a scale.

### Syntax

*Obj*->[IDLanROIGroup::]Scale, *Sx*[, *Sy*[, *Sz*]]

### Arguments

#### Sx

The X scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in X, *Sx*[1] represents the scale in Y, *Sx*[2] represents the scale in Z. IDL converts and applies this data in double-precision floating-point.

#### Sy

The Y scale factor. IDL converts and applies this data in double-precision floating-point.

#### Sz

The Z scale factor. IDL converts and applies this data in double-precision floating-point.

### Keywords

None.

### Version History

5.3	Introduced
-----	------------

## IDLanROIGroup::Translate

The IDLanROIGroup::Translate procedure method modifies the vertices of all regions within the group by applying a translation.

### Syntax

*Obj*->[IDLanROIGroup::]Translate, *Tx*[, *Ty*[, *Tz*]]

### Arguments

#### **Tx**

The *X* translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

#### **Ty**

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

#### **Tz**

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

### Keywords

None.

# IDLffDICOM

An IDLffDICOM object contains the data for one or more images embedded in a DICOM Part 10 file. The API to the IDLffDICOM object provides accessor methods to the basic data elements of a DICOM file, namely the group/element tag, value representation, length, and data values. Additional methods deal with the file header preamble, data dictionary description for individual elements, and embedded sequences of elements. Most methods take a DICOM group/element tag as a parameter. An alternative parameter to the DICOM tag in some methods is the reference. A reference value is a LONG integer that is unique to each element in the DICOM object. This value can be used to directly access a specific element and to differentiate between elements in the DICOM file that have the same group/element tag. Valid reference values are always positive.

See [“IDLffDICOM Object DICOM Conformance Summary”](#) on page 3006 for information regarding IDL DICOM file reading support.

---

**Note**

The [IDLffDicomEx](#) object greatly expands on the capabilities of the IDLffDICOM object and requires an additional license key to access the functionality. The IDLffDicomEx object includes methods for reading and writing pixel data to a DICOM file, and specifying the data compression. You can also add, modify, or remove public and private DICOM attribute tags, public and private sequences, and sets of repeating tags within sequences. See [Medical Imaging in IDL](#) for details.

---

## Superclasses

None

## Creation

See [“IDLffDICOM::Init”](#) on page 3035.

## Properties

Objects of this class have the following properties. See [“IDLffDICOM Properties”](#) on page 3010 for details on individual properties.

- [VERBOSE](#)

## Methods

This class has the following methods:

- [IDLffDICOM::Cleanup](#)
- [IDLffDICOM::DumpElements](#)
- [IDLffDICOM::GetChildren](#)
- [IDLffDICOM::GetDescription](#)
- [IDLffDICOM::GetElement](#)
- [IDLffDICOM::GetGroup](#)
- [IDLffDICOM::GetLength](#)
- [IDLffDICOM::GetParent](#)
- [IDLffDICOM::GetPreamble](#)
- [IDLffDICOM::GetReference](#)
- [IDLffDICOM::GetValue](#)
- [IDLffDICOM::GetVR](#)
- [IDLffDICOM::Init](#)
- [IDLffDICOM::Read](#)

# IDLffDICOM Object DICOM Conformance Summary

## Note

---

This Conformance Summary is for the IDLffDICOM object only and has no relevance to IDL's DICOM Network Services or DICOM Read/Write support (provided by the IDLffDicomEx object). See [www.rsinc.com/idl/dicom](http://www.rsinc.com/idl/dicom) for the current DICOM Conformance Statement. See the following information for the IDLffDICOM object's conformance information.

---

## Introduction

This section is an abbreviated DICOM conformance statement for the IDLffDICOM object, and specifies the compliance of this object's file reading support to the DICOM v3.0 standard. As described in the DICOM Standard PS 3.2 (Conformance), the purpose of this document is to outline the level of conformance to the DICOM standard and to enumerate the supported DICOM Service Classes, Information Objects, and Communications Protocols supported by the implementation of the IDLffDICOM object.

The IDLffDICOM object does not contain or support any of the DICOM services such as Storage, Query/Retrieve, Print, Verification, etc., so there will be no conformance claims relating to these services and no mention of any Application Entities for these services. Communications Protocol profiles will also be absent from this document for the same reasons. The remainder of this document will describe how the IDLffDICOM object handles the various Information Objects it is capable of reading.

## Reading of DICOM Part 10 files

IDL supports reading files that conform to the DICOM Standard PS 3.10 DICOM File Format. This format provides a means to encapsulate in a file the Data Set representing a SOP (Service Object Pair) Instance related to a DICOM IOD (Information Object Definition). Files written to disk in this DICOM File Format will be referred to as DICOM Part 10 files for the remainder of this document. Note that the IDLffDICOM object does NOT support the writing of files in this DICOM File Format, only reading.

## Encapsulated Transfer Syntaxes Supported

IDL supports reading DICOM Part 10 files whose contents have been written using the following Transfer Syntaxes. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2	Implicit VR Little Endian: Default Transfer Syntax for DICOM
1.2.840.10008.1.2.1	Explicit VR Little Endian
1.2.840.10008.1.2.2	Explicit VR Big Endian

*Table 6-1: Encapsulated Transfer Syntaxes Supported*

## Encapsulated Transfer Syntaxes NOT Supported

The IDLffDICOM object does NOT support reading DICOM Part 10 files whose contents have compressed data that has been written using the following Transfer Syntaxes. This object will NOT be able to access the data element (DICOM Tag field (7FE0,0010)) of files with these types of compressed data. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2.4.50	JPEG Baseline (Process 1): Default Transfer Syntax for Lossy JPEG 8 Bit Image Compression
1.2.840.10008.1.2.4.51	JPEG Extended (Process 2 & 4): Default Transfer Syntax for Lossy JPEG 12 Bit Image Compression (Process 4 only)
1.2.840.10008.1.2.4.52	JPEG Extended (Process 3 & 5)
1.2.840.10008.1.2.4.53	JPEG Spectral Selection, Non-Hierarchical (Process 6 & 8)
1.2.840.10008.1.2.4.54	JPEG Spectral Selection, Non-Hierarchical (Process 7 & 9)
1.2.840.10008.1.2.4.55	JPEG Full Progression, Non-Hierarchical (Process 10 & 12)

*Table 6-2: Encapsulated Transfer Syntaxes NOT Supported*

UID Value	UID Name
1.2.840.10008.1.2.4.56	JPEG Full Progression, Non-Hierarchical (Process 11 & 13)
1.2.840.10008.1.2.4.57	JPEG Lossless, Non-Hierarchical (Process 14)
1.2.840.10008.1.2.4.58	JPEG Lossless, Non-Hierarchical (Process 15)
1.2.840.10008.1.2.4.59	JPEG Extended, Hierarchical (Process 16 & 18)
1.2.840.10008.1.2.4.60	JPEG Extended, Hierarchical (Process 17 & 19)
1.2.840.10008.1.2.4.61	JPEG Spectral Selection, Hierarchical (Process 20 & 22)
1.2.840.10008.1.2.4.62	JPEG Spectral Selection, Hierarchical (Process 21 & 23)
1.2.840.10008.1.2.4.63	JPEG Full Progression, Hierarchical (Process 24 & 26)
1.2.840.10008.1.2.4.64	JPEG Full Progression, Hierarchical (Process 25 & 27)
1.2.840.10008.1.2.4.65	JPEG Lossless, Hierarchical (Process 28)
1.2.840.10008.1.2.4.66	JPEG Lossless, Hierarchical (Process 29)
1.2.840.10008.1.2.4.70	JPEG Lossless, Non-Hierarchical, First-Order Prediction (Process 14 [Selection Value 1]): Default Transfer Syntax for Lossless JPEG Image Compression
1.2.840.10008.1.2.5	RLE Lossless

*Table 6-2: Encapsulated Transfer Syntaxes NOT Supported (Continued)*

## Encapsulated SOP Classes Supported

The IDLffDICOM object supports reading DICOM Part 10 files whose contents encapsulate the data of the following SOP Classes. The SOP Class UID is in the file's DICOM Tag field (0008,0016).

UID Value	UID Name
1.2.840.10008.5.1.4.1.1.1	CR Image Storage
1.2.840.10008.5.1.4.1.1.2	CT Image Storage
1.2.840.10008.5.1.4.1.1.4	MR Image Storage

*Table 6-3: Encapsulated SOP Classes Supported*

UID Value	UID Name
1.2.840.10008.5.1.4.1.1.6.1	Ultrasound Image Storage
1.2.840.10008.5.1.4.1.1.7	Secondary Capture Image Storage
1.2.840.10008.5.1.4.1.1.12.1	X-Ray Angiographic Image Storage
1.2.840.10008.5.1.4.1.1.12.2	X-Ray Radiofluoroscopic Image Storage
1.2.840.10008.5.1.4.1.1.20	Nuclear Medicine Image Storage
1.2.840.10008.5.1.4.1.1.128	Positron Emission Tomography Image Storage

*Table 6-3: Encapsulated SOP Classes Supported (Continued)*

## Handling of odd length data elements

The DICOM Standard PS 3.5 (Data Structures and Encoding) specifies that the data element values which make up a DICOM data stream must be padded to an even length. The toolkit upon which IDL's DICOM reading functionality is built strictly enforces this specification. If IDL encounters an incorrectly formed odd length data field while reading a DICOM Part 10 file it will report an error and stop the reading process.

## Handling of undefined VRs

The VR (Value Representation) of a data element describes the data type and format of that data element's values. If IDL encounters an undefined VR while reading a DICOM Part 10 file, it will set that data element's VR to be UN (unknown).

## Handling of retired and private data elements

Certain data elements are no longer supported under the v3.0 of the DICOM standard and are denoted as retired. Also, some DICOM implementations may require the communication of information that cannot be contained in standard data elements, and thus create private data elements to contain such information. Retired and private data elements should pose no problem to IDL's DICOM Part 10 file reading capability. When the IDLffDICOM object encounters a retired or private data element tag during reading a DICOM Part 10 file, it will treat it just like any standard data element: read the data value and allow it to be accessed via the IDLffDICOM::GetValue method.

## IDLffDICOM Properties

IDLffDICOM objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffDICOM::Init](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [VERBOSE](#)

### VERBOSE

A Boolean value that indicates whether informational messages are printed to the Output Log during the operational life of the object. If this value is true, the informational messages are printed to the Output Log. Otherwise, the messages are not printed.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffDICOM::Cleanup

The IDLffDICOM::Cleanup procedure method destroys the IDLffDICOM object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLffDICOM:]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER="*"))
obj->DumpElements
OBJ_DESTROY, obj

; Executing this statement should produce an invalid object
; reference error since obj no longer exists:
obj->DumpElements
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::DumpElements

The IDLffDICOM::DumpElements procedure method dumps a description of the DICOM data elements of the IDLffDICOM object to the screen or to a file.

### Syntax

*Obj*->[IDLffDICOM::]DumpElements [, *Filename*]

### Arguments

#### Filename

A scalar string containing the full path and filename of the file to which to dump the elements. The file is written as ASCII text.

### Keywords

None

### Examples

The columns output by DumpElements are the element reference, the (group, element) tuple, the value representation, the description, the value length, and some of the data values.

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements

; Dump the contents of the current DICOM object to a file under
; Windows:
obj->DumpElements, 'c:\rsi\elements.dmp'

; Dump the contents of the current DICOM object to a file under
; UNIX:
obj->DumpElements, '/rsi/elements.dmp'

OBJ_DESTROY, obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetChildren

The IDLffDICOM::GetChildren function method is used to find the member element references of a DICOM sequence. It takes as an argument a scalar reference to a DICOM element representing the parent of the sequence.

### Syntax

*Result* = *Obj*->[IDLffDICOM::]GetChildren(*Reference*)

### Return Value

Returns an array of references to the elements of the object that are members of that sequence. The scalar parent reference is possibly obtained by a previous call to GetReference or any method that generates a reference list. Any member of a sequence may also itself be the parent of another sequence. If the scalar reference argument is not the parent of a sequence, the method returns -1.

### Arguments

#### Reference

A scalar reference to a DICOM element that is known to be the parent of a DICOM sequence.

### Keywords

None

### Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get a list of references to all elements that are sequences:
refs = obj->GetReference(VR='SQ')

; Cycle through the returned list and print out the immediate
; children references and descriptions of each sequence:
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
    IF (refs[i] NE -1) THEN $
        BEGIN
            children = obj->GetChildren(refs[i])
```

```
FOR j = 0, N_ELEMENTS(children)-1 DO $
  BEGIN
    PRINT, children[j]
    PRINT, obj->GetDescription(REFERENCE=children[j])
  ENDFOR
ENDIF
ENDFOR
OBJ_DESTROY, obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetDescription

The IDLffDICOM::GetDescription function method takes optional DICOM group and element arguments and returns an array of STRING descriptions.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetDescription([Group [, Element]]  
[, REFERENCE=list of element references])
```

### Return Value

Returns an array of strings describing the field's contents as per the data dictionary in the DICOM specification PS 3.6. If no arguments or keywords are specified, the returned array contains the descriptions for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no DICOM elements can be found matching the search criteria, -1 will be returned.

### Arguments

#### Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

#### Element

An optional argument specified only if the *Group* argument has also been specified. Set this argument to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

### Keywords

#### REFERENCE

Set this keyword to a list of element reference values from which to return description values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the description of the patient name element:
arr = obj->GetDescription('0010'x,'0010'x)
PRINT, arr

; Get array of all of the descriptions from the patient info group:
arr = obj->GetDescription('0010'x)
FOR i = 0, N_ELEMENTS(arr)-1 DO BEGIN
    PRINT, arr[i]
ENDFOR

OBJ_DESTROY, obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetElement

The IDLffDICOM::GetElement function method takes optional DICOM group and/or element arguments and returns an array of DICOM Element numbers for those parameters.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetElement([Group [, Element]]  
[, REFERENCE=list of element references])
```

### Return Value

Returns an array of integers representing the DICOM Element numbers for the parameters of the *Group* and *Element* arguments. If no arguments or keywords are specified, the returned array contains Element numbers for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

### Arguments

#### Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

#### Element

An optional argument specified only if the Group argument has also been specified. Set this argument to the value for the DICOM element to search for, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

### Keywords

#### REFERENCE

Set this keyword to a list of element reference values from which to return element number values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the element numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
    num = obj->GetElement(REFERENCE=refs[i])
    PRINT,num
ENDFOR

; Get the element numbers from the Patient Info group, 0010:
elements = obj->GetElement('0010'x)
PRINT, elements

OBJ_DESTROY,obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetGroup

The IDLffDICOM::GetGroup function method takes optional DICOM group and/or element arguments and returns an array of DICOM Group numbers for those parameters.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetGroup([Group[, Element]]  
[, REFERENCE=list of element references])
```

### Return Value

Returns an array of integers representing the DICOM Group numbers for *Group* parameters. If no arguments or keywords are specified, the returned array contains Group numbers for all groups in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

### Arguments

#### Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

#### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

### Keywords

#### REFERENCE

Set this keyword to a list of element references from which to return group number values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the group numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
    num = obj->GetGroup(REFERENCE=refs[i])
    PRINT, num
ENDFOR

; Get the group numbers from the Patient Info group, 0010:
grp = obj->GetGroup('0010'x)
PRINT, grp

OBJ_DESTROY,obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetLength

The IDLffDICOM::GetLength function method takes optional DICOM group and/or element arguments and returns an array of LONGs.

### Syntax

*Result = Obj->*[IDLffDICOM::]GetLength(*[Group [, Element]] [, REFERENCE=list of element references]*)

### Return Value

Returns an array of longword integers. The length is the field length that explicitly exists in the DICOM file, and represents the length of the element value in bytes. If no arguments or keywords are specified, the returned array contains the lengths for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

### Arguments

#### Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, all DICOM array elements are returned.

#### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

### Keywords

#### REFERENCE

Set this keyword to a list of element references from which to return length values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the length of the patient name element:
arr = obj->GetLength('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the lengths from the patient info group:
arr = obj->GetLength('0010'x)
PRINT, arr
OBJ_DESTROY, obj
```

## Version History

---

5.2	Introduced
-----	------------

---

## IDLffDICOM::GetParent

The IDLffDICOM::GetParent function method is used to find the parent references of a set of elements in a DICOM sequence.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetParent(ReferenceList)
```

### Return Value

Returns the parent references of a set of elements in a DICOM sequence. It takes as an argument an array of references that represent DICOM elements. If no members of the *ReferenceList* are members of a sequence, a -1 is returned, and for each member of the *ReferenceList* which is not a member of a sequence, a -1 is returned.

### Arguments

#### ReferenceList

An array of references to DICOM elements that are known to be members of a DICOM sequence.

### Keywords

None

### Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the Referenced Study Sequence
; element, if it exists:
ref = obj->GetReference('0008'x, '1110'x)
PRINT, ref
PRINT, obj->GetDescription(REFERENCE = ref)

; Get and print the parent sequence, if it exists.
; This should result in a -1 since this element is not
; a member of a sequence:
parent = obj->GetParent(ref)
PRINT, parent
```

```
PRINT, obj->GetDescription(REFERENCE=parent)

; Get the children of the Referenced Study Sequence
; element, if it exists:
refs = obj->GetChildren(ref[0])
PRINT, refs
PRINT, obj->GetDescription(REFERENCE = refs)
OBJ_DESTROY, obj
```

## Version History

5.2	Introduced

## IDLffDICOM::GetPreamble

The IDLffDICOM::GetPreamble function method returns the preamble of a DICOM v3.0 Part 10 file.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetPreamble()
```

### Return Value

Returns a 128-element byte array containing the preamble, which is a fixed 128 byte field available for implementation specified usage. If it is not used by the implementor of the file, it will be set to all zeroes.

### Arguments

None

### Keywords

None

### Examples

```
; Create a DICOM object, read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get an array of the byte contents of the DICOM file preamble:
arr = obj->GetPreamble()
PRINT, arr

OBJ_DESTROY, obj
```

### Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetReference

The IDLffDICOM::GetReference function method takes optional DICOM group and/or element arguments and returns an array of references to matching elements in the object.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetReference([Group [, Element]]  
[, DESCRIPTION=string] [, VR=DICOM VR string])
```

### Return Value

Returns an array referencing the matching elements in the object. References are opaque, meaning that they have no specific significance other than a correspondence to the element they refer to. If no arguments or keywords are specified, the returned array contains references to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

### Arguments

#### Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

#### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element to search for, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

### Keywords

#### DESCRIPTION

Set this keyword to a string containing text to be searched for in each element's DICOM description. An element will be returned only if the text in this string can be found in the description. The text comparison is case-insensitive.

## VR

Set this keyword to a DICOM VR string. An element will be returned only if its value representation matches this string.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the patient name element:
ref = obj->GetReference('0010'x,'0010'x)
PRINT, ref

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION = 'patient')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
    PRINT, refs[i]
    PRINT, obj->GetDescription(REFERENCE = refs[i])
ENDFOR

; Get references to all elements with a VR of DA (date):
refs = obj->GetReference(vr = 'DA')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
    PRINT, refs[i]
    PRINT, obj->GetDescription(REFERENCE = refs[i])
ENDFOR

OBJ_DESTROY, obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::GetValue

This method takes optional DICOM group and/or element arguments and returns an array of POINTERS to the values of the elements matching those parameters.

### Syntax

```
Result = Obj->[IDLffDICOM::]GetValue([Group [, Element]]  
    [, REFERENCE=list of element references] [, /NO_COPY])
```

### Return Value

Returns an array of pointers to the values of the elements matching the *Group* and *Element* parameters. If no arguments or keywords are specified, the returned array contains pointers to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

### Arguments

#### Group

Set this optional argument to the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

#### Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

### Keywords

#### REFERENCE

Set this keyword to a list of element references from which to return pointer values.

## NO\_COPY

If this keyword is set, the pointers returned point to the actual data in the object for the specified DICOM fields. If not set (the default), the pointers point to copies of the data instead, and need to be freed by using PTR\_FREE.

## Examples

### Example 1

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the image data
array = obj->GetValue('7fe0'x, '0010'x)
OBJ_DESTROY, obj

TVScl, *array[0]
PTR_FREE, array
```

### Example 2

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get all of the image data element(s), 7fe0,0010, from the file:
array = obj->GetValue('7fe0'x,'0010'x,/NO_COPY)

; Get the row & column size of the image(s):
rows = obj->GetValue('0028'x,'0010'x,/NO_COPY)
cols = obj->GetValue('0028'x,'0011'x,/NO_COPY)

; If the image has a samples per pixel value greater than 1
; it is most likely a color image, get the samples per pixel:
isColor = 0
samples = obj->GetValue('0028'x,'0002'x,/NO_COPY)
IF (SIZE(samples,/N_DIMENSIONS) NE 0) THEN BEGIN
    IF (*samples[0] GT 1) THEN isColor = 1
ENDIF

; Next, we need to differentiate between files with color data
; that is either color-by-plane or color-by-pixel, get the planar
; configuration:
IF (isColor EQ 1) THEN BEGIN
    isPlanar = 0
    planar = obj->GetValue('0028'x,'0006'x, /NO_COPY)
    IF (SIZE(planar, /N_DIMENSIONS) NE 0) THEN BEGIN
```

```

        IF (*planar[0] EQ 1) THEN isPlanar = 1
    ENDIF
ENDIF

; Display the first NumWin images from the file:
IF N_ELEMENTS(array) GT 10 THEN NumWin = 10 $
ELSE NumWin = N_ELEMENTS(array)
offset = 0
FOR index = 0, NumWin-1 DO BEGIN
    ; Create window for each image that is the size of the image:
    WINDOW,index,XSize=*cols[0],YSize=*rows[0],XPos=offset,YPos=0
    WSET,index
    ; Display the image data
    IF (isColor EQ 1) THEN $
        IF (isPlanar EQ 1) THEN $
            ; color-by-plane
            TVScl,TRANPOSE(*array[index],[2,0,1]),/TRUE $
        ELSE $
            ; color-by-pixel
            TVScl,*array[index],/TRUE $
        ELSE $
            ; monochrome
            TVScl,*array[index]
            offset = offset+10
        ENDIF
    ENDFOR

; Clean up
OBJ_DESTROY,obj

```

## IDLffDICOM::GetVR

The IDLffDICOM::GetVR function method takes optional DICOM group and/or element arguments and returns an array of VR (Value Representation) STRINGS for those parameters.

### Syntax

```
array = Obj->[IDLffDICOM::]GetVR([Group [, Element]]  
    [, REFERENCE=list of references])
```

### Return Value

Returns an array of strings containing VRs (Value Representations) for the *Group* and *Element* parameters. A VR is a DICOM value representation as described in the DICOM specification PS 3.5. If no arguments or keywords are specified, the returned array contains VRs for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

### Arguments

#### Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

#### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

### Keywords

#### REFERENCE

Use the specified list of references from which to return VR STRING values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the VR of the patient name element:
arr = obj->GetVR('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the VRs from the patient info group:
arr = obj->GetVR('0010'x)
PRINT, arr

OBJ_DESTROY,obj
```

## Version History

## IDLffDICOM::Init

The IDLffDICOM::Init function method creates a new IDLffDICOM object and optionally reads the specified file as defined in the IDLffDICOM::Read method.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Result = OBJ_NEW( 'IDLffDICOM' [, Filename] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLffDICOM::]Init([Filename] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

An optional scalar string argument containing the full path and filename of a DICOM v3.0 Part 10 file to open, read into memory, then close, when the object is created. It is the same as calling: result->Read(Filename).

## Keywords

Any property listed under “IDLffDICOM Properties” on page 3010 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Examples

```
; Create a DICOM object:
obj = OBJ_NEW( 'IDLffDICOM' )

; Create a DICOM object and read in a DICOM file named
; mr_brain.dcm:
obj = OBJ_NEW( 'IDLffDICOM', $
    FILEPATH('mr_brain.dcm', SUBDIRECTORY=['examples', 'data']))

; Create a DICOM object and allow the user to choose a DICOM file
; to be read:
obj = OBJ_NEW( 'IDLffDICOM', DIALOG_PICKFILE(FILTER='*'))
```

## Version History

---

5.2	Introduced
-----	------------

---

## IDLffDICOM::Read

The IDLffDICOM::Read function method opens and reads from the specified disk file, places the information into the DICOM object, then closes the file.

### Syntax

*Result* = *Obj*->[IDLffDICOM::]Read(*Filename* [, **ENDIAN**={1 | 2 | 3 | 4}])

### Return Value

Return a 1 if successful and 0 otherwise.

### Arguments

#### Filename

A scalar string argument containing the full path and filename of a DICOM Part 10 file to open and read into memory.

### Keywords

#### ENDIAN

Set this keyword to configure the endian format when reading a DICOM file.

- 1 = Implicit VR Little Endian
- 2 = Explicit VR Little Endian
- 3 = Implicit VR Big Endian
- 4 = Explicit VR Big Endian

### Examples

```
; Create a DICOM object and read a DICOM file:  
obj = OBJ_NEW('IDLffDICOM')  
var = obj->Read(DIALOG_PICKFILE(FILTER = '*'))  
OBJ_DESTROY, obj
```

## Version History

5.2	Introduced
-----	------------

## IDLffDICOM::Reset

The IDLffDICOM::Reset procedure method removes all of the elements from the IDLffDICOM object, leaving the object otherwise intact.

### Syntax

*Obj*->[IDLffDICOM::Reset](#)

### Arguments

None

### Keywords

None

### Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements
obj->Reset

; DumpElements should produce no output here:
obj->DumpElements
OBJ_DESTROY, obj
```

### Version History

# IDLffDXF

An IDLffDXF object contains geometry, connectivity and attributes for graphics primitives.

---

**Note**

IDL supports version 2.003 of the DXF Library.

---

---

**Note**

IDL does not provide DXF functionality under Macintosh OS X or on 64-bit platforms.

---

This object treats a DXF file as a list of entities. Note, these are not directly mapped to DXF entity types, rather they are an abstraction of the DXF types. The Read method is used to read the contents of a DXF file into the current entity list. The user may then query this list using the GetContents method to determine the types and number of entities in the file. The user may retrieve arrays of entities from the list using the GetEntity method and add additional entities using the PutEntity method. Entities can also be removed from the list (RemoveEntity) or the entire list destroyed (Reset). The current list of entities can also be written to disk as a DXF file. Note, this object converts DXF entities to IDL entities and back. This conversion is not reversible; thus, if a DXF file is read and then written, the data in the file is not changed, but the internal DXF entity types may be changed by IDL. As an example, DXF face3d entities may be written as DXF polyline entities.

The object has one attribute which can be modified using the Get/SetPalette methods. This palette is used to convert color index values. The palette is not actually written to the DXF file. So, if the user wanted to specify entity colors from a 256 entry table, that table would be set using SetPalette, but the actual colors written to the file are the closest colors matched to the fixed AutoCAD color palette. There are two special color values: (0) = color by block color, (256) = color by layer color.

In this object, blocks and layers are treated as named entities with attributes, but are special in that all other entities have a block and layer entity reference in them. This allows the user to use these entity names as filters for many operations. There is a default block and a default layer. The default block has the name "" (the null string), and the default layer is '0'. The user may change the (non-name) attributes for these implicit blocks using PutEntity.

## Superclasses

None

## Creation

See “[IDLffDXF::Init](#)” on page 3061

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- [IDLffDXF::Cleanup](#)
- [IDLffDXF::GetContents](#)
- [IDLffDXF::GetEntity](#)
- [IDLffDXF::GetPalette](#)
- [IDLffDXF::Init](#)
- [IDLffDXF::PutEntity](#)
- [IDLffDXF::Read](#)
- [IDLffDXF::RemoveEntity](#)
- [IDLffDXF::Reset](#)
- [IDLffDXF::SetPalette](#)
- [IDLffDXF::Write](#)

## Version History

5.2	Introduced
-----	------------

## IDLffDXF Properties

Objects of this class have no properties of their own.

## IDLffDXF::Cleanup

The IDLffDXF::Cleanup procedure method performs all cleanup on the object.

### Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLffDXF::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## Version History

5.2	Introduced
-----	------------

## IDLffDXF::GetContents

The IDLffDXF::GetContents function method returns a description of the content of the DXF file.

See the [Examples](#) following the GetEntity method description for an illustration of the difference between the GetContents and the GetEntity methods.

### Note

The Read or PutEntity methods must have been called previously for the results of this method to be valid.

Valid DXF ENTITY Types	DXF_TYPE ( 0=default)

<b>Valid DXF ENTITY Types</b>	<b>DXF_TYPE ( 0=default)</b>
POINT	16
SPLINE	17
BLOCK	18
INSERT	19
LAYER	20

*Table 6-4: DXF Entity Types (Continued)*

This object uses a small number of IDL named structures to return the data associated with each entity. This means that several of these DXF types are returned in the same structures, using different values of the DXF\_TYPE field. The mapping of DXF entities to IDL named structures is as follows (each of these structures is documented in the GetEntity method):

<b>IDL Structure</b>	<b>DXF Entity</b>
IDL_DXF_ELLIPSE	arc, circle, ellipse
IDL_DXF_POLYLINE	line, line3d, trace, polyline, lwpolyline
IDL_DXF_POLYGON	face3d, solid, polyline (3-d mesh)
IDL_DXF_POINT	point
IDL_DXF_XLINE	ray, xline
IDL_DXF_SPLINE	spline
IDL_DXF_TEXT	text, multitext
IDL_DXF_BLOCK	block
IDL_DXF_INSERT	insert
IDL_DXF_LAYER	layer

*Table 6-5: DXF mapping to IDL structures*

## Syntax

```
Result = Obj->[IDLffDXF::]GetContents( [Filter] [, BLOCK=string]
    [, COUNT=variable] [, LAYER=string] )
```

## Return Value

Returns an integer array containing the DXF entity type codes and the number of occurrences of each entity type contained in the object

## Arguments

### Filter

An integer array of the DXF entity types to which the return types are restricted. If set, Result can contain only types given in this argument and count will also reflect that restriction.

## Keywords

### BLOCK

Set this keyword to a string value containing the block name to obtain the entities from. The default is all blocks.

### COUNT

A long array containing the number of each entity type contained within the DXF object. If the Filter argument was provided, the numbers reflect the reduced set of entities caused by the Filter argument.

### LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

## Version History

5.2	Introduced
-----	------------

## IDLffDXF::GetEntity

The IDLffDXF::GetEntity function method returns an array of data for the requested entity type.

### Syntax

```
Result = Obj->[IDLffDXF::]GetEntity(Type [, BLOCK=string] [, INDEX=value] [, LAYER=string])
```

### Return Value

Returns one of the named structure formats described in “[Structure Formats](#)” on page 3049.

### Arguments

#### Type

The integer DXF entity type from which to obtain the geometry information.

### Keywords

#### BLOCK

Set this keyword to a block name specifying the graphic block from which to obtain the entity geometry information. The default is all blocks. Setting this keyword to the null string "" will cause this method to only return entities from the default DXF entity block.

#### INDEX

Set this keyword to a scalar index or a long array of indices of entities of the given type to return. If not set, this method returns all entities for the given type.

#### LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

## Fields Common to All Structures

### BLOCK

The name of the block this entity is in (these may be in the default block “”).

### COLOR

A color index value into the current object palette with 0=use block color and 256=use layer color.

### EXTRUSION

The DXF extrusion vector (if any).

### LAYER

The name of the layer this entity is in (the default layer is '0').

### LINETYPE

Defined the same as the user linestyle for IDLgrPolyline::Init.

---

**Note**

IDL will always return a solid line regardless of the linestyle in DXF

---

### THICKNESS

In AutoCAD units.

### DXF\_TYPE

Set to one of the values listed in IDLffDXF::GetContents.

---

**Note**

It is the user's responsibility to free all the pointers returned in these structures when the entity is no longer needed.

---

## Structure Formats

### Structure IDL\_DXF\_ELLIPSE

Field	Data Type
PT0	Double [3]
PT1_OFFSET	Double [3]
MIN_TO_MAJ_RATIO	Double
START_ANGLE	Double
END_ANGLE	Double
EXTRUSION	Double [3]
LINESTYLE	Integer [2]
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

*Table 6-6: Fields of the IDL\_DXF\_ELLIPSE Structure*

This object is centered at PT0 and has a radius defined by the vector PT1\_OFFSET. This vector determines the length and orientation of the major axis of an ellipse as well.

The MIN\_TO\_MAJ\_RATIO value specifies the length of the minor axis as a fraction of the major axis length. For a circle, this value is 1.0.

The START\_ANGLE and END\_ANGLE values select the portion of the curve to be drawn. If they are equal, the entire circle or ellipse is drawn.

## Structure IDL\_DXF\_POLYGON

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
COLOR	Integer
EXTRUSION	Double [3]
FIT_TYPE	Integer
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

*Table 6-7: Fields of the IDL\_DXF\_POLYGON Structure*

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polygons (see the POLYGONS keyword for IDLgrPolygon::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH\_DIMS; the vertices represent a quad mesh of dimensions (MESH\_DIMS[0], MESH\_DIMS[1]).

### Note

If a connectivity array is not supplied and the MESH\_DIMS are left at 0,0, then IDL will tessellate the vertex list and store the polygon with the resulting connectivity list. If tessellation fails, IDL will throw an error that should be detected and dealt with using the CATCH mechanism. An alternative to this is to pass the polygon to the IDLgrTessellator object, which returns a zero instead of throwing an error if tessellation fails. The results of a successful tessellation can be put into a DXF

entity and passed to the IDLffDXF object, which will not attempt to tessellate the polygon as it has already been tessellated.

VERTEX\_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT\_TYPE, CURVE\_FIT, and SPLINE\_FIT return the type of curve fit (if any) this polygon assumes.

## Structure IDL\_DXF\_POLYLINE

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
COLOR	Integer
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
THICKNESS	Double
LINETYPE	Integer [2]
EXTRUSION	Double [3]
FIT_TYPE	String
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 6-8: Fields of the IDL\_DXF\_POLYLINE Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polylines (see the POLYLINES keyword for IDLgrPolyline::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH\_DIMS; the vertices represent a quad mesh of dimensions (MESH\_DIMS[0], MESH\_DIMS[1]).

VERTEX\_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT\_TYPE, CURVE\_FIT, and SPLINE\_FIT return the type of curve fit (if any) this polyline assumes.

## Structure IDL\_DXF\_POINT

Field	Data Type
PT0	Double [3]
UCSX_ANGLE	Double
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

*Table 6-9: Fields of the IDL\_DXF\_POINT Structure*

PT0 is the location of the point in space.

UCSX\_ANGLE is an internal DXF orientation parameter used for symbol plotting.

## Structure IDL\_DXF\_SPLINE

Field	Data Type
CTR_PTS	Pointer
FIT_PTS	Pointer
KNOTS	Pointer
WEIGHTS	Pointer
COLOR	Integer
DEGREE	Integer
PERIODIC	Integer
RATIONAL	Integer
PLANAR	Integer
LINEAR	Integer
KNOT_TOLERANCE	Double
CTL_TOLERANCE	Double
FIT_TOLERANCE	Double
START_TANGENT	Double [3]
END_TANGENT	Double [3]
THICKNESS	Double
LINestyle	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

*Table 6-10: Fields of the IDL\_DXF\_SPLINE Structure*

This structure is returned verbatim from the DXF spline structure without interpretation. It is up to the user to interpret these values.

## Structure IDL\_DXF\_TXT

Field	Data Type
PT0	Double [3]
TEXT_STR	String
COLOR	Integer
HEIGHT	Double
WIDTH_FACTOR	Double
BOX_WIDTH	Double
DIRECTION	Double [3]
ROT_ANGLE	Double
JUSTIFICATION	Integer (0=left, 1=center, 2=right, 3=aligned, 4=middle, 5=fit)
VERTICAL_ALIGN	Integer (0=baseline, 1=bottom, 2=middle, 3=top)
SHAPE_FILE	String
THICKNESS	Double
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

*Table 6-11: Fields of the IDL\_DXF\_TXT Structure*

PT0 is the location of the text string.

TEXT\_STR is the actual string.

HEIGHT specifies the overall scaling of the glyphs while WIDTH\_FACTOR is a correction in the baseline direction (anisotropic scaling). For multi-line text, BOX\_WIDTH determines where the line breaks should be placed (0.0 for single line text).

The text baseline is specified by `DIRECTION` and its rotation about the  $z$ -axis is specified by `ROT_ANGLE`. Justification is specified by `JUSTIFICATION` and `VERTICAL_ALIGN`. `SHAPE_FILE` is the name of the glyph file used to image this string. The shape file is NOT read by IDL.

### Structure `IDL_DXF_XLINE`

Field	Data Type
<code>PT0</code>	Double [3]
<code>UNIT_VEC</code>	Double [3]
<code>COLOR</code>	Integer
<code>THICKNESS</code>	Double
<code>LINestyle</code>	Integer [2]
<code>EXTRUSION</code>	Double [3]
<code>DXF_TYPE</code>	Integer
<code>BLOCK</code>	String
<code>LAYER</code>	String

*Table 6-12: Fields of the `IDL_DXF_XLINE` Structure*

`PT0` is the start of a ray or a point on a infinite line in space in the case of an `XLINE` entity.

`UNIT_VEC` determines the direction of the line in space.

## Structure IDL\_DXF\_INSERT

Field	Data Type
SCALE	Double [3]
PT0	Double [3]
ROTATION	Double
INSTANCE_BLOCK	String
NUM_ROW_COL	Integer [2]
DISTANCE_BETWEEN	Double [2]
DXF_TYPE	Integer
BLOCK	String
COLOR	Integer
LAYER	String

*Table 6-13: Fields of the IDL\_DXF\_INSERT Structure*

The insert entity allows for the “instancing” of a block in a grid fashion.

INSTANCE\_BLOCK is the name of a block to repeat.

The block is scaled by SCALE and rotated about the Z axis by ROTATION. The grid begins at PT0 and contains the number of rows and columns specified by NUM\_ROW\_COL (Note: 0 rows or columns will always give a single instance of the block).

The spacing of the grid is specified by DISTANCE\_BETWEEN.

## Structure IDL\_DXF\_BLOCK

Field	Data Type
PT0	Double [3]
COLOR	Integer
NAME	String
DXF_TYPE	Integer

*Table 6-14: Fields of the IDL\_DXF\_BLOCK Structure*

This entity specifies a BLOCK. Blocks have a location in space (PT0) [objects in the block are interpreted relative to this point], a name, and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

## Structure IDL\_DXF\_LAYER

Field	Data Type
COLOR	Integer
NAME	String
DXF_TYPE	Integer

*Table 6-15: Fields of the IDL\_DXF\_LAYER Structure*

This entity specifies a LAYER. Layer is a NAME and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

## Examples

This example illustrates the difference between the GetEntity and GetContents methods within the IDLffDXF object method. The GetContents method gives a description of the content of the file read, listing the entity types and the number of occurrences. GetEntity accesses the values returned by GetContents and determines how the entities can be logically combined into common structures for drawing efficiency.

```

PRO view_heart
; Determine path to data file.
heartFile = FILEPATH('heart.dxf', $
    SUBDIRECTORY = ['examples', 'data'])
; Initialize DXF data access object.
oHeart = OBJ_NEW('IDLffDXF')
; Read data within DXF file into access object.
status = oHeart->Read(heartFile)
; Determine what type of entities (and how many of
; each entity) exist in the file.
heartTypes = oHeart->GetContents(COUNT = heartCounts)
PRINT, 'Entity Types: ', heartTypes
PRINT, 'Count of Types: ', heartCounts
; Initialize a model for displaying polygon and polyline
; objects.
oModel = OBJ_NEW('IDLgrModel')
; Obtain the tissue data. The tissue is accessed into
; IDL as a single polygon.
tissue = oHeart->GetEntity(heartTypes[1])
HELP, tissue
HELP, tissue, /STRUCTURE
; Initialize color parameter.
tissueColor = [255, 0, 0]
; Initialize polygon data.
vertices = tissue.vertices
connectivity = tissue.connectivity
; Initialize the polygon object.
oTissue = OBJ_NEW('IDLgrPolygon', $
    *vertices, POLYGONS = *connectivity, $
    COLOR = tissueColor)
; Add the polygon to the model.
oModel->Add, oTissue
; Clean-up all the related pointers.
PTR_FREE, tissue.vertices, tissue.connectivity, $
    tissue.vertex_colors
PTR_FREE, vertices, connectivity
; Display the polylines and the polygon in the XOBJVIEW
; utility.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75
; Clean-up the object references.
OBJ_DESTROY, [oHeart, oModel]
END

```

An XOBJVIEW window with the mesh heart object appears when this program is compiled and run. The following lines are found in the IDLDE Output Log window.

```

IDL> view_heart
% Compiled module: VIEW_HEART.
% Compiled module: FILEPATH.

```

```

% Loaded DLM: DXF.
Entity Types:           7           10           18           20
Count of Types:        13          1624           1           2

```

The Entity Types (7, 10, 18, and 20) are the GetContents method return values corresponding to the occurrence of DXF ENTITY types found in the object: POLYLINES, FACE3D, BLOCK, and LAYER, respectively. Note there are a total of 1624 FACE3D entity types, but for efficiency and speed IDL logically combines all of the similar entities into a single structure that can be used in an IDLgrPolygon object. This is illustrated by the output resulting from the first Help command in the program as shown below.

```

TISSUE          STRUCT    ==>IDL_DXF_POLYGON Array[1]
** Structure IDL_DXF_POLYGON, 13 tags, length=72:
  EXTRUSION      DOUBLE    Array[3]
  VERTICES       POINTER    <PtrHeapVar3>
  CONNECTIVITY   POINTER    <PtrHeapVar4>
  VERTEX_COLORS  POINTER    <PtrHeapVar5>
  MESH_DIMS      INT        Array[2]
  CLOSED         INT        Array[2]
  COLOR          INT        256
  FIT_TYPE       INT        -1
  CURVE_FIT      INT        0
  SPLINE_FIT     INT        0
  DXF_TYPE       INT        10
  BLOCK         STRING     ''
  LAYER         STRING     '0----'
% Compiled module: XOBJVIEW.
% Compiled module: UNIQ.
% Compiled module: IDENTITY.
% Compiled module: XMANAGER.

```

Note that the tissue is represented as an array of polygons having 1 element. This is evident by the mesh representation of the heart object showing the 1624 individual polygons as a single object.

## Version History

5.2	Introduced
-----	------------

## IDLffDXF::GetPalette

The IDLffDXF::GetPalette procedure method returns the current color table in the object.

### Syntax

*Obj*->[IDLffDXF::]GetPalette, *Red*, *Green*, *Blue*

### Arguments

#### Red

Returns an array of the red components to the current color table.

#### Green

Returns an array of the green components to the current color table.

#### Blue

Returns an array of the blue components to the current color table.

### Keywords

None

### Version History

5.2	Introduced
-----	------------

## IDLffDXF::Init

The IDLffDXF::Init function method initializes the DXF object.

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

```
Result = OBJ_NEW('IDLffDXF' [, Filename] )
```

or

```
Result = Obj->[IDLffDXF::]Init( [Filename] ) (In a lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

A scalar string optional argument containing the full path and filename of a DXF file to be read as the object is created.

## Keywords

None

## Version History

5.2	Introduced
-----	------------

## IDLffDXF::PutEntity

The IDLffDXF::PutEntity procedure method inserts an entity into the DXF object. The type of the entity is determined from the DXF\_TYPE field of the entity structure. If DXF\_TYPE is set to 0, the type is implied by the entity structure.

---

**Note**

Line3D entity types will be written as Line entities due to the obsolete status of Line3D. Polyline entities will be automatically converted to Lightweight Polyines where applicable.

---

## Syntax

*Obj*->[IDLffDXF:]PutEntity, *Data*

## Arguments

### Data

An array of Entity structures as defined by the GetEntity method.

---

**Note**

If the entity references a non-existent block or layer, one will automatically be created. Blocks and layers can also be created by passing IDL\_DXF\_BLOCK or IDL\_DXF\_LAYER structures to this routine.

---

## Keywords

None

## Version History

---

5.2	Introduced
-----	------------

---

## IDLffDXF::Read

The IDLffDXF::Read function method reads a file, parsing the DXF object information contained in the file, and inserts it into itself.

### Syntax

*Result* = *Obj*->[IDLffDXF::]Read(*Filename*)

### Return Value

Returns a 1 indicating success in reading the file, otherwise 0.

### Arguments

#### Filename

A scalar string containing the full path and filename of the DXF file to be read.

### Keywords

None

### Examples

```
; Read all the lines from the electrical layer:
oDXF = OBJ_NEW('IDLffDXF')
IF (oDXF->Read('myDXF.dxf')) THEN BEGIN
    contents = oDXF->GetContents(4,COUNT=numLines, $
        LAYER='Electrical')
    IF (numLines ne 0) THEN BEGIN
        lines = oDXF->GetEntity(4,LAYER='Electrical')
    ENDIF
ENDIF
ENDIF
```

### Version History

5.2	Introduced
-----	------------

## IDLffDXF::RemoveEntity

The IDLffDXF::RemoveEntity procedure method removes the specified entity or entities from the DXF object.

### Syntax

*Obj*->[IDLffDXF::]RemoveEntity[, *Type*] [, INDEX=*value*]

### Arguments

#### Type

An optional scalar string containing the DXF type to be removed from the DXF object.

#### Note

Specifying a block or layer entity will cause all the entities in that layer or block to be removed.

### Keywords

#### INDEX

Set this keyword to a scalar long or a long array of indices to remove from the DXF object. If not set, or set negative, all entities of the given type are removed.

### Version History

5.2	Introduced
-----	------------

## IDLffDXF::Reset

The IDLffDXF::Reset procedure method removes all the entities from the DXF object.

### Syntax

*Obj*->[IDLffDXF::Reset](#)

### Arguments

None

### Keywords

None

### Version History

5.2	Introduced
-----	------------

## IDLffDXF::SetPalette

The IDLffDXF::SetPalette procedure method sets the current color table in the object.

### Syntax

*Obj*->[IDLffDXF::SetPalette](#), *Red*, *Green*, *Blue*

### Arguments

#### Red

Sets the red components of the current color table to this array.

#### Green

Sets the green components of the current color table to this array.

#### Blue

Sets the blue components of the current color table to this array.

### Keywords

None

### Version History

5.2	Introduced
-----	------------

## IDLffDXF::Write

The IDLffDXF::Write function method writes a file for the DXF entity information this object contains.

### Syntax

*Result* = *Obj*->[IDLffDXF::]Write(*Filename*)

### Return Value

Returns a 1 if successful in writing the file, 0 otherwise.

### Arguments

#### Filename

A scalar string containing the full path and filename of the DXF file to be written.

### Keywords

None

### Examples

```
; Write a square to a new DXF file using lines:
oDXF = OBJ_NEW('IDLffDXF')
lines = {IDL_DXF_POLYLINE}
lines.dxf_type = 4
lines.layer='myLayer'
lines.thickness = 1.0

; Create clockwise square:
lines = REPLICATE(lines, 4)
lines[0].vertices = PTR_NEW([[0.0,0.0,0.0], $
    [0.0,1.0,0.0]])
lines[0].connectivity = PTR_NEW([0,1])
lines[1].vertices = PTR_NEW([[0.0,1.0,0.0], $
    [1.0,1.0,0.0]])
lines[1].connectivity = PTR_NEW([0,1])
lines[2].vertices = PTR_NEW([[1.0,1.0,0.0], $
    [1.0,0.0,0.0]])
lines[2].connectivity = PTR_NEW([0,1])
lines[3].vertices = PTR_NEW([[1.0,0.0,0.0], $
```

```
        [0.0,0.0,0.0]))
lines[3].connectivity = PTR_NEW([0,1])
oDXF->PutEntity, lines
IF (not oDXF->Write('mySquare.dxf')) THEN $
    PRINT, 'Write Failed.'
    ; Clean up the memory in the structs:
    OBJ_DESTROY, oDXF
    FOR i=0,3 DO BEGIN
        PTR_FREE, lines[i].vertices, lines[i].connectivity
    ENDFOR
```

# IDLffJPEG2000

An IDLffJPEG2000 object contains the data for one or more images embedded in a JPEG2000 file as well as functionality for reading and writing JPEG2000 files. For additional information on the JPEG 2000 file format, see “[Overview of IDL and JPEG2000](#)” on page 3072.

## Superclasses

None

## Creation

See “[IDLffJPEG2000::Init](#)” on page 3100.

## Properties

Objects of this class have the following properties. See “[IDLffJPEG2000 Properties](#)” on page 3077 for details on individual properties.

- [BIT\\_DEPTH](#)
- [BIT\\_RATE](#)
- [COLOR\\_SPACE](#)
- [COMMENT](#)
- [DIMENSIONS](#)
- [DISPLAY\\_RESOLUTION](#)
- [FILENAME](#)
- [JP2](#)
- [N\\_LAYERS](#)
- [N\\_LEVELS](#)
- [N\\_COMPONENTS](#)
- [N\\_TILES](#)
- [OFFSET](#)
- [PALETTE](#)
- [PERSISTENT](#)
- [PROGRESSION](#)
- [QUIET](#)
- [READ](#)
- [REVERSIBLE](#)
- [SIGNED](#)
- [SUBSAMPLING](#)
- [TILE\\_DIMENSIONS](#)
- [TILE\\_OFFSET](#)
- [TILE\\_RANGE](#)
- [UUIDS](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

## Methods

This class has the following methods:

- [IDLffJPEG2000::Cleanup](#)

- [IDLffJPEG2000::GetData](#)
- [IDLffJPEG2000::GetProperty](#)
- [IDLffJPEG2000::GetTileProperty](#)
- [IDLffJPEG2000::GetUUID](#)
- [IDLffJPEG2000::Init](#)
- [IDLffJPEG2000::SetData](#)
- [IDLffJPEG2000::SetProperty](#)
- [IDLffJPEG2000::SetUUID](#)

## Version History

6.1	Introduced
6.2	Added BIT_RATE and UUIDS properties. Added GetUUID and SETUUID methods.

## Overview of IDL and JPEG2000

JPEG2000 is an open, international standard for image compression based on wavelet technology. It offers multiple advantages over other image file standards and compression methods. Among these advantages are:

- Low-bit rate compression performance equal to and often above that of other standards.
- Progressive transmission by quality, resolution, component, or region.
- Both lossless *and* lossy compression. (Lossless decompression is achieved naturally via progressions of increasing resolutions and/or quality.)
- Decompression of images which have user-selectable regions, resolutions, and quality.
- Random spatial access to the encoded stream of bits (code stream).
- Support for metadata, in the form of XML boxes.

A JPEG2000 encoded image and its most basic metadata comprise a code stream. This raw code stream may be placed in a file, usually given an extension of .j2k.

The JPEG2000 standard also allows for additional application-specific metadata to be added to a JPEG2000 file. A file that encapsulates the raw code stream and contains this additional metadata is referred to as a JP2 format file. IDL's support of the JP2 standard provides access to the following additional metadata types: color system specifications, palettes, XML containers, and display resolution information. These metadata are exposed through the [COLOR\\_SPACE](#), [PALETTE](#), [XML](#), and [DISPLAY\\_RESOLUTION](#) object properties. (See “[Properties](#)” on page 3070).

---

### Note

JP2 format files must always have the file-type extension of .j2k or .jpx (which are case insensitive).

---

The IDLffJPEG2000 object class in IDL provides access to the features of JPEG2000 and the JP2 file format for both input and output. This object class is detailed in the following section.

---

### Note

Portions of IDL's JPEG2000 functionality were developed using Unisearch's Kakadu software. Kakadu Software. Copyright © 2001. The University of New South Wales, UNSW, Sydney NSW 2052, Australia, and Unisearch Ltd, Australia.

---

## Examples

The following examples showcase various functionality when working with the IDLffJPEG2000 object.

### Example One

This example shows how to both use the bit rate keyword to create an image with four layers and how to get and display a specific layer:

```
PRO JP2_BIT_RATE_EXAMPLE

; create a new JPEG2000 file
; the file will have four layers with the given bits rates
oJP2 = OBJ_NEW('IDLffJPEG2000', 'jp2_bit_rate_example.jp2', $
    /WRITE, BIT_RATE=[.02, .022, .032, .1])

; set the image data [256x256]
oJP2->SetData, DIST(256)

; this will release the object
OBJ_DESTROY, oJP2

; open the file we just created
oJP2=OBJ_NEW('IDLffJPEG2000', 'jp2_bit_rate_example.jp2')

; create a window to display the four layers
WINDOW, xsize=512, ysize=512

; get and display each layer
TV, oJP2->GetData(MAX_LAYERS=1), 0
TV, oJP2->GetData(MAX_LAYERS=2), 1
TV, oJP2->GetData(MAX_LAYERS=3), 2
TV, oJP2->GetData(MAX_LAYERS=4), 3

; this will close the file
OBJ_DESTROY, oJP2

END
```

### Example Two

This example shows how to add a UUID box to a new JPEG2000 file and how to read a UUID box from an existing JPEG2000 file:

```
PRO JP2_UUID_EXAMPLE

; create a new jp2 file that we can write to
oJP2 = OBJ_NEW('idLFFJPEG2000', 'jp2_uuid_example.jp2', /WRITE)
```

```

; create a bogus id for the uuid box
id = BINDGEN(16)
id[*] = id[*] + 1

; create some data for the uuid box
data = BINDGEN(37)
data[*] = data[*] + 100

; add a new uuid box to the new jp2 file
oJP2->SetUUid, id, data

; set some image data
oJP2->Setdata, BYTARR(10,10)

; close the file
OBJ_DESTROY, oJP2

; open the file we just created in read only mode
oJP2 = OBJ_NEW('idLffJPEG2000', 'jp2_uuid_example.jp2')

; ask the jp2 object for a list of uuids in the file
; this will return an array of 16 uuids eg..[1,16], [2,16]....
oJP2->GetProperty, UUIDS=uuid_list
HELP, uuid_list

; we get the data for the first uuid found in the file
data1 = oJP2->GetUUid(uuid_list[0,*], LEN=len)
PRINT, 'data len = ', STRTRIM(len,2), ' data = ', data1

; this will cause the object to go away
OBJ_DESTROY, oJP2

END

```

## The JPEG2000 Canvas Coordinate System

JPEG2000 uses the concept of the canvas to align multiple image components and tiles in a single coordinate system. This section explains the layout of image components and tiles within the canvas coordinate system.

### Image Offsets and Image Subsampling

By default, images are placed on the canvas so that the image and canvas origins align. If an image offset is specified, the origin of all image components will be located at the specified *X* and *Y* offsets from the canvas origin.

Each image component can also be subsampled. The subsampling factors for a component indicate the scaling factor between the component dimensions and the

image dimensions. If an image has dimensions  $X_I$  by  $Y_I$ , and a component has subsampling factors  $X_S$  by  $Y_S$ , the dimensions of the component will be the ceiling of  $X_I/X_S$  by the ceiling of  $Y_I/Y_S$ . For example, suppose an image has an overall size of 512 by 384 samples. An image component that has subsampling factors of 2 by 2 will have dimensions 256 by 192 samples. Calling the `GetData` method to retrieve just this component will return a 256 by 192 array.

In the canvas coordinate system, the subsampling factors have been applied to each component so that the dimensions of all components are always equal.

---

### Note

When reading a region within the image with the `GetData` method, the values passed to the `REGION` keyword (`[StartX, StartY, Width, Height]`) are measured in the canvas coordinate system. The `StartX` and `StartY` values are measured from the canvas origin, and the `Width` and `Height` values are measured after any subsampling has been applied to the image components. This allows a single set of `Width` and `Height` values to be used for every component.

---

---

### Note

If all components in an image have subsampling factors of 1 by 1, the dimensions of each component will be equal to the value contained in the `DIMENSIONS` property. To calculate the dimensions of individual components when some components have subsamplings other than 1 by 1, the following code can be used:

```
object->GetProperty, DIMENSIONS = dimensions, $
    SUBSAMPLING = subsampling, N_COMPONENTS = n_components
comp_sizes = ULONARR(2, n_components)
FOR i = 0, n_components - 1 DO $
    comp_sizes[* , i] = CEIL(FLOAT(dimensions) /
    subsampling[* , i])
```

---

## Tile Dimensions and Tile Offsets

By default, images will have one tile that has the same dimensions and offset on the canvas as the image. If the tile dimensions are smaller than the image dimensions and the tile offsets are different than the images offsets, some tiles may extend beyond the borders of the image.

The values returned via the `TILE_DIMENSIONS` and `TILE_OFFSET` keywords in the `GetTileProperty` method are the dimensions and location of the tile on the image itself, and not necessarily the dimensions and location on the canvas. To determine

the overall dimensions of a tile, whether or not it falls outside the boundaries of the image, check the `TILE_DIMENSIONS` property with the `GetProperty` method.

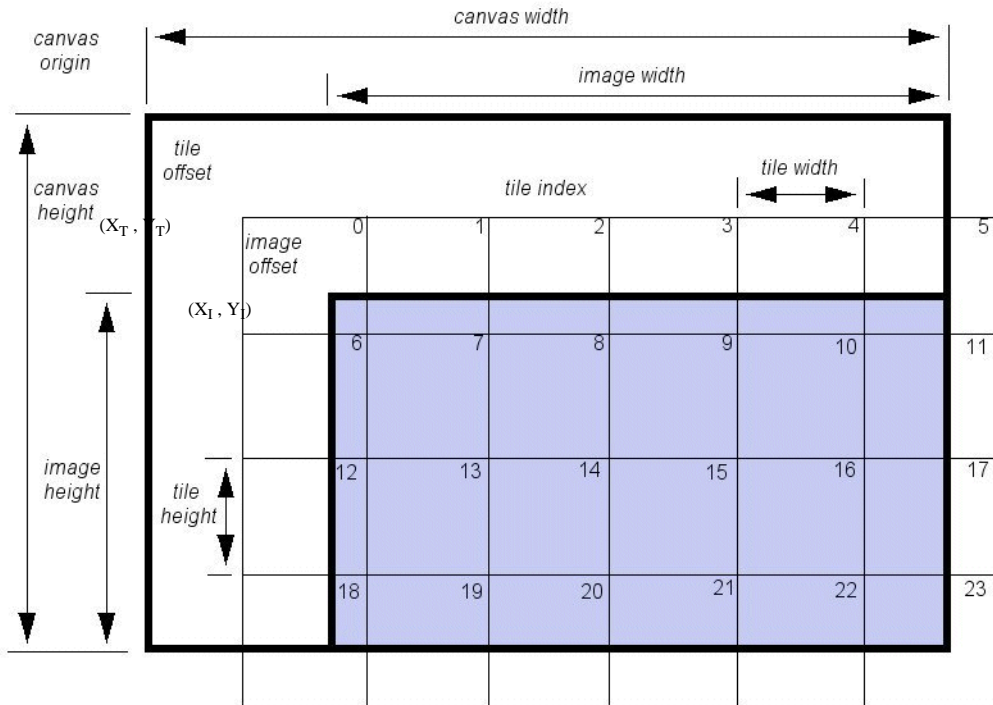

Figure 6-1: Image Tile Dimensions and Offsets

## IDLffJPEG2000 Properties

IDLffJPEG2000 objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffJPEG2000::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffJPEG2000::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffJPEG2000::SetProperty](#).

---

### Note

For more information about the “Property Type”, “Name String”, and “Registered” columns, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [BIT\\_DEPTH](#)
- [BIT\\_RATE](#)
- [COLOR\\_SPACE](#)
- [COMMENT](#)
- [DIMENSIONS](#)
- [DISPLAY\\_RESOLUTION](#)
- [FILENAME](#)
- [JP2](#)
- [N\\_LAYERS](#)
- [N\\_LEVELS](#)
- [N\\_COMPONENTS](#)
- [N\\_TILES](#)
- [OFFSET](#)
- [PALETTE](#)
- [PERSISTENT](#)
- [PROGRESSION](#)
- [QUIET](#)
- [READ](#)
- [REVERSIBLE](#)
- [SIGNED](#)
- [SUBSAMPLING](#)
- [TILE\\_DIMENSIONS](#)
- [TILE\\_OFFSET](#)
- [TILE\\_RANGE](#)
- [UUIDS](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

### BIT\_DEPTH

An integer vector containing the bit depth for each image component. Values must be in the range 1 ... 24.

---

### Note

When writing out JPEG2000 files, the default BIT\_DEPTH is 8 for all components, regardless of the data type supplied to SetData. If you are writing out short or long integer data, you may wish to set BIT\_DEPTH to a larger value for those components.

---

<b>Property Type</b>	Integer Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## BIT\_RATE

A floating-point vector containing the bit rate for each layer, measured in bits per pixel per component (or band). The number of elements in BIT\_RATE must be equal to the number of quality layers or, alternatively, may be two.

When writing files, the values in BIT\_RATE may be given in any order, and will be automatically sorted into ascending order. A value of -1 anywhere within the BIT\_RATE vector indicates that the highest quality layer should include all compressed bits. BIT\_RATE may also be set to a two-element vector, in which case the rates will be approximately logarithmically spaced between the two values.

When the /REVERSIBLE switch is set the last rate will be automatically set to -1 to ensure that the last layer contains the bits needed to recreate the original image data.

When the number of rates being set exceeds the number of layers being set an error is thrown. The value in the N\_LAYERS property must always be equal to or greater than the number of bit rates in the BIT\_RATE property (unless the number of bit rates is two).

<b>Property Type</b>	Float Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## COLOR\_SPACE

A string containing one of the following values:

- sLUM - a luminance (monochrome) space.
- sRGB - the sRGB space is a reasonably good model for color imagery which has been corrected to look good on a monitor.
- sYCC - a three-component color space derived by applying the standard YCbCr color transform to sRGB data; the YCbCr transform is identical to

the irreversible color transform defined by JPEG2000 at the code stream level.

- iccLUM - a monochrome color space defined by an embedded ICC profile.
- iccRGB - an RGB color space defined by an embedded ICC profile.
- <Null string> - none of the above. A null string will result if the source is not a JP2 source.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## COMMENT

A string vector containing an element for each comment associated with the object. If the object has no associated comments, the result will be a scalar null string.

<b>Property Type</b>	String Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DIMENSIONS

A two-element 64-bit integer array giving the width and height of the image. Values for DIMENSIONS should be in the range  $1 \dots 2^{32}-1$ .

<b>Property Type</b>	Integer Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## DISPLAY\_RESOLUTION

A two-element floating-point vector giving the default horizontal and vertical display resolution (in samples per meter). This property will return a value of [0.0, 0.0] if the file has no display resolution specified. This keyword is only valid for JP2 files.

**Note**

The JPEG2000 code stream stores the display resolution values using only 24 bits of precision. When writing files, you may notice slight differences between your input values and the values returned when reading the file.

<b>Property Type</b>	Float Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

**FILENAME**

A string containing the name of the file associated with the object

**Note**

FILENAME can only be set in Init as an argument.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes (as an argument)	<b>Registered:</b> No

**JP2**

A boolean returning 1 if the source or target is a JP2 file which supplies additional color interpretation and other functionality beyond the image data code stream, otherwise 0 is returned.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

**N\_COMPONENTS**

An integer containing the number of image components (or channels) in the entire file or code stream. If N\_COMPONENTS is not supplied in the first call to Init or

SetProperty, it will be the same as the number of components contained in the image parameters in the first call to SetData.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_LAYERS

A positive integer specifying the number of quality layers. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement.

When writing, the default is one. If N\_LAYERS is greater than one, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of the compressed bits.

When setting N\_LAYERS, the value is limited to 244

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_LEVELS

An integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15.

When writing files, a value of zero indicates that no wavelet transform will be used. If this keyword is omitted, then the default value of 5 is used. When writing JP2 files, if the PALETTE property is set then the default is N\_LEVELS=0.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_TILES

An integer specifying the number of tiles within the file.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## OFFSET

A two-element integer array giving the X and Y offsets of all image components. Values for OFFSET should be positive, in the range of a 32-bit integer  $0 \dots 2^{31}-2$ .

<b>Property Type</b>	Integer Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PALETTE

JP2 files may contain a “palette”, or color table, which efficiently stores images with only a few distinct colors. The palette associates a color index with each distinct color present in the image. Images stored in JP2 files with a palette consist of only one component which contains the color indices.

When writing a JP2 file, set this property to a 3-by- $n$  or an  $n$ -by-3 array of byte or integer values, where  $n$  is the number of intensity values, for the three color channels of red, green, and blue. In this case  $n$  must be a power of 2 and  $\leq 256$ .

When reading JP2 files, this property will return an  $n$ -by- $m$  array of byte or integer values, where  $n$  is the number of intensity values, and  $m$  is the number of lookup tables ( $m$  is usually 3, indicating red, green, and blue). If the associated object has no palette, this property will return a scalar zero.

### Note

---

When writing JP2 files, if PALETTE is present, then the default values for other properties are N\_LEVELS=0, REVERSIBLE=1, and YCC=0.

---

<b>Property Type</b>	Byte or Integer Array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## PERSISTENT

A boolean value that indicates whether the image contained in the object may be accessed more than once. If set to zero, the image contained within the object may not be accessed more than once, and data are discarded whenever possible, minimizing memory usage. The default is PERSISTENT=1, which allows access to the image multiple times. This keyword is ignored if the file is opened for writing.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## PROGRESSION

A string defining the progression order of the output. Progression order may be one of the following: LRCP, RLCP, RPCL, PCRL, CPRL. The four character identifiers have the following interpretation: L = layer; R = resolution; C = component; P = position. Data is written to the output file iteratively over the four progression identifiers in this string, that is, the output is written in four nested iteration levels. The first character in the identifier refers to the outermost level of the iteration, while the last refers to the innermost level. The default is LRCP. This property is ignored when used with files opened for reading.

For example, “LRCP” means that an image is encoded in the following order, with quality being the outermost loop:

- L - a series of one or more quality layers, each contributing a quality increment for the entire image at full resolution. The quality layers may be interpreted as sub-bitplanes containing the image data at a specified, possibly fractional, bit-rate.
- R - each resolution level of the image, which corresponds to the N\_LEVELS keyword used in encoding, and can be considered to contain the image data at a given size or resolution. Each level adds another level of detail to the previous levels.

- C - each image component of the above.
- P - each position (tile) within the image component.

In this example, if an image consists of 2 quality layers, 5 resolution levels, 3 components, and 16 positions or tiles, the image would be encoded in a series of packets as follows:

```
P0C0R0L0, P1C0R0L0, P2C0R0L0, ..., P15C0R0L0
P0C1R0L0, P1C1R0L0, P2C1R0L0, ..., P15C1R0L0
P0C2R0L0, P1C2R0L0, P2C2R0L0, ..., P15C2R0L0
P0C0R1L0, P1C0R1L0, P2C0R1L0, ..., P15C0R1L0
P0C1R1L0, P1C1R1L0, P2C1R1L0, ..., P15C1R1L0
P0C2R1L0, P1C2R1L0, P2C2R1L0, ..., P15C2R1L0
... ..
... ..
... ..
P0C2R4L0, P1C2R4L0, P2C2R4L0, ..., P15C2R4L0

P0C0R0L1, P1C0R0L1, P2C0R0L1, ..., P15C0R0L1
P0C1R0L1, P1C1R0L1, P2C1R0L1, ..., P15C1R0L1
P0C2R0L1, P1C2R0L1, P2C2R0L1, ..., P15C2R0L1
```

This encodes all components over the entire image at a given quality level, before sending the next quality refinement.

When encoding a large image with a large number of components, memory requirements will be minimized by sending each component by means of a separate call to `SetData`, and by specifying a progression order of “CPRL”.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## QUIET

A boolean that when set to a non-zero value suppresses the printing of warnings for this object. The default is not to suppress warnings.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## READ

A boolean set to 1 if the file is to be accessed for reading. The default is to open the file for reading.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## REVERSIBLE

A boolean that specifies the type of compression that should be used. A non-zero value indicates that reversible compression should be used. The default is to use irreversible compression. When writing JP2 files, if the PALETTE property is set then the default is REVERSIBLE=1.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SIGNED

An  $n$ -element boolean vector where  $n$  is the number of components. A value of one indicates pixels in that component are interpreted as signed numbers, otherwise the pixels are interpreted as unsigned numbers. The default is to interpret the numbers as unsigned.

### Note

---

When writing out JPEG2000 files, the default is SIGNED=0 for all components, regardless of the data type supplied to SetData. If you are writing out signed integer data, you should set SIGNED to 1 for those components.

---

<b>Property Type</b>	Boolean Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## SUBSAMPLING

A 2 by N\_COMPONENTS integer array containing the subsampling factors in the horizontal and vertical dimensions for each image component. The dimensions of each component will be the ceiling of the image dimensions divided by the respective subsampling factor.

<b>Property Type</b>	Integer Array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## TILE\_DIMENSIONS

A 2-element integer vector defining the width and height of each tile. When writing files, the default is to write one tile with the same dimensions as the image parameter. Values for TILE\_DIMENSIONS should be in the range  $1 \dots 2^{32}-1$ .

<b>Property Type</b>	Integer Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_OFFSET

A 2-element integer vector containing the X and Y offset of the first tile on the canvas.

When reading, the TILE\_OFFSET will return the X and Y offset of the first tile. The GetTileProperty method may be used to retrieve the TILE\_OFFSET for other tiles.

When writing, the default is TILE\_OFFSET=[0,0]. The values of TILE\_OFFSET must be less than or equal to the corresponding values of the OFFSET property. Values for TILE\_OFFSET should be positive, in the range  $0 \dots 2^3-2$ .

<b>Property Type</b>	Integer Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## TILE\_RANGE

A two-element integer vector giving the number of tiles in the X and Y directions.

<b>Property Type</b>	Integer Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## UUIDS

This property provides a mechanism to retrieve the UUIDs for the UUID boxes in the JPEG2000 file.

A JPEG2000 file can contain 0-*n* number of UUID boxes. A UUID is a 16 byte value. UUID stands for Universally Unique Identifier. Each UUID box is made up of a UUID field and a user data field. A UUID box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

The property returns one of the following:

- a scalar value of 0 when the file does not contain any UUID boxes
- a vector of byte arrays. Each array contains a 16 byte UUID. A UUID box that exists in the file but does not have any data (the data field is empty) is not included in the returned vector of UUIDs.

For example if the file contains 10 UUID boxes then this property returns a vector with 10 UUIDs. Each UUID is a 16 byte array.

<b>Property Type</b>	Byte Array Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## WRITE

A boolean that is 1 if the object is open for writing, 0 if not.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## XML

A string vector, each element of which contains a corresponding XML box of the object. If the object has no XML boxes, the result will be a scalar null string. This keyword is only valid for JP2 files.

<b>Property Type</b>	String Vector		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## YCC

When reading files, this property indicates whether the data was originally converted from the RGB color space to the YCC color space. If YCC is true, then when calling GetData, you may wish to return all three image components so that the YCC data can be correctly transformed back to RGB.

When writing files, set this property to a boolean which specifies whether RGB data should be converted to YCrCb before being written. If the image being written has three components, the default is to assume the image contains RGB components, which are automatically converted to YCrCb, and then written. The default action to convert RGB to YCC may be overridden by explicitly setting the YCC keyword to zero. When writing JP2 files, if the PALETTE property is set then the default is YCC=0. If the image being written does not have three components, this property is ignored.

Transforming the color coordinates from RGB to YCC decorrelates the three color components and improves compression performance for RGB images. JPEG2000 readers will then convert back to RGB.

**Note**

---

For the RGB-to-YCC conversion to occur, all three components must be provided at the same time (either the entire image or as separate tiles). If the components are provided in separate calls to `SetData`, the YCC conversion is not performed.

---

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffJPEG2000::Cleanup

The IDLffJPEG2000::Cleanup procedure method performs all cleanup on the object.

---

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

**Note**

Calling OBJ\_DESTROY will also close any files that have been opened for reading or writing.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj* - > [IDLffJPEG2000::]Cleanup (In a lifecycle method only.)

## Arguments

None

## Keywords

None

## IDLffJPEG2000::GetData

The IDLffJPEG2000::GetData function method returns image data from the IDLffJPEG2000 object.

### Syntax

```
Result = Obj->[IDLffJPEG2000::]GetData( [, COMPONENT=value]  
    [, DISCARD_LEVELS=value] [, MAX_LAYERS=value]  
    [, N_COMPONENTS=value] [, ORDER=value] [, REGION=value] [, /RGB]  
    [, TILE_INDEX=value])
```

### Return Value

An array with two or three dimensions containing the image data from the object. Dimensions of the result are: [3, *Width*, *Height*] if the RGB keyword is set; or [*nComponents*, *Width*, *Height*] if the RGB keyword is not set. *nComponents* is the number of components present in the file. Images with only one component (which are read with RGB not set) return a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depths  $\leq 8$  (or if RGB is set) the result will be of type byte. For bit-depths  $\geq 9$  and  $\leq 16$  the result will be of type integer or uint. For bit-depths  $> 16$  the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

---

#### Note

If the PERSISTENT keyword was set to zero when the object was created, the object may not be accessed after GetData is called, with the exception of the GetProperty and Cleanup methods.

---

---

#### Note

If the data in the file was transformed from RGB to YCC before saving, the library will only transform back from YCC to RGB if all three components are read in simultaneously. Reading in each component separately will return the data in the YCC space. The YCC property may be used to determine if the RGB-to-YCC conversion took place. If YCC is true, you may wish to avoid using the COMPONENT or N\_COMPONENTS keywords.

---

## Keywords

### COMPONENT

Set this keyword to an integer giving the index of the component at which to start reading. The number of components to read may be specified using the `N_COMPONENTS` keyword. The default is `COMPONENT=0`.

### DISCARD\_LEVELS

Set this keyword to an integer that indicates the number of resolution levels to be discarded, starting with the highest resolution level (the full image).

For example, setting this keyword equal to 2 will discard the two highest resolution levels — that is, the full- and half-resolution images. The returned array will contain the quarter-resolution image.

The resulting image dimensions are given by:

$$\text{CEIL}((\text{Dimensions} + \text{Offset}) / (2^{\text{DL}})) - \text{CEIL}(\text{Offset} / (2^{\text{DL}}))$$

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of `DISCARD_LEVELS`.

### MAX\_LAYERS

Set this keyword to the maximum number of quality layers which will appear to be present. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement. A value of 0, the default, implies that all layers should be retained. For example, specifying `MAX_LAYERS = 4` processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the `N_LAYERS` property.

### N\_COMPONENTS

Set this keyword to an integer giving the number of components to read, starting at the component index given by the `COMPONENT` keyword. If neither `COMPONENT` nor `N_COMPONENTS` is specified then all components will be read. If `COMPONENT` is specified then the default is `N_COMPONENTS=1`.

## ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `GetData` will automatically flip the result to match IDL's bottom-to-top order. Setting `ORDER` to a nonzero value will return the JPEG2000 image without doing the vertical flip.

## REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read in the canvas coordinate system. The region is specified as [`StartX`, `StartY`, `Width`, `Height`] ], where `StartX` and `StartY` must be in the range  $0 \dots 2^{32}-2$ , and `Width` and `Height` must be in the range  $1 \dots 2^{32}-1$ . The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

### Note

---

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions.

---

## RGB

If this keyword is set, the data stream will be interpreted as RGB imagery and all details concerning color transformations (for example: `sRGB`, `sLUM` and `sYCC`), together with restricted ICC-profiles for specifying more general 3-color “RGB-like” spaces, plus indexed color with palettes, are handled automatically. If this keyword is set, the result of this function will always have three components, red, green, and blue; and the dimensions of the result will be [`3`, `Width`, `Height`].

The JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the `YCC` keyword returned by the `::GetFileProperty` method.

If `RGB` is set and the file contains more than three components, only the first three components are returned. If `RGB` is set and the file contains less than three components an error is issued.

If `RGB` is not set, and three components are transferred, and a color transformation has been applied to the input stream, the three components which are encoded in a form of YCC will automatically be converted to RGB. If it is desired to avoid this conversion, then the user should transfer more or less than three components in the call or calls to `GetData`.

If RGB is not set and the number of components is not three, then each component in the data stream will be placed in the result without interpretation. Result will have dimensions: [N\_COMPONENTS, *Width*, *Height*].

The RGB keyword may not be specified if the COMPONENT or N\_COMPONENTS keywords are present.

## TILE\_INDEX

Set this keyword to an integer giving the tile index to read. If this keyword is specified then the REGION keyword is ignored.

## Examples

This example illustrates the use of GetData to read an image a number of different ways:

```

;Create object, open file.
a = OBJ_NEW('IDLffJPEG2000', 'boat2.jp2')

;Read the entire image.
b = a->GetData()

;Read a 512x512 portion of the image, starting
;at column 100, row 200.
b = a->GetData(REGION = [100, 200, 512, 512])

;Read the portion of the above, but sub-sample it down by a
;factor of 2, returning an nComponents x 256 x 256 image.
b = a->GetData(REGION = [100, 200, 512, 512], DISCARD_LEVELS=1)

;Read only the 2nd component.
;The result will have two dimensions.
b = a->GetData(COMPONENT = 1)

```

## IDLffJPEG2000::GetProperty

The IDLffJPEG2000::GetProperty procedure method returns information describing the properties of an IDLffJPEG2000 object in the supplied variable - keyword pairs.

### Syntax

*Obj*->[IDLffJPEG2000::](#)GetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLffJPEG2000 Properties](#)” on page 3077 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.1	Introduced
-----	------------

## IDLffJPEG2000::GetTileProperty

The IDLffJPEG2000::GetTileProperty procedure method returns information describing the properties of a tile in an IDLffJPEG2000 object in the supplied variable-keyword pairs. The object must be open for reading. An error is produced if the object is open for writing.

### Syntax

```
Obj->[IDLffJPEG2000::]GetTileProperty [, TileIndex [, TileComponent]],
    [, N_LAYERS=variable] [, N_LEVELS=variable] [, PROGRESSION=variable]
    [, REVERSIBLE=variable] [, TILE_DIMENSIONS=variable]
    [, TILE_OFFSET=variable] [, YCC=variable]
```

### Arguments

#### TileIndex

This argument specifies the index of the tile whose attributes are to be returned. JPEG2000 tiles are numbered in raster scan fashion, starting from 0 and going up to a maximum of 65535. The default value for this argument is 0.

#### TileComponent

This argument specifies the component index of the tile whose attributes are to be queried. Indices range from 0 to N\_COMPONENTS-1. The default value for this argument is 0.

### Keywords

#### N\_LAYERS

Set this keyword to a named variable in which to return the number of quality layers available for the tile. If this keyword is set, the TileComponent argument is ignored.

#### N\_LEVELS

Set this keyword to a named variable in which to return the total number of available resolution levels for this tile component.

## PROGRESSION

Set this keyword to a named variable in which to return a string containing the progression order for that tile. The returned value will be one of: LRCP, RLCP, RPCL, PCRL, CPRL.

See “[PROGRESSION](#)” on page 3083 under Properties for the definition of these values.

## REVERSIBLE

Set this keyword to a named variable in which to return 1 if the tile-component is compressed reversibly, 0 if irreversible.

## TILE\_DIMENSIONS

Set this keyword to a named variable in which to return a two-element vector containing the width and height of the tile, taking into account any clipping of the tile to the image.

## TILE\_OFFSET

Set this keyword to a named variable in which to return a two-element vector containing the horizontal and vertical offset of the tile, taking into account any clipping of the tile to the image.

## YCC

Set this keyword to a named variable in which to return 1 if a component color transform was used for the first 3 components of the tile specified by the TileIndex argument, 0 otherwise.

## Version History

6.1	Introduced
-----	------------

## IDLffJPEG2000::GetUUID

The IDLffJPEG2000::GetUUID function method allows you to get the data field from the specified UUID box.

A JPEG2000 file can contain 0-*n* number of UUID boxes. Each UUID box in a JPEG2000 file is made up of a UUID field and a user data field. A UUID box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

### Syntax

*Data* = *Obj*->[IDLffJPEG2000::]GetUUID(*UUID* [, **LENGTH**=*length*])

### Return Value

Returns one of the following:

- a scalar zero when the passed in UUID is not found in the file
- a byte array containing the data found in the data field of the UUID box.
- a scalar zero when the passed UUID is found in the file but does not contain any data (i.e. the data field is empty).

### Arguments

#### UUID

The UUID argument is required. The UUID argument must be a 16 byte array.

### Keywords

#### LENGTH

Length is an optional keyword. If present, the length variable will be set to the number of bytes in the returned data array. If present and the requested UUID is not found, length will be 0. If present and the requested UUID is found but does not contain any data (i.e. the data field is empty), the length will be -1.

## Version History

6.2	Introduced
-----	------------

## IDLffJPEG2000::Init

The IDLffJPEG2000::Init() function method initializes an IDLffJPEG2000 object that can be used to read (decode) image data from a JPEG2000 image file, or write (encode) image data to a JPEG2000 image file.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

*Obj* = OBJ\_NEW('IDLffJPEG2000' , *Filename*[ , *PROPERTY* = *value*])

or

*Result* = *Obj*->[IDLffJPEG2000::]Init(*Filename* [ , *PROPERTY* = *value*]) (In a *lifecycle method* only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

Set this argument to a scalar string containing the path and filename of a file containing JPEG 2000 compressed image data to be accessed through this object. If the file type suffix is .jp2 or .jpx, case insensitive, the file is a JP2 file. Otherwise the file contains a raw JPEG2000 code stream.

## Keywords

Any property listed under [“IDLffJPEG2000 Properties”](#) on page 3077 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

6.1	Introduced
-----	------------

## IDLffJPEG2000::SetData

The IDLffJPEG2000::SetData procedure method writes data to the IDLffJPEG2000 object.

### Syntax

```
Obj->[IDLffJPEG2000::]SetData([P1, ..., Pn] [, COMPONENT=value] [, /ORDER]
  [, TILE_INDEX=value])
```

### Arguments

Arguments may be one or more arrays containing the image components or tile components to be written to the JPEG2000 object. The arrays may have either two or three dimensions. Two-dimensional arrays contain one image or tile component with the dimensions of width and height. Three-dimensional arrays are dimensioned [*nComponents*, *width*, *height*]. All parameters must have the same width and height.

The array parameters are converted to byte data type if the bit-depth for the corresponding component is less than or equal to 8; to signed or unsigned integer, depending on the signed setting, for bit-depths from 9 - 16; and to signed or unsigned long integers, depending on the signed setting for bit-depths over 16.

---

#### Note

The bit depths used for output are determined from the BIT\_DEPTH property, and not from the data type of the input arguments. If you are writing out short or long integer data, you should set the BIT\_DEPTH property before calling SetData.

---

---

#### Note

The SIGNED property determines whether the data are written out using signed or unsigned integers, and is not affected by the data type of the input arguments. If you are writing out signed integer data, you may wish to set the SIGNED property before calling SetData.

---

### Image Dimensions, Tile Dimensions, and Component Number

Images may be written using multiple calls to SetData with each call transferring one or more tile components. A tile component contains one image component for a given tile and is the smallest unit of data that can be supplied to SetData. The dimensions of the entire image and tiles, plus the number of components are determined the first time they are specified to Init or SetProperty, and may not be changed once

established. If the dimensions or number of components are not specified explicitly they are inferred from the image parameters supplied in the first call to `SetData`.

If transferring an image with multiple calls to `SetData`, try to supply the data to `SetData` in a manner consistent with the progression setting of `PROGRESSION` to ensure optimum performance and minimize memory requirements.

---

**Note**

If you do not complete writing all of the tiles or components, or your array dimensions are not the same as the overall image dimensions, then the library will be unable to complete the code stream. In this case, reading the data back in may result in unexpected or incorrect values.

---

**Note**

If the `YCC` property is set (indicating that you want the library to convert from RGB to YCC before compressing the data), then you must supply all three image components in the same call to `SetData` (either the entire image or one tile at a time). If the components are provided in separate calls to `SetData`, the YCC conversion is not performed.

---

## Keywords

### COMPONENT

Set this keyword to be the index of the first component to be written by this call to `SetData`. Default is 0.

### ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `SetData` will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting `ORDER` to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

### TILE\_INDEX

Set this keyword to specify the index of the first tile to be written. JPEG2000 tiles are numbered in raster scan fashion, starting from 0. The default value for this keyword is 0. The tile indices must range from 0 to one less than the number of tiles in the image file, which is determined by the tile dimensions and image dimensions.

## Examples

Write a one-component image:

```
;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE)

;Write the image
jp2->SetData, BYTSCl(DIST(400,300))

OBJ_DESTROY, jp2
```

Read a one-component image:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

;Read it.
img = jp2_in->GetData()

OBJ_DESTROY, jp2_in
```

Write an indexed-color image with a palette:

```
;Load IDL color table #5, this example assumes we have 256 colors.
LOADCT, 5

;Read color tables
TVLCT, /GET, Red, Green, Blue

;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE, $
  PALETTE=[[Red], [Green], [Blue]])

;Write the image with the palette
jp2->SetData, BYTSCl(DIST(400,300))
OBJ_DESTROY, jp2
```

Read the above image and palette:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

jp2_in->GetProperty, PALETTE=palette

;Read without RGB keyword. img is a 400 by 300 byte image.
img = jp2_in->GetData()

;With the RGB keyword, the image is now [3, 400, 300]
img3d = jp2_in->GetData(/RGB)
```

```
OBJ_DESTROY, jp2_in
```

Show the images:

```
TVLCT, palette[*], palette [*, 1], palette[*], 2]
DEVICE, DECOMPOSED = 0
TV, img
DEVICE, DECOMPOSED = 1
TV, img3d, TRUE=1
```

Write a 100 component file, one component at a time:

```
j2k = OBJ_NEW('IDLffJPEG2000', 'test.j2k', /WRITE,
             N_COMPONENTS=100)
FOR i = 0, 99 DO j2k_in->SetData, $
    replicate(byte(i), 200, 300), COMPONENT = i
OBJ_DESTROY, j2k_in
```

Read the above file:

```
j2k_in = obj_new('IDLffJPEG2000', 'test.j2k')

;b is a [200, 300] array
b = j2k_in->GetData(COMPONENT=30)

;b is a [5, 200, 300] array
b = j2k_in->GetData(COMPONENT=50, N_COMPONENT = 5)

OBJ_DESTROY, j2k_in
```

## Version History

## IDLffJPEG2000:: SetProperty

This procedure sets the properties of an object that is open for writing. This method may not be called on files opened for reading.

### Syntax

*Obj*->[IDLffJPEG2000::]SetProperty [, *PROPERTY=**value*]

### Arguments

None.

### Keywords

Any property listed under “[IDLffJPEG2000 Properties](#)” on page 3077 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.1	Introduced
-----	------------

## IDLffJPEG2000::SetUUID

The IDLffJPEG2000::SetUUID procedure method allows you to add UUID boxes when creating a new JPEG2000 file. This method can only be called when the JPEG2000 object was created with the /WRITE switch. Each call to SetUUID will add a new *uuid* box to the JPEG2000 file.

A JPEG2000 file can contain 0-n number of *uuid* boxes. Each *uuid* box is made up of a *uuid* field and a user data field. A *uuid* box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

### Syntax

*Obj*->[IDLffJPEG2000::] SetUUID, *uuid*, *Data*

### Arguments

#### uuid

The *uuid* argument must be a 16 byte array. If *uuid* passed in already has been used in a previous SetUUID call, an error is issued. The *uuid* is written into the *uuid* field of the new *uuid* box.

#### Data

The *Data* argument must be an array. The array can be of any type and any length. SetUUID treats the array as a stream of bytes. The stream of bytes are written into the data field of the new *uuid* box.

### Keywords

None

### Version History

6.2	Introduced
-----	------------

# IDLffLangCat

The IDLffLangCat class is used to find and load an XML language catalog. A language catalog is composed of key names and key values. The key value of the specified key name can be retrieved to support internationalization. For example:

```
<KEY NAME='Menu:File:Open'>Open...</KEY>
```

in an English language catalog would appear as the following in a French language catalog:

```
<KEY NAME='Menu:File:Open'>Ouvrir...</KEY>
```

By handling files that contain keys and values like these, the IDLffLangCat class supports internationalization of user interfaces and other applications that need to display the same strings in more than one language.

The language catalogs included with IDL are in the `<IDL_DIR>/resource/langcat` directory and end in a `.cat` extension. You can use other catalogs, but all catalogs must end with the `.cat` extension.

---

## Note

The IDLffLangCat class supports catalog files written in 8-bit strings (which can be encoded for languages using special marks; see below). Also, you must have the corresponding fonts installed on your machine before you can use a particular language.

---

A language-catalog file can support accent marks such as those in French (which stray from the first 128 character codes defined by ASCII into the ISO-8859 encodings) if you do one of the following actions:

- Add `encoding='ISO8859-1'` to the XML tag element at the beginning of the file (e.g., `<xml version='1.0' encoding='ISO8859-1'>`)
- Save the XML file as Unicode

In general, you should use the encoding appropriate for your catalog's language. For the list of supported encodings and for more general information about XML, see [“About XML”](#) in Chapter 20 of the *Building IDL Applications* manual.

---

## Note

For more information on this class, including examples of how to use it, see [“Using Language Catalogs”](#) in the *Building IDL Applications* manual.

---

## Superclasses

None

## Creation

See [IDLffLangCat::Init](#).

## Properties

Objects of this class have the following properties. See “[IDLffLangCat Properties](#)” on page 3111 for individual properties.

- [APP\\_NAME](#)
- [APP\\_PATH](#)
- [AVAILABLE\\_LANGUAGES](#)
- [DEFAULT\\_KEYS](#)
- [DEFAULT\\_LANGUAGE](#)
- [DEFAULT\\_N\\_KEYS](#)
- [FILENAME](#)
- [KEYS](#)
- [LANGUAGE](#)
- [N\\_KEYS](#)
- [VERBOSE](#)

## Methods

This class has the following methods:

- [IDLffLangCat::AppendCatalog](#)
- [IDLffLangCat::Cleanup](#)
- [IDLffLangCat::GetProperty](#)
- [IDLffLangCat::Init](#)
- [IDLffLangCat::Query](#)
- [IDLffLangCat::SetProperty](#)

## IDLffLangCat Properties

IDLffLangCat objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffLangCat::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffLangCat::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffLangCat::SetProperty](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [APP\\_NAME](#)
- [APP\\_PATH](#)
- [AVAILABLE\\_LANGUAGES](#)
- [DEFAULT\\_KEYS](#)
- [DEFAULT\\_LANGUAGE](#)
- [DEFAULT\\_N\\_KEYS](#)
- [FILENAME](#)
- [KEYS](#)
- [LANGUAGE](#)
- [N\\_KEYS](#)
- [VERBOSE](#)

### APP\_NAME

The name of one or more current applications, returned in alphabetical order.

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## APP\_PATH

The directory or directories searched for each given application. Each directory path must be fully qualified and unambiguous (e.g., C:\RSI\IDL62\lib\itools).

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## AVAILABLE\_LANGUAGES

A list of all languages that exist in the input file or files. When APP\_NAME is specified, this property returns all languages where the language-catalog files have the same internal application name. The languages return in alphabetical order.

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DEFAULT\_KEYS

A list of all the currently loaded keys in the default language.

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DEFAULT\_LANGUAGE

The current default language.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## DEFAULT\_N\_KEYS

The number of currently loaded keys in the default language.

<b>Property Type</b>	Long		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## FILENAME

The name of each currently loaded language catalog (.cat) file. In setting this property, each name is either a fully qualified path (e.g., C:\RSI\IDL62\resource\langcat) to a location containing a file, or the name of a file in the current directory. In getting this property, it always returns the full path.

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## KEYS

A list of all the currently loaded keys, returned in upper-case.

<b>Property Type</b>	String or string array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## LANGUAGE

The current language.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## N\_KEYS

The number of currently loaded keys.

<b>Property Type</b>	Long		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## VERBOSE

The current setting of the verbose flag. If set, all catalog-loading messages will be sent to the output window. This list contains details resulting from an IDLffLangCat object initialization or modification, including the names and numbers of keys loaded, keys overwritten, and so on.

<b>Property Type</b>	Byte		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffLangCat::AppendCatalog

The IDLffLangCat::AppendCatalog function method adds keys from a file or files to those used to build the language catalog. All valid keys present in the current language will be inserted into the current key/value list. If any new languages are present in the new files, they will be added to the AVAILABLE\_LANGUAGES property. If a duplicate key name is found, its value will replace the existing key name's value.

### Note

Whenever the object encounters a key (or language) that already exists, the key (or language) is overwritten with the new value.

## Syntax

```
Result = Obj->[IDLffLangCat:]AppendCatalog( [, APP_NAME=applicationName]  
      [, FILENAME=filename] [, APP_PATH=applicationPath] )
```

## Return Value

Returns 1 if valid keys were found and loaded, or 0 otherwise.

## Arguments

None

## Keywords

### APP\_NAME

Set this keyword to a string or string array containing the name of each desired application for which to add keys. If APP\_NAME is specified, it overrides any input to FILENAME. You can use the '\*' wild card (e.g., 'MyApp\*' instead of ['MyAppMenu', 'MyAppErrors', ...]). You must provide either APP\_NAME or FILENAME.

### APP\_PATH

Set this keyword to a string or string array containing the name of each directory in which to search for the given application's keys. Each path must be fully qualified

(e.g., C:\RSI\IDL62\lib\itools). This keyword is ignored if [APP\\_NAME](#) is not specified.

## FILENAME

Set this keyword to a string or string array containing the name of each language-catalog file to load. If [APP\\_NAME](#) is specified, it overrides any input to FILENAME. Each string is either a fully qualified path (e.g., C:\RSI\IDL62\resource\langcat) to a location containing a file, or the name of a file in the current directory. You must provide either [APP\\_NAME](#) or FILENAME.

## Version History

6.1	Introduced
-----	------------

## IDLffLangCat::Cleanup

The IDLffLangCat::Cleanup procedure method performs all cleanup operations on the language catalog object, and should be called by the Cleanup method of a subclass.

---

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

### Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLffLangCat::]Cleanup *(In a lifecycle method only.)*

### Arguments

None

### Keywords

None

### Version History

---

6.1	Introduced
-----	------------

---

## IDLffLangCat::GetProperty

The IDLffLangCat::GetProperty procedure method retrieves a property or group of properties for an IDLffLangCat object.

Comparisons such as those done with [IDLffLangCat::Query](#) are case insensitive, but the values returned by GetProperty are exactly as the last encountered value. For example, if File 1 has LANGUAGE= 'English' and File 2 has LANGUAGE= 'english', then 'english' will be returned, although only one ENGLISH language exists in the current catalog.

### Syntax

*Obj*->[IDLffLangCat::](#)GetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under [“IDLffLangCat Properties”](#) on page 3111 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.1	Introduced
-----	------------

## IDLffLangCat::Init

The IDLffLangCat::Init function method initializes an IDLffLangCat object.

### Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Any invalid input will result in a failure to create a valid object. Invalid input includes the following cases:

- The requested language is not found in any of the input files
- Any application in APP\_NAME is not found
- Any file in FILENAME is not found
- Any directory in APP\_PATH does not exist
- The requested default language is not found

You can set the VERBOSE keyword to view the output log for a detailed description of the creation (or failure) of the object. You can also set [CONTINUE\\_ON\\_ERROR](#) to override the failure behavior if you have the language specified, regardless of the language's existence.

## Syntax

```
Obj = OBJ_NEW( 'IDLffLangCat', Language [, PROPERTY=value]  
              [, /CONTINUE_ON_ERROR] )
```

or

```
Result = Obj->[IDLffLangCat::]Init( Language [, PROPERTY=value]  
                                   [, /CONTINUE_ON_ERROR] ) (In a lifecycle method only.)
```

## Return Value

Returns the new object if successful or a null object otherwise if initialized with OBJ\_NEW, or returns 1 if successful or 0 otherwise if called from a subclass's Init method.

## Arguments

### Language

A string containing the name of the language to load from the catalog.

## Keywords

Any property listed under “[IDLffLangCat Properties](#)” on page 3111 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

You must specify either APP\_NAME or FILENAME for this method. If APP\_NAME is specified, it overrides any input to FILENAME.

### CONTINUE\_ON\_ERROR

If set, the object will be created as long as the language is specified, regardless of the validity of any of the input parameters. If not set, the object will not be created if any input is invalid. If a language is not specified or is specified incorrectly (e.g., as a multiple element array), the object will not be created, and an error will be thrown, regardless of the value of this keyword.

## Version History

6.1	Introduced
-----	------------

## IDLffLangCat::Query

The IDLffLangCat::Query function method returns the string or string array that corresponds to all supplied key values.

### Syntax

```
Result = Obj->[IDLffLangCat::]Query( Key [, DEFAULT_STRING=string] )
```

### Return Value

Returns a string or string array that corresponds to all supplied key values. If no key can be found, then the default string or, if no default string is supplied, a null string is returned.

### Arguments

#### Key

A string or string array used as the key or keys against which the query is performed. If a given key does not exist in the current language, the default language is queried (if one exists).

### Keywords

#### DEFAULT\_STRING

Set this keyword to a string or string array to be used if the key is not found in the catalog. If a scalar string is supplied, it will be returned for all keys not found. For example, if DEFAULT\_STRING is “Key not found,” this string is returned for each failed query on a key or keys. If a string array is supplied, only those values whose indices match the missing keys will be returned. That is, you can have different default strings for different cases of failed query matches (e.g., “No File key found” and “No Tools key found” returned, respectively, for failed queries on keys associated with a File menu and a Tools menu).

### Version History

6.1	Introduced
-----	------------

## IDLffLangCat:: SetProperty

The IDLffLangCat::SetProperty procedure method sets the value of a property or group of properties for an IDLffLangCat object.

### Syntax

*Obj*->[IDLffLangCat::]SetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “IDLffLangCat Properties” on page 3111 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.1	Introduced
-----	------------

# IDLffMrSID

An IDLffMrSID object class is used to query information about and load image data from a MrSID (.sid) image file.

**Note**

The IDLffMrSID object is available only under Microsoft Windows.

## Superclasses

None

## Creation

See [IDLffMrSID::Init](#)

## Properties

Objects of this class have the following properties. See “[IDLffMrSID Properties](#)” on page 3124 for details on individual properties.

- [QUIET](#)

## Methods

This class has the following methods:

- [IDLffMrSID::Cleanup](#)
- [IDLffMrSID::GetDimsAtLevel](#)
- [IDLffMrSID::GetImageData](#)
- [IDLffMrSID::GetProperty](#)
- [IDLffMrSID::Init](#)

## Version History

5.5	Introduced
-----	------------

## IDLffMrSID Properties

IDLffMrSID objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLffMrSID::Init`.

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- `QUIET`

### QUIET

A Boolean value to indicate whether error messages are suppressed while constructing the IDLffMrSID object. If this value is true, the errors messages are suppressed. Otherwise, the messages are printed to the Output Log.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffMrSID::Cleanup

The IDLffMrSID::Cleanup procedure method deletes all MrSID objects, closing the MrSID file in the process. It also deletes the IDL objects used to communicate with the MrSID library.

---

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

### Syntax

OBJ\_DESTROY, *Obj*

*or*

*Obj*->[IDLffMrSID:]Cleanup (In a lifecycle method only.)

### Arguments

## IDLffMrSID::GetDimsAtLevel

The IDLffMrSID::GetDimsAtLevel function method is used to retrieve the dimensions of the image at a given level. This can be used, for example, to determine what level is required to fit the image into a certain area.

### Syntax

*Result* = *Obj*->[IDLffMrSID::]GetDimsAtLevel (*Level*)

### Return Value

Returns a floating-point two-element vector containing the dimensions of the image at a given level.

### Arguments

#### Level

A scalar integer specifying the level at which the dimensions are to be determined. This level must be in the range returned by the LEVELS keyword of IDLffMrSID::GetProperty.

### Keywords

None

### Examples

Initialize the MrSID file object.

```
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))
```

Get the range of levels of resolution contained within the file.

```
oFile->GetProperty, LEVELS = lvls
PRINT, lvls
```

IDL prints,

```
-9    4
```

Print the image dimensions at the lowest image resolution where image level = 4.

```
imgLevelA = MAX(lvls)
dimsAtA = oFile->GetDimsAtLevel(imgLevelA)
PRINT, 'Dimensions of lowest resolution image is', dimsAtA
```

IDL prints,

```
32 32
```

Print the image dimensions at full resolution where image level = 0

```
dimsAtFull = oFile->GetDimsAtLevel(0)
PRINT, 'Dimensions of full resolution image is', dimsAtFull
```

IDL prints,

```
512 512
```

Print the image dimensions at the highest resolution where image level = -9

```
highestLvl = MIN(lvls)
dimsAtHighest = oFile->GetDimsAtLevel(highestLvl)
PRINT, 'Dimensions of highest resolution image is', dimsAtHighest
```

IDL prints,

```
262144 262144
```

Clean up object references.

```
OBJ_DESTROY, [oFile]
```

## Version History

5.5	Introduced
-----	------------

## IDLffMrSID::GetImageData

The IDLffMrSID::GetImageData function method extracts and returns the image data from the MrSID file at the specified level and location.

### Syntax

```
Result = Obj->[IDLffMrSID::]GetImageData ([, LEVEL = lvl]  
[, SUB_RECT = rect])
```

### Return Value

Returns an  $n$ -by- $w$ -by- $h$  array containing the image data where  $n$  is 1 for grayscale or 3 for RGB images,  $w$  is the width and  $h$  is the height.

#### Note

---

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left corner of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left corner of the image.

---

### Arguments

None

### Keywords

#### LEVEL

Set this keyword to an integer that specifies the level at which to read the image.

If this keyword is not set, the maximum level is used which returns the minimum resolution (see the LEVELS keyword to IDLffMrSID::GetProperty).

#### SUB\_RECT

Set this keyword to a four-element vector  $[x, y, xdim, ydim]$  specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying portions of a high-resolution image.

If this keyword is not set, the whole image will be returned. This may require significant memory if a high-resolution image level is selected.

If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

---

### Note

The elements of SUB\_RECT are measured in pixels at the current level. This means the point  $x = 10$ ,  $y = 10$  at level 1 will be located at  $x = 20$ ,  $y = 20$  at level 0 and  $x = 5$ ,  $y = 5$  at level 2.

---

## Examples

```

PRO MrSID_GetImageData

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile->GetProperty, LEVELS = lvlS
PRINT, lvlS
; IDL prints, -9, 4

; Get the image data at level 0.
imgDataA = oFile->GetImageData(LEVEL = 0)
HELP, 'image array data at full resolution', imgDataA
; IDL prints, Array[1, 512, 512] indicating a grayscale 512 x 512
array.

; Display the full resolution image.
oImgA = OBJ_NEW('IDLgrImage', imgDataA)
oModelA = OBJ_NEW('IDLgrModel')
oModelA->Add, oImgA
XOBJVIEW, oModelA, BACKGROUND = [0,0,0], $
    TITLE = 'Full Resolution Image', /BLOCK

; Get the image data of a higher resolution image,
imgDataB = oFile->GetImageData(LEVEL = -2)
HELP, imgDataB
; IDL returns [1,2048,2048] indicating a grayscale 2048 x 2048
array.

```

```
; To save processing time, display only a 1024 x 1024 portion of
; the high resolution, using 512,512 as the origin.
imgDataSelect = oFile->GetImageData(LEVEL = -2,$
    SUB_RECT = [512, 512, 1024, 1024])
oImgSelect = OBJ_NEW('IDLgrImage', imgDataSelect)
oModel = OBJ_NEW('IDLgrModel')
oModel->Add, oImgSelect

XOBJVIEW, oModel, BACKGROUND = [0,0,0], $
    TITLE = 'Detail of High Resolution Image', /BLOCK

; Clean up object references.
OBJ_DESTROY, [oFile, oImgA, oModelA, oImgSelect, oModel]

END
```

## Version History

5.5	Introduced
-----	------------

## IDLffMrSID::GetProperty

The IDLffMrSID::GetProperty function method is used to query properties associated with the MrSID image.

### Syntax

```
Obj->[IDLffMrSID::]GetProperty [, CHANNELS=nChannels]  
    [, DIMENSIONS=Dims] [, LEVELS=Levels] [, PIXEL_TYPE=pixelType]  
    [, TYPE=strType] [, GEO_VALID=geoValid] [, GEO_PROJTYPE=geoProjType]  
    [, GEO_ORIGIN=geoOrigin] [, GEO_RESOLUTION=geoRes]
```

### Arguments

None

### Keywords

#### CHANNELS

Set this keyword to a named variable that will contain the number of image bands. For RGB images this is 3, for grayscale it is 1.

#### DIMENSIONS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*width, height*] that specifies the dimensions of the MrSID image at level 0 (full resolution).

#### GEO\_ORIGIN

Set this keyword to a named variable that will contain a two-element double precision array of the form [*x, y*] that specifies the location of the center of the upper-left pixel.

#### GEO\_PROJTYPE

Set this keyword to a named variable that will contain an unsigned integer that specifies the geoTIFF projected coordinate system type code. For example, type code 32613 corresponds to PCS\_WGS84\_UTM\_zone\_13N.

For more information on the geoTIFF file type and available type codes see:

<http://www.remotesensing.org/geotiff/geotiff.html>

## GEO\_RESOLUTION

Set this keyword to a named variable that will contain a two-element double precision array of the form [*xres*, *yres*] that specifies the pixel resolution.

## GEO\_VALID

Set this keyword to a named variable that will contain a long integer that is set to:

- 1 - If the MrSID image contains valid georeferencing data.
- 0 - If the MrSID image does not contain georeferencing data or the data is in an unsupported format.

### Note

---

Always verify that this keyword returns 1 before using the data returned by any other GEO\_\* keyword.

---

## LEVELS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*minlvl*, *maxlvl*] that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

## PIXEL\_TYPE

Set this keyword to a named variable that will contain the IDL basic type code for a pixel sample. For a list of the data types indicated by each type code, see the “IDL Type Codes” section of the [SIZE](#) function.

## TYPE

Set this keyword to a named variable that will contain a string identifying the file format. This should always be MrSID.

## Examples

```
PRO MrSID_GetProperty

; Initialize the MrSID object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))
```

```
; Get the property information of the MrSID file.
oFile->GetProperty, CHANNELS = chan, LEVELS = $
    lvls, Pixel_Type = pType, TYPE = fileType, GEO_VALID = geoQuery

; Print MrSID file information.
PRINT, 'Number of image channels = ', chan
; IDL returns 1 indicating one image band.

PRINT, 'Range of image levels = ', lvls
; IDL returns -9, 4, the minimum and maximum level values.

PRINT, 'Type code of image pixels = ', pType
; IDL returns 1 indicating byte data type.

PRINT, 'Image file type = ', FileType
; IDL returns "MrSID"

PRINT, 'Result of georeferencing data query = ', geoQuery
; IDL returns 0 indicating that the image does not contain
; georeferencing data.

; Destroy object references.
OBJ_DESTROY, [oFile]

END
```

## Version History

5.5	Introduced
-----	------------

## IDLffMrSID::Init

The IDLffMrSID::Init function method initializes an IDLffMrSID object containing the image data from a MrSID image file.

---

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

*Result* = OBJ\_NEW('IDLffMrSID', *Filename* [, *PROPERTY=**value*])

or

*Result* = *Obj*->[IDLffMrSID::]Init(*Filename* [, *PROPERTY=**value*]) (In a lifecycle method only.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

A scalar string argument containing the full path and filename of a MrSID file to be accessed through this IDLffMrSID object.

---

**Note**

This is a required argument; it is not possible to create an IDLffMrSID object without specifying a valid MrSID file.

---

## Keywords

Any property listed under [“IDLffMrSID Properties”](#) on page 3124 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Examples

```
oMrSID = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $  
SUBDIRECTORY = ['examples', 'data']))
```

- [IDLffShape::SetAttributes](#)

## Version History

5.4	Introduced
5.6	Added N_RECORDS, DBF_ONLY properties

## Overview of ESRI Shapefiles

An ESRI Shapefile stores nontopological geometry and attribute information for the spatial features in a data set.

A Shapefile consists of a main file (.shp), an index file (.shx), and a dBASE table (.dbf). For example, the Shapefile “states” would have the following files:

- states.shp
- states.shx
- states.dbf

### Naming Conventions for a Shapefile

All the files that comprise an ESRI Shapefile must adhere to the 8.3 filename convention and must be lower case. The main file, index file, and dBASE file must all have the same prefix. The prefix must start with an alphanumeric character and can contain any alphanumeric, underscore (\_), or hyphen (-). The main file suffix must use the .shp extension, the index file the .shx extension, and the dBASE table the .dbf extension.

### Major Elements of a Shapefile

A Shapefile consists of the following elements that you can access through the IDLffShape class:

- Entities
- Attributes

#### Entities

The geometry for a feature is stored as a shape comprising a set of vector coordinates (referred to as ‘entities’). The (non-null) entities in a Shapefile must all be of the same type. The following are the possible types for entities in a Shapefile:

Shape Type	Type Code
Point	1
PolyLine	3
Polygon	5

*Table 6-16: Entity Types*

Shape Type	Type Code
MultiPoint	8
PointZ	11
PolyLineZ	13
PolygonZ	15
MultiPointZ	18
PointM	21
PolyLineM	23
PolygonM	25
MultiPointM	28
MultiPatch	31

*Table 6-16: Entity Types (Continued)*

When retrieving entities using the `IDLffShape::GetEntity` method, an IDL structure is returned. This structure has the following fields:

Field	Data Type
SHAPE_TYPE	IDL_LONG
ISHAPE	IDL_LONG
BOUNDS	Double[8]
N_VERTICES	IDL_LONG
VERTICES	Pointer (to Vertices array)
MEASURE	Pointer (to Measure array)
N_PARTS	IDL_LONG
PARTS	Pointer (to Parts array).
PART_TYPES	Pointer (to part types)
ATTRIBUTES	Pointer to attribute array.

*Table 6-17: Entity Structure Field Data Types*

The following table describes each field in the structure:

Field	Description
SHAPE_TYPE	The entity type.
ISHAPE	A read-only field containing the index of the specific entity within the shape object. This value is set automatically when the shape file is written.
BOUNDS	<p>A bounding box that specifies the range limits of the entity. This eight element array contains the following information:</p> <ul style="list-style-type: none"> <li>• Index 0 — X minimum value</li> <li>• Index 1 — Y minimum value</li> <li>• Index 2 — Z minimum value (if Z is supported by type)</li> <li>• Index 3 — Measure minimum value (if measure is supported by entity type)</li> <li>• Index4 — X maximum value</li> <li>• Index5 — Y maximum value</li> <li>• Index6 — Z maximum value (if Z is supported by the entity type)</li> <li>• Index7 — Measure maximum value (if measure is supported by entity type)</li> </ul> <p><b>Note</b> - If the entity is a point type, the values contained in the bounds array are also the values of the entity.</p>
N_VERTICES	The number of vertices in the entity. If this value is one and the entity is a POINT type (POINT, POINTM, POINTZ), the vertices pointer will be set to NULL and the entity value will be maintained in the BOUNDS field.

*Table 6-18: Entity Structure Field Descriptions*

Field	Description
VERTICES	<p>An IDL pointer that contains the vertices of the entity. This pointer contains a double array that has one of the following formats:</p> <ul style="list-style-type: none"> <li>• [2, <i>N</i>] - If Z data is not present</li> <li>• [3, <i>N</i>] - If Z data is present</li> </ul> <p>where <i>N</i> is the number of vertices. These array formats can be passed to the polygon and polyline objects of IDL Object Graphics.</p> <p><b>Note</b> - This pointer will be null if the entity is a point type, with the values maintained in the BOUNDS array.</p>
MEASURE	<p>If the entity has a measure value (this is dependent on the entity type), this IDL pointer will contain a vector array of measure values. The length of this vector is N_VERTICES.</p> <p><b>Note</b> - This pointer will be null if the entity is of type POINTM, with the values contained in the BOUNDS array.</p>
N_PARTS	<p>If the values of the entity are separated into parts, the break points are enumerated in the parts array. This field lists the number of parts in this entity. If this value is 0, the entity is one part and the PARTS pointer will be NULL.</p>
PARTS	<p>An IDL pointer that contains an array of indices into the vertex/measure arrays. These values represent the start of each part of the entity. The index range of each entity part is defined by the following:</p> <ul style="list-style-type: none"> <li>• Start = Parts[I]</li> <li>• End = Parts[I+1]-1 or the end of the array</li> </ul>

Table 6-18: Entity Structure Field Descriptions (Continued)

Field	Description
PART_TYPES	<p>This IDL pointer is only valid for entities of type MultiPatch and defines the type of the particular part. If the entity type is not MultiPatch, part types are assumed to be type RING (SHPP_RING).</p> <p><b>Note</b> - This pointer is NULL if the entity is not type MultiPatch.</p>
ATTRIBUTES	<p>If the attributes for an entity were requested, this field contains an IDL pointer that contains a structure of attributes for the entity. For more information on this structure, see <a href="#">“Attributes”</a> on page 3142.</p>

*Table 6-18: Entity Structure Field Descriptions (Continued)*

## Attributes

A Shapefile provides the ability to associate information describing each entity (a geometric element) contained in the file. This descriptive information, called attributes, consists of a set of named data elements for each geometric entity contained in the file. The set of available attributes is the same for every entity contained in a Shapefile, with each entity having its own set of attribute values.

An attribute consist of two components:

- A name
- A data value

The name consists of an 11 character string that is used to identify the data value. The data value is not limited to any specific format.

The two components that form an attribute are accessed differently using the shape object. To get the name of attributes for the specific file, the ATTRIBUTE\_NAMES keyword to the [IDLffShape::GetProperty](#) method is used. This returns a string array that contains the names for the attributes defined for the file.

To get the attribute values for an entity, the `IDLffShape::GetAttributes` method is called or the `ATTRIBUTES` keyword of the `IDLffShape::GetEntity` method is set. In each case, the attribute values for the specified entity is returned as an anonymous IDL structure. The numeric order of the fields in the returned structure map to the numeric order of the attributes defined for the file. The actual format of the returned structure is:

```
ATTRIBUTE_0 : VALUE,
ATTRIBUTE_1 : VALUE,
ATTRIBUTE_2 : VALUE,
...
ATTRIBUTE_<N-1> : VALUE
```

To access the values in the returned structure, you can either hard code the structure field names or use the structure indexing feature of IDL.

## Accessing Shapefiles

The following example shows how to access data in a Shapefile. This example sets up a map to display parts of a Shapefile, opens a Shapefile, reads the entities from the Shapefile, and then plots only the state of Colorado:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape',
DIALOG_PICKFILE(FILE='shape_entity.shp', /WRITE), $
/UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
PRECISION=0

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
```

```
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = mynewshape->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape->IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
mynewshape->IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, mynewshape

END
```

This results in the following:

Figure 6-2: Example Use of Shapefiles

## Creating New Shapefiles

To create a Shapefile, you need to create a new Shapefile object, define the entity and attributes definitions, and then add your data to the file. For example, the following program creates a new Shapefile (`states.shp`), defines the entity type to be “Point”, defines 2 attributes (`CITY_NAME` and `STATE_NAME`), and then adds an entity to the new file:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
    PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
    PRECISION=0
```

```

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = mynewshape->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape->IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
mynewshape->IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, mynewshape

END

```

## Updating Existing Shapefiles

You can modify existing Shapefiles with the following:

- Adding new entities
- Adding new attributes (only to Shapefiles without any existing values in any attributes)
- Modifying existing attributes

### Note

---

You cannot modify existing entities.

---

For example, the following program adds an entity and attributes for the city of Boulder to the `states.shp` file we created in the previous example:

```
PRO ex_shapefile_modify

;Open the states Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']), /UPDATE)

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -105.25100
entNew.BOUNDS[1] = 40.026878
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -105.25100
entNew.BOUNDS[5] = 40.026878
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = myshape->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Boulder'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
myshape->IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
myshape->IDLffShape::SetAttributes, 1, attrNew

;Close the shapefile
OBJ_DESTROY, myshape

END
```

## IDLffShape Properties

IDLffShape objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffShape::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffShape::Init](#).

---

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

---

Objects of this class have the following properties.

- [ATTRIBUTE\\_INFO](#)
- [ATTRIBUTE\\_NAMES](#)
- [DBF\\_ONLY](#)
- [ENTITY\\_TYPE](#)
- [FILENAME](#)
- [IS\\_OPEN](#)
- [N\\_ATTRIBUTES](#)
- [N\\_ENTITIES](#)
- [N\\_RECORDS](#)
- [UPDATE](#)

### ATTRIBUTE\_INFO

A array of structures containing the attribute information for each attribute. The attribute information structures have the following fields:

Field	Description
NAME	A string that contains the name of the attribute
TYPE	The IDL type code of the attribute
WIDTH	The width of the attribute

*Table 6-19: Attribute Information Fields*

Field	Description
PRECISION	The precision of the attribute

Table 6-19: Attribute Information Fields (Continued)

The file must be open to obtain this information.

<b>Property Type</b>	Structure		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## ATTRIBUTE\_NAMES

A string array containing the names of each attribute in the Shapefile object.

<b>Property Type</b>	String array		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## DBF\_ONLY

A non-zero, positive integer value indicating whether the underlying dBASE table (.dbf) component of the shapefile is opened while all other entity related files are left closed. The following two values are accepted for this property:

- 1 - Open an existing .dbf file,
- Greater than 1 - Create a new .dbf file

### Note

The UPDATE keyword is required to open the .dbf file for updating.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## ENTITY\_TYPE

If retrieving this property, its value is an integer representing the type code for the entities contained in the Shapefile object. If the value is unknown, this method returns -1. For more information on entity type codes, see “Entities” on page 3138.

If setting this property, its value is an integer representing the entity type of a new Shapefile. Use this setting only when creating a new Shapefile. For more information on entity types, see “Entities” on page 3138.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## FILENAME

A string representing the fully qualified path name of the Shapefile in the current Shapefile object.

<b>Property Type</b>	String		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## IS\_OPEN

An integer value representing information about the status of a Shapefile. The following values can be returned:

0	File is not open
1	File is open in read-only mode
3	File is open in update mode

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## N\_ATTRIBUTES

A longword integer representing the number of attributes associated with a Shapefile object. If the number of attributes is unknown, this property returns 0.

<b>Property Type</b>	Long		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## N\_ENTITIES

A longword integer representing the number of entities contained in Shapefile object. If the number of entities is unknown, this property returns 0.

<b>Property Type</b>	Long		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## N\_RECORDS

A longword integer representing the number of records in the dBASE table (.dbf) component of the Shapefile. In a normal operating mode, this process is accomplished by getting the number of entities. However, in DBF\_ONLY mode, no entity file exists.

<b>Property Type</b>	Long		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> No	<b>Init:</b> No	<b>Registered:</b> No

## UPDATE

A Boolean value indicating whether the file opened for writing. The file is opened for writing if this property is set to true. The default is read-only.

<b>Property Type</b>	Boolean		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> No	<b>Set:</b> No	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffShape::AddAttribute

The IDLffShape::AddAttribute method adds an attribute definition to a Shapefile. Adding a the attribute definition is required before adding the actual attribute data to a file. For more information on attributes, see [“Attributes”](#) on page 3142.

### Note

You can only define new attributes to Shapefiles that do not have any existing values in any attributes.

## Syntax

*Obj*->[IDLffShape::]AddAttribute, *Name*, *Type*, *Width* [, PRECISION=*integer*]

## Arguments

### Name

Set to a string that contains the attribute name. Name values are limited to 11 characters. Arguments longer than 11 characters will be truncated.

### Type

Set to the IDL type code that corresponds to the data type that will be stored in the attribute. The valid types are:

3	Longword integer
5	Double-precision floating-point
7	String

### Width

Set to the width of the field for the data value of the attribute. The following table describes the possible values depending on the defined *Type*:

Longword Integer	Maximum size of the field
------------------	---------------------------

Double-precision floating-point	Maximum size of the field
String	Maximum length of the string

## Keywords

### PRECISION

Set this keyword to the number of positions to be included after the decimal point. The default is 8. This keyword is only valid for fields defined as double-precision floating-point.

## Examples

In the following example, we add the attribute “ELEVATION” to an existing Shapefile. Note that if the file already contains data in an attribute for any of the entities defined in the file, this operation will fail.

```
PRO ex_addattr_shapefile

;Open a shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
  SUBDIR=['examples', 'data']), /UPDATE)

;Define a new attribute for the Shapefile
myshape->IDLffShape::AddAttribute, 'ELEVATION', 3, 4, $
  PRECISION=0

;Close the shapefile
OBJ_DESTROY, myshape

END
```

## Version History

5.4	Introduced
-----	------------

## IDLffShape::Cleanup

The IDLffShape::Cleanup procedure method performs all cleanup on a Shapefile object. If the Shapefile being accessed by the object is open and the file has been modified, the new information is written to the file if one of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

### Note

---

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

---

## Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLffShape::]Cleanup *(In a lifecycle method only.)*

## Arguments

None

## Keywords

None

## Version History

5.4	Introduced
-----	------------

## IDLffShape::Close

The IDLffShape::Close procedure method closes a Shapefile. If the file has been modified, it is also written to the disk if neither of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

If the file has been modified and one of the previous conditions is not met, the file is closed and the changes are not written to disk.

## Syntax

*Obj*->[IDLffShape::]Close

## Arguments

None

## Keywords

None

## Version History

5.4	Introduced
-----	------------

## IDLffShape::DestroyEntity

The IDLffShape::DestroyEntity procedure method frees memory associated with the entity structure. For more information on the entity structure, see “Entities” on page 3138.

### Syntax

*Obj*->[IDLffShape::]DestroyEntity, *Entity*

### Arguments

#### Entity

A scalar or array of entities to be destroyed.

### Keywords

None

### Examples

In the following example, all of the entities from the `states.shp` Shapefile are read and then the DestroyEntity method is called to clean up all pointers:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
    ;Read the entity x
    ent = myshape->IDLffShape::GetEntity(x)
    ;Clean-up of pointers
    myshape->IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape
END
```

## Version History

5.4	Introduced
-----	------------

## IDLffShape::GetAttributes

The IDLffShape::GetAttributes function method retrieves the attributes for the entities you specify from a Shapefile.

### Syntax

```
Result = Obj->[IDLffShape::]GetAttributes([Index] [, /ALL]  
[, /ATTRIBUTE_STRUCTURE] )
```

### Return Value

Returns an anonymous structure array. For more information on the structure, see “Attributes” on page 3142.

### Arguments

#### Index

A scalar or array of longs specifying the entities for which you want to retrieve the attributes, with 0 being the first entity in the Shapefile.

---

#### Note

If you do not specify *Index* and the ALL keyword is not set, the attributes for the first entity (0) are returned.

---

### Keywords

#### ALL

Set this keyword to retrieve the attributes for all entities in a Shapefile. If you set this keyword, the *Index* argument is not required.

#### ATTRIBUTE\_STRUCTURE

Set this keyword to return an empty attribute structure that can then be used with the [IDLffShape::SetAttributes](#) method to add attributes to a Shapefile.

## Examples

In the first example, we retrieve the attributes associated with entity at location 0 (the first entity in the file):

```
attr = myShape->getAttributes( 0)
```

In the next example, we retrieve the attributes associated with entities 10 through 20:

```
attr = myShape->getAttributes( 10+indgen(11) )
```

In the next example, we retrieve the attributes for entities 1,4, 9 and 70:

```
attr = myShape->getAttributes( [1, 4, 9, 70] )
```

In the next example, we retrieve all the attributes for a Shapefile:

```
attr = myShape->getAttributes( /ALL )
```

## Version History

---

## IDLffShape::GetEntity

The IDLffShape::GetEntity function method returns the entities you specify from a Shapefile.

### Syntax

*Result* = *Obj*->[IDLffShape::]GetEntity([*Index*] [, /ALL] [, /ATTRIBUTES])

### Return Value

Returns a type {IDL\_SHAPE\_ENTITY} structure array. For more information on the structure, see “Entities” on page 3138.

---

#### Note

Since an entity structure contains IDL pointers, you must free all the pointers returned in these structures when the entity is no longer needed using the [IDLffShape::DestroyEntity](#) method.

---

---

#### Note

Since entities cannot be modified in a Shapefile, an entity is read directly from the Shapefile each time you use the IDLffShape::GetEntity method even if you have already read that entity. If you modify the structure array returned by this method for a given entity and then use IDLffShape::GetEntity on that same entity, the modified data will NOT be returned, the data that is actually written in the file is returned.

---

## Arguments

### Index

A scalar or array of longs specifying the entities for which you want to retrieve with 0 being the first entity in the Shapefile. If the ALL keyword is set, this argument is not required. If you do not specify any entities and the ALL keyword is not set, the first entity (0) is returned.

## Keywords

### ALL

Set this keyword to retrieve all entities from the Shapefile. If this keyword is set, the Index argument is not required.

### ATTRIBUTES

Set this keyword to return the attributes in the entity structure. If not set, the ATTRIBUTES tag in the entity structure will be a null IDL pointer.

## Examples

In the following example, all of the entities from the `states.shp` Shapefile are read:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
  SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
  ;Read the entity x
  ent = myshape->IDLffShape::GetEntity(x)
  ;Clean-up of pointers
  myshape->IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

## Version History

5.4	Introduced
-----	------------

## IDLffShape::GetProperty

The IDLffShape::GetProperty procedure method returns the values of properties associated with a Shapefile object. These properties are:

- Number of entities
- The type of the entities
- The number of attributes associated with each entity
- The names of the attributes
- The name, type, width, and precision of the attributes
- The status of a Shapefile
- The filename of the Shapefile object

## Syntax

*Obj*->[IDLffShape::]GetProperty [, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLffShape Properties” on page 3148 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Examples

In the following example, the number of entities and the entity type is returned:

```
PRO entity_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
SUBDIR=['examples', 'data']))

; Get the number of entities and the entity type.
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent, $
ENTITY_TYPE=ent_type
```

```

; Print the number of entities and the type.
PRINT, 'Number of Entities: ', num_ent
PRINT, 'Entity Type: ', ent_type

; Close the Shapefile.
OBJ_DESTROY, myshape

END

```

This results in the following:

```

Number of Entities:      51
Entity Type:             5

```

In the next example, the definitions for attribute 1 are returned:

```

PRO attribute_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the info for all attribute.
myshape->IDLffShape::GetProperty, ATTRIBUTE_INFO=attr_info

; Print Attribute Info.
PRINT, 'Attribute Number: ', '1'
PRINT, 'Attribute Name: ', attr_info[1].name
PRINT, 'Attribute Type: ', attr_info[1].type
PRINT, 'Attribute Width: ', attr_info[1].width
PRINT, 'Attribute Precision: ', attr_info[1].precision

; Close the Shapefile.
OBJ_DESTROY, myshape

END

```

This results in the following:

```

Attribute Number:      1
Attribute Name:       STATE_NAME
Attribute Type:       7
Attribute Width:      25
Attribute Precision:  0

```

## Version History

5.4	Introduced
-----	------------

## IDLffShape::Init

The IDLffShape::Init function method initializes or constructs a Shapefile object.

---

### Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

---

## Syntax

```
Result = OBJ_NEW('IDLffShape' [, Filename] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLffShape::]Init([, Filename] [, PROPERTY=value])  (In a  
lifecycle method only.)
```

## Return Value

When this method is called indirectly, as part of the call to the OBJ\_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. If this file exists, it is opened. If the file does not exist, a new Shapefile object is constructed. You do not need to use [IDLffShape::Open](#) to open an existing file when specifying this argument.

---

### Note

The .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

---

## Keywords

Any property listed under “[IDLffShape Properties](#)” on page 3148 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Examples

In the following example, we create a new Shapefile object and open the `examples/data/states.shp` file:

```
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))
```

## Version History

---

5.4	Introduced
-----	------------

---

## IDLffShape::Open

The IDLffShape::Open function method opens a specified Shapefile.

### Syntax

```
Result = Obj->[IDLffShape:]Open( 'Filename' [, /DBF_ONLY]  
    [, ENTITY_TYPE='value'] [, /UPDATE] )
```

### Return Value

Returns 1 if the file can be read successfully. If not able to open the file, it returns 0.

### Arguments

#### Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. Note that the .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

### Keywords

#### DBF\_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (.dbf) component of the shapefile is opened. All entity related files are left closed. Two values to this keyword are accepted: 1 - Open an existing .dbf file, > 1 - Create a new .dbf file

The UPDATE keyword is required to open the .dbf file for updating.

#### ENTITY\_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when creating a new Shapefile. For more information on entity types, see “Entities” on page 3138.

#### UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

## Examples

In the following example, the file `examples/data/states.shp` is opened for reading and writing:

```
status = myShape->Open(FILEPATH('states.shp', $  
    SUBDIR=['examples', 'data']), /UPDATE)
```

## Version History

5.4	Introduced
-----	------------

## IDLffShape::PutEntity

The IDLffShape::PutEntity procedure method inserts an entity into the Shapefile object. The entity must be in the proper structure. For more information on the structure, see “Entities” on page 3138.

---

### Note

The shape type of the new entity must be the same as the shape type defined for the Shapefile. If the shape type has not been defined for the Shapefile using the ENTITY\_TYPE keyword for the IDLffShape::Open or IDLffShape::Init methods, the first entity that is inserted into the Shapefile defines the type.

---

### Note

Only new entities can be inserted into a Shapefile. Existing entities cannot be updated.

---

## Syntax

*Obj*->[IDLffShape::]PutEntity, *Data*

## Arguments

### Data

A scalar or an array of entity structures.

## Keywords

None

## Examples

In the following example, we create a new shapefile, define a new entity, and then use the PutEntity method to insert it into the new file:

```
PRO ex_shapefile_putentity

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape',
DIALOG_PICKFILE(FILE='shape_entity.shp', /WRITE), $
/UPDATE, ENTITY_TYPE=1)
```

```
; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity.
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Add the new entity to new shapefile.
mynewshape->IDLffShape::PutEntity, entNew

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

## Version History

5.4	Introduced
-----	------------

## IDLffShape::SetAttributes

The IDLffShape::SetAttributes procedure method sets the attributes for a specified entity in a Shapefile object.

### Syntax

*Obj*->[IDLffShape::]SetAttributes, *Index*, *Attribute\_Num*, *Value*

or

*Obj*->[IDLffShape::]SetAttributes, *Index*, *Attributes*

### Arguments

#### Attribute\_Num

The field number for the attribute whose value is being set. This value is 0-based.

#### Attributes

An Attribute structure whose fields match the fields in the attribute table. If *Attributes* is an array, the entities specified in *Index*, up to the size of the Attributes array, are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

The type of this Attribute structure must match the type that is generated internally for Attribute table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE\_STRUCTURE keyword of the IDLffShape::GetProperty method.

#### Index

A scalar specifying the entity in which you want to set the attributes. The first entity in the Shapefile object is 0.

#### Value

The value that the attribute is being set to. If the value is not of the correct type, type conversion is attempted.

If *Value* is an array and *Index* is a scalar, the value of record is treated as a starting point. Using this feature, all the attribute values of a specific field can be set for a Shapefile.

## Keywords

None

## Examples

In the following example, we create a new shapefile, define the attributes for the new file, define a new entity, define some attributes, insert the new entity, and then use the `SetAttributes` method to insert the attributes into the new file:

```
PRO ex_shapefile_setattributes

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape',
DIALOG_PICKFILE(FILE='shape_entity.shp', $
    /WRITE), /UPDATE, ENTITY_TYPE=1)

; Set the attribute definitions for the new Shapefile.
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
    PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
    PRECISION=0

; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Create structure for new attributes.
attrNew = mynewshape->IDLffShape::GetAttributes( $
    /ATTRIBUTE_STRUCTURE)

; Define the values for the new attributes.
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

; Add the new entity to new shapefile.
mynewshape->IDLffShape::PutEntity, entNew
```

```
; Add the Colorado attributes to new shapefile.  
mynewshape->IDLffShape::SetAttributes, 0, attrNew  
  
; Close the shapefile.  
OBJ_DESTROY, mynewshape  
  
END
```

# IDLffXMLDOMAttr

The IDLffXMLDOMAttr object represents an attribute that is part of an element object. Typically, the allowable values for the attribute are defined in a DTD.

Attribute objects are subclasses of the [IDLffXMLDOMNode](#) abstract superclass, but are not actually child nodes of the elements they describe and are not considered as part of the DOM tree. Therefore, an attribute object does not have a parent or siblings, and so the `ParentNode()`, `NextSibling()`, and `PreviousSibling()` methods always return a null object reference. The DOM takes the view that attributes are properties of elements, rather than having a separate identity.

An attribute's value may be explicitly assigned or may take on a default value as described by a DTD. If neither of these alternatives is true, the attribute does not exist in the element. Use the [IDLffXMLDOMAttr::GetSpecified](#) method to determine if the value was explicitly specified or has taken on the default value.

If the value of an attribute may contain entity references, then the attribute node may have either text or entity-reference child nodes.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMAttr::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMAttr::Cleanup](#)
- [IDLffXMLDOMAttr::GetName](#)
- [IDLffXMLDOMAttr::GetSpecified](#)
- [IDLffXMLDOMAttr::GetValue](#)

- [IDLffXMLDOMAttr::Init](#)
- [IDLffXMLDOMAttr::SetValue](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMAttr Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

## IDLffXMLDOMAttr::Cleanup

The IDLffXMLDOMAttr::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMAttr::GetName

The IDLffXMLDOMAttr::GetName function method returns the name of the attribute node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMAttr::]GetName()

### Return Value

Returns a scalar string containing the name of the attribute node.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMAttr::GetSpecified

The IDLffXMLDOMAttr::GetSpecified function method returns a scalar integer indicating how the value of the attribute node was set.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMAttr::]GetSpecified()

### Return Value

Returns 1 if the value of the attribute node was explicitly set in the XML document or was set programmatically with the [IDLffXMLDOMAttr::SetValue](#) method. Returns 0 if the attribute's value was established from the default value declared in the document's DTD.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMAttr::GetValue

The IDLffXMLDOMAttr::GetValue function method returns the value of the attribute node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMAttr::]GetValue()

### Return Value

Returns a scalar string containing the value of the attribute node.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMAttr::Init

The IDLffXMLDOMAttr::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetAttributes](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMAttr::SetValue

The IDLffXMLDOMAttr::SetValue procedure method sets the value of the attribute node, using the *Value* argument.

### Syntax

*Obj*->[IDLffXMLDOMAttr::]SetValue, *Value*

### Arguments

#### Value

A scalar string used to set the value of the attribute node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

# IDLffXMLDOMCDATASection

The IDLffXMLDOMCDATASection object is used to escape blocks of text containing characters that would otherwise be regarded as markup. The only delimiter that is recognized in a CDATA section is the “]]>” string that ends the CDATA section. CDATA sections cannot be nested. The primary purpose is for including material such as XML fragments without needing to escape all the delimiters.

There are no methods specific to this class except Cleanup and Init.

## Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

[IDLffXMLDOMText](#)

## Creation

See [IDLffXMLDOMCDATASection::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMCDATASection::Cleanup](#)
- [IDLffXMLDOMCDATASection::Init](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCDATASection Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)
- [IDLffXMLDOMCharacterData](#)
- [IDLffXMLDOMText](#)

## IDLffXMLDOMCDATASection::Cleanup

The IDLffXMLDOMCDATASection::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCDATASection::Init

The IDLffXMLDOMCDATASection::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

# IDLffXMLDOMCharacterData

The IDLffXMLDOMCharacterData class extends the [IDLffXMLDOMNode](#) class with a set of methods for accessing character data in the DOM tree. This is an abstract class in the sense that there will never be an instance of this class, but its methods are available to its subclasses.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMCharacterData::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMCharacterData::AppendData](#)
- [IDLffXMLDOMCharacterData::Cleanup](#)
- [IDLffXMLDOMCharacterData::DeleteData](#)
- [IDLffXMLDOMCharacterData::GetData](#)
- [IDLffXMLDOMCharacterData::GetLength](#)
- [IDLffXMLDOMCharacterData::Init](#)
- [IDLffXMLDOMCharacterData::InsertData](#)
- [IDLffXMLDOMCharacterData::ReplaceData](#)
- [IDLffXMLDOMCharacterData::SetData](#)
- [IDLffXMLDOMCharacterData::SubstringData](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

## IDLffXMLDOMCharacterData::AppendData

The IDLffXMLDOMCharacterData::AppendData procedure method appends a string to the character data in the node.

### Syntax

*Obj*->[IDLffXMLDOMCharacterData:]AppendData, *String*

### Arguments

#### String

A scalar string to be added at the end of the character data.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::Cleanup

The IDLffXMLDOMCharacterData::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::DeleteData

The IDLffXMLDOMCharacterData::DeleteData procedure method deletes a number of characters from the character data in the node, starting at an offset.

### Syntax

*Obj*->[IDLffXMLDOMCharacterData:]DeleteData, *Offset*, *Count*

### Arguments

#### Offset

A scalar value that indicates where to begin deleting characters.

#### Count

A scalar number of characters to delete.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::GetData

The IDLffXMLDOMCharacterData::GetData function method returns the character data in the node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMCharacterData::]GetData()

### Return Value

Returns a scalar string containing the character data in the node.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::GetLength

The IDLffXMLDOMCharacterData::GetLength function method returns the number of characters in the node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMCharacterData::]GetLength()

### Return Value

Returns a scalar string containing the number of characters in the node. This value may be zero.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::Init

The IDLffXMLDOMCharacterData::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMCharacterData::InsertData

The IDLffXMLDOMCharacterData::InsertData procedure method inserts a string in the node's character data at a specified offset.

### Syntax

*Obj*->[IDLffXMLDOMCharacterData:]InsertData, *Offset*, *String*

### Arguments

#### Offset

A scalar value that indicates where in the character data to begin inserting the string contained in *String*.

#### String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::ReplaceData

The IDLffXMLDOMCharacterData::ReplaceData procedure method replaces a number of characters, starting at an offset in the node's character data, with a string.

### Syntax

*Obj*->[IDLffXMLDOMCharacterData:]ReplaceData, *Offset*, *Count*, *String*

### Arguments

#### Offset

A scalar value that indicates where in the character data to begin replacement.

#### Count

A scalar number of characters in the character data to replace.

#### String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::SetData

The IDLffXMLDOMCharacterData::SetData procedure method sets the node's character data to a string.

### Syntax

*Obj*->[IDLffXMLDOMCharacterData::]SetData, *String*

### Arguments

#### String

A scalar string to be set in the node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMCharacterData::SubstringData

The IDLffXMLDOMCharacterData::SubstringData function method returns a string composed of a substring of the node's character data.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMCharacterData::]SubstringData( *Offset*, *Count* )

### Return Value

Returns a string containing a substring of the node's character data that starts at *Offset* and has a length specified by *Count*.

### Arguments

#### Offset

A scalar value that indicates where in the character data to begin the substring.

#### Count

A scalar length of the substring.

### Keywords

None

### Version History

6.1	Introduced

# IDLffXMLDOMComment

The IDLffXMLDOMComment class represents the content of a comment, the characters between the starting “<!--” and the ending “-->”.

There are no methods specific to this class except Cleanup and Init.

## Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

## Creation

See [IDLffXMLDOMComment::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMComment::Cleanup](#)
- [IDLffXMLDOMComment::Init](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMComment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)
- [IDLffXMLDOMCharacterData](#)

## IDLffXMLDOMComment::Cleanup

The IDLffXMLDOMComment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMComment::Init

The IDLffXMLDOMComment::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

# IDLffXMLDOMDocument

The IDLffXMLDOMDocument class represents the entire XML document as the root of the document tree and by providing the primary access to the document's data.

This class is also the class factory for DOM tree nodes such as [IDLffXMLDOMText](#) since all DOM tree nodes must belong to a specific document. To this end, this class includes methods that create DOM tree nodes of all the various types.

Note that nodes created with these factory methods belong to the document, but are not part of the DOM tree structure until they are inserted into the DOM tree. See the relevant methods in the [IDLffXMLDOMNode](#) class for details on inserting nodes into the DOM tree.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMDocument::Init](#).

## Properties

Objects of this class have the following properties. See “[IDLffXMLDOMDocument Properties](#)” on page 3207 for details on individual properties.

- [NODE\\_DESTRUCTION\\_POLICY](#)

## Methods

This class has the following methods:

- [IDLffXMLDOMDocument::Cleanup](#)
- [IDLffXMLDOMDocument::CreateAttribute](#)
- [IDLffXMLDOMDocument::CreateCDATASection](#)
- [IDLffXMLDOMDocument::CreateComment](#)
- [IDLffXMLDOMDocument::CreateElement](#)
- [IDLffXMLDOMDocument::CreateDocumentFragment](#)

- [IDLffXMLDOMDocument::CreateEntityReference](#)
- [IDLffXMLDOMDocument::CreateNodeIterator](#)
- [IDLffXMLDOMDocument::CreateProcessingInstruction](#)
- [IDLffXMLDOMDocument::CreateTextNode](#)
- [IDLffXMLDOMDocument::CreateTreeWalker](#)
- [IDLffXMLDOMDocument::GetDoctype](#)
- [IDLffXMLDOMDocument::GetDocumentElement](#)
- [IDLffXMLDOMDocument::GetElementsByTagName](#)
- [IDLffXMLDOMDocument::GetProperty](#)
- [IDLffXMLDOMDocument::Init](#)
- [IDLffXMLDOMDocument::Load](#)
- [IDLffXMLDOMDocument::Save](#)
- [IDLffXMLDOMDocument::SetProperty](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
6.2	Added <code>NODE_DESTRUCTION_POLICY</code> property. Added <code>CreateNodeIterator</code> , <code>CreateTreeWalker</code> , <code>GetProperty</code> and <code>SetProperty</code> methods.

## IDLffXMLDOMDocument Properties

IDLffXMLDOMDocument objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffXMLDOMDocument::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffXMLDOMDocument::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffXMLDOMDocument::SetProperty](#).

### Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2947.

Objects of this class have the following properties.

- [NODE\\_DESTRUCTION\\_POLICY](#)

In addition, objects of this class inherit properties from the following superclass:

- [IDLffXMLDOMNode](#)

### NODE\_DESTRUCTION\_POLICY

A scalar integer that specifies the node destruction policy for all node objects created directly or indirectly by a document object. The property value is not changed if you attempt to set it to other than one of the supported values:

0	When OBJ_DESTROY destroys a node object, it also destroys all node objects that the node created. These nodes, in turn, destroy all the nodes that they created, and so on. This is the default property value.
1	OBJ_DESTROY destroys only the node object for which it is called.

The destruction policy used for node destruction is obtained from the document object's property at the time a node object is destroyed. Thus, the document object's node destruction policy property can be changed between node destructions to use a specific destruction policy for certain nodes.

For all values of this property, all of the nodes created directly or indirectly by the document object are destroyed when the document object itself is destroyed.

For example, consider the following code:

```
oChild = oElement->getFirstChild()
oParent = oElement->getParentNode()
OBJ_DESTROY, oElement
```

If `NODE_DESTRUCTION_POLICY` has a value of 0 when `OBJ_DESTROY` is called, all three nodes, `oChild`, `oParent`, and `oElement`, are destroyed. If the property has a value of 1 when `OBJ_DESTROY` is called, only `oElement` is destroyed.

<b>Property Type</b>	Integer		
<b>Name String</b>	<i>not displayed</i>		
<b>Get:</b> Yes	<b>Set:</b> Yes	<b>Init:</b> Yes	<b>Registered:</b> No

## IDLffXMLDOMDocument::Cleanup

The IDLffXMLDOMDocument::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

### Syntax

OBJ\_DESTROY, *Obj*

or

*Obj*->[IDLffXMLDOMDocument:]Cleanup *(In a lifecycle method only.)*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateAttribute

The IDLffXMLDOMDocument::CreateAttribute function method creates and names an attribute node that is owned by the document. The new attribute can be set in an Element node with the [IDLffXMLDOMElement::SetAttributeNode](#) method.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateAttribute( *Name* )

### Return Value

Returns an object reference to the new [IDLffXMLDOMAttr](#) node.

### Arguments

#### Name

A scalar string containing the attribute name.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateCDATASection

The IDLffXMLDOMDocument::CreateCDATASection function method creates a CDATASection node that is owned by the document and stores a string in the CDATASection node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateCDATASection( *String* )

### Return Value

Returns an object reference to the new IDLffXMLDOMCDATASection node.

### Arguments

#### String

A scalar string to put in the new CDATASection node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateComment

The IDLffXMLDOMDocument::CreateComment function method creates a comment node that is owned by the document and stores a string in the comment node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateComment( *String* )

### Return Value

Returns an object reference to the new IDLffXMLDOMComment node.

### Arguments

#### String

A scalar string to put in the new comment node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateDocumentFragment

The IDLffXMLDOMDocument::CreateDocumentFragment function method creates a document-fragment node that is owned by the document.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateDocumentFragment()

### Return Value

Returns an object reference to the new [IDLffXMLDOMDocumentFragment](#) node.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateElement

The IDLffXMLDOMDocument::CreateElement function method creates an element node that is owned by the document and sets the element's name to a tag name.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateElement( *TagName* )

### Return Value

Returns an object reference to the new IDLffXMLDOMElement node.

### Arguments

#### TagName

A scalar string that contains the name of the element.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateEntityReference

The IDLffXMLDOMDocument::CreateEntityReference function method creates and names an entity reference node that is owned by the document.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateEntityReference( *Name* )

### Return Value

Returns an object reference to the new [IDLffXMLDOMEntityReference](#) node.

### Arguments

#### Name

A scalar string that contains the entity reference name.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateNodeIterator

The IDLffXMLDOMDocument::CreateNodeIterator function method is used to create an instance of an [IDLffXMLDOMNodeIterator](#) object. This function returns an object reference to that instance.

Please note the following exceptions in node iteration:

- Attributes are never children of DOM nodes, so they are not visited by the node iterator. Showing attributes is only meaningful when the iterator root node is an attribute.
- Entities are not part of the DOM tree, so they are not visited by the node iterator. Showing entities is only meaningful when the iterator root node is an entity.
- Notations are not part of the DOM tree, so they are not visited by the node iterator. Showing notations is only meaningful when the iterator root node is a notation.

### Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateNodeIterator( RootNode
    [, FILTER\_NAME=string] [, FILTER\_USERDATA=variable]
    [, WHAT\_TO\_SHOW=value] )
```

### Arguments

#### RootNode

An object reference to an object that is a subclass of [IDLffXMLDOMNode](#) that refers to a node in the DOM tree. The iterator's current position is set immediately before this node. If this object reference is NULL, the iterator's current position is set immediately before the document node.

### Keywords

#### FILTER\_NAME

Set this keyword to a scalar string containing the name of an IDL function that is called each time the iterator is about to visit a node. The purpose of this function is to allow the iterator to ask the IDL application if it should visit a particular node, and hence return it in response to an [IDLffXMLDOMNodeIterator::NextNode](#) or

[IDLffXMLDOMNodeIterator::PreviousNode](#) method call. The code in this function should analyze the incoming node and then return a value that instructs the iterator to accept or reject the node.

If this keyword is not specified, the node iterator visits every node.

Nodes that are accepted are returned by [IDLffXMLDOMNodeIterator::NextNode](#) and [IDLffXMLDOMNodeIterator::PreviousNode](#). Nodes that are rejected are not returned by these methods.

The filter function is called by the iterator for the given node after the determinations are made with respect to the [WHAT\\_TO\\_SHOW](#) setting. Therefore, the filter function is not called for nodes that are rejected by the [WHAT\\_TO\\_SHOW](#) property.

The filter function specified by `FILTER_NAME` must have the following parameters:

- **Node Object** — an object reference to an instance of an [IDLffXMLDOMNode](#) subclass. This parameter is required and is supplied by the iterator on every call.
- **USERDATA** — an optional keyword parameter set by the iterator to a variable containing a copy of the data provided in the [FILTER\\_USERDATA](#) keyword. If [FILTER\\_USERDATA](#) is not specified, `USERDATA` is not passed by the iterator.

The function must return one of three scalar integer values:

Value	Function
1	ACCEPT: this node is visited by the node iterator
2	REJECT: this node is not visited by the node iterator
3	SKIP: this node is not visited by the node iterator (same as REJECT)

*Table 6-20: Return Values for CreateNodeIterator's Filter Function*

SKIP and REJECT have the same meanings for a node iterator, but have different meanings for a tree walker. This makes it possible for a single filter function to be used with either a node iterator or tree walker. If the function returns a value that is not supported, the iterator visits the node, as if the return value was 1 (ACCEPT). If the function returns a value that cannot be converted to a scalar, IDL throws an error.

The function should not destroy the node object passed as the first parameter.

## FILTER\_USERDATA

Set this keyword to an IDL variable containing data to pass to the filter function each time the iterator calls the filter function. The iterator creates a copy of this variable to pass on each call.

Supplying this keyword without [FILTER\\_NAME](#) produces no effect on the iterator.

## WHAT\_TO\_SHOW

Set this keyword to a scalar unsigned integer containing a bitmask, where each bit indicates types of nodes that the iterator visits. If this keyword is not specified, the node iterator visits every node.

Type	Value (Hex)	Value (Decimal)
ALL	'ffff'xu	65535U
Element	'0001'xu	1U
Attribute	'0002'xu	2U
Text	'0004'xu	4U
CDATA Section	'0008'xu	8U
Entity Reference	'0010'xu	16U
Entity	'0020'xu	32U
Processing Instruction	'0040'xu	64U
Comment	'0080'xu	128U
Document	'0100'xu	256U
Document Type	'0200'xu	512U
Document Fragment	'0400'xu	1024U
Notation	'0800'xu	2048U

*Table 6-21: Bitmasks for CreateNodeIterator's WHAT\_TO\_SHOW Keyword*

The node iterator performs the WHAT\_TO\_SHOW test for a node before calling any user-provided filter function.

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateProcessingInstruction

The IDLffXMLDOMDocument::CreateProcessingInstruction function method creates a processing-instruction node that is owned by the document and stores two strings in the processing-instruction node.

### Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateProcessingInstruction( Target,  
    Data )
```

### Return Value

Returns an object reference to the new [IDLffXMLDOMProcessingInstruction](#) node.

### Arguments

#### Target

A scalar string to store in the processing-instruction target.

#### Data

A scalar string to store in the processing-instruction data.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateTextNode

The IDLffXMLDOMDocument::CreateTextNode function method creates a text node that is owned by the document and stores a string in the text node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]CreateTextNode( *String* )

### Return Value

Returns an object reference to the new IDLffXMLDOMText node.

### Arguments

#### String

A scalar string to put in the new text node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::CreateTreeWalker

The IDLffXMLDOMDocument::CreateTreeWalker function method is used to create an instance of an [IDLffXMLDOMTreeWalker](#) object. This function returns an object reference to that instance.

Please note the following exceptions in tree-walking:

- Attributes are never children of DOM nodes, so they are not visited by the tree walker. Showing attributes is only meaningful when the walker root node is an attribute.
- Entities are not part of the DOM tree, so they are not visited by the tree walker. Showing entities is only meaningful when the walker root node is an entity.
- Notations are not part of the DOM tree, so they are not visited by the tree walker. Showing notations is only meaningful when the walker root node is a notation.

### Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateTreeWalker( RootNode
    [, FILTER_NAME=string] [, FILTER_USERDATA=variable]
    [, WHAT_TO_SHOW=value] )
```

### Arguments

#### RootNode

An object reference to an object that is a subclass of [IDLffXMLDOMNode](#) that refers to a node in the DOM tree. The tree walker's current position is set at this node. If the object reference is NULL, the walker's current position is set to the document node.

### Keywords

#### FILTER\_NAME

Set this keyword to a scalar string containing the name of an IDL function that is called each time the tree walker is about to visit a node. The purpose of this function is to allow the walker to ask the IDL application if it should visit a particular node, and hence return it in response to a call to one of the tree walker's navigation methods (e.g., [IDLffXMLDOMTreeWalker::NextNode](#)). The code in this function should

analyze the incoming node and then return a value that instructs the walker to accept or reject the node.

If this keyword is not specified, the tree walker visits every node.

The various tree-walker movement methods return nodes that are accepted by the filter function. The movement methods do not return nodes that are rejected or skipped by the filter function. The walker does not consider nodes that are children of a rejected node, but does consider children of nodes that are skipped.

The tree walker calls the filter function for the given node after making determinations with respect to the [WHAT\\_TO\\_SHOW](#) setting. However, unlike the node iterator, the walker still calls the filter function for nodes not meeting the [WHAT\\_TO\\_SHOW](#) criteria. This is required so that the filter function can direct the walker to either REJECT or SKIP a node whose type is not in the [WHAT\\_TO\\_SHOW](#) list. If the filter function returns ACCEPT for a node not meeting the [WHAT\\_TO\\_SHOW](#) criteria, the walker SKIPS the node. That is, a filter function cannot override the rejection of a node because of the [WHAT\\_TO\\_SHOW](#) setting; it can only direct the walker to REJECT or SKIP such a node.

The filter function specified by `FILTER_NAME` must have the following parameters:

- **Node Object** — an object reference to an instance of an [IDLffXMLDOMNode](#) subclass. This parameter is required and is supplied by the tree walker on every call.
- **USERDATA** — an optional keyword parameter set by the tree walker to a variable containing a copy of the data provided in the [FILTER\\_USERDATA](#) keyword. If [FILTER\\_USERDATA](#) is not specified, USERDATA is not passed by the walker.

The function must return one of three scalar integer values:

Value	Function
1	ACCEPT: the tree walker visits this node
2	REJECT: the tree walker does not visit this node or its children
3	SKIP: the tree walker does not visit this node, but considers the node's children for visiting

*Table 6-22: Return Values for CreateTreeWalker's Filter Function*

If the function returns a value that is not supported, the tree walker visits the node, as if the return value were 1 (ACCEPT). If the function returns a value that cannot be converted to a scalar, IDL throws an error.

The function should not destroy the node object passed as the first parameter.

## FILTER\_USERDATA

Set this keyword to an IDL variable containing data to pass to the filter function each time the tree walker calls the filter function.

Supplying this keyword without [FILTER\\_NAME](#) produces no effect on the tree walker.

## WHAT\_TO\_SHOW

Set this keyword to a scalar unsigned integer containing a bitmask, where each bit indicates types of nodes that the tree walker visits. If this keyword is not specified, the walker visits every node.

Type	Value (Hex)	Value (Decimal)
ALL	'ffff'xu	65535U
Element	'0001'xu	1U
Attribute	'0002'xu	2U
Text	'0004'xu	4U
CDATA Section	'0008'xu	8U
Entity Reference	'0010'xu	16U
Entity	'0020'xu	32U
Processing Instruction	'0040'xu	64U
Comment	'0080'xu	128U
Document	'0100'xu	256U
Document Type	'0200'xu	512U
Document Fragment	'0400'xu	1024U
Notation	'0800'xu	2048U

Table 6-23: Bitmasks for CreateTreeWalker's WHAT\_TO\_SHOW Keyword

The tree walker performs the `WHAT_TO_SHOW` test for a node before calling any user-provided filter function.

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMDocument::GetDoctype

The IDLffXMLDOMDocument::GetDoctype function method creates an instance of [IDLffXMLDOMDocumentType](#) and returns its object reference.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]GetDoctype()

### Return Value

Returns an object reference to the new instance of [IDLffXMLDOMDocumentType](#), or a null object reference if a document does not have a DTD.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::GetDocumentElement

The IDLffXMLDOMDocument::GetDocumentElement function method creates an instance of an [IDLffXMLDOMElement](#) and returns its object reference. The IDLffXMLDOMElement object refers to the node that is the root element of the document.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMDocument::]GetDocumentElement()

### Return Value

Returns an object reference to the new instance of [IDLffXMLDOMElement](#).

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::GetElementsByTagName

The IDLffXMLDOMDocument::GetElementsByTagName function method creates an [IDLffXMLDOMNodeList](#) object containing all element nodes in the document tree with the specified tag name and returns an object reference to the [IDLffXMLDOMNodeList](#) object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

### Syntax

*Result = Obj->*[IDLffXMLDOMDocument::]GetElementsByTagName( *TagName* )

### Return Value

Returns an object reference to the [IDLffXMLDOMNodeList](#) object.

The returned node list is “live,” in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an [IDLffXMLDOMNodeList](#) object is still returned, but contains no nodes.

### Arguments

#### TagName

A scalar string containing the tag name that is used to match the elements. The value “\*” matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocument::GetProperty

The IDLffXMLDOMDocument::GetProperty procedure method is used to get the values of various properties of the document object.

### Syntax

*Obj*->[IDLffXMLDOMDocument::](#)GetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLffXMLDOMDocument Properties](#)” on page 3207 that contains the word "Yes" in the "Get" column of the property table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

### Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMDocument::Init

The IDLffXMLDOMDocument::Init function method initializes the object. It can also load and parse an XML document, using the same keywords that [IDLffXMLDOMDocument::Load](#) does. (For more information on loading, see that method's description.)

### Syntax

```
Obj = OBJ_NEW('IDLffXMLDOMDocument'  
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]  
  [, /EXPAND_ENTITY_REFERENCES] [, FILENAME=string]  
  [, MSG_ERROR=string] [, MSG_FATAL=string] [, MSG_WARNING=string]  
  [, /QUIET] [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value])
```

or

```
Result = Obj->[IDLffXMLDOMDocument::]Init(  
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]  
  [, /EXPAND_ENTITY_REFERENCES] [, FILENAME=string]  
  [, MSG_ERROR=string] [, MSG_FATAL=string] [, MSG_WARNING=string]  
  [, /QUIET] [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value])  
  (In a lifecycle method only.)
```

### Return Value

Returns an object reference to the newly created object when this method is called indirectly, as part of the call to the OBJ\_NEW function.

Returns 1 if initialization was successful or 0 otherwise, when this method is called directly within a subclass Init method.

### Arguments

None

## Keywords

### Note

Any property listed under “[IDLfXMLDOMDocument Properties](#)” on page 3207 that contains the word "Yes" in the "Init" column of the property table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### EXCLUDE\_IGNOREABLE\_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM tree. Note that in order for the parser to distinguish between ignorable and non-ignorable white space, validation must be turned on with the [VALIDATION\\_MODE](#) keyword and there must be a DTD. This keyword has no effect if [VALIDATION\\_MODE](#) is 0 or if there is no DTD for the XML document.

### EXPAND\_ENTITY\_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

### FILENAME

Set this keyword to a scalar string containing the name of the XML file to load and parse.

The keyword string can also specify a URL. In this case, the object reads the XML data from the specified URL over the network and builds the document tree without the XML data needing to be present in a local file.

The following example reads XML from an RSS feed containing weather information for Denver, Colorado:

```
FUNCTION filter, oNode
  name = oNode->getNodeName()
  IF name EQ 'title' OR name EQ 'description' THEN $
    RETURN, 1 ; accept
```

```

        RETURN, 3 ;; skip
    END

    PRO weather
        oDoc = OBJ_NEW( 'IDLffXMLDOMDocument', $
            FILENAME='http://weather.gov/data/current_obs/KDEN.rss' )
        oNodeIterator = oDoc->createNodeIterator( OBJ_NEW(), $
            FILTER_NAME='filter' )

        oNode = oNodeIterator->nextNode()
        WHILE OBJ_VALID( oNode ) DO BEGIN
            ; Assuming only one text node per element
            PRINT, (oNode->GetFirstChild()->getNodeValue()
                oNode = oNodeIterator->nextNode()
            ENDWHILE
        PRINT
        OBJ_DESTROY, oDoc
    END

```

## MSG\_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- **Filename** – A scalar string containing the name of the file being parsed
- **Line number** – A scalar integer containing the line number in the file where the parsing error occurred
- **Column number** – A scalar integer containing the column number in the file where the parsing error occurred
- **Message** – A scalar string containing the parser error message

## MSG\_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for [MSG\\_ERROR](#).

## MSG\_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for [MSG\\_ERROR](#).

## QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

## SCHEMA\_CHECKING

Set this keyword to an integer value to indicate the type of validation the parser should perform. XML schemas describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation occurs. Possible values are:

0	No schema checking is performed.
1	Schema checking is performed only if a schema is provided. This is the default value.
2	Full schema constraint checking is performed if a schema is provided. This feature checks the schema grammar itself for additional errors.

## VALIDATION\_MODE

Set this keyword to one of the following values:

0	The parser does not report validation errors. This is the default value.
1	The parser reports validation errors only if a DTD is specified.
2	The parser always reports validation errors.

This keyword ignores all other values.

## Version History

6.1	Introduced
6.2	Added SCHEMA_CHECKING keyword

## IDLffXMLDOMDocument::Load

The IDLffXMLDOMDocument::Load procedure method loads XML data from the source specified by the [FILENAME](#) keyword. The XML parser then parses the data, using any related DTD or schema specifications. The results of the parse are used to construct a DOM document tree that can then be accessed through this document object.

If the [FILENAME](#) keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

### Note

---

This method invalidates all object references to node objects created with the previous document.

---

IDL issues messages for any parser warnings or errors unless the [QUIET](#) keyword is set. If a parsing error that is more severe than a warning is encountered during parsing, IDL issues a single additional message after parsing and returns to the interpreter, even if [QUIET](#) is set. The IDL CATCH facility can intercept this message. If this message is issued, the document tree is empty, containing no nodes.

## Syntax

```
Obj->[IDLffXMLDOMDocument::]Load  
    [, /EXCLUDE_IGNOREABLE_WHITESPACE]  
    [, /EXPAND_ENTITY_REFERENCES] [, FILENAME=string]  
    [, MSG_ERROR=string] [, MSG_FATAL=string] [, MSG_WARNING=string]  
    [, /QUIET] [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value]
```

## Arguments

None

## Keywords

### EXCLUDE\_IGNOREABLE\_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM tree. Note that in order for the parser to distinguish between ignorable and non-

ignorable white space, validation must be turned on with the **VALIDATION\_MODE** keyword and there must be a DTD. This keyword has no effect if **VALIDATION\_MODE** is 0 or if there is no DTD for the XML document.

## EXPAND\_ENTITY\_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

## FILENAME

Set this keyword to a scalar string containing the name of the XML file to load and parse. If this keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

The keyword string can also specify a URL. In this case, the object reads the XML data from the specified URL over the network and builds the document tree without the XML data needing to be present in a local file.

The following example reads XML from an RSS feed containing weather information for Denver, Colorado:

```

FUNCTION filter, oNode
    name = oNode->getNodeName()
    IF name EQ 'title' OR name EQ 'description' THEN $
        RETURN, 1 ; accept
    RETURN, 3 ;; skip
END

PRO weather
    oDoc = OBJ_NEW( 'IDLffXMLDOMDocument', $
        FILENAME='http://weather.gov/data/current_obs/KDEN.rss' )
    oNodeIterator = oDoc->createNodeIterator( OBJ_NEW(), $
        FILTER_NAME='filter' )

    oNode = oNodeIterator->nextNode()
    WHILE OBJ_VALID( oNode ) DO BEGIN
        ; Assuming only one text node per element
        PRINT, (oNode->GetFirstChild()->getNodeValue()
        oNode = oNodeIterator->nextNode()

```

```
        ENDWHILE
        PRINT
        OBJ_DESTROY, oDoc
    END
```

## MSG\_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- **Filename** – A scalar string containing the name of the file being parsed
- **Line number** – A scalar integer containing the line number in the file where the parsing error occurred
- **Column number** – A scalar integer containing the column number in the file where the parsing error occurred
- **Message** – A scalar string containing the parser error message

## MSG\_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for [MSG\\_ERROR](#).

## MSG\_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for [MSG\\_ERROR](#).

## QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

## SCHEMA\_CHECKING

Set this keyword to an integer value to indicate the type of validation the parser should perform. XML schemas describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the

specified schema, if one is provided. If no schema is provided, no validation occurs. Possible values are:

0	No schema checking is performed.
1	Schema checking is performed only if a schema is provided. This is the default value.
2	Full schema constraint checking is performed if a schema is provided. This feature checks the schema grammar itself for additional errors.

## VALIDATION\_MODE

Set this keyword to one of the following values:

0	The parser does not report validation errors. This is the default value.
1	The parser reports validation errors only if a DTD is specified.
2	The parser always reports validation errors.

This keyword ignores all other values.

## Version History

6.1	Introduced
6.2	Added SCHEMA_CHECKING keyword

## IDLffXMLDOMDocument::Save

The IDLffXMLDOMDocument::Save procedure method serializes the current DOM document belonging to this document object and writes it to the output source specified by the [FILENAME](#) keyword.

### Syntax

```
Obj->[IDLffXMLDOMDocument::]Save [, ENCODING=string]  
    [, /EXPAND\_ENTITY\_REFERENCES] [, FILENAME=string]  
    [, /PRETTY\_PRINT]
```

### Arguments

None

### Keywords

#### ENCODING

Set this keyword to a scalar string specifying the encoding to be used when the XML DOM document is written to a file. If this keyword is not specified and the document was loaded with the [IDLffXMLDOMDocument::Init](#) or [IDLffXMLDOMDocument::Load](#) methods from a file, the document is written to a file using the same encoding used to load the file. If this keyword is not specified and the document was created programatically, the document is written to the file using UTF-8 encoding.

#### Note

---

For the list of supported XML encodings, see “[About XML](#)” in Chapter 20 of the *Building IDL Applications* manual.

---

If an encoding is specified that is not supported, no error is reported and this method writes an empty file.

#### EXPAND\_ENTITY\_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text as the DOM tree is written to the output file. The DOM tree itself is not changed. The default behavior is to write the entity references to the output file.

## FILENAME

Set this keyword to the name of the XML file in which to store the XML data. If FILENAME is not set or is set to "" (null string), this method will return without storing any data on the file system.

FILENAME can contain a directory path (e.g., 'C:\RSI\test.xml'). IDL throws an error and stops if any of the following conditions are true:

- The directory does not exist
- The directory exists, but is not writable
- The file exists, but is not writable

## PRETTY\_PRINT

Set this keyword to format the output by adding white space to produce a pretty-printed, indented, reader-friendly form.

## Version History

6.1	Introduced
6.2	Added ENCODING keyword

## IDLffXMLDOMDocument:: SetProperty

The IDLffXMLDOMDocument::SetProperty procedure method is used to set the values of various properties of the parser.

### Syntax

*Obj*->[IDLffXMLDOMDocument::](#)SetProperty [, *PROPERTY=variable*]

### Arguments

None

### Keywords

Any property listed under “[IDLffXMLDOMDocument Properties](#)” on page 3207 that contains the word “Yes” in the “Set” column of the property table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

### Version History

6.2	Introduced
-----	------------

# IDLffXMLDOMDocumentFragment

The `IDLffXMLDOMDocumentFragment` class references a document-fragment node.

It is very common to want to be able to extract a portion of a document's tree or to create a new fragment of a document. Imagine implementing a user command such as “cut” or rearranging a document by moving fragments around. It is desirable to have an object that can hold such fragments, and it is quite natural to use a node for this purpose. While it is true that a document object could fill this role, it can potentially be a heavyweight object, depending on the underlying implementation. What you need for this purpose, instead, is a very lightweight object, and the document-fragment node is such an object.

Furthermore, various operations such as inserting nodes as children of another node may take document-fragment objects as arguments; this results in all the child nodes of the document-fragment node being moved to the child list of this node.

The children of a document-fragment node are zero or more nodes representing the roots of any sub-trees defining the structure of the document. Document-fragment nodes do not need to be well-formed XML documents (although they do need to follow the rules imposed upon well-formed XML parsed entities, which can have multiple root nodes). For example, a document-fragment node might have only one child, and that child node could be a text node. Such a structure model represents neither an HTML document nor a well-formed XML document.

When a document-fragment node is inserted into a document tree (or, indeed, any other node that may take children), the children of the document-fragment node and not the document-fragment node itself are inserted into the node. This insertion process makes the document-fragment node very useful when you want to create nodes that are siblings. Because the document-fragment node acts as the parent of these nodes, you can use the standard methods from the node object, such as `InsertBefore()` and `AppendChild()`.

There are no methods specific to this class except `Cleanup` and `Init`.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMDocumentFragment::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMDocumentFragment::Cleanup](#)
- [IDLffXMLDOMDocumentFragment::Init](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMDocumentFragment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

## IDLffXMLDOMDocumentFragment::Cleanup

The IDLffXMLDOMDocumentFragment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

## IDLffXMLDOMDocumentType::Init

The IDLffXMLDOMDocumentType::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

# IDLffXMLDOMElement

The IDLffXMLDOMElement class references an element node, which is one of the most common node types in an XML document.

Elements can have attributes associated with them, which can be obtained with the [IDLffXMLDOMNode::GetAttributes](#) method. The IDLffXMLDOMElement class also has methods for getting an attribute object or an attribute value by its name.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMElement::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMElement::Cleanup](#)
- [IDLffXMLDOMElement::GetAttribute](#)
- [IDLffXMLDOMElement::GetAttributeNode](#)
- [IDLffXMLDOMElement::GetElementsByTagName](#)
- [IDLffXMLDOMElement::GetTagName](#)
- [IDLffXMLDOMElement::Init](#)
- [IDLffXMLDOMElement::RemoveAttribute](#)
- [IDLffXMLDOMElement::RemoveAttributeNode](#)
- [IDLffXMLDOMElement::SetAttribute](#)
- [IDLffXMLDOMElement::SetAttributeNode](#)

In addition, this class inherits the methods of any superclasses.

## Version History

## IDLffXMLDOMElement Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

## IDLffXMLDOMELEMENT::Cleanup

The IDLffXMLDOMELEMENT::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMELEMENT::GetAttribute

The IDLffXMLDOMELEMENT::GetAttribute function method returns the value of the attribute specified by *Name*.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMELEMENT::]GetAttribute( *Name* )

### Return Value

Returns a scalar string containing the value of the attribute specified by *Name*.

### Arguments

#### Name

A scalar string used to specify the name of the attribute for which to get the value.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMElement::GetAttributeNode

The IDLffXMLDOMElement::GetAttributeNode function method creates an [IDLffXMLDOMAttr](#) object and returns its object reference.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMElement::]GetAttributeNode( *Name* )

### Return Value

Returns an object reference to the [IDLffXMLDOMAttr](#) object. The object refers to the attribute node specified by name. If this node does not exist, this function returns a null object reference.

### Arguments

#### Name

A scalar string used to specify the attribute node to get.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMElement::GetElementsByTagName

The `IDLffXMLDOMElement::GetElementsByTagName` function method creates an [IDLffXMLDOMNodeList](#) object containing all descendant element nodes in the document tree with the specified tag name and returns an object reference to the [IDLffXMLDOMNodeList](#) object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

### Syntax

*Result* = *Obj*->[[IDLffXMLDOMElement::](#)]GetElementsByTagName( *TagName* )

### Return Value

Returns an object reference to the [IDLffXMLDOMNodeList](#) object.

The returned node list is “live,” in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an [IDLffXMLDOMNodeList](#) is still returned, but contains no nodes.

### Arguments

#### TagName

A scalar string containing the tag name that is used to match the elements. The value “\*” matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMElement::GetTagName

The IDLffXMLDOMElement::GetTagName function method returns the name of the element.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMElement::]GetTagName()

### Return Value

Returns a scalar string containing the name of the element.

### Argument

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMELEMENT::Init

The IDLffXMLDOMELEMENT::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMELEMENT::RemoveAttribute

The IDLffXMLDOMELEMENT::RemoveAttribute procedure method removes a specified attribute from the element node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMELEMENT::]RemoveAttribute( *Name* )

### Arguments

#### Name

A scalar string that contains the name of the attribute to remove from the element.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMELEMENT::RemoveAttributeNode

The IDLffXMLDOMELEMENT::RemoveAttributeNode function method removes a specified attribute node from the element node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMELEMENT::]RemoveAttributeNode( *OldAttr* )

### Return Value

Returns an object reference to an IDLffXMLDOMAttr node referring to the attribute node that was removed.

### Arguments

#### OldAttr

An object reference to an IDLffXMLDOMAttr object that refers to an attribute node to be removed from the element node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMELEMENT::SetAttribute

The IDLffXMLDOMELEMENT::SetAttribute procedure method adds a new attribute to the element node.

### Syntax

*Obj*->[IDLffXMLDOMELEMENT::]SetAttribute, *Name*, *Value*

### Arguments

#### Name

A scalar string that contains the name of the attribute.

#### Value

A scalar string that contains the value of the attribute.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMElement::SetAttributeNode

The IDLffXMLDOMElement::SetAttributeNode function method adds an attribute node to the element node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMElement::]SetAttributeNode( *NewAttr* )

### Return Value

Returns an object reference to an IDLffXMLDOMAttr node, if an old attribute is replaced by the new. This method returns a null object reference if no attribute was replaced by this method.

### Arguments

#### NewAttr

An object reference to an IDLffXMLDOMAttr object that refers to an attribute node that is to be set in the element node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

# IDLffXMLDOMEntity

The IDLffXMLDOMEntity class references an entity, either parsed or unparsed, in an XML document. Entities are placeholders in XML and are inserted into documents by entity references. Entity nodes have no parents. Entity nodes and their descendants are read-only.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMEntity::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMEntity::Cleanup](#)
- [IDLffXMLDOMEntity::GetNotationName](#)
- [IDLffXMLDOMEntity::GetPublicId](#)
- [IDLffXMLDOMEntity::GetSystemId](#)
- [IDLffXMLDOMEntity::Init](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced

## IDLffXMLDOMEntity::GetSystemId

The IDLffXMLDOMEntity::GetSystemId function method returns the system ID of the entity, if it is specified.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMEntity::]GetSystemId()

### Return Value

Returns a scalar string containing the system ID of the entity, or an empty string if the system ID is not specified.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMEntity::Init

The IDLffXMLDOMEntity::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMDocumentType::GetEntities](#) coupled with [IDLffXMLDOMNamedNodeMap::GetNamedItem](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

# IDLffXMLDOMEntityReference

The IDLffXMLDOMEntityReference class references entity reference nodes. Entity references in the source XML file are meant to be substituted by the entity contents upon parsing. Any entity reference nodes left in the document tree may exist because the entity was not found, or the parser was instructed to not expand entity references.

Entity references are read-only.

There are no methods specific to this class except Cleanup and Init.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMEntityReference::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMEntityReference::Cleanup](#)
- [IDLffXMLDOMEntityReference::Init](#)

In addition, this class inherits the methods of any superclasses.

## Version History

## IDLffXMLDOMEntityReference::Init

The IDLffXMLDOMEntityReference::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

# IDLffXMLDOMNamedNodeMap

The IDLffXMLDOMNamedNodeMap class is a container for nodes (see [IDLffXMLDOMNode](#) and its subclasses) and uses the node's name to access the nodes in the container.

For example, consider this XML:

```
<show title="My Title" date="Nov 12, 1999" author="Me">
```

The entire line is a DOM element node. A `GetAttributes` call returns a `NamedNodeMap` that contains three attribute node objects. The attribute node object containing the date, for example, has a node name of 'date' and a node value of 'Nov 12, 1999'.

The benefit of the named node map is that the nodes are accessed by their node names. Thus, to access the date node, you would use the string 'date' and would not have to worry about its position in the list.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMNamedNodeMap::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMNamedNodeMap::Cleanup](#)
- [IDLffXMLDOMNamedNodeMap::GetLength](#)
- [IDLffXMLDOMNamedNodeMap::GetNamedItem](#)
- [IDLffXMLDOMNamedNodeMap::Init](#)
- [IDLffXMLDOMNamedNodeMap::Item](#)

- [IDLffXMLDOMNamedNodeMap::RemoveNamedItem](#)
- [IDLffXMLDOMNamedNodeMap::SetNamedItem](#)

In addition, this class inherits the methods of any superclasses.

## Version History

-----	------------

## IDLffXMLDOMNamedNodeMap::GetLength

The IDLffXMLDOMNamedNodeMap::GetLength function method returns the number of nodes in the named node map.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNamedNodeMap::]GetLength()

### Return Value

Returns an integer containing the number of nodes in the named node map.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNamedNodeMap::GetNamedItem

The IDLffXMLDOMNamedNodeMap::GetNamedItem function method returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied name.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNamedNodeMap::]GetNamedItem( *Name* )

### Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied name. If the node is not found, this function returns a null object reference.

### Arguments

#### Name

A scalar string that contains the name used to locate the node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNamedNodeMap::Init

The IDLffXMLDOMNamedNodeMap::Init function method initializes the object, but this class should not be instantiated directly. Instead, the [IDLffXMLDOMNode::GetAttributes](#) method is used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMNamedNodeMap::Item

The IDLffXMLDOMNamedNodeMap::Item function method returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to an index.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNamedNodeMap::]Item( *Index* )

### Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

### Arguments

#### Index

An integer that contains the index into the named node map.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNamedNodeMap::RemoveNamedItem

The IDLffXMLDOMNamedNodeMap::RemoveNamedItem function method removes the node from the named node map that corresponds to a name.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNamedNodeMap::]RemoveNamedItem( *Name* )

### Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the removed node if it exists. If the node does not exist, this function returns a null object reference.

### Arguments

#### Name

A scalar string that contains the name used to locate the node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNamedNodeMap::SetNamedItem

The IDLffXMLDOMNamedNodeMap::SetNamedItem function method adds a node to the named node map. After adding the node, the node can be accessed using the node's name attribute. If a node with the same name is already present in the map, then the node in the map is replaced by this new node.

Some node types have fixed name tags due to the nature of the node type. For example, an [IDLffXMLDOMText](#) node's name tag always has the value “#text” because it always contains text in its value tag. For a list of other nodes with fixed name tags see “[IDLffXMLDOMNode::GetNodeName Return Values](#)” on page 3300. (The fixed names are the names in quotation marks.)

---

### Note

You cannot place nodes with fixed name tags into a named node map because it uses the nodes' name tags to search for a requested node.

---

## Syntax

*Result* = *Obj*->[IDLffXMLDOMNamedNodeMap::]SetNamedItem( *Node* )

## Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that references the node that was replaced, if the method replaces a node in the map. Otherwise, the method returns a null object reference.

## Arguments

### Node

An object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node to add to the map.

## Keywords

None

## Version History

6.1	Introduced
-----	------------

# IDLffXMLDOMNode

The IDLffXMLDOMNode class is an abstract class used as a superclass for other IDLffXMLDOM node classes.

Because this class is an abstract class, there will never be an instance of this class. Rather, this class's functionality described here is accessed through an instance of one of its subclasses.

An object instance of this class is a reference to a corresponding node in the DOM document tree. Use the appropriate methods for this class, defined below, to access and manipulate the DOM data.

This class keeps track of any objects it creates (e.g., via the [IDLffXMLDOMNode::GetFirstChild](#) method) and destroys these objects when it is destroyed.

## Superclasses

None

## Creation

See [IDLffXMLDOMNode::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMNode::AppendChild](#)
- [IDLffXMLDOMNode::Cleanup](#)
- [IDLffXMLDOMNode::CloneNode](#)
- [IDLffXMLDOMNode::GetAttributes](#)
- [IDLffXMLDOMNode::GetChildNodes](#)
- [IDLffXMLDOMNode::GetFirstChild](#)

- [IDLffXMLDOMNode::GetLastChild](#)
- [IDLffXMLDOMNode::GetNextSibling](#)
- [IDLffXMLDOMNode::GetNodeName](#)
- [IDLffXMLDOMNode::GetNodeType](#)
- [IDLffXMLDOMNode::GetNodeValue](#)
- [IDLffXMLDOMNode::GetOwnerDocument](#)
- [IDLffXMLDOMNode::GetParentNode](#)
- [IDLffXMLDOMNode::GetPreviousSibling](#)
- [IDLffXMLDOMNode::HasChildNodes](#)
- [IDLffXMLDOMNode::Init](#)
- [IDLffXMLDOMNode::InsertBefore](#)
- [IDLffXMLDOMNode::RemoveChild](#)
- [IDLffXMLDOMNode::ReplaceChild](#)
- [IDLffXMLDOMNode::SetNodeValue](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## IDLffXMLDOMNode::AppendChild

The IDLffXMLDOMNode::AppendChild function method adds a new node to the end of the calling node's children list.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]AppendChild( *NewChild* )

### Return Value

Returns an object reference to the new child node.

### Arguments

#### NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being added.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::Cleanup

The IDLffXMLDOMNode::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::CloneNode

The IDLffXMLDOMNode::CloneNode function method creates a copy of the calling node (i.e., an instance of an IDLffXMLDOMNode subclass) and returns the object reference to the cloned node. The class of the cloned node is the same as the class of the calling node. The cloned node has no parent.

Cloning an element node copies all attributes and their values and does not copy child nodes unless the **DEEP** keyword is set. Cloning any other type of node simply copies the node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]CloneNode( [, /DEEP] )

### Return Value

Returns an object reference to the cloned node.

### Arguments

None

### Keywords

#### DEEP

Set this keyword to cause all of a node's children to be cloned along with the calling node. By default, only the calling node is cloned.

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetAttributes

The IDLffXMLDOMNode::GetAttributes function method creates an instance of an [IDLffXMLDOMNamedNodeMap](#) and returns an object reference to that object. The named node map can then be used to access the attributes of an element object.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetAttributes()

### Return Value

Returns an object reference to the new [IDLffXMLDOMNamedNodeMap](#) object. If the calling object is not an [IDLffXMLDOMElement](#), a null object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetChildNodes

The IDLffXMLDOMNode::GetChildNodes function method creates an instance of an [IDLffXMLDOMNodeList](#) object, which can then be used to access the child nodes. If there are no children, the node list object contains no nodes.

The contents of the node list object are updated as changes are made to the tree, such as children being added or removed from the calling node's children list.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetChildNodes()

### Return Value

Returns an object reference to the new [IDLffXMLDOMNodeList](#) object.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetFirstChild

The IDLffXMLDOMNode::GetFirstChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the first child of the calling node in the DOM tree. The type of the object corresponds to the type of the first child node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetFirstChild()

### Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetLastChild

The IDLffXMLDOMNode::GetLastChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the last child of the calling node in the DOM tree. The type of the object corresponds to the type of the last child node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetLastChild()

### Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetNextSibling

The IDLffXMLDOMNode::GetNextSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the next sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the next sibling node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetNextSibling()

### Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a next sibling in the DOM tree. If there is no sibling, a null object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetNodeName

The IDLffXMLDOMNode::GetNodeName function method returns the name of the node, depending on the calling node's subclass type.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetNodeName()

### Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute name
IDLffXMLDOMCDATASection	"#cdata-section"
IDLffXMLDOMComment	"#comment"
IDLffXMLDOMDocument	"#document"
IDLffXMLDOMDocumentFragment	"#document-fragment"
IDLffXMLDOMDocumentType	document type name
IDLffXMLDOMElement	tag name
IDLffXMLDOMEntity	entity name
IDLffXMLDOMEntityReference	name of entity reference
IDLffXMLDOMNotation	notation name
IDLffXMLDOMProcessingInstruction	target
IDLffXMLDOMText	"#text"

Table 6-24: IDLffXMLDOMNode::GetNodeName Return Values

### Arguments

None

## Keywords

None

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetNodeType

The IDLffXMLDOMNode::GetNodeType function method returns the subclass type of the calling node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetNodeType()

### Return Value

Returns an integer whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	2
IDLffXMLDOMCDATASection	4
IDLffXMLDOMComment	8
IDLffXMLDOMDocument	9
IDLffXMLDOMDocumentFragment	11
IDLffXMLDOMDocumentType	10
IDLffXMLDOMElement	1
IDLffXMLDOMEntity	6
IDLffXMLDOMEntityReference	5
IDLffXMLDOMNotation	12
IDLffXMLDOMProcessingInstruction	7
IDLffXMLDOMText	3

Table 6-25: IDLffXMLDOMNode::GetNodeType Return Values

### Arguments

None

## Keywords

None

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetNodeValue

The IDLffXMLDOMNode::GetNodeValue function method returns the value of the calling node, depending on its subclass type.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetNodeValue()

### Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute value
IDLffXMLDOMCDATASection	content of the CDATA section
IDLffXMLDOMComment	content of the comment
IDLffXMLDOMDocument	empty string
IDLffXMLDOMDocumentFragment	empty string
IDLffXMLDOMDocumentType	empty string
IDLffXMLDOMElement	empty string
IDLffXMLDOMEntity	empty string
IDLffXMLDOMEntityReference	empty string
IDLffXMLDOMNotation	empty string
IDLffXMLDOMProcessingInstruction	entire content excluding the target
IDLffXMLDOMText	content of the text node

*Table 6-26: IDLffXMLDOMNode::GetNodeValue Return Values*

### Arguments

None

## Keywords

None

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetOwnerDocument

The IDLffXMLDOMNode::GetOwnerDocument function method returns an object reference to the [IDLffXMLDOMDocument](#) used to create the node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetOwnerDocument()

### Return Value

Returns an object reference to the [IDLffXMLDOMDocument](#) used to create the node. If the calling node is an [IDLffXMLDOMDocument](#), the method returns a null object reference.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetParentNode

The IDLffXMLDOMNode::GetParentNode function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the parent node in the DOM tree. The type of the created object corresponds to the type of the parent node.

All node classes except [IDLffXMLDOMAttr](#), [IDLffXMLDOMDocument](#), [IDLffXMLDOMDocumentFragment](#), and [IDLffXMLDOMEntity](#) may have parents.

A node that has just been created and not yet added to the tree does not have a parent.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetParentNode()

### Return Value

Returns an object reference to the new object, which refers to the calling node's parent in the DOM tree. The type of the new object corresponds to the type of the parent node. If there is no parent, a null object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::GetPreviousSibling

The IDLffXMLDOMNode::GetPreviousSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the previous sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the previous sibling node.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]GetPreviousSibling()

### Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a previous sibling in the DOM tree. If there is no sibling, a null object reference is returned.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::HasChildNodes

The IDLffXMLDOMNode::HasChildNodes returns a value indicating whether the calling node has children.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]HasChildNodes()

### Return Value

Returns 1 if the calling node has children, or 0 otherwise.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::Init

The IDLffXMLDOMNode::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMNode::InsertBefore

The IDLffXMLDOMNode::InsertBefore function method inserts a new node into the calling node's children list at the location before a reference node.

If the reference node is not specified or is a null object reference, the new node is inserted at the end of the list of children.

If the new node is an [IDLffXMLDOMDocumentFragment](#), all of its children are inserted in the same order before the reference node.

If the new node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

### Syntax

```
Result = Obj->[IDLffXMLDOMNode::]InsertBefore( NewChild [, RefChild] )
```

### Return Value

Returns an object reference to the new child node.

### Arguments

#### NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node to insert.

#### RefChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the reference node. The new child node is inserted before the reference node. The reference node must be a child of the calling node.

### Keywords

None

## Version History

6.1	Introduced
-----	------------

## IDLfXMLDOMNode::RemoveChild

The IDLfXMLDOMNode::RemoveChild function method removes an existing child node from the calling node's child list.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

### Syntax

```
Result = Obj->[IDLfXMLDOMNode::]RemoveChild( OldChild )
```

### Return Value

Returns an object reference to the old child node.

### Arguments

#### OldChild

An object reference to an instance of an IDLfXMLDOMNode subclass that refers to the node that is being removed. The old child node must be a child of the calling node.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::ReplaceChild

The IDLffXMLDOMNode::ReplaceChild function method replaces an existing child node with a new child node into the calling node's child list.

If the new child node is an [IDLffXMLDOMDocumentFragment](#), the old child node is replaced by all the [IDLffXMLDOMDocumentFragment](#) children, which are inserted in the same order.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNode::]ReplaceChild( *NewChild*, *OldChild* )

### Return Value

Returns an object reference to the old child node.

### Arguments

#### NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node to put into the tree, replacing the old child node.

#### OldChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being replaced. The old child node must be a child of the calling node.

## Keywords

None

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNode::SetNodeValue

The IDLffXMLDOMNode::SetNodeValue procedure method sets the node's value to the contents of a string.

---

**Note**

This method is applicable only to the following node types: Attribute, Text, CDATA, Comment, and ProcessingInstruction. For all other node types, the method does nothing. For more information, see [“IDLffXMLDOMNode::GetNodeValue Return Values”](#) on page 3304.

---

### Syntax

*Obj*->[IDLffXMLDOMNode::]SetNodeValue, *NodeValue*

### Arguments

#### NodeValue

A scalar string value used to set the node's value.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

# IDLffXMLDOMNodeIterator

The `IDLffXMLDOMNodeIterator` class is used to navigate a DOM tree by creating a node object for accessing a DOM node and then destroying that node object as the iterator moves to another DOM node. The iterator creates an object and returns an object reference to that object each time the iterator moves, destroying the object that it last returned when the iterator last moved. This process lets the application visit the nodes in a DOM tree efficiently and easily.

The iterator moves back and forth through a document in a depth-first document-order traversal that corresponds to the order of the starting tags in an XML document. The node iterator is conceptually a “current” node pointer into the DOM tree. The pointer is positioned between nodes, so there is no concept of a current node. Instead, nodes on either side of the iterator's current position are referred to as the next and previous nodes. When the iterator moves, it returns either the next node or the previous node, depending on the direction it moves. The iterator is then positioned after the next node or before the previous node, again depending on the direction.

When the iterator is positioned at the start of a list of nodes, it has a next node, but no previous node. When the iterator is positioned at the end of a list of nodes, it has a previous node, but no next node.

The node specified when the iterator is created is the root node for the iterator. The iterator is positioned before the root node when the iterator is created. The nodes following the root node are the root node's children, if any. The iterator cannot move to siblings or to the parent of the root node. The root node therefore represents the top node of the subtree visible to the iterator.

The iterator never destroys the [IDLffXMLDOMDocument](#) objects that it might return. The iterator can only return an `IDLffXMLDOMDocument` object if an `IDLffXMLDOMDocument` object is the root node.

Objects of this class are created with the [IDLffXMLDOMDocument::CreateNodeIterator](#) method.

## Superclasses

None

## Creation

See [IDLffXMLDOMNodeIterator::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMNodeIterator::Cleanup](#)
- [IDLffXMLDOMNodeIterator::Init](#)
- [IDLffXMLDOMNodeIterator::NextNode](#)
- [IDLffXMLDOMNodeIterator::PreviousNode](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.2	Introduced
-----	------------

## **IDLffXLMDOMNodelterator Properties**

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## IDLffXMLDOMNodeIterator::Cleanup

The IDLffXMLDOMNodeIterator::Cleanup procedure method performs cleanup on the node-iterator object. As part of this cleanup, the method destroys any other objects that were created by the iterator object. In particular, the node object returned when the iterator was last moved is destroyed. The destruction of the iterator object does not affect any corresponding nodes in the DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMNodeIterator::Init

The `IDLffXMLDOMNodeIterator::Init` function method initializes the object, but this class should not be instantiated directly. Instead, use the [IDLffXMLDOMDocument::CreateNodeIterator](#) method to create instances of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMNodeIterator::NextNode

The `IDLffXMLDOMNodeIterator::NextNode` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that appears after the iterator's current position in document-order traversal. The iterator's current position is then updated to the position immediately after the node returned by this method.

This method destroys the object returned by the most recent previous invocation of [IDLffXMLDOMNodeIterator::NextNode](#) or [IDLffXMLDOMNodeIterator::PreviousNode](#).

### Syntax

*Result* = *Obj*->[[IDLffXMLDOMNodeIterator::](#)]NextNode()

### Return Value

Returns the object reference to the object that refers to the next node in the DOM tree.

If the iterator is positioned after the last node in the subtree under the iterator's root node, this method returns a null object reference, and the iterator's position does not change.

The first time this method is called after the iterator is created, the return value is the iterator's root node.

### Arguments

None

### Keywords

None

### Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMNodeIterator::PreviousNode

The `IDLffXMLDOMNodeIterator::PreviousNode` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that appears before the iterator's current position in document-order traversal. The iterator's current position is then updated to the position immediately before the node returned by this method.

This method destroys the object returned by the most recent previous invocation of [IDLffXMLDOMNodeIterator::NextNode](#) or [IDLffXMLDOMNodeIterator::PreviousNode](#).

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNodeIterator::]PreviousNode()

### Return Value

Returns the object reference to the object that refers to the previous node in the DOM tree.

If the iterator is positioned before the iterator's root node, this method returns a null object reference, and the iterator's position does not change. This is the situation immediately after an iterator's creation.

### Arguments

# IDLffXMLDOMNodeList

The IDLffXMLDOMNodeList class is a container for nodes (see [IDLffXMLDOMNode](#) and its subclasses).

## Superclasses

None

## Creation

See [IDLffXMLDOMNodeList::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMNodeList::Cleanup](#)
- [IDLffXMLDOMNodeList::GetLength](#)
- [IDLffXMLDOMNodeList::Init](#)
- [IDLffXMLDOMNodeList::Item](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNodeList Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## IDLffXMLDOMNodeList::Cleanup

The IDLffXMLDOMNodeList::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNodeList::GetLength

The IDLffXMLDOMNodeList::GetLength returns the number of nodes in the node list.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNodeList::]GetLength()

### Return Value

Returns an integer containing the number of nodes in the node list.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNodeList::Init

The IDLffXMLDOMNodeList::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMNodeList::Item

The IDLffXMLDOMNodeList::Item returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to an indexed node from the node list.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNodeList::]Item( *Index* )

### Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the node list that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

### Arguments

#### Index

An integer that contains the index into the node list.

# IDLffXMLDOMNotation

The IDLffXMLDOMNotation class represents a notation in the DTD. Notations are obtained from the [IDLffXMLDOMDocumentType](#) class.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMNotation::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMNotation::Cleanup](#)
- [IDLffXMLDOMNotation::GetPublicID](#)
- [IDLffXMLDOMNotation::GetSystemID](#)
- [IDLffXMLDOMNotation::Init](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNotation Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

## IDLffXMLDOMNotation::Cleanup

The IDLffXMLDOMNotation::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

-----	------------

## IDLffXMLDOMNotation::GetPublicID

The IDLffXMLDOMNotation::GetPublicID returns the public ID of the notation.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNotation::]GetPublicID()

### Return Value

Returns a scalar string containing the public ID of the notation.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMNotation::GetSystemID

The IDLffXMLDOMNotation::GetSystemID returns the system ID of the notation.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMNotation::]GetSystemID()

### Return Value

Returns a scalar string containing the system ID of the notation.

### Arguments

None

### Keywords

None

### Version History

-----	------------

## IDLffXMLDOMNotation::Init

The IDLffXMLDOMNotation::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

# IDLffXMLDOMProcessingInstruction

The IDLffXMLDOMProcessingInstruction class represents a processing instruction node in an XML document.

## Superclasses

[IDLffXMLDOMNode](#)

## Creation

See [IDLffXMLDOMProcessingInstruction::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMProcessingInstruction::Cleanup](#)
- [IDLffXMLDOMProcessingInstruction::GetData](#)
- [IDLffXMLDOMProcessingInstruction::GetTarget](#)
- [IDLffXMLDOMProcessingInstruction::Init](#)
- [IDLffXMLDOMProcessingInstruction::SetData](#)

In addition, this class inherits the methods of its superclasses (if any).

## Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMProcessingInstruction Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

## IDLffXMLDOMProcessingInstruction::Cleanup

The IDLffXMLDOMProcessingInstruction::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

## IDLffXMLDOMProcessingInstruction::GetData

The IDLffXMLDOMProcessingInstruction::GetData returns the content of the processing instruction.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMProcessingInstruction::]GetData()

### Return Value

Returns a scalar string containing the content of the processing instruction.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMProcessingInstruction::GetTarget

The IDLffXMLDOMProcessingInstruction::GetTarget returns the target of the processing instruction.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMProcessingInstruction::]GetTarget()

### Return Value

Returns a scalar string containing the target of the processing instruction.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced

## IDLffXMLDOMProcessingInstruction::Init

The IDLffXMLDOMProcessingInstruction::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMProcessingInstruction::SetData

The IDLffXMLDOMProcessingInstruction::SetData procedure method sets the content of the processing instruction.

### Syntax

*Obj*->[IDLffXMLDOMProcessingInstruction:]SetData, *Content*

### Arguments

#### Content

A scalar string containing the data to set in the processing instruction.

### Keywords

None

### Version History

6.1	Introduced

# IDLffXMLDOMText

The IDLffXMLDOMText class references a text node in an XML document.

## Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

## Creation

See [IDLffXMLDOMText::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMText::Cleanup](#)
- [IDLffXMLDOMText::Init](#)
- [IDLffXMLDOMText::IsIgnorableWhitespace](#)
- [IDLffXMLDOMText::SplitText](#)

In addition, this class inherits the methods of any superclasses.

## Version History

## IDLffXMLDOMText::Init

The IDLffXMLDOMText::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMText::IsIgnorableWhitespace

The IDLffXMLDOMText::IsIgnorableWhitespace function method indicates whether the text node contains ignorable whitespace.

In order for the parser to distinguish between ignorable and non-ignorable white space, validation must be performed during parsing with a DTD or schema.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMText::]IsIgnorableWhitespace()

### Return Value

Returns 1 if the text node contains ignorable whitespace, or 0 if the text node contains whitespace that is not ignorable.

### Arguments

None

### Keywords

None

### Version History

6.1	Introduced
-----	------------

## IDLffXMLDOMText::SplitText

The IDLffXMLDOMText::SplitText function method breaks a text node into two nodes, splitting the text at the specified offset. Both nodes are kept in the same tree as siblings. The method both modifies its caller and creates an instance of a new IDLffXMLDOMText object, which contains the text following the offset point. When the offset is equal to the length of the string, the new node has no value data.

### Syntax

*Result* = *Obj*->[IDLffXMLDOMText::]SplitText( *Offset* )

### Return Value

Returns an object reference to the new IDLffXMLDOMText object.

### Arguments

#### Offset

An integer containing the offset into the string at which to split it.

### Keywords

None

### Version History

6.1	Introduced
-----	------------

# IDLffXMLDOMTreeWalker

The IDLffXMLDOMTreeWalker class is used to navigate a DOM tree by creating a node object for accessing a DOM node and then destroying that node object as the tree walker is moved to another DOM node. The walker creates an object and returns an object reference to that object each time the walker moves, destroying the object that it last returned when the walker last moved. This process lets the application visit the nodes in a DOM tree efficiently and easily.

The tree walker is conceptually a “current” node pointer into the DOM tree. When the walker moves, it returns an object reference to a newly created instance of a node that represents the DOM node where the walker is now positioned.

The node specified when the tree walker is created is the root node for the walker. The walker is positioned at the root node when the walker is created. The walker cannot move to an ancestor of the root node. The root node, its children, and all of its siblings and their children compose the subtree visible to the walker.

The tree walker never destroys the [IDLffXMLDOMDocument](#) objects that it might return. The walker can only return an [IDLffXMLDOMDocument](#) object if an [IDLffXMLDOMDocument](#) object is the root node.

Objects of this class are created with the [IDLffXMLDOMDocument::CreateTreeWalker](#) method.

## Superclasses

None

## Creation

See [IDLffXMLDOMTreeWalker::Init](#).

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- [IDLffXMLDOMTreeWalker::Cleanup](#)

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::Init](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)
- [IDLffXMLDOMTreeWalker::SetCurrentNode](#)

In addition, this class inherits the methods of any superclasses.

## Version History

6.2	Introduced
-----	------------

## **IDLffXMLDOMTreeWalker Properties**

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## IDLffXMLDOMTreeWalker::Cleanup

The IDLffXMLDOMTreeWalker::Cleanup procedure method performs cleanup on the tree-walker object. As part of this cleanup, the method destroys any other objects that were created by the walker object. The destruction of the walker object does not affect any corresponding nodes in the DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

### Syntax

OBJ\_DESTROY, *Obj*

### Arguments

None

### Keywords

None

### Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::FirstChild

The `IDLffXMLDOMTreeWalker::FirstChild` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that is the first child of the node to which the walker is currently pointing.

If the current node has no visible children, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[[IDLffXMLDOMTreeWalker::](#)]FirstChild()

### Return Value

Returns an object reference to the first child of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible children.

### Arguments

None

## Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::GetCurrentNode

The `IDLffXMLDOMTreeWalker::GetCurrentNode` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree to which the walker is currently pointing.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

### Syntax

*Result* = *Obj*->[\[IDLffXMLDOMTreeWalker::\]GetCurrentNode\(\)](#)

### Return Value

Returns the object reference to the object that refers to the tree walker's current position in the DOM tree.

### Arguments

None

### Keywords

None

## Version History

6.2	Introduced
-----	------------

## IDLffXMLDOMTreeWalker::Init

The IDLffXMLDOMTreeWalker::Init function method initializes the object, but this class should not be instantiated directly. Instead, use the [IDLffXMLDOMDocument::CreateTreeWalker](#) method to create instances of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

## IDLffXMLDOMTreeWalker::LastChild

The `IDLffXMLDOMTreeWalker::LastChild` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that is the last child of the node to which the walker is currently pointing.
